Maria Cecilia Loschiavo dos Santos is a philosopher and associate professor of Design at the School of Architecture and Urbanism, University of São Paulo, where she received her MA (1975) and PhD (1993) in Aesthetics. She has been a visiting scholar in postdoctoral programs at the following universities: University of California, Los Angeles (UCLA) (1995-96 and 2007-08); University of Campinas, Brazil (1997); Nihon University, Tokyo, (1999); Canadian Center for Architecture, Montreal (2001). She has published many articles in Brazilian design magazines and international academic conferences. She is the author of several books, among them 'Móvel Moderno no Brasil', sponsored by FAPESP and a joint publication of the University of São Paulo Press and Studio Nobel in São Paulo. She is a scientific consultant for Brazilian Research Agencies, such as FAPESP and CNPq. Currently she is the co-ordinator of the Workshop of Social Design at the Institute of Advanced Studies, at the University of São Paulo. Dr. Loschiavo dos Santos current research is about Discarded Products, Design and Homelessness in Global Cities and she is deeply committed to design and social responsibility issues. She was awarded the First Prize by the Museu da Casa Brasileira for her book 'Móvel Moderno no Brasil'. She is the screenwriter of the documentary movie 'A Margem da Imagem' (On the Fringes of São Paulo: Homeless) which concentrates on themes such as social exclusion, unemployment, alcoholism, insanity, religiousness, contemporary public spaces, urban degradation, identity and citizenship. The film was officially selected for the São Paulo Short Film Festival 2002 and awarded the 'Best documentary' film at the Gramado Film Festival, 2003.

Embodiment, Immediacy and Thinghood in the Design of Human-Computer Interaction

Fabian Hemmert, Deutsche Telekom Laboratories, Berlin, Germany, fabian.hemmert@telekom.de

Gesche Joost, Deutsche Telekom Laboratories, Berlin, Germany, gesche.joost@telekom.de

Abstract

This paper is concerned with the design of Human-Computer Interaction (HCI). It criticizes the position that proposes ‘Embodied Interaction’ to be the underlying principle of the transition from textual, to graphical, to tangible interfaces.

Firstly, it is hypothesized that it is not the level of embodiment that has increased, but the level of immediacy. It is furthermore proposed that the concept of thinghood, as described in the works of Heidegger, is a fruitful starting point for the design of human-computer interfaces.

In the second part of this paper, the recent history of HCI practice is reviewed, with regard for its involvement of embodiment, immediacy and thinghood. It is then argued that embodiment has always been there unchangedly, while immediacy and thinghood have changed – not only in degree, but also in kind.

In the third part, three projects are reported. Each of the projects researches, through design, the physical display of digital entities. The projects do so by picking up Heidegger’s characteristics of thinghood: extendedness, substantiality, and proximity.

It is concluded that making digital entities physically graspable can help us to make the immaterial accessible and, in doing so, ready-to-hand.

Keywords

embodiment; design; HCI; thinghood; immediacy; philosophy.

Human-Computer Interaction (HCI) has been dominated by Graphical User Interface (GUI) for the past two decades. Recent positions, however, postulate that a transition is in progress: From graphical to embodied interaction (Dourish, 2001).

A trend can indeed be observed in recent developments, for instance in Tangible User Interfaces (TUIs) (Ishii & Ullmer, 1997), in Natural User Interfaces (NUIs) (Seow et al., 2009), and in Reality-Based Interfaces (RBIs) (Jacob et al., 2008). However, this paper proposes that, in such developments, it is not the level of embodiment that increases, but, instead, changes occur in the levels and kinds of immediacy and thinghood.

A definition of ‘Embodied Interaction’ can be found in Dourish’s work ‘Where the Action is: The Foundations of Embodied Interaction’ (Dourish, 2001), as the combination of ‘tangible computing and social computing’.

While embodiment may seem suitable to conceptualize the current trend in HCI, this paper proposes two alternatives: immediacy and thinghood.

Immediacy

Immediacy is a term used in media theory. Bolter and Grusin refer to immediacy as a form of remediation (Bolter & Grusin, 2000): According to Bolter and Grusin, remediation can be observed in the transition between developmental phases of media (e.g. from painting to photography) and takes one of two forms: hypermediacy and immediacy.

'Hypermediacy' refers to the vanishing of content behind a type of media – for example, the vanishing of what can actually be seen on Niépce's first photographs behind what is visible in the second place: the potential of photography as a media itself.

Immediacy, on the other hand, refers to the vanishing of the media behind the content. In the progress of media adoption, a type of media can become, according to Bolter and Grusin, sufficiently integrated into a beholder's experience to allow him to focus on the content.

A similar notion can be found in 20th century existential philosophy. Heidegger coined the term ready-to-hand, for tools that 'become one with us' and thereby vanish in their usage (as compared to present-at-hand). It might be interesting to see parallels between these concepts and Bolter and Grusin's work.

Another Heideggerian term that could be of potential utility in HCI is thinghood, which will be elaborated on in the following section.

Thinghood

In 'Being and Time' (Heidegger, 1927), Heidegger introduces a set of three characteristics for thinghood. It consists of extendedness, substantiality, and proximity.

Extendedness

Heidegger notes extendedness to be one central property of thinghood (Heidegger, 1996, p. 96). Malpas adds, with regard to spatiality, that Heidegger uses '(...) space as that realm of extendedness in which a multiplicity of (...) entities [,] can be located' (Malpas, 2007, p. 48). But which other 'realms of extendedness' do exist, if not spatial ones?

He also points to an inherent structure of containment: The 'place' or topos of a thing is thus understood to be the inner surface of the body (where 'body' here means simply the thing in its physical extendedness) within which that thing is enclosed (Malpas, 2007, p. 69).

Malpas points out that 'Heidegger does indeed distinguish between two senses of spatiality – (…) objective spatiality (…) [and] (…) situatedness (…)'. He continues to elaborate on the latter: '[N]o conception of space as objective will be adequate to the understanding of that situatedness – objective space allows only for standardized 'locations', not for situatedness as such. The result is that we cannot treat situatedness as based in the measurable extendedness, and yet, since situatedness also has a spatiality of its own, we must distinguish between space understood in 'objective' terms and an alternative conception of space, (...) which we can refer to as 'existential.' (Malpas, 2007, p. 79)

'If there is any sense in which the bodily being of being-there is spatial, then, it is in a sense that is secondary to temporality in much the same way as the various modes of spatiality are also secondary. For this reason, Heidegger is unable to give any central place in his analysis to embodiment - indeed, since he has already committed himself to the dependent character of extended spatiality from almost the beginning of his analysis, the body as such simply falls outside the frame of Heidegger's discussion. (...) the body is secondary in the structure of being-there, (...) it threatens to make being-there into something spatial. (...) spatiality also threatens the loss of any sense of the 'there' in the stretched-out dimensionality of pure extendedness' (Malpas, 2007, p. 129).

What Malpas proposes here is that Heidegger's view of extendedness is two-fold: A spatial perspective, and an 'existential', conceptual perspective. The two of these will be taken into consideration when historically reviewing HCI practice for its usage of extendedness.

Proximity

Citing Heidegger, Malpas defines Proximity as 'simple and immediate presence' (Malpas, 2007, p. 56). He continues: 'The structure of equipmentality establishes, and indeed consists in, an ordering of things and thereby establishes a certain structure of relations in which things are brought into proximity with one another.' What becomes clear here is that no human is required for proximity, merely 'two things'.

Malpas adds: ‘However, that structure, although it consists in certain places and regions, does not, as such, establish anything as proximate to Being-there - indeed, that structure does not itself bring any particular 'there' with it. The structure of equipmentality is thus an ordering of things (...).‘ (Malpas, 2007, p. 85)

Malpas also adds that proximity an inherent facet of ‘place’ is: ‘Occurrence 'in ... proximity' is itself an occurrence in and of place - it is an occurrence that needs no special such ‘place’ but, is rather the happening of place as such.’ (Malpas, 2007, p. 307)

What becomes visible here is that such a review of Heideggerian aspects of Embodiment cannot lead directly to actionable guides to the design of Embodied HCI, but help one to see things from a new perspective.

Substantiality

Substantiality, after Heidegger, is characterized by Malpas as ‘(...) the usual conception as tied to material extendedness alone’ (Malpas, 2007, p. 260). He also adds the potential of manipulability: ‘(...) the treatment of the natural world as a source of 'raw material' for human production and as open to human manipulation and control (...)’ (Malpas, 2007, p. 281).

If transferred to HCI, the concept of manipulability would be considered the input. As for the corresponding output, Malpas notes for the perceivable presence: ‘Heidegger, of course, looks especially to (…) what Aristotle called 'ousia', the really real, the primary being, 'substance'. Heidegger claimed that one of the great breakthroughs in his own thinking was to realize that this Greek understanding of being was based in the prioritization of a certain mode of temporality, namely the present, and so understood the being of things in terms of the 'presence' or 'presencing' of things in the present - in terms of the way they 'stand fast' here and now.’ (Malpas, 2007, p. 61)

From Theory to Practice

The previously reviewed concepts are, by their very nature, abstract and purely theoretical. The preceding part of this work has reviewed these concepts, as they may help us to analyze the paradigms underlying current and past HCI through a new analytical lens.

The following part of this paper will do so: It is a historical analysis of HCI practice, analyzing the involved characteristics of embodiment, immediacy, and thinghood.

The last part of this work is an investigation of how we could interact with digital contents in the future in a more immediate way. As the means of investigation, we propose a Research through Design approach. This seems worthwhile, as the target field is dominated by interplay of theory, bodies and artefacts. Producing concrete artefacts that represent abstract theories may prove to be a suitable means to learn how human-computer interaction could be designed in the future, and if immediacy is a valuable model for this endeavour.

Embodiment, Immediacy and Thinghood in HCI Practice

In this section, we will review the practice of HCI in different developmental stages of the past decades: Command-Line Interfaces, Graphical User Interfaces, and Tangible User Interfaces. Each stage will be analyzed for its characteristics of

- *Embodiment* (Dourish, 2001),
- *Immediacy* (Bolter & Grusin, 2000), and
- *Thinghood* (Heidegger, 1927).

Command-Line Interfaces

In Command-Line Interfaces (CLIs), digital content is interacted with through textually articulated commands and responses. The primary input is the keyboard; the primary output is a text-based display.

Embodiment in Command-Line Interfaces

Working with computers that utilize CLIs is a physical activity. Content is manipulated through physical buttons, and work occurs often in social context. It may be argued that digital content is not physically represented, but that does not affect the physicality of the keyboard. This media, the keyboard, is even *ready-to-hand* after having used it for a sufficient amount of time: Command-Line Interfaces draw on embodied skills.

Immediacy in Command-Line Interfaces

Digital content in CLIs is displayed on a screen, in written, textual form. This style of output matches the manipulatory input: *Written* commands, regardless of the type of digital content at hand. For instance, a car traffic simulation would have to be programmed into the system textually, and result in number results, rather than rich graphical results (e.g. a map, or a graphic chart). Text is the mediator, which may be useful in some cases, but inappropriate and cumbersome in others.

Thinghood in Command-Line Interfaces

Most digital content in CLIs is displayed *virtually* and *mediatedly.* They may retain their substantiality, extendedness and proximity, but none of these properties is directly available to users in any interactions. Users have to interpret the verbal descriptions: CLIs thereby operate on the level of *described* things.

Graphical User Interfaces

In Graphical User Interfaces (GUIs), digital content is accessed through graphical and textual items on different representational levels. It is manipulated through mouse and keyboard interactions.

Embodiment in Graphical User Interfaces

Interacting with GUIs is predominantly shaped through interacting through a mouse. A keyboard may be involved, too, but for clarity reasons, we will focus on the mouse here. A mouse inherently picks up on embodied skills: Spatiality and pressure (as in clicking). Also, interaction often occurs in social contexts – people have learned to cope with the fact that a mouse is a single-user device. GUI Interaction is embodied, and can, similar to the CLI, become ready-to-hand just through sufficient practice.

Immediacy in Graphical User Interfaces

Digital contents are represented graphically in GUIs. This leaves more room for representational styles than the CLI does: Things can be represented iconically, symbolically, or indexically (Peirce, Houser, & Kloesel, 1998). Interpreting these signs can be much easier than interpreting textual representations, and so can be manipulating them: Changing the size of a digital object can be achieved through pointing to its edge with the cursor, mediated through the mouse, grasping it, mediated through the mouse button, and altering it through a respective movement. The interaction is still mediated, but less mediated than in the CLI: Representation and Manipulation occur in the same space, virtual graphics, even though through tools (like mice) that make this space accessible for users.

Thinghood in Graphical User Interfaces

Digital content in GUIs is displayed *virtually* on a screen, but can be displayed in more *immediate* forms: Images. Thereby, they gain thinghood on the levels of *extendedness*, *substantiality* and *proximity* – represented in virtual space, on a screen*.* GUIs operate on the level of *depicted* things.

Tangible User Interfaces

In Tangible User Interfaces (TUIs), digital content is physically manifest, and thereby physically manipulated and perceived.

Embodiment in Tangible User Interfaces

TUIs draw on embodied skills: They represent digital contents physically, and often also react to physical input. This display and manipulation can occur socially accessible in the real world. It should be noted that almost every user interface hardware, including mouse and keyboard, is necessarily tangible, as it needs to allow manual interaction.

Immediacy in Tangible User Interfaces

TUIs have the potential to map input and output closely together, which makes interacting with their digital inner a seemingly analogue activity. Here, the term *immediacy* seems to describe particularly well what occurs to the user: Physical representations can be manipulated physically, directly, leading to changes in the digital layer.

Thinghood in Tangible User Interfaces

In his paper 'Tangible Bits' (Ishii & Ullmer, 1997), which is considered the starting point of TUIs, Ishii draws on Heidegger to explain the possible benefits of the TUI paradigm. Indeed, the characteristics of things proposed by Heidegger can be observed in many TUIs: physical *extendedness*, physical *substantiality*, and physical *proximity*.

TUIs operate on the level of *physical* things.

Summary

Comparing the historical phases of HCI, from CLIs to GUIs and TUIs, the level of embodiment has not changed: All human-computer interaction is both physical, as computers necessarily are, and social, as humans always have been.

Immediacy, however, seems to have increased. The styles of textual, graphical and physical representation bring digital contents more closely to us. They also foster the coincidence of input and output (Ishii & Ullmer, 1997), which makes interacting with them a seemingly *direct* experience.

Thinghood also provides an interesting view on things: All interactions operate, necessarily, on some level of thinghood. The level of CLIs is the level of *de-scribed* things, the level for GUIs is the level of *de-picted* things, and for TUIs, it is the level of *physical* things. The prefix 'de-' suggests that the -*picting* and –*scibing* originate in something: The object itself. It may be well possible that the physical representation of the TUI is more direct, as it is by no means 'de-materialized', but rather the contrary, *material*.

Making Digital Content Graspable

Heideggerian thinghood is increasingly prominent in Tangible User Interfaces. It might be interesting to see if the Heideggerian concepts can help us to make digital contents more ready-to-hand.

To investigate this matter, we present three projects from our research that have taken different steps to make immaterial digital content, as a first step towards readiness-to-hand, present-at-hand.

Substantiality: Weight-Shifting Mobiles

Fig. 1: The Weight-Shifting Mobiles prototype.

In this project, weight is considered a physical pendant of *substantiality*. The mobile phone developed here is able to shift its centre of gravity by moving an iron mass on its inside.

Users appreciated the fact that they were now able to ‘feel’ the digital content. They were able to estimate the weight’s position on the device’s inside at a considerable niveau of accuracy, and enjoyed the subtleness of the approach (Hemmert, Hamann, Löwe, Zeipelt, & Joost, 2010b).

Extendedness: Shape-Changing Mobiles

Fig. 2: The Shape-Changing Mobiles prototype.

In this project, a deformation of a mobile phone’s case is investigated as for its utility as a display for digital contents. In this example, immaterial digital entities are represented through physical volume: *extendedness*. For instance, digital items that are off the screen of the mobile phone can be displayed through a thickening of its casing toward the respective edge.

Users intuitively understood the mapping, and appreciated the leveraging of their hands sensitivity, rather than being visually overloaded even more (as they often experienced it in GUIs) (Hemmert, Hamann, Löwe, Zeipelt, & Joost, 2010a).

Proximity: Ambient Life

Fig. 3: The Ambient Life prototype.

This project operates on another level. It proposes a metaphor for digital content: life. The project investigates signs of life like breath and pulse as a means of display for the inner state of a mobile phone. For instance, the phone can be ‘calm’ when no calls have been missed, no new text messages have arrived, and the battery level is sufficient. It switches to ‘excited’ mode as soon as it needs the user's attention. This metaphor draws on our perception of living beings, and also exaggerates the already close relationship between user and mobile phone: It explores the role of *proximity*.

Users typically fell into one of two groups, with the first group being attracted by the 'cuteness' of the system, and the second group being disgusted – an interesting circumstance, as the simulation caused reactions that would normally occur as reactions to animals, and not as reactions to phones (Hemmert, 2008).

Conclusion

The three projects presented here investigate the three characteristics of *thinghood* proposed by Heidegger; Users generally appreciated the directness of these approaches. However, such physical displays seem to be generally limited in their communicative bandwidth: They are often only one- or two-dimensional, being able to display only a small number of data points. The richness of these displays does not lie in the number of things they can display, but in the quality of the few things that can be displayed.

The means of this investigation, *research through design*, have shown their strength in order to make abstract concepts manifest, experiential and situated in both the researchers' and the users' life-world.

We conclude that *thinghood* is a fruitful source of *inspiration for the design* of *immediate* interaction. A physical body in a social world is our medium to interact with computers, which is the reason why HCI is, as it always has been, embodied.

The Inclusive Incapability-Culture-Economy Cube: A design framework for complex barriers

Praima Israsena Na Ayudhya, Chulalongkorn University, Thailand

Abstract

Inclusive design is an evolving and complex concept, the definition of which can be extended to address not only age and disability, but also race, income, education, and culture. As most of products are originally designed in developed countries, conventional elder-care products present serious difficulties and exclude users with different cultural customs and lower economic status. There is an urgent need for a design framework, based on an expansive understanding of not only age and disability, but also income, education and culturally related barriers, which will lead to a minimizing of the impact of these differences and thereby extend the effectiveness of “inclusive design”. Through case studies of Thai elder care product development, this paper aims to explore the inclusive design approaches that are suitable for all ranges of users with different capability, culture and purchasing power. Techniques for this research, in the first phase, include contextual interview and observation as well as self-documentary of 50 pairs of Thai elderly and their caregivers. The subjects were selectively chosen based on age, gender, length of dependency, the relationship to each other, functional dependency in ADL, living conditions, and equipment used for elder care. These enable us to identify the details of inclusive design barriers and to develop population profiles based on three expanded design dimensions for greater inclusion: individual incapability, cultural specificity and economic limitation. In the second phase, the relationships between design approaches and included user groups were analyzed through 150 design case studies of Thai eldercare product development. The findings enable the development of the “Incapability-Cultural -Economic Cube” (I.C.E Cube), an active inclusive design framework for all ranges of users with different capability, culture and purchasing power. The model is illustrated in this paper by a range of product examples from Thai elder-care case studies.

Keywords

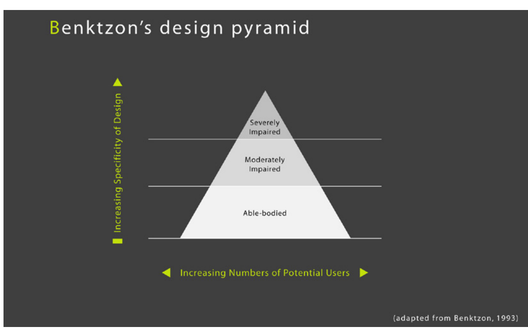
Inclusive design; cultural factors; economic factors; elder care; design framework

Inclusive design refers to designs that accommodate the widest range of potential users. Inclusive design is an evolving and complex concept, the definition of which can be extended to address not only age and disability, but also income, education, and culture. Besides individual capabilities, cultural differences and economic status are important barriers to inclusive design. These are the reasons why most inclusive solutions and guidelines carried out in developed countries present serious difficulties and exclude users in the developing world. This research aims to explore the complex barriers of inclusive design and to develop an inclusive design framework for all ranges of users with different capability, culture and purchasing power.

1. Inclusive design

Inclusive design is an approach to the design of all products and environments to be as usable as possible by as many people as possible regardless of age, ability or situation. It accommodates people with disabilities, older people, children, and others who are non-average in a way that is not stigmatizing and benefits all users. Designing for a broad range of users from the beginning of the process can increase usability of an environment or product without significantly increasing its cost. It results in easier use for everyone and it reduces the need for design modifications later when abilities or circumstances change. Other terms for Inclusive design used around the world include Design for All, Universal Design, and Barrier-Free Design. Terminology and meanings differ from one country to another and often reflect each nation's societal values. Significant cultural differences between countries have influenced how the movement has been adopted and evolved in each location but the common goal of social inclusion transcends national laws, policies, and practices.

During the past 25 years, considerable advances have been made in the fields of designing for disabled and elderly user. Many design approaches were proposed focusing on the suitability of users' capabilities. The User Pyramid design approach (Benktzon, 1993) reflects the wide range of user capabilities and their impact on the design process by categorizing the target user capabilities: able-bodied, moderately impaired and severely impaired (Figure 1). Building on Benktzon's User Pyramid, Keates et al (2000) have developed the 'Inclusive Design Cube' model that relates capability level, population profile and suitable design approaches consisting of: user-aware design, modular/customizable design, and special purpose design (Figure 2).



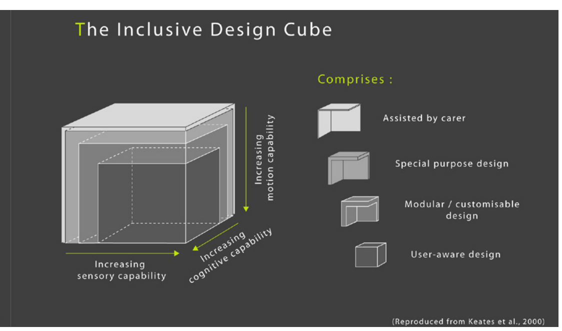


Figure 1 The Design Pyramid (Benktzon, 1993)   Figure 2 The Inclusive Design Cube (Keates, 2000)

However, "Inclusive design" is an evolving and complex concept the definition of which can be extended to address not only age and disability, but also race, income, education, and culture. Design can exclude and discriminate against certain groups in society with different cultures and economic status. As most of products are originally designed in developed countries, the market sector in the developing world is being ignored and large sections of the population are being excluded. Thus, conventional products present serious difficulties and exclude users with limited capability, different culture and lower economic status. There is an urgent need for the development of design methods, based on a comprehensive understanding of not only age and disability, but also income, education and culture related factors. Through a case study of Thai elder care product development, this paper aims to extend the dimensions of inclusive design and to present a methodological design approach for implementing inclusive design across incapability, cultural and economic diversity.

2. Thai elder care

The demographic trends of the past decades are leading to unprecedented increases not only in the absolute numbers of older persons but also in the relative share of the population that belong to the elderly age groups. The countries of the Asian region, without exception, will experience a rapid growth of their aged populations and an overall ageing of their national populations over the next few decades. This will occur in a context where the extent to which family resources, which have traditionally been the major source of support for the aged, are likely to be diluted. The dilution will occur due to the higher ratio of older people to economically active people, to greater female workforce participation outside of the home, and to fundamental changes in the structure and functioning of the family (Hugo, 1996). In Thailand, the elderly population increased from 1.21 million in 1960 to 4.02 million in 1990 and will reach 10.78 million in 2020. However, the matter which is seriously considered is population aging. Population aging means an increase in the elderly share of the total population. In 1960 only 4.6% of the whole population was elderly people aged 60 and over. In 1990 the elderly population share in Thailand was 7.36% of the total population. They will represent 15.28% by 2020. In 1960, the total dependency ratio was 91.55%, of which almost all of the dependent populations were children. During the process of population aging, aged dependency ratio increases. The aged dependency ratio will be inevitably higher than the child dependency ratio (Jitapunkul and Bunnag, 1999).

While much design and research related to elder care has been carried out in the West, only a portion of it can be applied to the Thai context. Besides the difference of elder care by untrained family caregivers in Thailand, the culture and ways of life are also different from the West. There are still specific problems and unmet needs in Thailand that have not been studied, such as the fact that Thais are used to sleeping on the floor, and also think it is safer than sleeping in a bed. Suitable equipment that has not been produced in the West, is thus needed. More over, economy is also an important barrier to the application of western design guidelines. In some cases, it creates an even greater problem, for example, some are unable to afford adult disposable diapers and/or do not understand the proper sanitary treatment of them. They try washing, reusing, or extending the usage of each diaper, which causes health problems. These barriers are left unexplored, negatively affecting the lives of both the caregivers and the elderly (Israsena & Boonvong, 2007).

3. Research objective

1). to uncover inclusive design barriers in Thailand, through the exploration of Thai elder-care problems and limitations in applying products, originally designed in the developed countries, in Thai context.

2) to explore the inclusive design approaches that are suitable for all ranges of users with different capability, culture and purchasing power.

4. Research methodology

4.1 Subjects

Fifty pairs of elderly and caregivers were selectively chosen from Chulalongkorn Hospital, a public hospital in Bangkok, Thailand. The subjects were selected based on age, gender, length of dependency, their relationships such as being family members, a maid, or a trained caregiver, the elderly's level of self-reliance, the elderly's functional dependency in ADL, the types of caring activities demanded, the living condition, and equipment for elder care.

4.2 Data collecting methods

In the first phase of this research, in order to closely study inclusive design barriers, two data collecting techniques were employed in this study: self-documentary study and contextual interview & observation.

4.2.1 Self-documentary study:

In order to collect information of real daily activities, subjects were asked to record details of challenges in a diary with questions for the causes of the elderly's dependency, the schedule of daily activities of the elderly and the caregiver in 24 hours, and details on mobility, bathing, toileting, feeding, uses of medication, sleeping and monitoring. The caregiver was to record the steps in each elder care activity, problems in each step, the advantages and disadvantages of the environment and products used, using either a disposable camera or a digital camera to record pictures, and provide a description attached to the pictures.

4.2.2 Contextual interview and observation:

To get information in the real context, researchers went in to observe and interview elderly and caregivers during daily care activities. The interview consisted of questions similar to the self-documentary study mentioned earlier.

4.3 Analysis methods

The information from the self-documentary study and contextual interview and observation is processed using qualitative analysis methods in the form of tables and diagrams to study inclusive design barriers, the relationships between the challenges in elder care and the living conditions as well as the equipment in the home.

In the second phase of the research, to better understand the relations among inclusive design barriers, dimensions and design approaches the process of elder care design development was analyzed. The problems and barriers found in the first part of the research were set as objectives for design development. Analyzing the design development processes employed, a pattern of design approaches suitable for each target group was identified. The findings enabled the development of the "Incapability-Cultural-Economic Cube" (I.C.E Cube), an active inclusive design framework for all ranges of users with different capability, culture and purchasing power.

5. Results & discussion

5.1 Phase I: Inclusive design barriers in Thailand

The results to be discussed in the first part are from the self-documentary study and the contextual interview and observation, which explain the causes of inclusive design barriers in Thailand. The study found that most families with purchasing power in the city, where a primarily Western lifestyle is adopted, are using imported products and are facing only individual incapability (sensory, cognitive, motion) barriers similar to those of the West. On the other hand, low-income families who both live in the city and the countryside have to deal with problems that are specific to Thailand which are left unexplored and unsolved. With limited space, this paper will not describe or illustrating all the problems found in Thailand, but will focus only on the local-specific problems that have severe effects on the elderly and caregivers. The findings point out Thai barriers in applying products originally designed in the developed countries in 3 dimensions: cultural, economic and incapability.

5.1.1 Thai local cultural barriers:

While much design and research related to elder care has been carried out in the West, only a portion of it can be applied to the Thai context. Besides the difference of elder care by untrained family caregivers in Thailand, Thai culture and ways of life also very different from those of the West. Thai cultural barriers in applying western products include:

a). Lifestyle practices: sleeping on the floor, dining on the floor, wearing a wrap-around instead of pants, eating with one hand using a short spoon, showering using a bowl.

b). Customs: respect for the elderly, the forbiddance of standing and passing things over the elderly's head, the importance of "low" and "high" parts of the body (e.g. using separate towels for the head, body, behind, and feet), and the importance of food arrangement for people of status.

c). Preferences and attitudes: not favoring things to be permanently installed and things that need a technician to install (e.g. a grab bar), not favoring buying a whole product for elder care but preferring to buy parts to retrofit to existing products in the household, preferring to easily modify things or to find a short cut and save costs, but without considering the consequences.

d). Information processing: Thai elderly and caregivers have a limited literacy level or do not like to read. They choose to remember things and pass them along, particularly the elderlies' drug prescriptions and processes of elder care. Without writing them down, understanding them, or giving importance to processes that they view as complex, matters of hygiene and nutrition are missed.

e). Environmental arrangement: As most houses are quite small, Thai people in the countryside choose to sleep on the floor while many urban inhabitants who have beds tend to place a side of the bed along the wall. A higher importance is given to social interaction with family members than for privacy, such as moving the elderly, who has difficulty in using the stairs, to sleep in the living room downstairs in order to be surrounded with family members. Thais tend to use a space for various functions by moving things in and out according to activities, so they do not like to install anything large permanently. Instead, Thais prefer foldable and mobile furniture, which are not so strong, such as foldable tables and chairs.

5.1.2 Thai local economic barriers:

Financial limitations in Thailand make it difficult to afford costly equipment and disposable products such as adult diapers. This factor causes people to find other ways to solve problems, which have both good and bad results in elder care. The origins of Thai economic barriers include:

a). Caregivers lack the opportunity to work and earn a living as many have to quit their jobs or take leave during the day to care for the elderly.

b). Certain activities demand much more energy than family members, who are aging or have health problems, can handle. Thus, families resort to hiring maids, caregivers, or nurses.

c). Certain activities in elder care require high expenses, particularly in toileting, where costly disposable items like adult diapers and catheters are needed.

5.1.3 Thai local incapability barriers:

Local specific problems in Thai elder care arise from cultural origins mentioned earlier, Thai local incapability barriers will be detailed as follows under mobility, bathing, toileting, feeding, use of medication, sleeping and monitoring activities.

a). Mobility: Thai houses are quite small and narrow. The use of walkers and wheelchairs is not always possible. The elderlies have to hold on to foldable tables and wall-hung sinks which are not steady and unsafe. The narrowness of Thai houses also result in beds being placed along the wall or choosing to sleep on the floor. The elderlies who sleep on the floor are unable to get up by themselves. Moving from the floor to sit in a chair or a wheelchair is very difficult while sliding seated on the floor is slow and problematic. Caregivers choose to pull them on the floor or not to move them at all. Instead, caregivers make room for the elderly to sit against the wall, stretching out their legs, for various activities such as eating.

b). Bathing: Where many families move the elderly to sleep in the living room, the elderly has to use maid's or guest's bathroom. This type of bathroom has no space for a shower chair and requires the elderly to move in a longer distance to the bathroom. Without the installation of a grab bar, elderlies have to stand holding on to the unstable wall-hung sink or sit on the toilet bowl to bathe. Both are difficult for them to maintain balance. In cases where the elderly sleeps on the floor, the caregiver pulls their mat outside to bathe them on the patio, forcing uncomfortable positions.

c). Toileting: The problems of toileting inside the bathroom brought about by moving the elderly to sleep in the living room are: lack of privacy, narrow bathrooms far from the sleeping area without separate wet and dry areas, the risk of slipping, the difficulty of moving, and lack of appropriate ergonomics. Toileting outside the bathroom by using an adult diaper is very problematic due to hot climate and unaffordable expense. Some have the wrong idea that disposable diapers can be reused, which lead to health risks. Some Thais try to find cheaper solutions such as modifying a plant watering can into a bigger urinal container so the caregiver does not have to take it out to empty as often. As the catheter is costly, wastefully, and requires a caregiver with skills, some have tried using in-house items such as a tube connected to a liquid soap dispenser or a soap bar sharpened into a cone shape, or a finger without wearing a glove. Some of these modified items are usable, whereas others pose health risks.

d). Feeding: Most low-income people in the countryside eat on the floor, either at a small low table or on their lap. This forces them to be in a bending position for long periods. Thais are used to eating with a short spoon using only one hand. With age, the elderly loses energy and precision in cutting and spooning the food, leading to leaks and spills. Another difficulty with elderly food is tube-feeding, which requires expertise and skill. There is a lack of knowledge, understanding of the correct way of sterilizing and properly organized environment. Most Thais do not invest in modern devices such as equipment steamer specifically for the elderly. Instead, they try modifying the process and make use of existing in-home items, such as immersing the feeding devices into an electric water boiler.

e). Use of medication: Most Thais do not have the basic language skills to be able to read and write Thai and English. Caregivers and the elderly try to remember what doctors and pharmacists prescribe, without reading or noting it down. In preparing medicine, most Thais use in-home items in cutting and crushing pills, such as a knife, a cutting board, and a spoon, or even cutting with their fingernails. These methods are sometimes unhygienic. Pills often bounce away and get lost. The limited knowledge and understanding in the use of medicine put the elderly at risk.

f). Sleeping and monitoring: As mentioned earlier, Thai houses are usually very small and narrow, causing people to place the bed along the wall or sleep on the floor. The hot weather, the use of mosquito nets, plastic sheets for urine spills, and adult diapers contribute to sleeping discomfort. Thais give great importance to social ranking and seniority, so caregivers cannot sleep higher than elderlies. Most caregivers sleep on the floor and become a barrier in the walking path.

Local specific problems in Thai elder care arise from economics and cultural origins mentioned earlier are important barriers to the application of western design and guidelines.

5.2 Phase II: Inclusive design approaches

Setting design objectives based on the problems and barriers discovered in real Thai elder care practice, the design team has developed more than 150 design solutions suitable for all user groups in Thailand. Examples can be seen on figure 3.

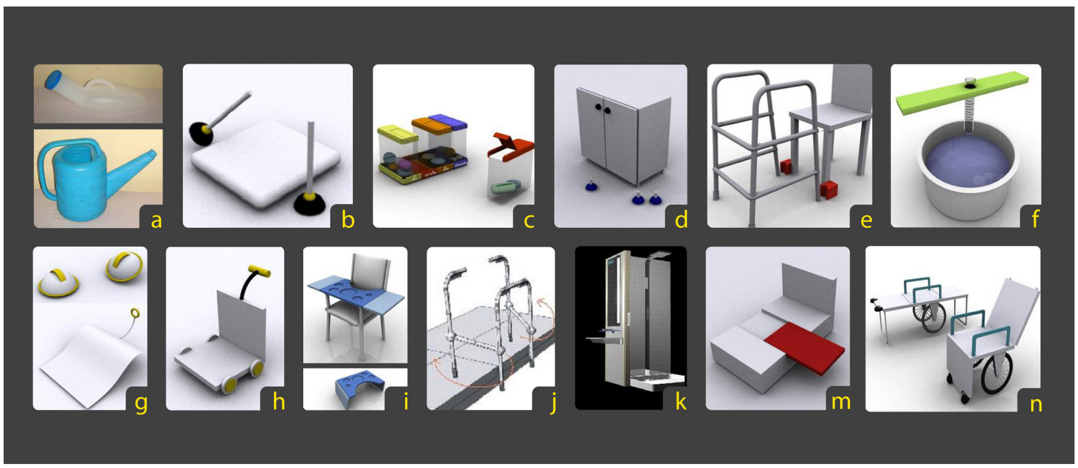

Figure 3 Examples of design solutions generated from integrated inclusive design approaches

The team has employed various inclusive design approaches in developing the design solutions. The Inclusive Incapability-Culture-Economy (I.C.E.) Cube was developed based on the analysis of the relations between the employed design approaches and the included user groups. Some examples are illustrated on table 1. Analyzing the relations between the inclusive design approaches employed in developing each design solution (namely: total solution design, retrofits for existing devices, ideas for in-home adapting, global solution design, adapted solution design, local solution design, user-aware design, modular/customizable design, and special purpose design) and the include users regarding culture (local, blended, and global culture), economy (no, low, and high income), and ability (no, reduced, and fully capable), a pattern of suitable approaches could be identified. Derived from a better understanding of the complex barriers, inclusive design approaches and their relations to the included users, the 'I.C.E. Cube' model was developed. The 'I.C.E. Cube' model (Figure 4) is represented in simple graphic form to communicate the finding and guide the inclusive design process in the future.

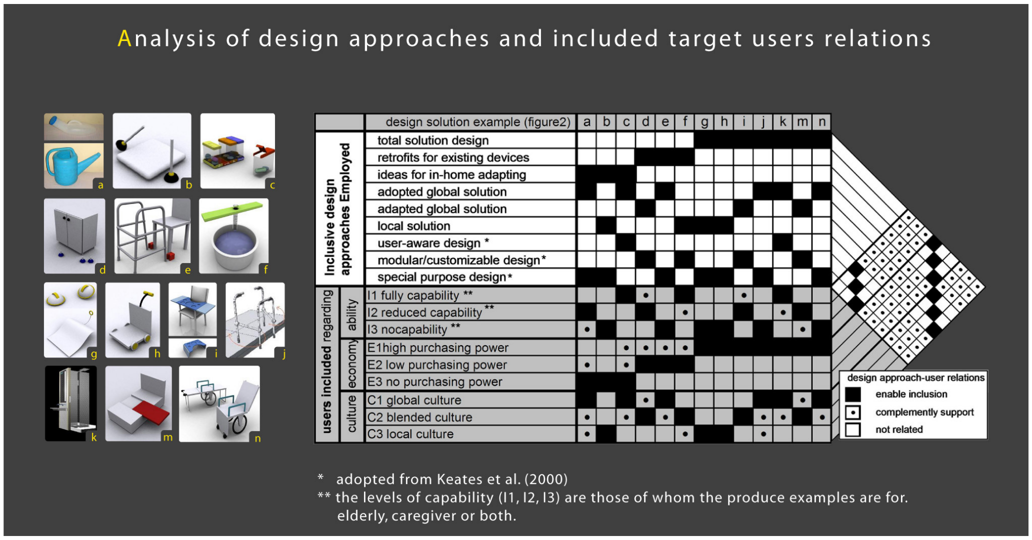

Table 1 The analysis of inclusive design approaches and included target users relations

Building on the concept of the User Pyramid (Benktzon, 1993) and the Inclusive Design Cube (Keates et al, 2000), the author has developed 'The Inclusive ICE Cube' to model the whole population in three dimensions (3 axes), with regard to individual incapability, cultural specificity, and economic limitation. Figure 4 (left) presents the whole Thai population as profiles divided horizontally in three layers ranging from the bottom layer which represents users with lowest risk of exclusion to the top layer which represent users with highest risk of design exclusion according to three dimensions of barriers: individual incapability, economic limitation and cultural difference.

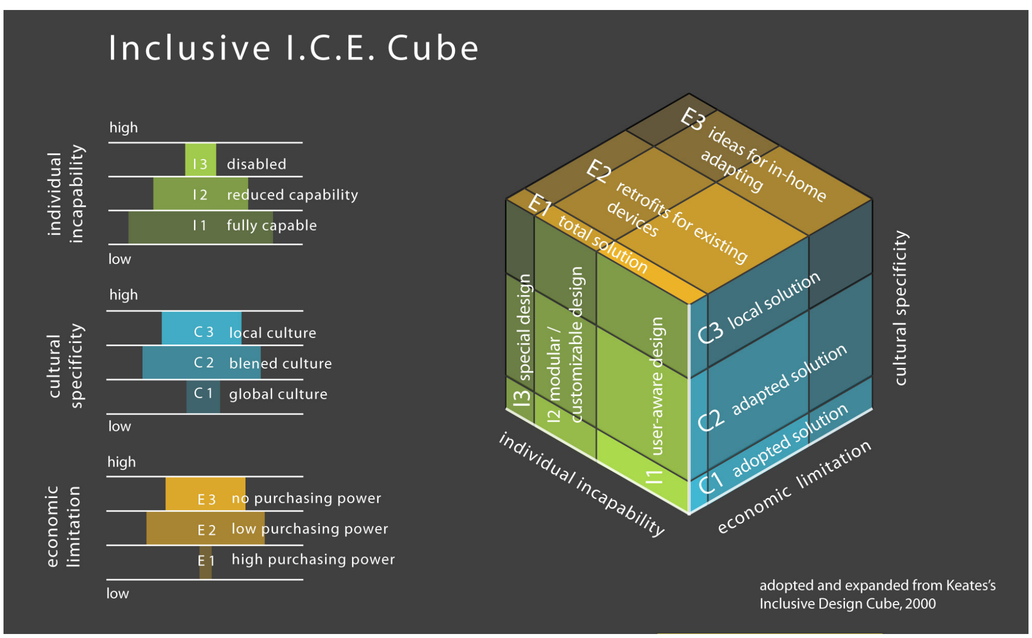

Figure 4 [left] profiles of Thai population at risk of design exclusion as a result of individual incapability, economic limitation and cultural different barriers; [right] The Inclusive Incapability-Culture-Economy (I.C.E.) Cube

The ‘Inclusive ICE Cube’ relates the three dimensions to population (included in the enclosed volume) and suitable design approaches that can be used in conjunction: total solution design (E1), retrofits for existing devices (E2), ideas for in-home adapting (E3), adopted solution design (C1), adapted solution design (C2), local solution design (C3), user-aware design (I1), modular/customizable design (I2), and special purpose design (I3). For example, ideas for in-home adapting (E3), local solution design (C3), and user-aware design (I1) approaches should be used in combination for low-income users with specific culture.

5.2.1 Inclusive approaches for individual incapability barriers

Adopted from Keates’ Inclusive Design Cube, the capability axis represents cognitive, motor and sensory capabilities of individuals ranging from full capability to no capability.

a). Special Purpose Design (I3)

At the low capability end, it is likely that many of the needs of daily living will be met by care givers. As capability increases, special purpose design (I3) will provide products to suit specific needs, wheelchairs for example, where such products are not intended for general use by the whole population.

b). Modular or customizable design (I2)

Modular or customizable design (I2) allows for variations in products to accommodate a wider range of abilities. These can be done by designing of components that can be assembled in a variety of ways to meet individual needs.

c). User aware design (I1)

User aware design (I1) is intended to result in products with appeal to as wide a range of capability as possible.

5.2.2 Inclusive approaches for economic limitation barriers

The economic axis represents the users’ purchasing power ranging from unlimited/full purchasing power to limited/no purchasing power.

a). “Way”- ideas for in-home adaption (E3)

At the no purchasing power end, the suitable approach would be designing creative ways for users themselves to adapt household items or environment (E3). Appropriate technology design will provide solutions with no financial barrier. For instance, making a mitten from a wash cloth and modifying a plant watering can into a bigger urine container (figure 3-a).

b). “Part”- retrofits for existing devices (E2)

As purchasing power increases, designing low-cost retrofits for existing devices in the home (E2) provides greater value from a smaller investment and extends the life of existing equipment, such as, metal cup placed in an electric water boiler to warm up liquid food or sterilize feeding equipment (figure 3-f).

c). “Whole”- total design solution (E1)

Finally, total design solutions (E1), by either product redesigning or creating a new product class, will enable more efficient solutions for users with higher purchasing power. A two layer adult diaper allows the elderly to remove a layer during the night by themselves or an easy-to-install bathroom can be placed near sleeping area. As most of the Thai population has limited purchasing power, ideas for in-home adapting (E3) and retrofits for existing devices (E1) are most useful. Interestingly, while the two approaches are essential for the low-income users, they are preferred for the whole population as well.

5.2.3 Inclusive approaches for cultural specificity barriers

The cultural axis represents lifestyle practice, customs, preference, information processing, and environmental arrangement related to users' culture. The range of cultural specificity is from global culture, to blended culture, and to local culture. To overcome the culture barriers several design approaches can be used.

a). Local solution (C3)

At the local culture end, local solution design for specific culture practice and customs (C3) will provide products to suit specific needs, for example a softer mat could be designed to have a pulling handle and body strap for safely sliding the elderly across the floor, as was discovered to be a practice of convenience (figure 3-g), or lower wheelchairs to allow users who lie on the floor to move around without having to pull themselves up (figure 3-h). Such products are not intended for general use by the whole global population.

b). Adapted solution (C2)

Adapted global solution (C2) allows a global product concept and technology to accommodate a wider range of users within different cultures. For example a foldable food tray with cup and plate holders that can be used both with a chair and on the floor (figure 3-i).

c). Adopted solution (C1)

Finally, adopted global solution (C1) is intended to result in products with appeal to as wide a range of users in global culture as possible.

To optimize inclusive design effectiveness, design approaches in the three dimensions of the I.C.E. cube should be used in combination. Results from in-depth interviewing and observation pointed out that design solutions and approaches intended for users with reduced capability (I2) are also preferable for fully capable users (I1). Similarly, solutions and approaches intended for users in blended culture (C2) are acceptable in global culture (C1), while those intended for low-income users (E2) are applicable for high-income users as well. On the other hand, solutions and approaches intended for users who are disabled (I3) or in local culture (C3) are so specific that they are usually not applicable for other user groups (figure 5). Interestingly, many design solutions intended for no-income users (E3), if done well, can be preferred by higher income users (E2, E1) as well (figure 3-c). Making a mitten from a wash cloth is a good example (figure 5).

6. Research application

The "Incapability-Cultural -Economic Cube" (I.C.E Cube) could be used as an active inclusive design framework for all ranges of users with different capability, culture and purchasing power. The detail findings in the first phase of this research can also be applied to other contexts, with the consideration of the following:

a). Excluding the problems specific to Thailand, the general problem findings and solutions can be applied to any other country. Solutions can be carried out in a more innovative level in countries with financial and technological advantages.

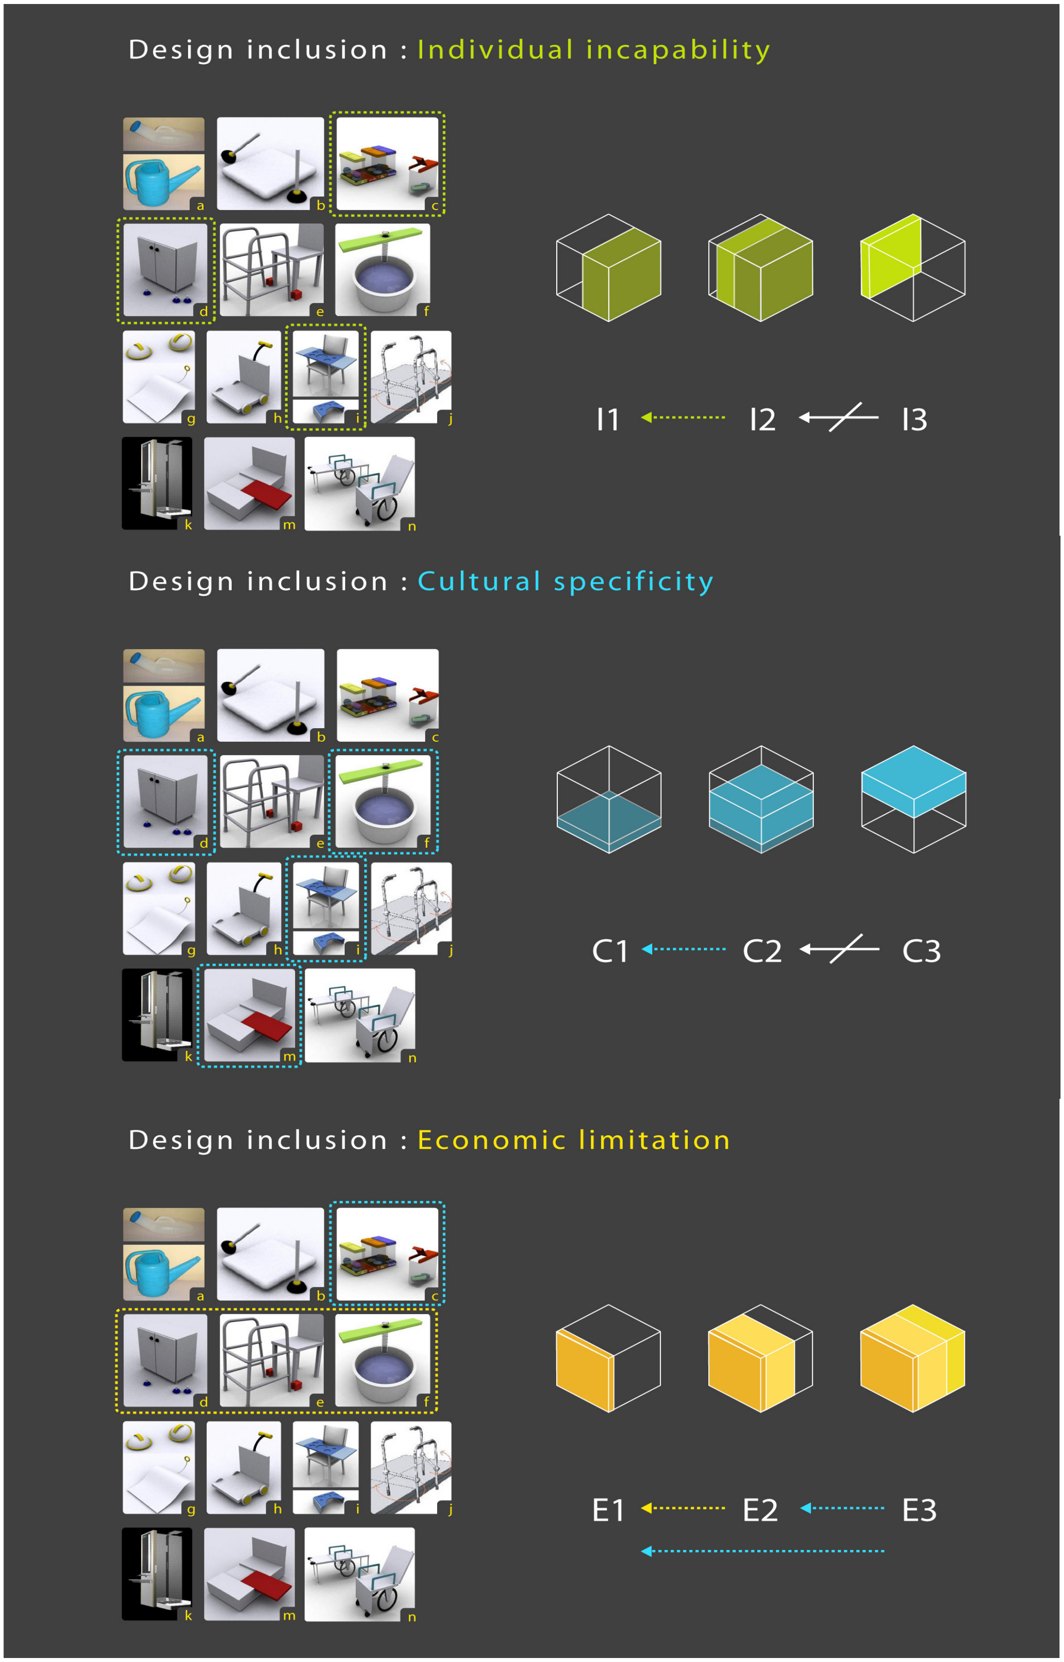

Figure 5 Degree of design inclusion along each inclusive design dimension: individual incapability, cultural specificity and economic limitation

b). For the problems specific to Thailand, in terms of culture, the findings and solutions can be applied to countries with similar cultural characteristics and behaviors, such as sitting and sleeping on the floor. These similar cultures would be in East Asia, namely, Japan and the neighboring countries of Thailand.

c). For the problems specific to Thailand, in terms of limitations in purchasing power and literacy, the findings and solutions can be applied for other developing countries with similar limitations.

Nevertheless, the context in each country varies, so further research should study specific problems locally.

7. Further research

This research, in the first phase, aimed to study the broad problems covering all the elder-care activities. Further research for product development could be more in-depth. Behavioral prototypes can be used as a tool to collect information on each device, involving experts from other fields. A multi-disciplinary teamwork would provide the most useful information in developing elder care products.

The ‘Inclusive I.C.E. Cube’ is only a starting point for inclusive design across capability, cultural and economic diversity. Further work could be done to develop this concept in terms of dimensions and user ranges in order to turn it into a more completed framework and set of design principles.

8. Conclusion

Elder care in Thailand has specific problems rooted in cultural, economic and physical factors. The adoption of methods and devices from abroad has limitations in application, and some even lead to more complex problems. Therefore, problem-solving through design in elder care should start at the root causes with an in-depth understanding of problems and preferences in purchasing or using devices. The design approaches should be compatible with the local lifestyle and economic status. This research proved that the adoption of conventional products from the developed countries present serious difficulties and exclude users with limited capability, specific culture and lower purchasing power. The understanding or the problems and barriers enable the I.C.E. Cube to be developed. The concept of the I.C.E. Cube intended to provide a framework for active design guidance for all range of users with different capability, culture and purchasing power. Lastly, although similar problems in the Thai context can be found in similar cultures and developing countries with economic limitations, but each country has specific needs and requires the study of local problems in order to achieve the best solutions.

Deepest thanks and appreciation go to the Royal Thai Government and Chulalongkorn University for funding this research.

Praima Israsena Na Ayudhya, Ph.D.

Dr. Praima Israsena Na Ayudhya is currently teaching at the Department of Industrial Design, Chulalongkorn University, Thailand, where her work is concerned with the applications of design research, frameworks, methods and tools that inform strategies and design directions. She holds a bachelor's degree in Industrial Design (first-class distinction with gold medal) from Chulalongkorn University, an M.A. in Design & Environmental Analysis from Cornell University (Phi Beta Kappa Academic Honor), and a Ph.D. in Design from the Institute of Design, IIT. She has also worked as a research consultant with and for clients in the US and Thailand such as Razorfish (USA), Hewlett Packard (USA), and Sony Ericsson (Thailand).

Far Beyond Dualisms in Methodology - An Integrative Design Research Medium "MAPS"[1]

Wolfgang Jonas, University of Kassel, Germany

Rosan Chow, Deutsche Telekom Laboratories, University of Arts Berlin, Germany

Katharina Bredies, Deutsche Telekom Laboratories, University of Arts Berlin, Germany

Kathrin Vent, University of Kassel, Germany

Abstract

Design research is an academic issue and increasingly a success factor for industrial, organizational and social innovation. Efficient methodical support is crucial. The fierce rejection of 1st generation design methods in the early 1970s resulted in the postmodernist attitude of "no methods", and subsequently in the strong adoption of scientific ways of thinking for design research. The situation regarding methodology has been characterized by unproductive dualisms such as scientific vs. designerly methods, normative vs. descriptive methods, research vs. design. The potential of the early (1st generation) methods is neglected and the practical usefulness of design research is impeded. The suggestion for 2nd generation methods, conceived as discursive instruments, as discussed by Rittel and others has hardly been taken up in design. The development of MAPS is aimed at the support of practice-oriented design, innovation and research processes. The long-term aim is the development of an *integrated knowledge and communication platform for research through design*. MAPS is based upon the idea of a productive reconciliation of the strong dualisms between "scientific" and "designerly" modes of inquiry and supports the emerging concept of *design thinking*. The paper reports on the ongoing research and development process from MAPS1.0 towards MAPS2.0 and beyond.

research through design, methodology, MAPS, integrative design research medium

INTRODUCTION

Background and context

Design Research is both an academic issue and increasingly an essential success factor for industrial, organizational and social innovation. Design and innovation in these contexts are characterized by complexity on the problem side and contingency on the solution side. The fierce rejection of 1st generation design methods in the early 1970s resulted in the postmodernist attitude of "no methods", and subsequently, after more than a decade, in the strong adoption of scientific paradigms and methods for

---

[1] "MAPS" stands for Matching Analysis Projection Synthesis and is available at http://www.designprocess.de. The title refers to Chow&Jonas (2008).

design research. The potential of the early (1^{st} generation) methods is neglected and the practical usefulness of design research is impeded as a result of the strong scientific bias. Besides, suggestions for 2^{nd} generation methods as discussed by Rittel (1972) and others have hardly been taken up in design. The current methodological dualisms fail to address these issues as a whole. There is no doubt that design and innovation projects today are increasingly knowledge-intensive and research-based. Nevertheless uncritical adoption of scientific methods and ways of thinking is showing strains. Certain sub-problems in design research projects need proper scientific ways of inquiry, but we suggest that the scientific approach alone is not sufficient.

The request for accelerated and systematic innovation suggests a need and an opportunity to adopt design as the generic process model of innovation. The emerging paradigm of "research through design" (Jonas 2007) provides a methodological and epistemological model for bridging the gap and creating the relation between "problems" and "solutions", that means for problem definition (dealing with complexity), solution generation (dealing with contingency) and project formation (dealing with the process that generates new facts and artefacts = forms). It also holds promise to end the dualisms by integrating both. Resolving the dualisms is a must if design research is to proceed to fulfil its potential and to meet its ambitious claims:

"black"	**Or "white"**	**→ And ("the beauty of grey")**
scientific methods	designerly methods	the flexible design process structures both scientific and designerly methods to allow the integration of heterogeneous scientific contributions
"proper" research	research through design	research through design, conceived as mentioned above, is proper and rigorous design-specific research
pre-rationalization	post-rationalization	both modes of reflection are complementary and proceed in a circular relation
descriptive methods	normative methods	both methodological concepts are necessarily complementary in designing
1st order methods	2nd order methods	a 2^{nd} order cybernetic view integrates both perspectives and resolves the apparent contradiction
control	conversation	the character of the process depends entirely on the observers´ interpretation of the situation, conversation seems to be the more effective approach
tool	medium	the character of the instrument depends on the users´ interpretation of the process, medium seems to be a more productive concept
rigourous	undisciplined	rigour in the trans-discipline of design is fairly complex and still barely understood; the hypothesis is that in trans-disciplinary endeavours such as design one has to be rigorously undisciplined in order to be relevant
research	design	essentially, research is a special mode of design, in practice there is a continuous transfer zone between the two, we have to re-discover "the beauty of grey"

Table 1: Overcoming dualisms in design research (Chow&Jonas 2008).

The challenge now is to operationalize these theoretical concepts of design thinking without destroying or suppressing the intuitive qualities of the design process by the rational approach, but to enhance them and to make them more explicit and communicable.

Questions, hypotheses and assumptions

The research questions are (a) theoretical: how to integrate design methods and scientific methods under a designerly paradigm of knowledge creation?, and (b) methodological: how to make them operable in a way which creates added value for designers and design researchers? The project is based upon the following assumptions:

a) Research THROUGH design is the appropriate paradigm of knowledge generation in design and mode-2 science today. (Glanville 1980, Knorr-Cetina 1981, Latour 1991, Nowotny et.al. 2001, Rheinberger 2001, Jonas 2007, Findeli 2008a,b).

b) There is more continuity in methodology than normally assumed. From a 2nd order cybernetic perspective, which accounts for the necessary and inevitable involvement of the designer / researcher in the process, it is possible to integrate the early (1st generation) methods as well as scientific methods into a more continuous and consistent concept of 2nd order design methodology, see fig. 1. Findeli (2006) identifies the same modes, albeit in a different terminology:

• AS: "Premier type : modèle de la théorie minimale",

• ABOUT: "Deuxième type: la théorie comme cadre interprétatif",

• FOR: "Troisième type: le design comme science appliquée",

• THROUGH: "Quatrième type: le design comme théorie située et pratique éclairée".

Observer position Observer looking	Outside the design system 1st order cybernetics	Inside the design system 2nd order cybernetics
outwards	research FOR design	research THROUGH design
inwards	research ABOUT design	research AS (?) design (inaccessible)

Fig. 1: The concepts of research FOR / THROUGH / ABOUT design – as related to the cybernetic concept of observer positions with respect to the design system (where design activities take place, see Glanville 1997).

We hypothesize that in order to operationalize research through design, the instrument, which we name MAPS must provide the following functions and characteristics:

• MAPS is an instrument FOR design (→ normative, improving the process, aiming at pre-rationalization),

• MAPS is based upon assumptions that are results of research ABOUT design (→ descriptive, building on post-rationalization of existing processes / models),

• MAPS is aiming at the support of research THROUGH design (→ conversational, an interplay of different observer positions, pre- and post-rationalization).

• MAPS gives space for research AS design (→ generative, the necessarily inaccessible component of every abductive process). This is the epistemological core.

RESEARCH THROUGH DESIGN – AN EMERGING PARADIGM

Designerly ways of thinking

Findeli (2008a,b) provides a brief epistemological clarification of the much-quoted "designerly way of thinking in design". He contends that it can contribute to research in general by delivering valid and trustworthy knowledge about a part of the world considered as its specific field of knowledge. The scope or field of design research, according to Findeli, is *general human ecology.* It is the stance or epistemological bent of design research, which makes the difference: it is normative, diagnostic, prescriptive and not primarily analytical / descriptive as in the sciences. Design has a *projective* stance, the world is seen as a *project*, not an object of inquiry. And this feature is not a deficit at all (Findeli (2008b):

"Recent developments in human and social sciences have dealt extensively with the issue of objectivity as a possible and desirable horizon in research. The interpretive or hermeneutic turn has shown that objectivity is not a relevant and fruitful criterion for research in those disciplines, and that rigorous inquiry is nevertheless possible without diving into extreme relativism or scepticism. On the other hand, the pragmatist epistemological tradition - where the engagement of the researcher is also required - may also be invoked to propose a robust epistemological framework for design research, not to mention action research (renamed "project-grounded research" in design research) as one of its incarnation in methodological applications.

… definition:

Design research is a systematic search for and acquisition of knowledge related to general human ecology considered from a designerly way of thinking, i.e. project-oriented, perspective."

Elsewhere, this is usually called research through design (RTD).

3-stage models - APS

There is a myriad of design process models, as the collection from Dubberly (2004) testifies. We do not want to provide just another model but to suggest an integration. Beside this messy pluralism – if we take a more general and slightly fuzzy view – we realize that hybrid and integrative models are emerging that acknowledge the "beauty of grey" between "mere design" and "proper research" and argue explicitly for a specific epistemological status of design research. There is a striking triadic pattern showing up: a genuine design-specific structure, albeit still in diverse terminologies, of the research process emerging in various "sciences of the artificial" (disciplines dealing with the teleological / purposive transfer of an existing state into a preferred one), such as design (Jones 1970, Archer 1981, Nelson and Stolterman 2003, Jonas 2007), management (Weick 1969, Simon 1969, 1977), HCI (Fallman 2008).

author	**Phases / macro steps / components of design (research)**		
Jones 1970	divergence	transformation	convergence
Archer 1981	science	design	arts
Simon 1977 / Weick 1969	intelligence	design	choice
Nelson&Stolterman 2003	the true	the ideal	the real
Jonas 2007	Analysis	Projection	Synthesis
Fallman 2008	Design Studies	Design Exploration	Design Practice

Table 2: Triadic concepts / domains of knowing in design research indicating a generic model of the designerly research process (see also Chow 2009).

The so-called APS-approach (Hugentobler, Jonas and Rahe 2004, Jonas 2007) (APS stands for ANALYSIS PROJECTION SYNTHESIS) has been elaborated and developed into an operational tool (Jonas&Chow 2008). The underlying theoretical model consists of the hypercyclic combination of three domains of knowing ("the true", "the ideal", "the real", Nelson&Stolterman 2003) - the macro-level, and 4 steps of the basic learning cycle (research, analysis, synthesis, realization, Kolb 1984) - the micro-level. The claim is that APS represents the generic structure of a design research process in the paradigm of research through design.

APS and further …

Three generic design process models from Simon / Weick (1977 / 1969), Nelson&Stolterman (2003) and Jonas (2007) provide the basis for the further deveolpment of our theory. They are different but compatible and can be synthesized in a productive manner. Jonas´ operational "macro phases" of the design process (Analysis, Projection, Synthesis) are related to Nelson&Stolterman´s epistemological "domains of knowing" (the true, the ideal, the real). Simon&Weick´s generic steps of the management process (Intelligence, Design, Choice) are integrated, because Boland (2004) has demonstrated that it makes sense and provides further insight to consider the 3 macro steps of the design research process (which we call A, P, S from now on) in arbitrary sequence. So it is essential to mention that the 3 macro steps of the design research process are arranged not in a linear but in a circular sequence, allowing any possible punctuation of the process:

1. **intelligence – design – choice (APS): Herbert Simon´s rational man economic theory,**
2. design – choice – intelligence (PSA): the "what have I done?" manager,
3. choice – intelligence – design (SAP): the existential introvert,
4. intelligence – choice – design (ASP): the chronically disappointed manager – "if I had only…",
5. **design – intelligence – choice (PAS): Karl Weick´s sensemaking manager,**
6. choice – design – intelligence (SPA): the existential hero.

According to Boland, from the six possible combinations of punctuations it is most reasonable to put Choice (SYNTHESIS) to the last moment. Therefore the sequence 1 - APS and the sequence 5 - PAS are the only desirable ones.

"NARRATIVE 1. INTELLIGENCE – DESIGN – CHOICE

The sequence of intelligence – design – choice is Simon´s own punctuation in which intelligence recognizes a need for intervention, design makes alternatives available for consideration, and choice selects the best (satisficing) one. This is the classic view of rational man who is intentionally goal seeking and uses intelligence and forethought to guide organizational action. Our literature is full of examples showing that this model does not represent how humans actually behave. Simon "saves" this model for economists by posing that individuals are boundedly rational and do not seek best or optimal solutions as a strong economic model might suggest, but rather search for solutions until one that is "good enough" is found – the boundedly rational person therefore satisfices. This image of a satificing human, as attractive as it may be, has an undesirable consequence that follows from its temporal dynamic. In light of Simon´s own recognition of the importance of problem representation, we see that this punctuation of managing is easily trapped by the common wisdom of those in a problematic situation – its sequence begins with a pre-understanding of the situation that can promote a myopic circularity in which the way we happen to be thinking about *things becomes institutionalized in the representation and definition of the world we face. My intuition is that this way of punctuating management action leads to a finer and finer attention to problem representations that grow increasingly irrelevant to the human condition. Welfare policy, education policy, transportation policy, and most public policy issues seem to fall prey to the traps of this form of punctuation."*

"NARRATIVE 5. DESIGN – INTELLIGENCE – CHOICE

Here, we have design as the shaping of things while engaged with others in the flow of action, and the producing of outcomes that are surprising to even the individual herself. Interaction with others generates equivocal enactment that is then subject to a sensemaking process. During sensemaking, intelligence is applied to order those elements of the raw action in ways that make the situation meaningful, aesthetically pleasing, and morally acceptable. This intelligence is followed by a choice of which meanings and sensemaking structures to carry forward into future enactments. This is a cybernetic system modeled after an evolutionary process, much like Weick´s sensemaking model with its pattern of variation, selection, and retention. Here, goals (if they are ever explicitly considered at all) are only understood retrospectively, and the raw, surprising enactments of design are the primary driving force of organizing. Weick´s many years of research on the sensemaking model of organizing shows how powerful this view of punctuating action is for understanding organizing behaviors both successful and unsuccessful. It is, in a sense, the antidote to the rational man model of the first narrative, grounded in a phenomenological appreciation of human action."

The distinction refers also to Lawson´s (1980) notion of scientists being more "problem-oriented" (analyzing the problem so that the solution can be derived from that) in contrast to designers being more "solution-oriented" working and thinking (generating tentative solutions until the best one emerges).

We can derive archetypical processes from the above considerations. The APS model **p**laces intelligence and goal-driven problem-solving as the driving activities (Simon 1977). Design research departing from a more or less known context, aiming at … solutions. The PAS model **p**laces design as the driving activity (Weick 1969). Design research departing from a highly unclear context, aiming at … innovations. Eliminating the doubles, we arrive at nine archetypical processes:

1	A	P	S	APS a "complete" design research process	Intelligence and goal driven problem-solving as the driving and leading activities in the design research process with / without Synthesis
2	A	P		AP a concept / futures studies process (without synthesis/realization)	
3	A		S	AS a "normal" design process (without proper projection)	
4	P	A	S	PAS a "complete" design innovation process	Design projection as the driving and leading activity in the innovation / exploration / research process with / without Synthesis
5	P	A		PA an exploration process (without synthesis/realization)	
6	P		S	PS a "risky", "speculative" trial&error process (without analytical grounding)	
7	A			A an analytic research process (inquiry into "the true")	disciplinary, domain-specific research or practice
8		P		P a projective futures studies process (inquiry into "the ideal")	
9			S	S a synthetic realization process (inquiry into "the real")	

Table 3: Nine archetypical design and design research processes.

By the way: Based upon these considerations it seems possible to describe the model of RTD as closely related to mode-2 science Nowotny et.al. characterize mode-2 science through primacy of the application context, transdisciplinary working situations, institutional heterogeneity (project-orientation), social accountability and new practices and criteria of quality control. In a mode-2 perspective there is a growing convergence of the design- and the research process; a shift from understanding to changing. We argue that it is the PROJECTION phase which integrates science and design and thus establishes the model of mode-2 science. This has to be elaborated elsewhere in more detail.

	ANALYSIS	PROJECTION	SYNTHESIS
Design			
Design Research (equals mode-2 science)			
Scientific Research (mode-1 science)			

Table 4: PROJECTION links Design & Science and establishes the model of mode-2 science.

CONCEPT OF MAPS

Distinctions of MAPS

MAPS is aimed to dissolve the toolbox' apparent rigidity and its conditioning and to provide a flexible, discursive and productive knowledge-supported medium. In the light of user experience with MAPS1.0 and against the background of deeper research into management processes (Boland 2004) and user-centered design research processes (Chow 2005) we realize the need to make the model more open and flexible. MAPS is designed to assist design researchers to specify / categorize (problem) situations, to match process patterns to the specified situation (and specify the role of design research), to select methods / tools related to the process, and to capture and retrieve design knowledge. Furthermore the new tool will assist the user in analyzing existing projects and processes (post-rationalization) as well as in configurating own processes (pre-rationalization). This contributes to the development of a knowledge base on design research processes. We consider four different functions / conditions of use:

• 'HELP': when experienced design researcher needs to locate quickly references on design research process, methods, tools.

• 'INSTRUCT': when design researcher needs step-by-step instruction on design research process, methods and tools.

• 'PROMOTE': when design researcher needs to explain the value and process of design research to partners and clients quickly.

• 'COLLABORATE': when design researcher needs to work closely with partners and clients.

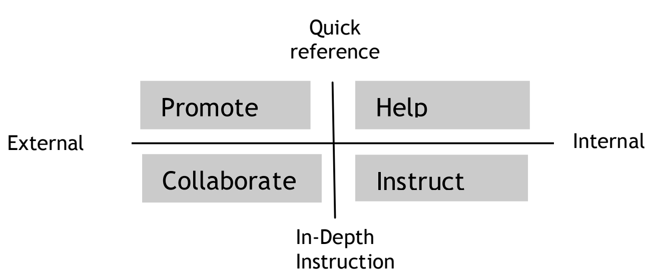

Fig. 2: MAPS provides four different functions.

The wider MAPS system

MAPS is aiming at the support of practice-oriented design, innovation and research processes. The long-term aim is the development of an integrated knowledge and communication platform for research THROUGH design. The outcomes of research through design projects are models in the widest sense: artefacts and new knowledge. MAPS assists problem specification by means of a questionnaire, which collects the main characteristics of the project. It suggests, if necessary, the use of a systemic model of the situation, which evolves during the process. MAPS provides an archive of methods. The methods are tagged according to the generic APS process model. MAPS generates preliminary process proposals, based upon the generic process model and using the outcome of the questionnaire (this is pre-rationalization). The process can be modified according to new and changing insights and requirements at any time, so that MAPS has the function of a communicative / reflective tool during the process. The final process can be documented and stored in a project archive for further evaluation and use (this is post-rationalization). Finally the growing project archive will feed MAPS and will generate new knowledge regarding the appropriate use of methods for the configuration of processes. Prototypical processes for certain situations may emerge, so that transferability of processes will be a longer-term effect of the use of MAPS.

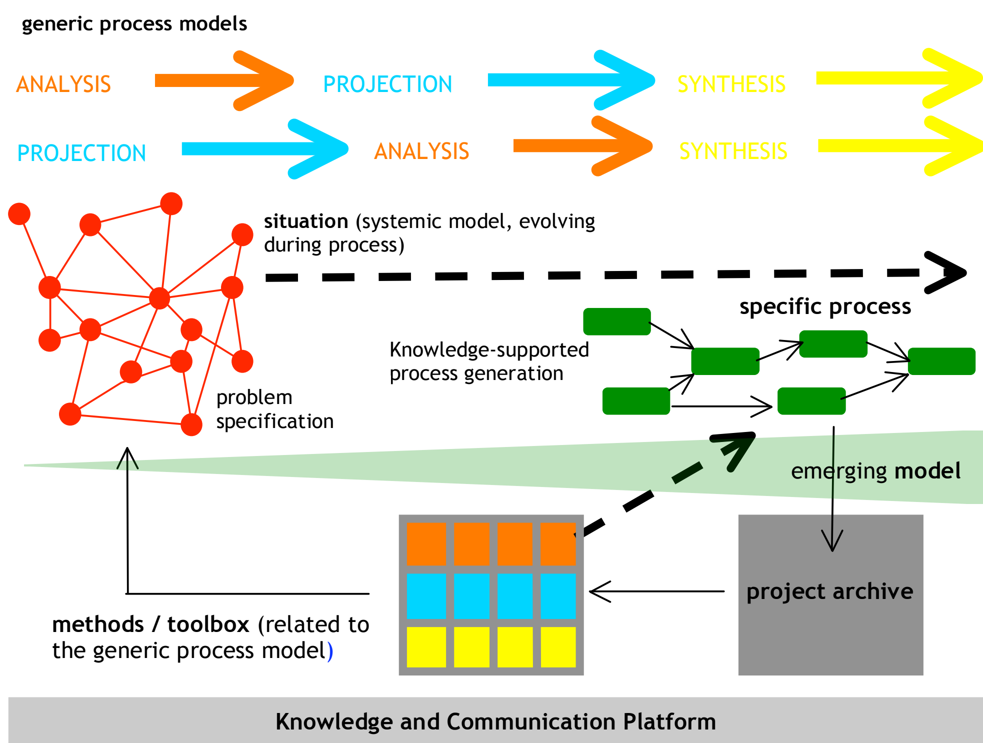

Fig. 3: The wider design concept of MAPS and its use.

OPERATIONALIZATION OF MAPS

Following from these theoretical considerations we have conducted in-depth user-studies in the context of a communication and information technological research center. Users from Business, Engineering, Design Design Research, were included.Following from these interviews, we transferred the four ideal functions as conceived above (Fig. 2) into three demonstrative use-scenarios or working modes for MAPS. They serve as guidelines for the development of the system and the specific user-interfaces:

• "WIZARD-mode" is an assistance tool, mainly for beginners, for knowledge-supported configuration of processes. It is highly normative, using the questionnaire for the specification of process requirements.

• "PLANNER-mode" is a discursive tool / workspace for planning a process timeline for a team of experts, possibly from different disciplines. It is intensively using the methods toolbox and the methods descriptions.

• "REFERENCE-mode" is a reference tool with easy access to the methods database and the project archive and links. Effective user-generated knowledge capture and retrieval features are implemented here

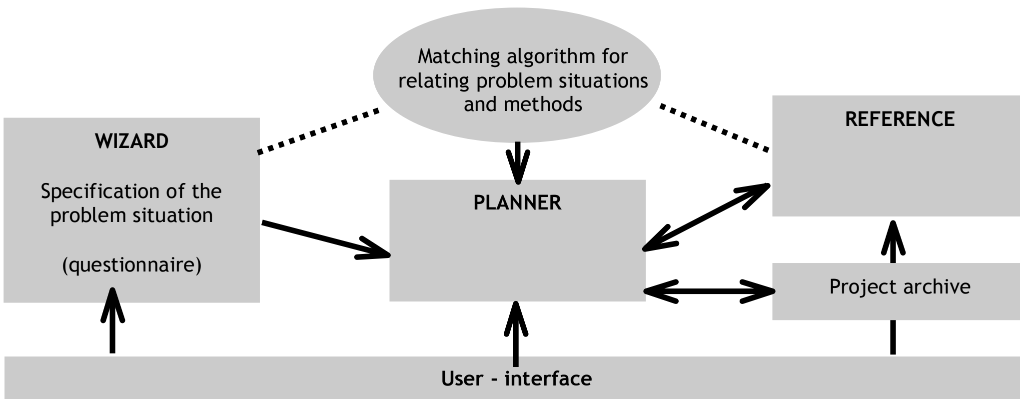

Fig. 4: Main components of MAPS2.0.

The questionnaire in the WIZARD mode is a tool for the user to specify his / her project situation. By answering the questions the user is also selecting tags that characterize the project. At the same time the tags are instruments for method profiling, that means characterizing their usability / usefulness for specific purposes. The set of tags is shared by the questionnaire (problem side) and the methods archive (solution side); they are the connecting elements. MAPS uses tags to match the situation with the suitable methods. That means for example: a problem situation can be designerly / scientific and a method can be designerly / scientific, etc. Matching the profiles of the situation and of the methods available contributes to the intelligent knowledge-supported selection of methods and tools for specific project situations. The matching algorithm for the meaningful relation of problem situations and methods is essential and still in the process of development and refinement ….

The four idealized functions (Fig. 2) are matched with users needs and made usable by three different interaction modes.

Function	**User needs**	**Mode**
Help	Easy handling (Step by Step)	Wizard
	Not so complex. Preselection of Information	Wizard
	Pre-rationalization	Wizard
	Not so interested in process, just need some advice on methods	Reference or Planner
	Favorite methods	Reference
Instruct	Archive	Reference

	Lots of in-depth information	Reference
	Search for particular method	Reference
	Fast & efficient	Reference
Promote	Access to other people's processes	Planner
	Post-rationalization	Planner
	Streamlining processes	Planner or Reference
Collaborate	Show process plan to client	Wizard or Planner
	Fix process	Planner
	Access to own history	Planner
	Reuse processes & methods	Planner or Reference

Table 5: User-centered functions and interactions of MAPS.

WIZARD is the mode for non-experts, who seek recommendation regarding the configuration of their design research process. See Fig. 5.

Julia (Design Think Tank) is a young designer who has just joined a design consultancy for a month. Her first project is to assist a senior designer to develop mobile communication for teenagers. She is very practice-oriented, creative and used to work intuitively. In her design education she has not learned to reflect and communicate her design process. But now she has to make explicit her methods and process. She is under time pressure for this short-term project and she needs to get information quickly and is looking for easy-to-understand cookbook descriptions of process and methods. Julia starts using WIZARD to get quick and plausible results. She also browses through REFERENCE and gets interested in the archived experience reports and ratings from colleagues and thinks about reusing existing templates, etc.

PLANNER is for those who have much experience in planning and carrying out projects. Users can enter PLANNER either through first using WIZARD or directly. See Fig. 6.

Barbara (Product Development) is a very pragmatic project leader with an engineering background. She leads a multi-professional team and needs to co-ordinate and to organize the group and information flow. She needs to plan in advance in details for every single project. Consensus among project members is highly important; therefore transparent and explicit communication is essential for successful teamwork. She needs clear overview of the project: what is happening when, with whom and where. Her projects are longer term with definite milestones. Moreover she is interested in new methods that improve efficiency and effectiveness. Barbara enters PLANNER, retrieves a successful project from the archive and modifies it according to the requirements of the actual project. From time to time she browses in REFERENCE in order to check out the newest methods and updates that might be useful for her team. Sometimes she also adds new methods that she finds useful to share with colleagues.

REFERENCE is for all to get information about methods. The user can search for the database of methods in various ways. Furthermore, (s)he can evaluate and comment existing methods and add own methods. See Fig. 7.

Herbert (Research Consultant) has a scientific background and is a very analytical worker. From his long consulting experience he has in-depth theoretical and practical knowledge about processes and methods. He needs and prefers scientific references, links, published case studies and literature for his work. He needs information and sound knowledge. He likes to keep record of his own projects to show clients. Furthermore, he is permanently looking for new knowledge and he is constantly building his professional network. So Herbert is a frequent user of REFERENCE where he comments and rates existing methods, looks for interesting new methods and projects and frequently adds new methods.

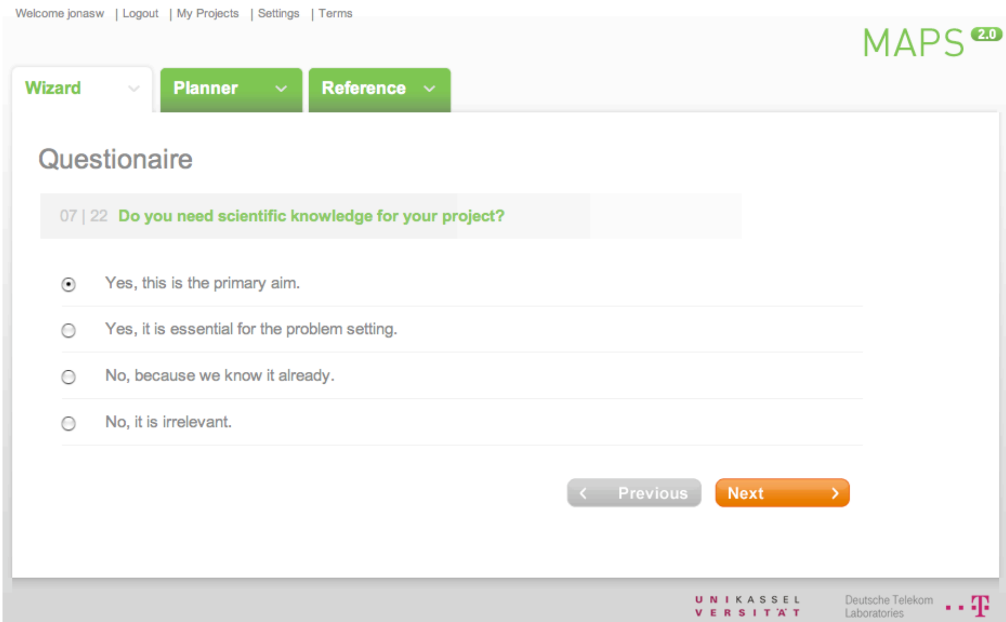

Fig. 5: Knowledge supported process configuration in the WIZARD mode.

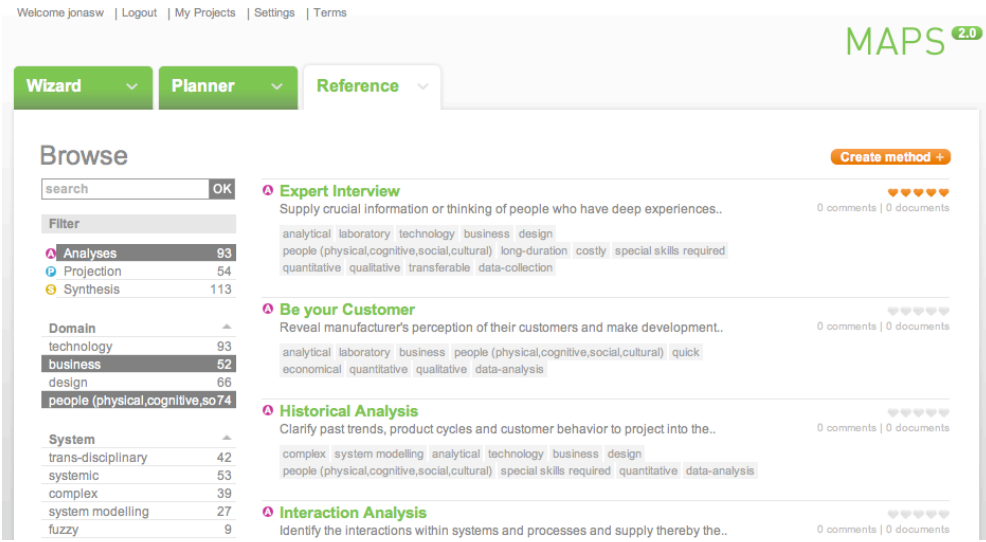

Fig. 7: Method description in the REFERENCE mode.

CONCLUSIONS

It is not difficult to find descriptions and representations of processes for designing, problem solving, and innovative product development. Evbuomwan et. al. (1996) and Dubberly (2004) provide a comprehensive collection of philosophies and process models. However, most of these representations, although informed by practical experiences, can hardly be considered systematic or rigorous. And even the more thoughtful representations come short in a few critical aspects, since they overlook the problematic situation, i.e. the relevant contextual factors of the project, or they conflate process models with methods and tools, or they fail to distinguish the epistemological domains of knowing (the true, the ideal, the real), or they are focussed on specific application areas such as software, HCI, architecture, etc. Table 6 provides an overview.

Our ambitious claim may be supported by the observation that there is self-similarity in the project. The entire ongoing development process of MAPS can be described so far as A – P – S – A – P – A – S … with open end: A: Analysing existing process models and tools – P: Projecting a tool for design research (theoretical concept) – S: Synthesising the first version of MAPS (toolbox and MAPS1.0) – A: Analysing user experience with MAPS1.0 – P: Projecting the improved version of MAPS – A: Analysing user needs for the new version – S: Synthesising the improved version MAPS2.0 – …

The rather rigid toolbox structure of MAPS1.0 has been made much more open and flexible in MAPS2.0. Three different modes are available by means of a user-friendly interface. Further improvements are required for each of the three modes:

• WIZARD: Filtering algorithm for matching problem situations and methods needs refinement. MAPS-users have to contribute.

• PLANNER: Connecting interfaces to project planning software might be helpful.?

• REFERENCE: User collaboration is required for the evaluation of the existing methods, for the thorough examination of the tagging logic, and the introduction of new methods

We are looking forward to MAPS3.0…

Wolfgang Jonas

studied naval architecture at the Technical University of Berlin, he holds a PhD in engineering (1983) and a lecturing qualification (Habilitation) in design theory (1994). Since 1994 he has been professor for "process design" at the University of Art and Design Halle, for "design theory" at the University of the Arts Bremen and for "system design" at the School of Art and Design, University of Kassel. His focus of interest: systemic design theory, design methods, scenario planning, research through design.

Rosan Chow

is a research scientist at the Deutsche Telekom Laboratories at. She holds a Bachelor and a Masters Degree in Communication Design and a Ph.D in Designwissenschaft. She has studied, practised and sessionally taught design in Canada, United States and Germany. She is a research fellow at the Communication Research Institute in Australia and the project manager of the newly established Design Research Network. Her research focuses on design theory and design research methodology.

Katharina Bredies

is a research scientist and PhD candidate at Deutsche Telekom Laboratories. She holds a Diploma in product and interface design from the University of Arts Bremen. In her dissertation, she explores the impact of irritating interfaces on the 'interpretative flexibility' of an artefact. Besides, she assists in research projects on design methodology and theory.

Kathrin Vent

is currently working as interaction designer for ACT-NET, a European project for evaluation and visualization of informal learning processes. She studied Product Design with focus on System Design at the University of Kassel and at the Escola d'Art i Superior de Disseny de València in Spain. Besides practicing design, she is preparing her PhD Thesis which focuses on learning processes in systemic design.

In Touch with Representation: Iconic, Indexical and Symbolic Signification in Tangible User Interfaces

Gesche Joost, Deutsche Telekom Laboratories, Berlin, Germany, gesche.joost@telekom.de

Fabian Hemmert, Deutsche Telekom Laboratories, Berlin, Germany, fabian.hemmert@telekom.de

Abstract

In this paper, we discuss the value of semiotics to inquire tangible user interfaces (TUI) in human-computer interaction (HCI). Drawing on Peirce's three types of representation – icon, index, and symbol (Peirce, Houser, & Kloesel, 1998) – we analyze signification processes in the design of tangible UIs. As a case study, we draw on several prototypical interfaces and analyze their semiotic structure. We focus specifically on three different significations for a similar application on a mobile phone: Displaying a new event on a mobile phone (e.g. an unread text message or a missed incoming call). The aim is to establish a basis in semiotics for TUIs that can inform the mapping between physical and virtual parameters. Taking semiotics as basis can help to enhance interface design as the interface 'specifies the optimal set of signs for the interaction between two entities' (Nadin, 1988, p. 273).

Keywords

tangible user interfaces, semiotics, representation, interface design, design research.

Tangible UIs is an emerging research field as the value of haptic perception in HCI is getting more and more into the focus of research and development endeavours. At the same time, easy handling and low-cost availability of prototyping tools for physical interaction (e.g. the Processing environment or the Arduino board (Cuartielles, Banzi, Mellis, & Igoe)) opened up new opportunities for interaction design. Today, it is possible to design prototypes for new digital products rapidly, making the interaction concept explicit and developing it further in fast iterations. Therefore, the production cycle for tangible UIs became shorter, and prototypes in the status of 'perpetual beta' are increasingly popular in interaction design. This practice can be described as *thinking through prototyping,* as the design of the actual prototype plays a major role in the whole research process.

Therefore, it appears crucial to provide a theoretical foundation for the interactive processes that are enabled through these interfaces. We propose that combining the *efficient practice of tangible interaction* with the *analytical potential of communication theory* might provide a basis for findings beyond a purely practice-based approach in HCI. Therefore, we argue that it is worthwhile to investigate the underlying *semiotic principles* of tangible UIs – principles that are derived from the study of signs in communication processes and applied to interactive communication between humans and computers. Physical representations of the virtual can be designed in various ways for TUIs, and semiotics can provide a valuable guide to find the right signification for a given purpose, including parameters like function, context, user, and interaction.

Background

In this section, we discuss relevant findings in *semiotics* and *tangible interaction design*, in order to provide a foundation for the semiotic analysis and contextualization of the three tangible UIs presented in this paper.

Icon, Index and Symbol in Semiotics

Charles Sanders Peirce introduced three basic semiotic categories that describe the relation between Object, Representamen, and Interpretant (Peirce, Houser, & Kloesel, 1998). The *icon* 'is a sign fit to be used as such because it possesses the quality signified.' [p. 307] Peirce gives the example of a geometrical figure drawn on a piece of paper that resembles a triangle. The *index*, the second category of signs, is a sign that is 'in real reaction with the object denoted' [p. 307]. His example is a weathercock that is physically connected with the wind, and, being a sign, is an index of the wind. The third category, the *symbol*, is defined as a sign that 'determines the interpretant sign' [p. 307]. Peirce's example is language itself, as it has a fundamental symbolic relation between letter, word and meaning. These categories had a deep impact on describing all processes of signification, especially when it comes to visual and iconic representation as in visual rhetoric or semiotics.

If we understand all design production as rhetorical action, as Richard Buchanan states (Buchanan, 1985), we can also apply these semiotic categories to interface and interaction in HCI. If we want to understand the communicative purpose of an interface and its semiotic structure, we can refer to *icon, index,* and *symbol* as basic categories. Hence, it is now aimed to understand the relation between the semiotic representation, the communicative function and the tangible UI. Mihai Nadin applied Peirce's semiotic paradigm to interface design in the late 1980s with a fundamental conclusion for interface design as such: 'Since the technology upon and for which we build interface changes very rapidly, pan-logical semiotic principles, in their breadth and depth, provide a foundation for improved interface design' (Nadin, 1988, p. 283). In his article, he investigated Command-Line Interfaces as well as GUIs. In this paper we argue that the basic assumptions and semiotic categories can also be applied to tangible UIs.

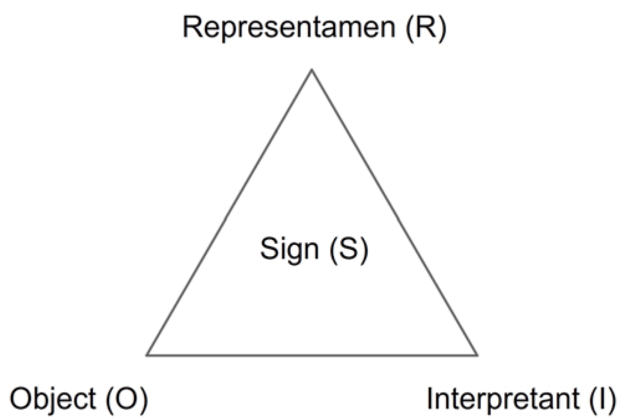

Figure 1, Peirce's definition of Sign.

Iconic, Indexical, and Symbolic Representations in Interface Design

Gui Bonsiepe defined the interface as a device turning 'Vorhandenheit' into 'Zuhandenheit', drawing on Heidegger's terminology. Therefore, he stressed the tool character of the interface as such and shed light on the aspect that an interface is more a relation between user, tool, and artefact than a simple input and output device. Nadin also enhanced the definition of the interface by defining every point of contact between user and computer system as part of the interface. As a result, there are many interfaces between the whole computer corporation and the market with users and potential users (Nadin, 1988, p. 274). We follow this broad definition of the interface when looking at tangible UIs. Furthermore, we stress aspects of time and physical space of interaction that draw on concepts of embodiment as being a specific quality of tangible interaction. Ishii and Ullmer, in 1997, proposed this style of interaction that couples 'bits and atoms' (Ishii & Ullmer, 1997).

Regarding the semiotic categories for interface design, the question is how object, representation and interpretant relate to each other in order to form a sign in the communication process between the entities. It is crucial to understand that the interpretant is not equal to a single user, but rather it characterizes the process of interpretation in which various users can be involved. All these significations (iconic, indexical, symbolic) are actualized through the interpretant and its human agency. Without this process of actualization there *is no* sign. Therefore, the interaction between object, representamen and interpretant in human-computer-interaction puts the signification into place.

The question is how iconic, indexical, and symbolic signification is used in interface design and in which forms they occur. Nadin gives the example of a virtual calculator that can be represented in all three forms – from an iconic representation of a physical calculator to a symbolic representation of the mathematical operations of calculating. In tangible UIs, the physical dimension comes into play and expands the realm of signification. The relation between object, representamen, and interpretant changes as there is no physical object being represented, but rather a function or action that is represented by the interface. This representation is actualized through the process of usage.

Signification in Tangible UIs

Iconic representations can be found in mappings based on *resemblance.* The icon resembles its representation in a certain way, although it can be an abstraction like we learned it from Peirce's example of the geometrical figure. When we look at Graphical User Interfaces (GUIs), we encounter some common examples of iconic representation, like e.g. the trash bin for the function of 'deleting files'. For TUIs, it is much harder to find examples as we are facing physical representations of virtual concepts.

In the LucidTouch project, Wigdor et al. (Wigdor, Forlines, Baudisch, Barnwell, & Shen, 2007) introduced a 'pseudo-transparent' device that displayed the user's fingers, interacting at the back of the device, on its display. The fingers on the device's back are filmed by a camera, and then shown on the display, as for enabling them to be used in the interaction with the GUI. The interaction with the device is, as the Wigdor et al. demonstrated, intuitively understandable, flexible in terms of its applications, yet limited to 'fingers represented by fingers'. The signs on screen resemble the fingers that touch the back of the device, and therefore, we can call it an iconic representation. In this example, we see a hybrid interface being a GUI with graphical display, and at the same time a tangible interface, because of its rich integration of the fingers into the virtual space (on the screen).

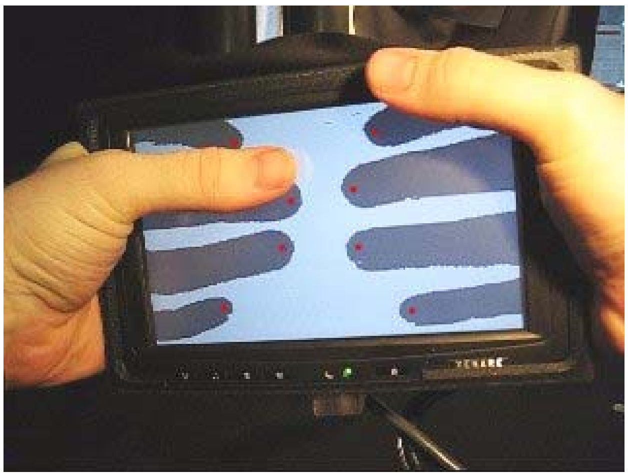

Fig. 2: The LucidTouch device.

Indexical representations can be observed in devices that draw on a *causal relationship* between digital entity and physical counterpart. In the FeelSpace project (Nagel, Carl, Kringe, Märtin, & König, 2005), Nagel et al. augmented users' perception with 'orientation information, obtained by a magnetic compass, via vibrotactile stimulation around the waist'. Here, the vibrotactile stimulation indicated the direction of north.

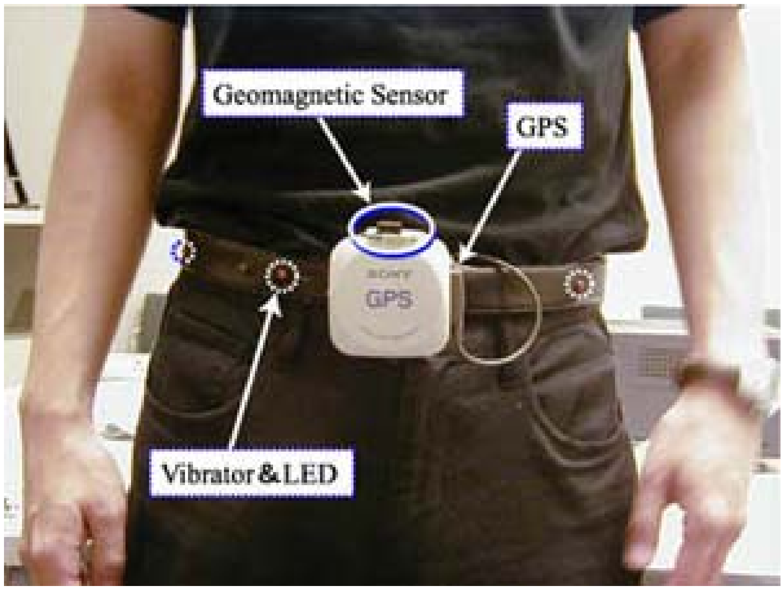

Fig. 3: The FeelSpace belt.

The actual digital data (zeroes and ones, respectively magnetic measurements data) is not represented in an iconic way here. Rather, it is interpreted, brought into connection with the belt's orientation, and then *linked* to a vibration into the direction of north. Therefore, we find an inherent link between the information and its representation within the TUI, an indexical representation. This kind of interpretation and reduction to a simple physical signal can be found more often in tangible interfaces. As the output channels are in many examples primarily used to provide a physical cue about the digital contents to the user, the representation is indexical. The model therefore is to have an output signal to the user that s/he can perceive in a haptic manner

Symbolic representations can be of use in many encoded physical representations. The *Marble Answering Machine* by Durrell Bishop (1992) is an example for such a type of representation. Here, a marble represents a message left on an answering machine. The user can interact with this object: Putting the marble into a hollow plays back the message. In this example, we find a *symbolic representation* of the digital content – a left message – that is translated into a tangible object, a marble. This mapping is not inherently obvious, as the data entity 'message' does not relate directly to the concept of 'marble'. In this symbolic representation, two semantic fields are connected that were separated before: a voice message that is related to the functionality and logic of an answering machine and to the usage of phones in general – and the marble, that is associated with child play.

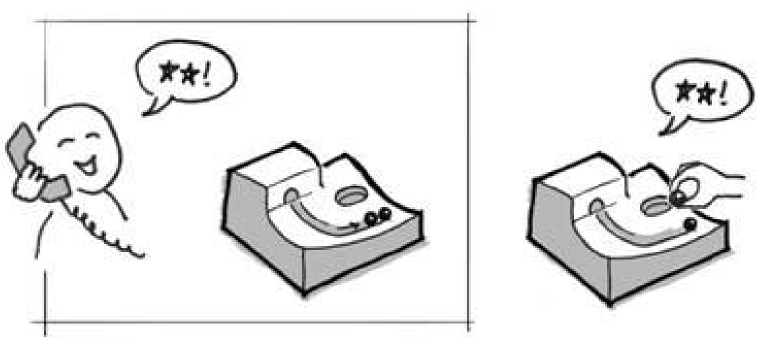

Fig. 4: The marble answering machine

Connecting these two fields adds a new semantic to both. The small, tangible children's toy gets an added functionality by representing a virtual voice message. The interaction with the marble still resembles the one of the children's toy: dropping it into a hollow, making rows of marbles, quite handy and easy. Therefore, this signification adds on the one hand a tangible interaction mode to a virtual message; on the other hand it applies the emotional value of a playful interaction to an answering machine. It should be noted that there is also an indexical component in this representation: The number of marbles 'waiting' on the device represents the number of messages waiting inside. In general, one finds often examples of a combination of different types of representations. As in the example of the answering machine, there are different layers of signification that form together the semiotic structure of the interface.

For now, we discussed examples for all three kinds of representation following Peirce's model. Therefore, we focused on the relation between a function and its semiotic translation within the interface. We discovered a higher degree of complexity in the semiotic structure of the three examples: an iconic and 'direct' representation of the user's fingers on the display; a tangible output signal representing certain information about directions; and a symbolic representation of missed calls adding a new layer of semantics to an answering machine.

In the following, we will draw on a case study of tangible UIs on mobile phones. We compare three different mappings for the same application: Displaying a new event on a mobile phone.

Case Study: Three Examples of Representation

We will now analyze from a semiotic point of view three research projects that we conducted in the past years: The *Dynamic Knobs* project (Fig. 5a), which employed an *indexical* representation, a project named *Weight Shifting Mobiles* (Fig. 5b), which also followed an *indexical* approach, and the *Ambient Life* project (Fig. 5c), which drew on *symbolic* representation.

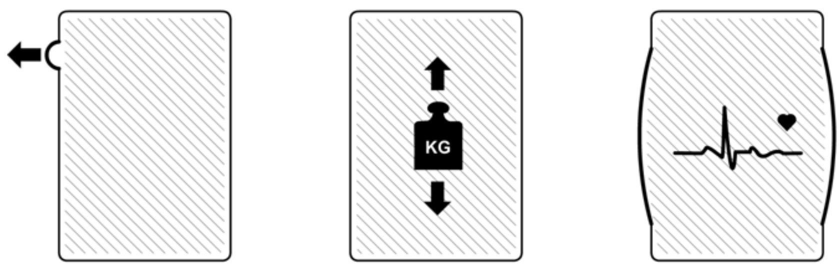

Fig. 5a-5c: Three prototypes, utilizing different means of user notification.

Dynamic Knobs: Indexical Representation

In common UIs of mobile phones, an event (e.g. new text message, missed call) is indicated on the display (GUI) as well as through a signal (vibration, ring tone). In the Dynamic Knobs project (Hemmert, Joost, Knörig, & Wettach, 2008), we utilized a physical representation of the mobile phone's internal events on its physical surface. A new event would result in a knob dynamically extending out of the phone's casing. Hence, the physical device itself changes its shape according to a change of status. The user can perceive an event in a tangible way by touching the physical shape of the device. The knob, a small entity sticking out of the rectangular shape of the phone's device, expands itself triggered by the internal event.

Fig. 6: The Dynamic Knobs prototype.

The principle is implemented through a servo motor in the phone's casing (Fig. 6), which moves a button out of the phone's case. On its surface, a pressure sensor is placed in order to measure the force exerted on it by a finger. The servo is strong enough to withstand most pressure a finger can exert, and the pressure sensor can measure weights between 10g and 10kg.

As soon as a call has been missed, the knob is extended out of the phone's casing. Therefore, we drew upon an indexical relation between an event (a missed call) and its representation (the physical knob). We argue that there is a physical relation between the sign 'protruding knob' pointing to the missed call (the event). Through interaction of the user by e.g. pressing the knob to listen to a voicemail, the sign is constituted. This interaction between tangible UI and user sheds light on the role of the interpretant. Through his or her interaction the process of signification is completed and the signs relates to its semantics.

This interface allows for direct interaction with the underlying virtual entities. In this particular example, the *being-there* of the message is particularly important, as its representation physically stands out of the phone's casing. Physical pressure can be applied to the – otherwise virtual – text message, like we discussed in the example of the marble answering machine. In further implementations, the length of a voice mail message was mapped to the length of the extended knob, so that the message could be 'squeezed' out of the phone while holding it next to one's ear. In this signification we find again a strong physical relation between sign and event when mapping the length of message with the extension of the knob. An indexical mapping with a physical representation allowed for convenient interaction with the digital content as the user had a direct hint how to interact with the interface.

User reactions

We conducted an informal user study with 6 users (2f, 4m, Ø32.2 yrs.), presenting them the prototype and asking them for their impressions. When confronted with this system and explained the concept of physical representation, they understood the pop-out knob as a *logical* representation of the digital entities. The approach was facing issues, however, when *more* than one event should be displayed, also *more knobs* would be required, as would other types of physical display for other types of virtual contents. Users emphasized that the principle proposed was *easily understandable*, yet *limited in its extendibility*. Nevertheless, the indexical representation was understood by most participants intuitively as being a reference to physical interfaces. Therefore, the signification seemed to be appropriate for the purpose.

Weight-Shifting Mobiles: Indexical Representation

In the second project, Weight-Shifting Mobiles (Hemmert, Hamann, Löwe, Wohlauf, & Joost, 2009), a moving weight was explored as a means of display in mobile phones. In one application, a new text message is displayed through the phone's centre of gravity being moved to the top of the screen. The message's placement inside the phone is physically *simulated*.

Fig. 7: Weight Shifting Mobiles Prototype

The proposed prototype employs a weight on a servo motor, which is affixed on the inside of a box. This weight-actuated box is then mounted underneath a mobile phone, which serves as the screen and button means for the 'weight actuated mobile'.

Interacting with a mobile device that employs an actuated centre of weight involves fine sensitivity for how the device *feels* in the hand. Its kinaesthetic behaviour changes with a moving centre of weight, and so, often, the information is perceived only in an ambient way, a circumstance that fitted the system's character of a non-visual information display. The event, e.g. a text message on the mobile phone, is signified in an indexical manner as it relates to a physical weight and location. A virtual event is therefore mapped to physical space and gravity. Interacting with the message, e.g. accessing it or browsing through a list of messages is assigned with physical parameters that are related to the interaction. This indexical mapping suggests a tactile sensing of navigation as well as a physical space and gravity of the mobile phone's informational space.

User reactions

A user test with 12 users (5f, 7m, Ø25.2 yrs.) was conducted. Users were engaged in a study regarding the accuracy at which they were able to estimate the weight's position, and also in a semi-structured interview that assessed their experiences. They appreciated the subtleness of the approach – they would be displayed additional information non-visually, yet perceivable while interacting. The idea of *information with weight as a sign of presence* in the device was considered intuitive, and was easily integrated with the users' interactions. However, users asked for *more realism* of the same interaction, e.g. to move the weight around in the phone by tilting it, instead of through the usage of buttons.

Ambient Life: Symbolic Representation

In the Ambient Life project (Hemmert, 2008a), a mobile phone is augmented with a permanent tactile heartbeat. Other iterations of the system (Hemmert, 2008b) included a 'breath'-like deformation of the phone's casing, following the same 'life-like' principle. In case of a new text message, the phone's heartbeat would then switch from the normal 'calm' heartbeat to an 'excited' pattern. This draws on the assumption that humans are inherently well-trained in the perception of life. It uses a *metaphorical signification*.

Fig. 8: Ambient Life Prototype

In the prototypes, the breathing is simulated through a servo motor that moves similar to a lung in a corpus. The heartbeat, as a second application, is simulated through a regular vibration motor, which is common to many current mobile phones on the market. The prototype of a mobile phone proposed in the 'Ambient Life' project informed the user about its state through instinctive cues. Interacting with it may, at first sight, be compared to interacting with a living being like a small animal. The metaphor would be a 'hamster in the pocket', as it simulates the mobile phone to be a living being, especially with an occasional need of attention. However, it is controlled through buttons and menus – not, as a real 'hamster' would – empathically, through touch and voice. It is, besides the pulse, purely technical. Therefore, the signification is symbolic as it maps two separated semantic fields – the one of living beings and its bodily functions and the one of virtual events on a mobile phone. The concept behind is to draw upon human ability to sense living being in an ambient way, like subtle breathing or heartbeat, and using it to inform about the status of a technical device. This mapping reminds of the children's toy 'Tamagotchi' from the 1990s were the user had to take care of a (non-functional) device like it would be a living being. This triggers a higher emotional involvement as it links to personal relationships in the real world. This prototype of 'Ambient Life' was, being a research prototype, not meant to explore new features of mobile phones for market use, but rather should trigger discourse on the question about our relationship to mobile devices today.

User Reactions

In a study, users (3f, 4m, Ø 27.1 yrs.) were handed the device and asked to carry it for two days. The phone randomly switched from 'calm' mode to 'excited' mode randomly several times per hour between 9:00 and 19:00. Users were instructed to 'take care' of the device, calming it down through a button press whenever it switched to 'excited' mode. The reactions to the heartbeat-augmented phone were mixed: In general, all users introduced to the phone fell into one of two groups: They would either perceive the device as 'cute', or perceive it as 'disgusting' – interestingly, none of the users was emotionally untouched by the device (which might have led to a perception of 'just a rhythmic vibration pattern'). The usage of the instinctive cue of the heartbeat allowed for a metaphorical *projection* of the phone into an *emotionally rich* context: living beings that need to be taken care of.

Along with that projection, it emerged that users *assumed more* than the functionalities that were actually implemented. For example, they assumed that the phone would be 'hungry', 'lonely', or 'in the need to be spoken to and caressed' – they attributed pet-like behavioural components (in this case: basic needs and emotion) to the phone.

Discussion

Analyzing different tangible UIs we formed the hypothesis that an iconic representation is hard to find. This is true due to the fact that there is always a semiotic translation between actions and physical representation within the interface. Therefore, an iconic representation based on resemblance is not likely to be implemented in TUIs. This category might be better applicable to GUIs – but this is a tentative finding that has to be investigated further.

In the first example, Dynamic Knobs, a functional event in mobile communication was represented by a physical sign in an indexical representation. Pressing the knob to trigger a function can be defined as an indexical representation, too. The second example, Weight-Shifting Mobiles, shows a physical representation of an action, in a dynamic way. The action of scrolling or navigating in space is represented via a similar movement that involves physical weight and movement. In a way, this representation is also partly symbolic as it attaches a symbolic weight to an operation in digital space. The third example, Ambient Life, is highly symbolic, as it refers to the metaphor of (artificial) life.

All these mappings draw on prior knowledge about conventions of interface design. One of these conventions is representing functions via specified elements like knobs or keys on a device. The indexical mapping applies an inherent logic connection between function and representation as we learned from Peirce’s example of the weathercock. This connection can be logically derived when interacting with a device. Therefore, in the example of Weight-Shifting Mobiles, this mapping is likely to be understood by the users through experiencing the interface. The symbolic mapping, in spite of this, is the most abstract one, where the representation is highly abstract.

Conclusion

In physical interaction design, the mapping between the physical and the virtual needs to be chosen with care – the pointed out semiotic translations can provide a valuable basis for this choice. We see from the discussion above that interface- and interaction design requires knowledge about the semiotic action that comes with it. Therefore, it is crucial to understand the kind of representation that is chosen to represent functionality. We suggest using the three semiotic categories, icon, index, and symbol, in order to describe the communicative function of the mappings that are made. We discussed several examples from HCI that involved different kinds of mappings for different interaction purposes. Further work has to be done on measuring user acceptance for these mappings according to the context of use. Furthermore, the applicability of these categories to interaction design has to be validated through alternative examples from interaction design. For such endeavours, we suggest to consider the aspects of flexibility, inherent logic, emotional richness as well as the necessary prerequisite knowledge.

Abstract

The use of system diagrams has encouraged information designers to tacitly consider the holistic context. However, because the traditional understanding about the nature of systems has been highly focused on the arrangement of components within a static model, users' experience is considered little. The goal of this research is to provide a theoretical framework to broaden designers' conception of the system diagram and enable them to design system diagrams that would prove most effective for different situations, needs, and design problems. Therefore, the key of system diagrams is to understand the relationship of how the system is organized, according to the intent of the designer, the purpose of the user action, and the function of the group. In order to further investigate this notion of a system diagram, we present four kinds of system diagrams where relationships emerge, depending on the following organizing principles: 1) law that holds together individual components, 2) rule that guides decision making, 3) function that supports users' action possibility, 4) condition that facilitates participation in cultural ideals. In addition, we examine numerous system diagrams that have been created in the Domestic Mail Manual Transformation Project by the Carnegie Mellon School of Design and the United States Postal Service. This is a design case study that not only illustrates the role of system diagrams throughout the design process but also identifies four cases of system diagrams according to different goals: structure diagram, pathway diagram, affordance diagram, and vision diagram.

Keywords

System diagram; information visualization; interaction design; design principle; case study

The role of information design has become increasingly important in our society, as people desire to regain their sense of control within an environment of information overload and growing idea complexity. However, many information design products take the approach of limiting people's choice of action rather than supporting decision making with open possibilities for action. For example, when there is an unexpected delay in a bus service, it is not easy to identify the problem and find another bus route if the users are only provided with scattered information. Without having a clear understanding of how the bus service system works holistically, users may not be able to take alternative actions if there is any breakdown in the sequential information initially given to them.

Among numerous approaches to resolve this problem, the use of system diagrams is the only one that allows information designers to tacitly consider the holistic context. There is a need for not only understanding the system itself, but also a need for studying system diagram as means of effectively communicating the system, which is abstract in nature. While the use of system diagram is still a key component in communicating and understanding the holistic structure of an information system, designers often have difficulty in discussing systems as an aspect of their work, even in contemporary discussions of design. Because the traditional understanding about the nature of systems has been highly focused on the arrangement of components within a static model, often the user's experience ends up fragmented and degraded.

The goal of this research is to provide a theoretical framework to broaden designers' conception of system diagrams and enable them to design system diagrams that would prove most effective for different situations, need, and design problems. In this paper, we will study the nature of the system diagram by presenting four kinds of system diagrams, analyzing different examples of system diagrams, and discussing how each mode of thinking is utilized in different needs and goals in the design process.

Organizing Principles of System Diagram

Encyclopedia of Science, Technology, and Ethics defines a system as "a set of distinctive relationships among a group of components that interact with one another and their environment through the exchange of energy, matter, and/or information" (Strijbos & Mitcham, 2005, p.1880). Although system thinking is regarded as dating back to the 1950s, it has been always prevalent in human history. But the big change today, states Richard Buchanan (2001b), is that the focus is no longer on material systems but on the aspect of the human who experiences the system. He further points out that:

> One of the most significant developments of system thinking is the recognition that human beings can never see or experience a system, yet we know that our lives are strongly influenced by systems and environments of our own making and by those that nature provides. By definition, a system is the totality of all that is contained, has been contained, and may yet be contained within it. We can never see or experience this totality. We can only experience our personal pathway through a system. (Buchanan, 2001b, p.12).

Then the question is—how can we possibly design a system diagram, if a system is the wholeness of the totality, and human beings can't experience the whole? In fact, the role of a system diagram is not a mere representation of particular phenomenon or fact. According to Charles S. Peirce, "diagram not only represents the related correlates, but also, and much more definitely represents the relations between them, as so many objects of the Icon" (Peirce, 1906, p.316). In this respect, system diagrams are about relationship.

Here we should not simplify a relationship as mere connectivity between numerous components, but rather take it as an idea or a thought that integrates different parts into a whole, that is, the organizing principle of the system. According to Buchanan, human beings can't see or experience the totality of the system and, therefore "in our effort to navigate the systems and environments that affect our lives, we create symbols or representations that attempt to express the idea or thought that is the organizing principle" (Buchanan, 2001b, p.12).

As the focus of system has shifted from things to human beings, a system diagram should be regarded as a visualization of the organizing principle of the system, which alters system into a *place* that opens up users' action possibilities and supports effective use of the system. In turn, the key of system diagram is more than to *represent* relationship among things. The key is to *understand* the relationship of how the system is organized, according to the intent of designer, the purpose of user action, and the function of group. In order to further investigate this notion of system diagram, we present four kinds of system diagrams where relationships emerge depending on the following organizing principles (figure 1): 1) law that holds together individual components, 2) rule that guides decision making, 3) function that supports users' action possibility, 4) condition that facilitates participation in cultural ideals. (Buchanan, 2008)

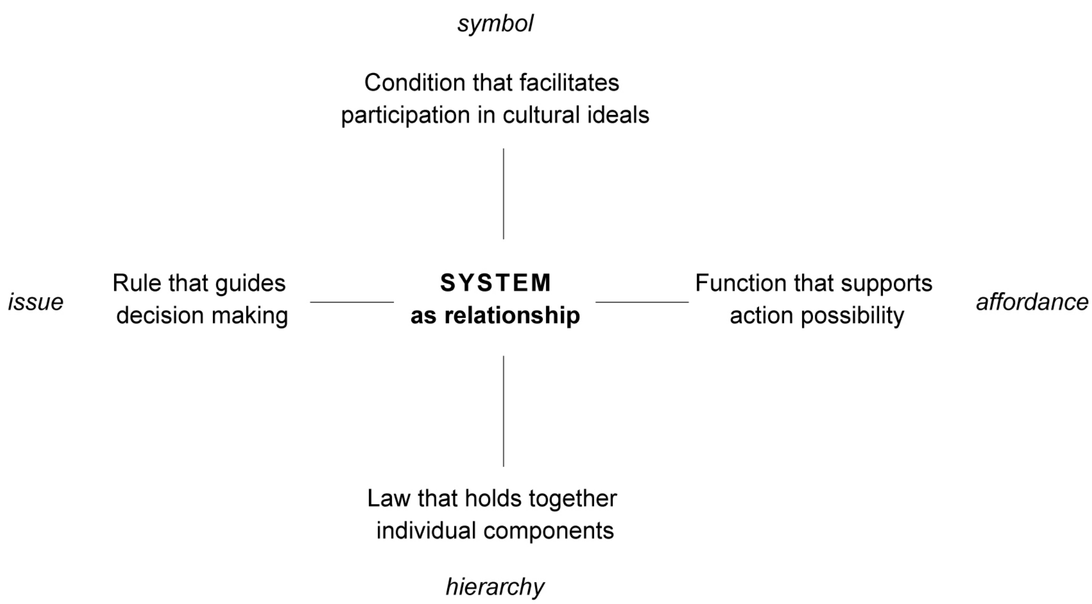

Figure 1. Organizing principles of system diagrams

System as law that holds together individual components

First of all, Herbert Simon's discussion on system gives insight to understanding system as an aggregation of individual components. Simon explains a complex system as "one made up of a large number of parts that have many interactions" (Simon, 1969, p183). As he seeks to find the essential quality of what is this interaction that constitutes the architecture of complex systems, ranging from artificial/natural adaptive systems, social systems to symbolic systems, he finds that the complex system is composed of subsystems and the subsystems are again made of their own subsystems. He sees this hierarchy to be the distinctive relationship among the parts that organize them into a system. As he states that "hierarchic systems have some common properties independent of their specific content. Hierarchy is one of the central schemes that the architect of complexity uses" (Simon, 1969, p184), hierarchy can be explained as a kind of law that serves as objective force that is universally applicable.

Network diagram is one of the representative system diagram that starts from this principle of hierarchical relationship among individual elements. Figure 2 is an example of social network analysis. Similar to a molecule made of electrons, individual people in the network diagram below would be mere elements without the hierarchical relationship visualized by the lines, the distances among people, and the overall positions of people. The repeated hierarchy of who gives order to whom and who belongs to whose command becomes the core organizing principle that holds those individuals together into a system and serves the purpose of analysis.

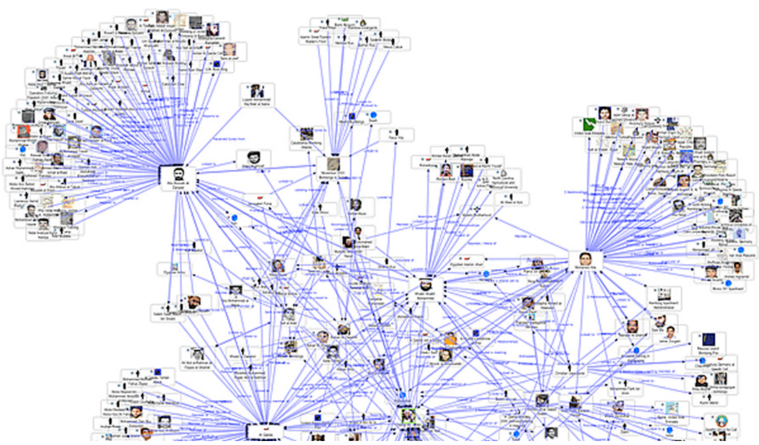

Figure 2. Network (http://www.fmsasg.com/) [1]

The system diagrams in figure 3 share the same element of the celestial bodies from the Solar system. However, the hierarchical law that serves as organizing principle is different in these two diagrams, which yield two different forms. The diagram on the left focuses on the hierarchy of size rather than exact representation of the distance. In comparison, the diagram on the right based on the hierarchy of distance omits the irrelevant hierarchy of size.

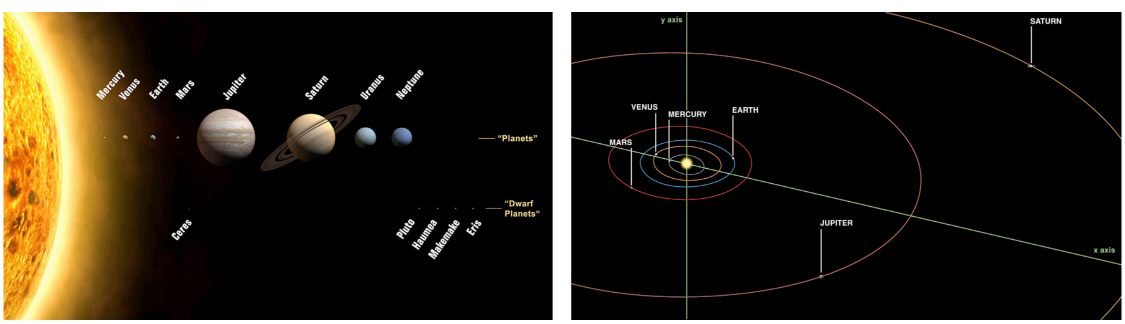

Figure 3. Solar system (http://en.wikipedia.org [2] and http://nasaimage.org [3])

System as rule that guides decision making

The next approach is based on the understanding of system as a set of rules that guide an agent's decision making. In contrast to the first approach that focuses on hierarchy among individual components, the emphasis of this approach is put on the role of the agent in the system, in particular, choices that individual agents can make. This is closely related to the discussion of information system by Kunz and Rittel when they define a system as "constructs of rules and procedures which are meant to serve the desired end" (Kunz & Rittel, 1984, p.57). It is important to note that they bring rules and procedures to their discussion of system. Instead of regarding a system as a piece of hardware that consists of individual components, they are instead interested in the human aspect of system, the agency that operates the system. In this respect, what organizes the second kind of system is rules that are arbitrarily chosen and changeable, not universal laws or truth.

In addition to this concept of agency, it is also important to discuss system as "an argumentative process" that is based on "a model of problem solving by cooperatives." This is articulated in Kunz and Rittel's discussion of an Issue-Based Information System (1970) where *issues* are identified as elements of system along with other elements, such as topics, positions, argument, etc. According to the authors, issues are "brought up and disputed because different positions are assumed" (Kunz & Rittel, 1970, p.2). Therefore, this kind of system leads individuals to continuously make decisions on the issues that are encountered by their reasoning process so that they reach the decision considered the most reasonable among all possible opinions.

One of the most common examples is a flowchart (figure 4). A flowchart is a diagrammatic representation of step-by-step procedures, and each step is connected to the next based on the cascade of issues that arrives at a ultimate solution to a problem. In this respect, flowcharts have been used as a method for problem solving, because they break down the whole process into manageable steps, where issues become focal points that determine the sequence of individual decision-making. Figure 5 is another example of system diagrams that visualizes the lifecycle of EMI Music products and operations. What makes this distinct from other kinds is the use of related environmental issues as color-coded arrows in order to organize key environmental areas, such as manufacturing facilities or music publishing suppliers.

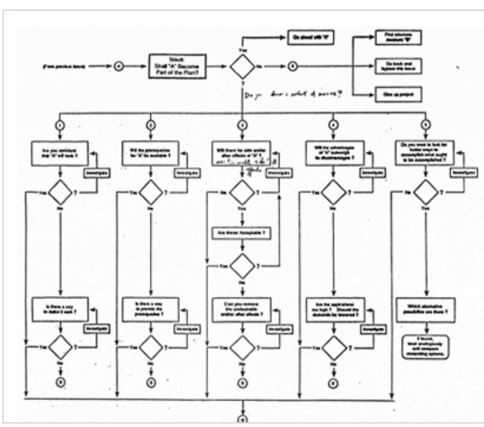

Figure 4. Flowchart [4]

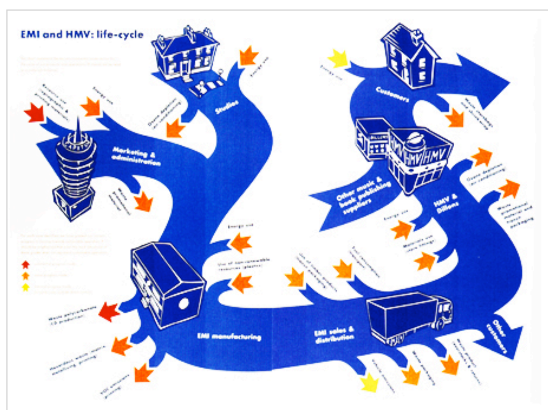

Figure 5. Music product life-cycle [5]

System as function that supports action possibility

The third view is to understand a system as an organic group. This view emphasizes a whole rather than parts, where the characteristic of the whole is lost if mechanically cut into parts. James J. Gibson proposes that human visual perception is not merely a channel but a system that requires all the parts to work together, with explanation that "vision is a whole perceptual system, not a channel of sense. One sees the environment not with the eyes but with the eyes-in-the-head-on-the-body-resting-on-the-ground" (Gibson, 1979, p.205). He further explains that a system has organs, compared to a sense with mere receptors. For Gibson, function is the key relationship that makes an organ a necessary part of the whole, as he states that "the perceptual capacities of the organism do not lie in discrete anatomical parts of the body but lie in systems with nested *functions*" (Gibson, 1979, p.205).

System and relationship in this third approach are especially meaningful within the context of experience design. Experience is our interaction with environment, and environment can be interpreted as a kind of system that supports our action possibility. However, it is not the case that any surrounding can serve as environment for an organism. Following Gibson, the environment and the animal are inseparable because the animal modifies the environment and the environement shapes the action of the animal. Therefore the environment *affords* the animal, in the sense that the environment as the system provides the function of good or bad. Based on this relationship of function, Gibson presents his theory of *affordance*, which can be explained as a necessary relationship of the ever-changing interaction between a living anmial and the environment.

An example of system diagram from this approach could be an airport sign system (figure 6). We may not easily recognize individual signs as affordance until our situation calls for the need to understand the function of each sign and how they work together in holistic relationship, in order to achieve our goal using this sign system. When the action-takers find out the relationship, they realize how the signs and maps in the environment work together just as navigating within a huge system diagram. This is the moment when meaningless pieces of signs are related to other signs together, and a surrounding is altered to an environment that provides systematic supports for action possibilities that are open to their different needs and goals.

Figure 6. Cologne-Bonn airport signage system [6] and map [7]

System as condition that facilitates participation in cultural ideals

The fourth kind of principle comes from the transcendent ideas that gives a unity to individual parts. In this approach to system diagrams, individual elements are still a recognizable, yet harmonious interaction among disparate parts of system and become an integrated whole to serve "a higher ethical, spiritual, cultural or aesthetic vision" (Buchanan, 2001a, p.82). In contrast to the three approaches described above, the distinctiveness of this approach is the emphasis on this transcendent whole. The fourth approach regards system as a condition that facilitates participation in these ideals, such as culture, truth, vision, or beauty, depending on the context and the purpose of system diagrams.

At this point, Kenji Ekuan's discussion of the aesthetics of the Japanese lunchbox (1998) can be useful to articulate this further. For Ekuan, the Japanese lunchbox is not merely a physical assortment of different kinds of food. All the ingredients are artistically arranged so that the visual layout pleases the eyes of the person who takes off the lid. However, the real beauty of lunchbox does not come from the skillful arrangement of elements, but from the harmonious integration of all distinct elements. Although individual ingredients are still recognized in this system, what is more important here is the appreciation of the cultural ideal that gives a unity to parts that otherwise remain separate. In this respect, the Japanese lunchbox serves as a symbol that embodies the cultural and spiritual ideal of Japanese culture. Its form and structure become the expression of the ideas of beauty as function or unification in diversity that is deeply embedded in Japanese culture.

Figure 7 is an example that illustrates this approach – a Tokyo subway map designed by Richard Wurman for the *Tokyo Access* guide (1984). In this map, what is first noticed is the symbol of yin yang along with the Imperial Palace marked as a red circle. When he created this subway map to emphasize the connections of two lines with reference to a familiar landmark, he deliberately altered the form of actual subway lines (left) to the yin yang symbol (right) so as to make it easier to understand and remember. In this example, the use of symbol is effective not merely because it simplifies the form of lines into an easily recognizable symbol. What is more important is that it symbolizes an idea of Japanese culture in its form, which organizes individual functional components (subway stations) into a unified whole (Japanese culture). In this repect, this can be an example of system diagrams that serves an intended function as well as expresses an idea of culture through its form that transcends individual human experiences.

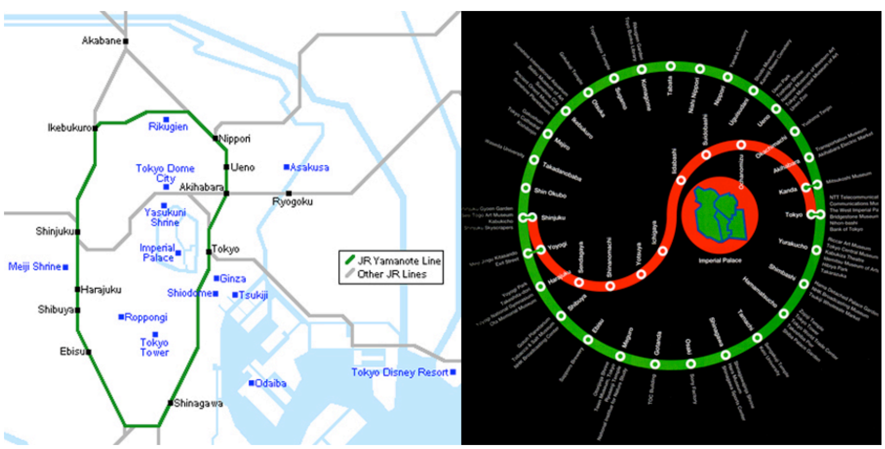

Figure 7. Tokyo subway map [8] and Tokyo transportation system [9]

Case Study: The USPS Domestic Mail Manual Transformation Project

So far we have investigated different kinds of relationships that are found in various system diagram examples. Understanding the relationships of individual components is the key to identify the organizing principle of a system. Then, is it possible to identify these relationships in the context of a design process? If so, what is the primary focus of each relationship in the activity of designing? When designing, system diagrams can be used in various stages of the process in order to serve different purposes of designers using system diagrams. System diagrams can serve as a roadmap at the very beginning of the design process or function as a means of communication with internal stakeholders or with clients during the process. They can also become a final product to inform customers. Although we may point out the distinct characteristic of system diagram examples in different phases of the design process, they can be distinguished one from another depending on the context and the purpose. This also changes the relationship as well as affects its formal representation.

From now on, we will examine how different kinds of relationships emerge in various system diagrams that have been created in a specific design research project. The Domestic Mail Manual (DMM) Transformation Project[1]was an interaction design project that moved beyond the traditional information design approach towards redesign. Similarly to the Australian Tax System design project (Preston, 2004; Body, 2008), the DMM Transformation project focused on designing the information system with a long-term goal of encouraging organizational change in the United States of Postal Service.

The DMM is a 1000-plus-page manual that contains all the mailing standards in the US. It serves as the operational core of a federal agency that employs 800,000 postal workers and supports an industry of more than nine million people. However, this manual did not provide employees and customers the tools to understand mailing options and guidance for making informed decisions because of the complexity, difficulty of use, and inaccessibility of the structure. Therefore, designing the information architecture became the most important concern, especially because the scope of the project did not include changing the actual wording of regulations. Since there was a big discrepancy between the existing topic-based structure and the way users make decisions, "understanding the relationships of the information contained in the DMM was the key to creating a structure that properly reflected the connections and dependencies within the document." (CMU and the USPS, 2005)

For this reason, human-centered design approach became the fundamental principle that guided multiple goals according to different design stages. During the restructuring of the architecture, numerous system diagrams were created to serve various goals. In what follows, we will illustrate four cases of system diagrams according to different goals, to show how the four kinds of relationships we discussed in the previous section are used in an actual design project.

Structure Diagram

One of the fundamental goals of this project was to design a new system architecture that improves efficiency of use. There was also a need to devise a resilient system that could evolve over time. In the initial stage of the project, designers continuously analyzed, tested, and restructured the contents with different versions while working closely with content experts at the USPS to ensure that the details of the structure were

---

[1] The DMM Transformation Project (2001-2005) was a research project in the Carnegie Mellon School of Design that was funded by the US Postal Service from 2001 to 2005. (Richard Buchanan, project director; Angela Meyer, project manager)

accurate. Different system diagrams were generated in this process to analyze existing structure (figure 8) and to represent changing architectures. Therefore, we needed a system diagram that focuses on simple and universal hierarchy that would serve as a basic reference point for the ongoing conversation.

After the redesign of the architecture, the team collaborated in fitting the actual content into the new structure. We introduced Adobe Framemaker application because of our concern of how to support the sustainable management of a document with such a complex cross-reference. As time goes by, there would inevitably be a need to change the document as the regulations in the content would be updated. Our solution was to create a working system for the ongoing editing and publication, including software, content, code, and maintenance guidelines, that allows the USPS to continue to develop the DMM. Figure 9 is a diagram of the publishing workflow of the DMM, which was prepared as part of the maintenance guideline. The major relationship depends on the analytical representation of how computer files are co-referenced. When compared to figure 10, which focuses on the architectural analysis, the content does not differ much but the represented relationship does since the need and purpose change. Figure 10 focuses on shape-class-topic hierarchy, whereas figure 9 focuses more on the hierarchy of regulation numbers.

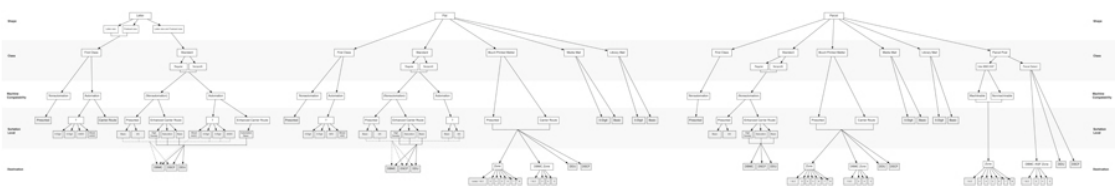

Figure 8. Rate structure analysis

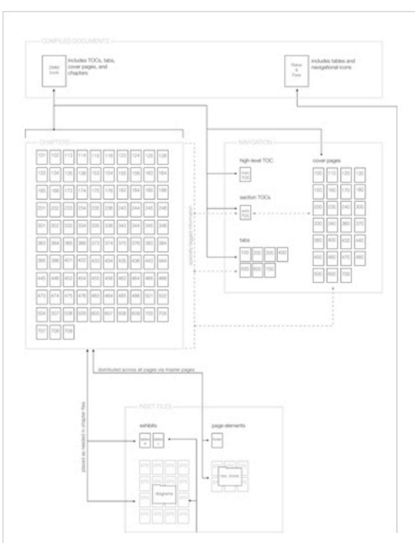

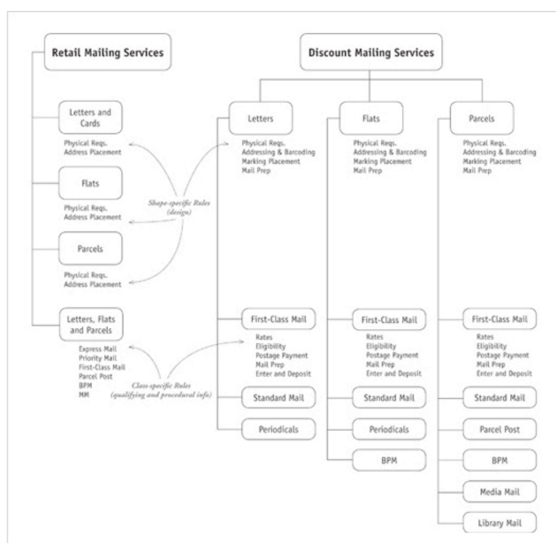

Figure 9. Framemaker file structure

Figure 10. Architectural analysis

Pathway Diagram

Another important goal of the project was "to develop user pathways to help customers find the information that they need in the DMM" (CMU and the USPS, 2005). In order to achieve this goal to guide users to make informed decision, figure 11 was built based on the idea of intuitive user pathways. Here, individual pathways are structured following the logic of decision-making based on cascade of questions that a user would logically ask when trying to decide *whether* and *how* to use the postal service, for instance, "the *issue* of shape" answering the question, "what are you mailing?"

In figure 11, what stands out the most is the connections made by lines with multiple cross-sections that lead to a certain destination, just like subway maps. Selection of this particular form was appropriate not only to emphasize the aspect of pathways but also to serve the intended function of this particular system diagram in the following two ways. First, pathway diagram makes procedure notion apparent so that the connections between modules are recognized as navigable pathways. When transitioning from the phase of redesigning the new information architecture to the phase of fitting the content into the new structure and its detailed adjustment, we needed a new system diagram different from the ones developed in the previous phase. This led us to create a new system diagram for this phase that could promote shared understanding of the team upon the new structure proposed. Second, this diagram was used to manage process and tasks. When we were deconstructing the existing structure of the DMM to fit the content into the new one, this diagram was used to visualize and check the progress as we finished each modules.

This relationship becomes clear when comparing figure 11 to one of the previous iterations for the same purpose (figure 12). In fact, there were some advantages in figure 12 in that the amount of each module and the regulation numbers could be more visible. However, that was not the primary relationship that figure 12 needed to visualize because the idea of navigable pathways that guide decision making process was not apparent. Furthermore, representing each module as book shapes seems to emphasize the materiality of documents rather than the connections between the modules. In a sense, the organizing principle in the figure 12 is closer to static hierarchical organization for structure diagrams.

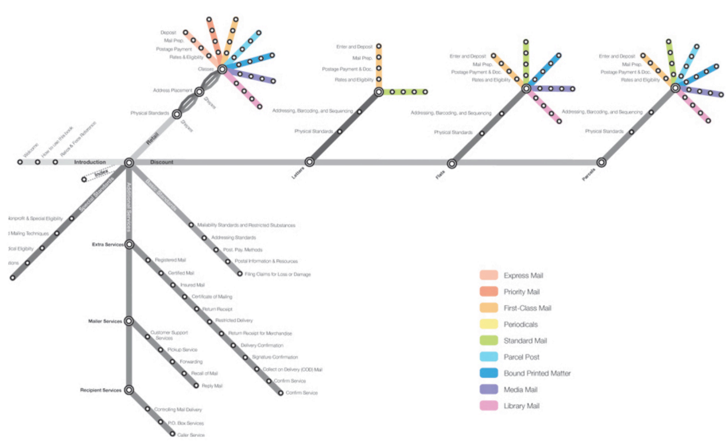

Figure 11. Pathway diagram

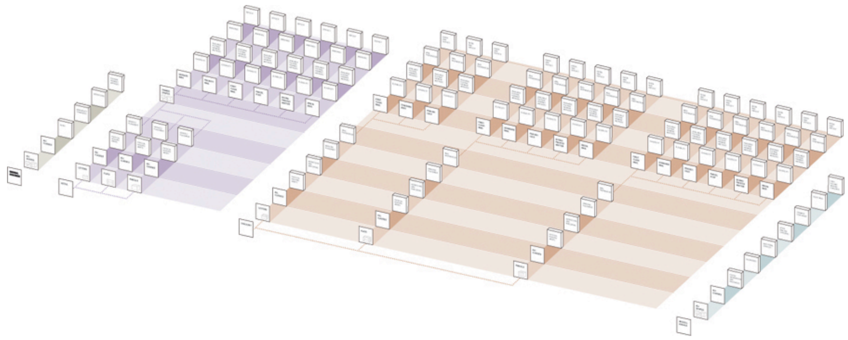

Figure 12. Proposed architecture

Affordance Diagram

Another goal of this project was to create a document that is intuitively meaningful to the user, focusing on an information system that presents the standards from a practical user perspective, that serves pragmatic needs, and is concrete. After we completed the restructuring of the architecture and inserted the content, we realized the need to prepare introductory material for the users. This introductory material was more than just a preface or a table of contents in that the purpose was not just to help the user find certain information. First, as the old DMM has been transformed to the new DMM, there was a need to offer a quick and easy explanation that helped users to understand the difference, and to let them know how to use the new DMM. Second, this introduction material also needed to serve as a promotional piece that encouraged USPS employees to embrace the new document and to educate themsleves.

Figure 13 is the core system diagram that illustrates the document structure of the new DMM. Here, *affordance* is the key organizing principle of this diagram based on the user-centered approach that accommodates users' needs as well as the creation of satisfying user experience by providing intuitive access and a seamless transition. This is articulated in the DMM process book as the following: "A good document architecture does more than just provide categories and arrangements for content. It is designed to create *affordances* for good user experience and is closely informed by users' real needs and expectations" (CMU and the USPS, 2005).

Figure 13 is an example where this relationship of affordance is reflected in various ways. First, it is found in the way the new DMM is physically represented in this diagram. In contrast to other shematic system diagrams, this one imitates the physical aspect of the new DMM, such as the color-coded divider tabs for each section or the binder for the entire volume (figure 14). The idea of a modular approach is also reflected in a similar way to best meet user's needs by modifyng the document. Second, the use of perspective implicitly reinforces this relationship of affordance, in particular by presenting the shape of the new DMM in the moment when opened for use, reflecting users' point of view. In order to use the new DMM, the first step is to assemble the whole documents into a binder for personalzation. This system diagram affords the user's action possibilities for how to assemble this document, not by directly instructing but by indirectly providing one of the major entry points for navigation of the documents. This organizing principle becomes evident when comparing figure 14 to another iteration. Figure 15 may be a more realistic representation of the volumes to some degree, because it shows the hierarchy of thickness of each module. However, this detailed description is not important in the context of user action.

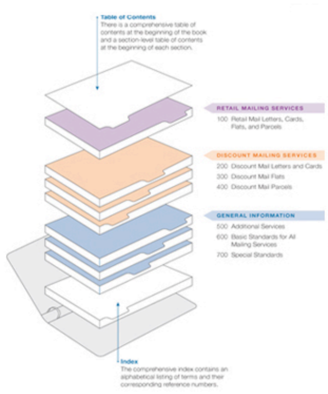

Fig 13. Oganization diagram Figure 14. New DMM's color-coded divider tabs

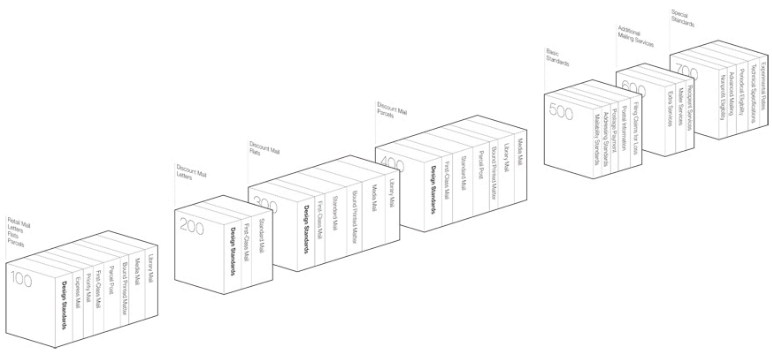

Figure 15. Module system

Vision Diagram

There were specific reasons in our project to encourage the shared vision. First of all, this was an academic project where students were in the continuous process of learning, and the role of the faculty was to stimulate the spirit of inquiry throughout the evolution of the product to create an environment where changing team members can adjust to unfamiliar design problems. The work itself was also complex and fragmented because there were multiple components being developed by different members, and the interweaving of task items required a holistic approach. A clear vision was needed in this process to allow the project to evolve as a whole.

The DMM process book (2005) provides the vision statement as: "the project will design a Domestic Mail Manual that speaks directly to users and tries to meet their needs in the clearest and most efficient ways." This vision of human-centered design remained as the fundamental value and culture in practice that drove the development of process, incorporated diverse people within the USPS system, and facilitated participation in the culture of change. In other words, human-centerdness was not only about the interaction between user and the document. Rather, it was about the culture of the organization that includes internal users, postal employees, and even those responsible for establishing and enforcing regulations. Therefore we needed to share it with the client as well as team members. Moreover, not only was this vision of human-centeredness an ambiguous idea but also was a novel concept at that time, even to the designers who joined the team. For this reason, system diagrams played a critical role in embodying this abstract idea in a visible form to promote its acceptance.

Figure 16 and 17 are examples of system diagrams created for this purpose. Both were made in the early phase of the project and were posted on the wall as roadmaps to maintain our vision. With rich use of symbols which effectively show the perspective and action of users, these diagrams tell the story of mailing as a whole. In comparison, figure 18, which served as the inspirational figure of the project throughout the process, was developed in a later phase when the need to share vision with the client arose. After proposing the initial architecture, we needed to prove that the new shape-base structure would be usable by providing the clients with the first glimpse of what the new DMM would be. The comprehensive nature of figure 18 helped to bring their attention to the high-level organizing principle of "user-intuitive shape" without unnecessary details. At the same time, this diagram sucessfully ensured the client that every piece of information has a logical place within the system, by focusing on the relationship of holistic integrity.

Figure 16. Shape-based framework

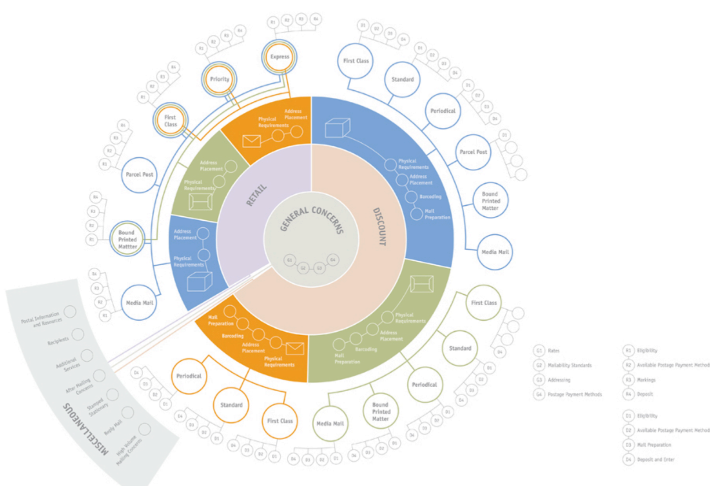

Figure 18. Architectural overview

Conclusion

We have identified four modes of thinking to differentiate relationships with the intention of clarifying the organizing principle of system diagrams. But the purpose of this distinction is by no means to argue which one of the relationship described above is better than the other. All are valuable for advancing the discussion of system diagrams in design and related disciplines. Better understanding of the essence of system diagram will also lead to a shifting perspective from regarding it as a mere data-rich statistical graphic to conceiving it as a place for invention or discovery, depending on various situations.

The situation of use for system diagrams is shifting. The emergence of complex information system, human-centered design, and participatory culture point to a further situational change for how system diagrams will be used, like our case study example. Users are also in need to understand the organizing principle of the complex information system in order to take action. As the problem of design becomes more complex, designers are also facing increased need to work in collaboration with experts from other fields, to bring in clients or users to participate in the design process, and to mediate these different stakeholders' collaborative work. There is a growing need for a system diagram that can work as a reliable reference tool and a shared structure to support group work in such a situation where multiple stakeholders are engaged.

What is needed in this situation is high-level thinking that will help designers foster different modes of thought to utilize designers' reasoning, while at the same time serve as a reference point that guides the direction for designers' reflective arguments. This research will contribute to design education and practice by broadening designers' understanding of the nature of systems, classifying system diagrams used in the design process according to its purpose, and by exploring its potential use for supporting users' action and shared group vision.

Author Biography

Soojin Jun

Soojin Jun is a Ph.D. candidate in the School of Design at Carnegie Mellon University. During her Masters and Ph.D. study, she has taught courses and conducted several interdisciplinary research projects with the United States Postal Service, the Human-Computer Interaction Institute and Dental Informatics at the University of Pittsburgh. Her professional experience includes employment at MetaDesign in San Francisco, SiegelGale in New York, MayaViz in Pittsburgh, and her design work has been awarded at international design competitions in 2001. She holds a B.F.A in Visual Communication Design at Seoul National University, Korea, and an MDes in Interaction Design at Carnegie Mellon University.

Miso Kim

Miso Kim is a Ph.D. candidate in the School of Design at Carnegie Mellon University. She is pursuing her interest in participation and service design in her Ph.D. study, along with teaching courses on interaction design, information design, and service design as well as being involved in research projects with the United States Postal Service, Department of Philosophy, or Human-Computer Interaction. She holds a B.S (2001) in Architecture at Sungkyunkwan University, Korea, an MDes (2004) in Communication Planning and Information Design at Carnegie Mellon University, and an MDes (2005) in Interaction Design at Carnegie Mellon University.

Joonhwan Lee

Joonhwan Lee is the CIO (Chief Information Technology Officer) of Neowiz Lab in Seoul, Korea. He holds a doctorate in the Human-Computer Interaction Institute from the School of Computer Science from Carnegie Mellon University, and has received a B.F.A in Industrial Design from Seoul National University, Korea, and an MDes in Interaction Design from Carnegie Mellon University. His research interest includes human-computer interaction, situationally appropriate user interaction, adaptive user interface, and information visualization.

Conceptualizations of the Materiality of Digital Artifacts and their Implications for Sustainable Interaction Design

Heekyoung Jung, Indiana University, USA, jung5@indiana.edu

Eli Blevis, Indiana University, USA, eblevis@indiana.edu

Erik Stolterman, Indiana University, USA, estolter@indiana.edu

Abstract

In this essay, we report on our survey of the design and HCI literature and other sources we have conducted in order to create an inventory of notions of digital materials past, present and future. We provide some thoughtful speculations and implications for design of digital artifacts with focus on emerging materials based on this survey. Our inventory includes state-of-art technologies and art and design projects covering the topics of organic user interfaces, smart materials, transitive materials, and so forth, as well as theoretical perspectives on materials in interaction design (Blevis, 2007; Löwgren and Stolterman, 2004). We construct design implications to include specific application scenarios of new material and interface technologies based on speculations for each theme of material perception that we uncover in our survey. These include (i) reducing the use of disposable materials—*how to reduce material consumption as personal lifestyles,* (ii) creating mechanisms of innovative, appropriate interaction—*how to reduce energy consumption by means of the use of digital artifacts constructed with new display technologies,* (iii) fostering ownership of sharable resources—*how to promote the feeling of ownership or security in sharing public resources,* (iv) updating things through the use of new materials—*how to renew old objects by adding new technologies instead of replacing them with new ones,* and (v) using materiality for engagement and expression—*how to promote peoples' attachment to artifacts by means of preserving sentiments and histories in the qualities of materials as a critical motivation for sustainable behaviour.* We provide specific examples that reflect on how such themes can foster sustainable design practice with new material and interface technologies by expanding the perception and understanding of the materiality of digital artifacts.

Keywords

design; material; materiality; digital artifacts; sustainable interaction.

As digital technology continues its rapid pace of development and pervades everyday life more and more, it exhibits increasing material effects both in terms of an augmented selection of materials in design practice and material consumption in use. Previous theoretical perspectives in the area of HCI and interaction design have suggested ways to promote sustainable interaction design along a number of dimensions, notably by emphasizing the need to promote renewal and reuse over the invention and disposal of digital artifacts with focus on the material effects of software technology (Blevis, 2007). Very recently, there has been a shift in focus from design for mitigating unsustainable behaviors that lead to climate change to design for adaptation to the likely effects of climate change (Blevis & Blevis, 2010). Sustainability concerns are part of the origins of our interest in digital materiality—nonetheless, our present writing concerns digital materiality directly in all contexts, including a world where resources have become more precious. We introduce the term *resource-conserving interaction design* to stand for both possibilities—a focus on sustainable behaviors and a focus on adapting to changing global conditions.

We are confronting new challenges and opportunities in interaction design especially with the introduction and advancement of new material and interface technologies such as tangible/organic user interfaces (Holman and Vertegaal, 2008), computational composite (Vallgårda and Redstrom, 2007), and transitive materials (Coelho et al., 2009). These new technologies blur the boundaries between hardware and software elements of digital artifacts, transforming the notion of materiality in interaction design. These new technologies require new conceptualization of materiality both in terms of how to use new materials in shaping an interactive object and how to predict its material effects in use. Specifically, as materials of traditional design have significance in determining the range of function, durability or cost of a product (Ashby & Johnson, 2002; Doordan, 2003), new material and interface technologies can also transform the way we design and use digital artifacts with new product ecosystems. For example, the invention of electronic papers might transform the user experience of reading books with new device interfaces as well as the process of purchasing books by eliminating the distribution of physical materials. Another possible example is programmable fashion—forms of clothing that can be updated for style by software means. The scenario of programmable fashion poses a question of how the fashion industry can adapt as the capability of updating styles of clothing becomes available by means of software programming. What is needed is a more developed conceptualization of what we mean by materiality in the context of digital technology. Such a conceptualization can support a better understanding of design potential of new material and interface technologies and appropriate strategies in design practices. Operating under an hypothesis that these technologies could contribute to supporting and promoting sustainable behaviors by transforming the way we use and value digital artifacts, our goal is to explore diverse dimensions of materiality in the context of resource-conserving interaction design.

Based on this background motivation, the present study first introduces a theoretical foundation regarding materials of digital artifacts to understand how materials of interaction design are increasingly different from those of traditional product design. Next, we provide a survey of recent trends of material and interface technologies from art and design projects, based on which the conceptual dimensions of materiality are explored in terms of perception and use of digital artifacts. Finally, we delineate design implications and possible research opportunities in relation to the explored dimensions of materiality of digital artifacts.

Materials of Digital Artifacts

Material is an essential element of design. Specifically, material selection—based on the understanding of physical properties of a variety of materials—is critical in forming aesthetic and functional qualities of an object in design practice (Lefteri, 2007). Moreover, unique symbolic meanings of a certain material based on its social or economic values—as in jewellery or garments—are also something designers need to consider beyond functional qualities of a design. Through the lens of materials, design can be considered as a process of creating meaning with proper materials and applying them to appropriate contexts based on exploratory practice with them. How to choose the right tools and methods to manipulate materials has always been a major issue of design practice. Moreover, materials are not just a given to be incorporated in the designer's calculation, but are a part of design problems (Doordan, 2003). Invention of a new material sometimes brings design innovations and changes our experiences with objects, as seen in many examples such as plastics in modern design (Monem, 2008). Likewise, the advent of new materials in the modern era often poses a new design problem—both in terms of operationalizing new manufacturing process for them (Vallgårda, 2009) and envisioning their social and cultural impact in use—rather than providing a simple solution for what design opportunity is considered.

Recently, designers of digital artifacts are facing a particular challenge regarding design material due to its complex composition of physical and digital qualities. Especially with respect to the software aspect of interaction design materials, Löwgren and Stolterman (2004) described digital technology as *material without qualities,* indicating its unlimited yet undefined design potentials—both aesthetic and functional qualities that designers could realize with digital technology. In other words, the design of digital artifacts is largely open, leaving designers with significant power to shape a future and also with corresponding responsibility. Especially, with advancement of tangible and physical computing interfaces, digital technology may be more seamlessly weaved into physical materials, and thus digital devices may be designed in many forms for a variety of purposes in everyday life beyond work-related tasks in office environments. Initiated by the notion of tangible bits (Ishii and Ullmer, 1997), there have been many studies exploring new applications of physical computing interfaces from product to architecture—as in studies of computational composite (Vallgårda, 2007) and transitive materials (Coelho et al., 2009), to name a few. Starting from the approaches for technical implementation, now the focus of research on tangible and physical computing has moved to design potential of new forms and interactive behaviors of computational objects. For example, Holman and Vertegaal (2008), in the context of human-computer interaction research, envisioned new, organic forms of computer devices by emphasizing three developments in computer technology, namely (i) advances in touch input technologies, (ii) flexible displays, and (iii) Kinetic Organic Interfaces. Brownell (2006), from the perspective of industrial design, highlighted transformational and interface aspects of design materials with enhanced functionality. Likewise, as computational technology is more physically materialized, it holds the potential not only to change forms of computer devices, but also to transform the way we interact with static objects and environments into computational activities. In our present writing, such physicality and forms of digital technology are considered to be main issues of new design materials of digital artifacts. Specifically we question how the development of tangible and physical interface technology can influence on the relationships between people and objects. In particular, we focus on the nature of material impact in use of digital materials that change the way in which people value enduring relationships with objects constructed in part from digital materials.

Materiality of Digital Artifacts

The increasing physicality of computational technology has brought challenges of complex design materials. They call for expanding conceptual dimensions of materiality of digital artifacts in order to predict how digital artifacts designed with new materials can transform user experience as well as social and material ecology. For example, these new materials can provide users with rich sensory experiences (Djajadiningrat, 2004), leading to more attachment to an object and achieving ensoulment or heirloom status of an object (Blevis and Stolterman, 2007). Specifically in terms of sustainability of digital artifacts, Blevis (2007) describes a designerly ethos to promote renewal and reuse over the invention and disposal of digital artifacts as a matter of promoting sustainable or resource-concerning behaviors with focus on the material effects of software technology. This notion has been advanced by investigating critical design qualities of digital artifacts that are loved and ensouled, and thus consequently contribute to sustainable relationship with users (Odom, Pierce, Blevis and Stolterman, 2009). While these approaches are analytical based on design theories and philosophy of material objects, there are also exploratory approaches for new design methods and processes with digital technology by considering social and material impact of design. For example, Bonanni, Parkes, and Ishii (2008) suggest the notion of *future craft* with examples of new design process and examples to more conscientiously include users in the design process through personalized digital materialization. Moreover, by tracking and visualizing material flows in manufacturing and distributing process, digital enhancement of material objects can promote more active sustainable behaviors in producing and purchasing industrial goods (Sterling, 2005; Bonanni et al., 2010).

Broadly speaking, new design materials or manufacturing processes associated with materials can transform the way we design, use, and relate to material objects. In this vein, the conceptualization of materiality of digital artifacts could serve as a lens to strategize design with digital technology considering its material effects in use. We categorized five themes that are related to material effects of digital technology—*disposability, energy consumption, sharability, reconfigurability, and expressive engagement*—by speculating on specific examples from art and design projects.

Disposability: reducing the use of disposable materials

Disposability is one of the most frequently discussed material effects of digital devices. As software technology quickly develops, disposability of digital artifacts is increasing; no matter how durable a device might be, it is easily discarded if its software is out-dated in terms of processing speed or data storage capacity (Blevis, 2007). Interaction designers tend to less care about outside (i.e. shapes, materials) than inside (i.e. software, contents) in designing digital artifacts (Critical Friends of Technology, 2003).

Moreover, digital device tends to be considered as an instance of similar types of other devices—as easily replicable as software programs. For example, BIC phone, a disposable mobile phone was introduced in 2008 with a pre-charged battery and a SIM (Subscriber Identity Module) card so that people can immediately use it by purchasing without a phone contract (Figure 1). This unit actually costs cheaper and is more easily replaceable than most contract-based phones. However, the convenience of prompt availability entails increasing disposability of hardware materials. The company had to deal with this issue by coming up with a recycling program where people can ship the phone back to them when they finished with it. Commodification of digital devices, in many cases, fosters disposability of materials by facilitating manufacturing and disposal process. As material consumption and disposal is closely related to lifestyle issues—specifically how people either embrace social concerns or act with conformity—a conscientious design strategy considering recycling materials need to be considered in close relation to social and cultural as well as economic values of digital artifacts.

While recycling is one strategy for increasing disposability, another possible design opportunity is to deeply appreciate material qualities and craft authentic values of a device. Magnhild Disington, a Norwegian fabric designer, offers an interesting perspective on the design of digital artifacts through her project of furry objects (Figure 2). Applying natural materials like wood, leather and fur to portable electronic devices, she designed unique character and sensory experiences, which can create a greater emotional value within the physical product. This approach questions whether the use of authentic materials in design of digital artifacts can be a solution for reducing disposability of digital devices by endowing them with unique values that cannot be replicated by similar other devices as in fashion design (Svendsen, 2006). Although this may not be the solution for increasing disposability of digital artifacts, it does expand design possibilities in terms of diversified material selection of digital artifacts toward sustainability.

Energy consumption: creating mechanisms of innovative, appropriate interaction

More and more, digital devices emphasize the non-physical materials over the physical ones—the physical form factor of devices like the iPhone and iPad reduce the physical materials to their simplicity, for example. Notwithstanding, many visions of digital technology—represented by the notion of calm technology and ubiquitous computing environment (Weiser & Brown, 1995)—require more energy consumption for continuous data sensing and capturing, prompt access, and ambient displays.

Considering, for example, the iPhone compared to an older bar type Nokia phone, much more interactivity depends on the use of the display in a manner, which consumes more power than the traditional phone (Figure 3). At the same time, versatile features and access to abundant information enabled by iPhone prompts more use of it in varying contexts compared to simple features of making phone calls or sending texts of older phones. Of course, these advanced information applications has made our life more convenient. However, in some sense, this technology or business oriented development—as opposite to value-sensitive design approach (Friedman, 1996)—has created additional human needs, resulting in more energy consumption.

Figure 3 Bar-Type Phone with Small Screen vs. iPhone with Touch Screen

There have been many studies to use 'visualization' of energy consumption as a part of user experience to persuade user behaviors to reduce energy consumption in daily life as enumerated in (Pierce, Odom, and Blevis, 2008; Pierce and Roedl, 2008). However, more fundamentally, research on more energy-efficient display technology is in demand with increasing display-centered digital artifacts such as e-papers or OLED (Organic Light Emitting Diode) lighting applications. With the development of organic user interfaces (Holman and Vertegaal, 2008), it is a promising design direction to develop alternative solutions for information display by exploring symbiotic use of natural material properties and their computational enhancement. There are some projects exploring energy-generating interactions that use physical engagement as source of power. For example, Villar and Hodges (2010) developed an interaction-powered rotary input device that sources its power from the physical effort required to operate it. When turned, its circuit provides a temporary power source for an embedded device, and doubles as a sensor that provides information about the direction and rate of input. Such design exploration with new forms and mechanisms of interaction can provide alternative solutions to current display-oriented digital devices by diversifying design opportunities of digital devices.

Sharability: fostering ownership of sharable resources

The development of network technology has enabled ubiquitous data access through online data storage or applications such as google documents, dropboxes, and Cloud computing. Cloud computing is Internet-based computing, whereby shared resources, software and information are provided to computers and other devices on-demand.

In spite of this convenience of data access, some people are uncomfortable working with online documents, without the comfort of knowing that the data resides on their own devices. This sentiment of ownership of actually "having" or "keeping" a digital material in the same manner as physical one may be one of the important issues in relation to feelings of privacy or security as well. In this vein, the vision of Cloud computing provides interesting design questions on how ubiquitous access to data can transform the conceptualization of ownership of a digital device by separating its software contents and physical interfaces.

This vision may help reduce material consumption by enabling public sharing of physical interfaces and display to access personal data. On the other hand, advanced networking technology like Cloud computing might actually foster more instances of physical interface that could be easily acquired and thrown away. In any case, the vision of the new network technology can influence how people own or share physical devices, and design can contribute to shaping a sustainable model to access ubiquitous data considering the aspects of privacy and security as well as sharability of material resources.

Figure 4 Ubiquitous Data Access

Reconfigurability: updating things through the use of new materials

As digital devices often work in connection with other devices, interaction designers now need to consider ecological aspects of a digital device (i.e., compatibility with other devices, upgradability to newer versions) beyond its own functional and aesthetic qualities. From an ecological perspective, it is critical to support reconfiguration of individual digital devices so that they can flexibly adapt to each individuals as a whole system.

However, in many cases, it is still not easy to customize or update physical and hardware aspects of a digital device compared to its software upgrade. This often leads people to have multiple devices with redundant features because subtle differences in physical forms and hardware aspects of each device—i.e., different screen sizes of a desktop computer, a laptop, or a smart phone—exhibit varying contextual affordances in use although technical features of these devices are basically similar with each other (Wortham, 2010). Moreover, digital devices easily become old-fashioned by losing their technical compatibility (not working in connection) or aesthetic commonality (not looking up-to-date) with other newer devices (Jung, et al., 2008). From the perspective of sustainability, it is a waste of resources that properly functioning digital artifacts are increasingly disposed or just left not used.

New design approaches for supporting flexible reconfiguration need to be considered, especially in terms of physical and hardware aspects of digital devices. Advanced material and interface technologies can provide new design solutions, for example, by modularizing software/hardware parts that can be assembled for different purposes of use, by adding new features to an old device for functional enhancement, or by transforming shapes of an artifact for aesthetic refreshment. For example, modu Ltd. introduces a mobile ecosystem where people can choose a new phone as often as they like, constantly taking different forms, functions and designs in a way to satisfy changing user needs, preferences and styles (modu Ltd., 2008). Another interesting example is the concept of transforming fashion by Hussein Chalayan that experiments potential of new technologies applied to fashion design either for functional or aesthetic purposes (Figure 5). In the Flat Futures project, Miquel Mora explored application scenarios of digital paper (Figure 6). With the concept of *objects wearing technology* in forms of interactive, dynamic digital paper, he envisions new ways to add or modify technical features with materials that are easy to handle.

Likewise, the advanced physical computational technology can envision new design scenarios of “programming hardware like software”, by transforming physical forms flexibly according to different contexts or purposes of use. With this potential, designers can more actively materialize ecological aspects of digital devices by blurring lines between objects.

Expressive engagement: using materiality for user engagement and expression

Touch screen interfaces, blurring the boundary between interface and information, have brought many benefits in terms of simple and intuitive interaction from direct manipulation as well as portability by merging physical and digital elements of a device. However, aesthetic qualities of form or tactile feeling have been relatively less considered in the design of digital artifacts, although people are very sensitive at perceiving subtle differences of such qualities.

Tactile properties of an object, affording rich sensory experiences and bodily engagement, can serve as an essential motivation for users to interact with and to feel attachment to an object. Upon the increasing priority of efficiency or functionality of digital devices, interaction designers need to more seriously consider how the corresponding trend of simple and minimal design will influence the relationship between user and device and what qualities of interaction will be lost or gained from such design beside function-oriented simplicity. For example, the concept of e-paper devices has many benefits to reduce the amount of paper consumption, but sensibility of physical books is still left as critical design challenges to overcome for popular use of digital paper.

With increasing design potential of physical computational technology, tactile/sensory qualities can be further explored in a way to build intimate and affective relationship between user and object. Physical properties of materials—how they invite user engagement or how they reflect the history of use (Figure 7)—can provide meaningful insights to interaction design, especially to explore diverse form properties of computational materials. Such design exploration with new computational materials can eventually contribute to increasing the feeling of attachment to an object by empowering users to more actively expressing their emotional conditions or personal identities through of an interactive object (Ahde, 2007; Webb, 2005).

Implications for Sustainable Interaction Design

As briefly introduced above, the materiality of digital artifacts is becoming more complicated due to its dynamic computational properties. As if traditional product design underlines the understanding of physical qualities of materials, the conceptual dimensions of material effects of digital technology could help designers calculate functional and aesthetic qualities of a digital artifact as empirical design knowledge. Considering interaction design material as a composition of both technical artifacts and social systems, we attempted to strategize design with new digital materials—particularly physical computational materials—speculating on their material effects in sustainable use of digital artifacts. In particular, our interests include, but are not limited to, questions on how tangible or physical computing interfaces would transform the relationship between user and digital artifacts from longitudinal and socio-ecological perspectives, how they could achieve or would lose certain design qualities compared to the interaction with non-digital artifacts, and how designers could strategize design with physically enhanced computational technology to promote sustainable interaction.

Based on the review of specific examples and design scenarios, we have described five themes of material effects of digital artifacts—*disposability, energy consumption, sharability, reconfigurability,* and *expressive engagement.* These themes are not mutually exclusive but closely related to each other. Each of the themes suggests a corresponding design implications and research directions in the service of sustainable interaction design and resource-conserving interaction design—specifically (i) reducing the use of disposable materials: *how to reduce material consumption as personal lifestyles,* (ii) creating mechanisms of innovative, appropriate interaction: *how to reduce energy consumption by means of the use of digital artifacts constructed with new display technologies,* (iii) fostering ownership of sharable resources: *how to promote the feeling of ownership or security in sharing public resources,* (iv) updating things through the use of new materials: *how to renew old objects by adding new technologies instead of replacing them with new ones,* and (v) using materiality for engagement and expression: *how to promote peoples' attachment to artifacts by means of preserving sentiments and histories in the qualities of materials as a critical motivation for sustainable behavior.*

The themes and implications in this essay are to explore design and research opportunities regarding sustainable interaction design with digital materials by questioning and speculating on the material effects of computational technology, instead of offering prescriptive solutions for sustainable interaction design. Further investigation for each theme needs to be followed for practical application of the implications described above.

Conclusion

In this essay, we introduced a theoretical foundation regarding materials of digital artifacts by comparing them to materials in traditional product design. Our survey of recent material and interface technologies described specific art and design examples in order to conceptualize the emerging material qualities of digital artifacts in terms of their material effects in use. As an overall observation based on this survey, we found that there is a need for interaction design and HCI research to pay more attention to the ongoing rapid and dynamic development of new physical materials. It is clear that these new materials bring potentials for new forms of interaction design where the physical is merged and blended with the digital.

The qualities of digital materials—including *disposability, energy consumption, sharability, reconfigurability, and experiential qualities (expressive engagement)*—suggest that there exist corresponding design implications for sustainable interaction. Application of these implications to interaction design practice requires more research from different disciplines, but the lens of materials helped us have a broader view of how to design with digital technology considering its material effects in terms of sustainable interaction. We argue that the future of sustainable interaction design is partly to be found in the exploration and examination of new materials with the aim to find new approaches suitable for resource-conserving interaction design.

Author Biography

Heekyoung Jung

Heekyoung Jung is a PhD candidate of Informatics in the Human-Computer Interaction Design program at the School of Informatics and Computing at Indiana University, Bloomington. Her main area of research is to develop design implications for new interface and material technologies by bridging the gap between design research and practice in the field of human-computer interaction. Specific research interests include aesthetics of human-computer interaction, tangible/embodied interaction, and digital ecosystems.

Eli Blevis

Eli Blevis is an Associate Professor of Informatics in the Human-Computer Interaction Design Program of the School of Informatics and Computing at Indiana University, Bloomington. His primary area of research, and the one for which he is best known, is sustainable interaction design. This area of research and his core expertise are situated within the confluence of human computer interaction as it owes to the computing and cognitive sciences, and design as it owes to the reflection of design criticism and the practice of critical design.

Erik Stolterman

Erik Stolterman is Professor of Informatics and Director of the Human Computer Interaction Program at the School of Informatics and Computing, Indiana University, Bloomington. Stolterman's main work is within interaction design, philosophy and theory of design, information technology and society, information systems design, and philosophy of technology. Stolterman has published a large number of articles and five books, including "Thoughtful Interaction Design" (2004, MIT Press) and "The Design Way" (2003).

Motion Design for Nonverbal Communication with a Humanoid Robot

Jinyung Jung, Korea Advanced Institute of Science and Technology, monagi@kaist.ac.kr

Myungsuk Kim, Korea Advanced Institute of Science and Technology

Abstract

In the near future, humanoid robots will act as the partners of human beings in daily life. Among numerous human-like competencies, motion of humanoid robots is critical for providing humans with richer interactions with such robots. Motion plays an essential role in complementing spoken communication. Moreover, the motions of humanoid robots generate nonverbal communication in various contexts. Through this nonverbal communication, humans can interact with robots not only directly but also indirectly or even unconsciously, as if the robot were simply part of the environment.

Before the developments of humanoid robots, embodied conversational agents (ECAs) were introduced as virtual embodied representations of humans that communicated multi-modally with humans and there has been a great deal of research on ECA behavior. ECAs and humanoid robots share many features in terms of how they communicate with humans. Nevertheless, simply adapting knowledge gathered from current ECA studies to a humanoid robot study is insufficient for the following reasons: 1. ECA studies lack knowledge focused on nonverbal communication, which has become more important in the physical world; 2. ECA studies have focused on developing agent-centered intelligence rather than a user-centered experience; 3. ECA studies have developed logics to generate motions automatically rather than to provide designers with the practical knowledge necessary to design desirable motions.

Motivated by these three arguments, we seek to pioneer a new field of motion design between robot engineering and design discipline. To bring this motion study into design discipline, we focused on human-centered experience through nonverbal communication with a humanoid robot. This paper aims to outline sharable user experience in order to help designer create desirable motions for humanoid robots in various speechless contexts.

Keywords

motion design; nonverbal communication; humanoid robot; sharable user experience

Recently, personal computers, digital gadgets and even home appliances are being designed to speak to the user. Product designers consider more anthropomorphic approaches in order to design our daily goods in an intuitive and interesting way, which is closely related to the trend of robotizing. The boundary between robots and products is blurring. Still, robots are superior to other products in one area: motion. The movable body parts of robots can provide higher pleasure beyond usability or intuitiveness. The humanoid body may be the best strategy to resonate human experience. There have been plenty of gesture studies on virtual characters, or embodied conversational agent (ECAs), however, not many of these studies have attempted to infuse ‘soul’ into such entities in terms of user-centered experience. Therefore, it is necessary to establish such design knowledge to support designers who wish to create desirable experiences that users will want to have, enjoy and share. The following chapter will identify the trends and limitations of previous studies on motion-based interaction with humanoids in order to verify the necessity of a user-centered perspective in motion design.

Review of related work

ECAs can be regarded as the ancestors of humanoid robots, as they have similar body features for human-like communication. Research on ECA behavior has influenced the behavior of robots. The most typical approach focuses on the relationship between verbal language and behavior. Cassel et al. (2001), for example, developed the 'BEAT: Behavior Expression Animation Toolkit' system to generate ECA behavior by extracting linguistic structures of text. For more natural synthesis of motions, Kipp et al. (2007) analyzed a number of gestures from human actors and applied them to the ECA. It is basically possible to transfer the behavioral algorithms from ECA research to humanoid robots. Kushida et al. (2005) tested the knowledge-link between those two lines of research and noted the additional benefits of a physical humanoid robot. Kidd and Breazeal (2004) explained the superiority of a physical robot in terms of providing better absorption, interest, credibility and dependency than ECAs.

Despite all of these connections between ECAs and humanoid robots, simply adapting knowledge from current ECA studies to a humanoid robot study is insufficient. First, ECA studies deal with the virtual world, not the physical world. Second, ECA studies have a tendency to develop agent-centered intelligence rather than a human-centered experience. Third, ECA studies have developed logics to generate motions rather than to provide designers with practical knowledge to design desirable motions. Regarding the first argument, some of the studies mentioned above have tested the possibility of knowledge-transfer from ECAs to physical robots; others have tried to emphasize the superiority of real-world-based interaction compared to virtual interaction. However, those benefits of the physical robot cannot be achieved unless we consider that physical robots share space in humans' daily lives. Humanoid robots cannot be hidden even when they have to remain 'nonverbal' for a large period of time. Therefore, nonverbal communication should be properly managed in terms of motion design to avoid damaging the entire human-robot interaction (HRI) experience. With regard to the second argument, developed algorithms and markup languages have dealt with generating automatic behaviors according to ECA speech. Many of these approaches have focused on developing the communicability of the ECA in an artificial intelligence (A.I.) sense. However, we also need to approach the quality of the experience from a user-centered perspective. Considering the third argument, previous studies have developed the better algorithms that cause an agent to perform motions for proper interactions with humans. Many of these studies created systematic logics by conducting literature studies, taking observations, performing experiments or even capturing humans' motions. Nevertheless, their final outputs, markup languages or the agents themselves seem to be complicated for direct use by the motion designers. We anticipate that the user-centered approach could provide designery insights to overcome all three of these limitations.

Nonverbal communication *gestalt* through humanoid motion

As reviewed in the section on related work, nonverbal communication is also critical for the overall HRI experience, and thus practical knowledge for the design of humanoid motion needs to be established. This chapter provides a baseline from which to apply the user-centered perspective to nonverbal communication with humanoid robots.

Human body and nonverbal communication

Relative to verbal communication, nonverbal communication has a closer relationship to the human body. Every language transfers messages on a certain level. Humans have developed verbal language as a social protocol for clearer and more effective communication. On the other hand, within our daily lives there is a higher proportion of time in which we remain nonverbal. Though we can stop speaking, we cannot stop communicating because the body is always in motion (Goffman, 1963).

Nonverbal communication generally means 'nonverbal and non-vocal communication' in which the mouth is not used to generate linguistic words or sounds. Semiotics for nonverbal communication assumes that the human body can function as the *signifiant,* the medium of communication, and studies how the human body performs symbolic functions or may even unconsciously influence other humans (Poyatos, 1976). Gestures, body language, kinetics, signals, gaze, tactile communication and proxemics are related to nonverbal communication (Kim et al., 1998).

Successful communication requires a consensus between both parties of the communication. According to Argyle (1975), nonverbal communication can easily be one-sided; nevertheless, as Goffman observed, we never stop communicating because our bodies never stop moving. Considering the intention of the sender, the perception of the receiver and the influence on the receiver, there can be 6 patterns of nonverbal communication, as shown in Table 1.

	Intention of sender	Perception of receiver	Influence on the receiver
1	O	O	O
2	O	X	X
3	O	X	O
4	X	O	O
5	X	X	X
6	X	X	O

Table 1 Patterns of nonverbal communication

The first case is the most ideal nonverbal communication, in which the sender and receiver share intended and perceived meanings. On the other hand, the second and fifth cases are not truly communication, because communication assumes interaction. However, the third and sixth cases are different from the first, second and fifth cases. Although the receiver does not fully understand the sender, the motion of the sender influences the receiver, regardless of the sender's intention. In brief, nonverbal communication may occur at various levels of concentration and communicator interaction. Nonverbal human motion may sometimes communicate only a small piece of information, such as 'I am alive,' or may even communicate nothing at all. Some motion can be reinterpreted from the receiver's perspective. In that sense, nonverbal communication is similar to art, which communicates sharable messages where reinterpretation according to the different experiences of the audience is partly expected.

Nonverbal communication Gestalt

Motion design for a humanoid robot is different from teaching motions to a human. Designers have to design all motion details for the robot, because even unconscious motions, which express the minimum lifelikeness, are not intrinsic behaviors for robots. To design such motions for a humanoid robot, we need to understand the concept of interaction gestalt. As Lim et al. (2007) explained, "interaction takes on a *gestalt,* a composition of qualities that creates a unified concept, configuration or pattern which is greater than the sum of its parts." In the same sense, Moore (1922) stated, "not simply the whole, but its constituent parts could not survive that destruction of other parts." In such an organic whole the constituent parts have a relation of mutual causal dependence on one another. This study agrees with these ideas of Moore and Lim. First, we separate motion design attributes from the type of nonverbal communication used. However, this approach is not an analytic approach which would issue a formal definition giving art necessary and sufficient conditions or an algorithm for classifying and evaluating its works. Dewey (1934, p. 155) said that such “formal definitions leave us cold.” Therefore, we argue that a set of motion design attributes, the elements of interaction, can be projected as a unified gestalt, by projecting them into a type of nonverbal communication. This study intends to concretely identify the relationship between motion design attributes and nonverbal communication in order to outline sharable experiences to design desirable motions for humanoid robots. We acknowledge the fact that experience is never the same from one individual to another and unique reinterpretation occurs in each instance of communication. Indeed, it would be advantageous for the motion design activity to be wide-open to a varied audience, similar to the way the arts communicate.

Motion design attributes for humanoid robots

A humanoid robot can be defined by its ability to communicate in a human-like manner, rather than its superficial resemblance to humans. Of course, the communicational ability of a robot determines its appearance, and thus robots have come to have similar morphological elements to humans to some degree. Though there is no clear boundary defining humanoid robots, any robots with the proper body elements and motion ability for human-like communication can be considered as humanoids. Because of their human resemblance, the motion design for humanoid robots needs to be carefully considered so users do not develop detrimentally false expectations of the robot’s capabilities (Duffy, 2003).

Dance is gaining in importance as a means of conveying body knowledge: it is perceived as an art form in itself and is becoming the subject of research. Dance study seeks to establish knowledge of how to interpret and produce body motions to sublimate dance as an archive, medium and interface between art and science, which is similar to the purpose of this study. The renowned researcher Rudolf Laban (1988) identified principles of human body movements and systematized the four attributes of movement: weight, time, flux and space. Based on these 4 attributes, we held a workshop to establish sub-attributes. Doctoral students, who had experience in HRI design projects from the industrial design department, participated in the workshop. First, participants brainstormed all of the adjectives that represent motion design attributes for humanoid robots. Next, they watched the 3D animation movie ‘Robots (FOX, 2005),’ which contains a set of well-refined imaginative ideas about how humanoid robots move, to supplement the initial brainstorming. Then, we printed those adjectives on sticky memos for use in a grouping session. Similar attributes were combined and opposite attributes were paired to become sub-attributes of weight, time, flux and space. Finally, we established eight sub-attributes: speed and scale for weight, rhythm and repetition for time, smoothness and accurateness for flux and direction and proximity for space. See the following for descriptions and Figure 1.

A. Weight: indicates the energy of motion. For a humanoid robot, more energy can mean more information or dominance, which is more easily perceived. Weight is proportional to both the speed and scale of motion.

- ***A-1. Speed (slow-to-quick)***: indicates how quickly the humanoid’s body parts move from one point to another. There is a continuous spectrum from slow to quick, which is always a relative concept. However, slow motion is perceptively distinguished from a stopped motion. (Example: Slow beat motion ↔ quick beat motion ↔ trembling motion)
- ***A-2. Scale (small-to-large)***: indicates how wide or long the humanoid’s body parts move from one point to another. There is a continuous spectrum from small to

large, which is always a relative concept. But, a small motion is perceptively distinguished from a stopped motion. (Example: timid hurrah ↔ powerful hurrah)

B. Time: indicates the degree of regularity or tension during a period of time. For a humanoid robot, this attribute can be related to character and emotions. There are two sub-attributes, rhythm and repetition.

B-1. Rhythm (Static-to-Rhythmic): indicates the level of cadence. There is a continuous spectrum from static to rhythmic. Static motion seems to be drier and more function-based than rhythmic motion. On the other hand, rhythmic motion can be perceived as more artistic, as in dance. (Example: greeting by simple nodding ↔ greeting in a Hip-hop style)

B-2. Repetition (Non-repetitive vs. Repetitive): indicates if there is any pattern of motion. Some motions can be performed only one time (non-repetitive), such as tracking something or by direct manipulation from an outside force, while another motion can be repeated as pre-programmed. (Example: continuously facing a moving object vs. rotating the head several times for stretching)

C. Flux: indicates the degree of tension in a stream of motion. For humanoid robots, this attribute can determine how lifelike they appear. There are two sub-attributes, smoothness and accuracy.

C-1. Smoothness (Stiff-to-Smooth): indicates how naturally the trajectory of the motion curves. This is a relative concept within a continuous spectrum from stiff to smooth. In general, static motion is more machine-like and less human-like than smooth motion. (Example: popping dance ↔ waving dance)

C-2. Accuracy (Approximate-to-Accurate): indicates how precise or sophisticated the motion is. This is a relative concept within a continuous spectrum from approximate to accurate. The need for accurateness depends on the level of information. (Example: directing north ↔ pointing at a specific object)

D. Space: indicates the orientation and distance of the motion in a physical space. For the humanoid robot, this attribute can be related to dominance and character. There are two sub-attributes, direction and proximity.

D-1. Direction (Inward-vs-Outward): indicates the directional characteristic of a motion. It can move inward or outward. In general, inward motion is easily perceived as passive or unconscious while outward motion is perceived as active and coming from a dominant character. (Example: shrinking motion vs. blooming motion)

D-2. Proximity (Far-to-Close (vs-touch)): indicates the distance at which the motion is perceived. This is a relative concept within the continuous spectrum from far to close. However, a close motion is distinguished from a touching motion. A distant motion is more difficult to perceive than a closer motion. A short distance between social entities can mean a closer relationship; therefore a touching motion may be the best approach for that purpose. (Example: waving hands from a long distance ↔ waving hands at a close distance vs. shaking hands)

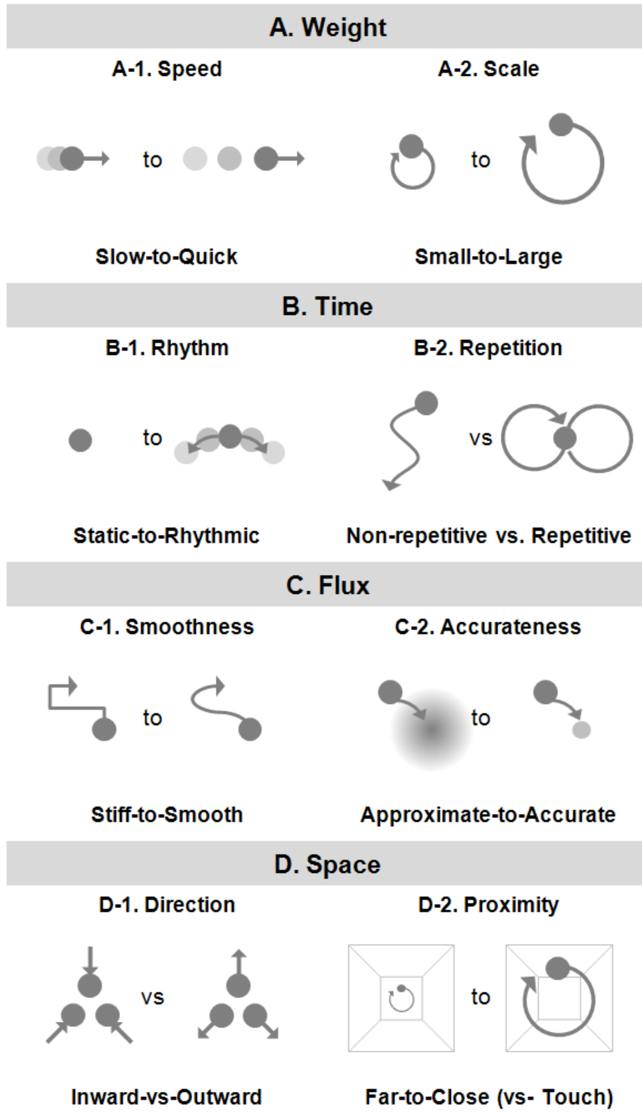

Figure 1 Motion design attributes for the humanoid robot

The established set of motion design attributes are not meant to be deconstructive; rather, we intend to provide them as general set of communication gestalt for humanoid robots. Of course, as these are general attributes, they can be used for other types of robot as well. However, we distinguish the social-oriented characteristics of a humanoid robot within a relationship using the following four types of nonverbal communication.

4 types of Nonverbal Communication Design for the Humanoid Robot

As we saw in Table 1, there are six kinds of nonverbal communication. However, design can deal with only four of them because the second and fifth cases were the result of miscommunication, which is never the designed aim. This chapter explains the four remaining types of nonverbal communication in the context of motion design for a humanoid robot. By considering the intention of the robot and the perception of the human audience, we can imagine the contextual conditions and name the situations as direct, diluted, bridged and ambient nonverbal communication. See the following descriptions and Figure 2 and 3.

1. ***Direct Nonverbal Communication***: This form of communication assumes that both parties of the communication consciously concentrate on one another. Therefore, this is often limited to one-on-one communication. By performing body motions, a humanoid robot can send a message (relatively clearer than the other types of nonverbal communication) to the human audience, which the human tries to understand and respond to, based on what he or she understood. Direct nonverbal communication can be more easily understood within verbal communication. For example, the robot can use symbolic gestures such as sign language, express emotions or even participate in physical contact, such as shaking hands.
2. ***Diluted Nonverbal Communication***: This form of communication assumes a special situation where a humanoid robot tries to send messages to an audience of multiple humans. Unlike in direct nonverbal communication, the human audience does not have to concentrate on the robot but is unconsciously influenced by its motion. Therefore, the audience is usually distracted and the communication is typically not accompanied by eye contact. For example, the humanoid can make motions intended for advertisement at a shopping mall or a dancing motion for performance on a stage.
3. ***Bridged Nonverbal Communication***: This form of communication assumes the opposite condition of diluted nonverbal communication. A humanoid robot unconsciously responds to environmental changes or people around it. When the robot performs responsive motions, eye contact or joint attention may occur, which the human audience can possibly perceive as interest or curiosity on the part of the robot (Duncan et al., 1977). Therefore, motion that is designed for bridged nonverbal communication implies a readiness for the next form of communication, so it provides more opportunities to initiate or sustain direct communications with the human audience. For example, a humanoid robot can look around as if searching for something interesting, turn its body toward some sound or nod in response to what humans say to it.
4. ***Ambient Nonverbal Communication***: This form of communication is the weakest of the four types of communication. Both parties remain unconscious of the communication, but sense their coexistence. The humanoid robot naturally expresses its lifelikeness through motion so that the human unconsciously perceives it as alive. If the robot stops its motion people might consider it as a burden, which can be bothersome. Ambient nonverbal communication is a sort of bridged nonverbal communication that helps people believe they can start to interact with the robot anytime they wish. For example, the robot can perform a breathing motion, a neck stretching motion, a thinking motion or act sleepy.

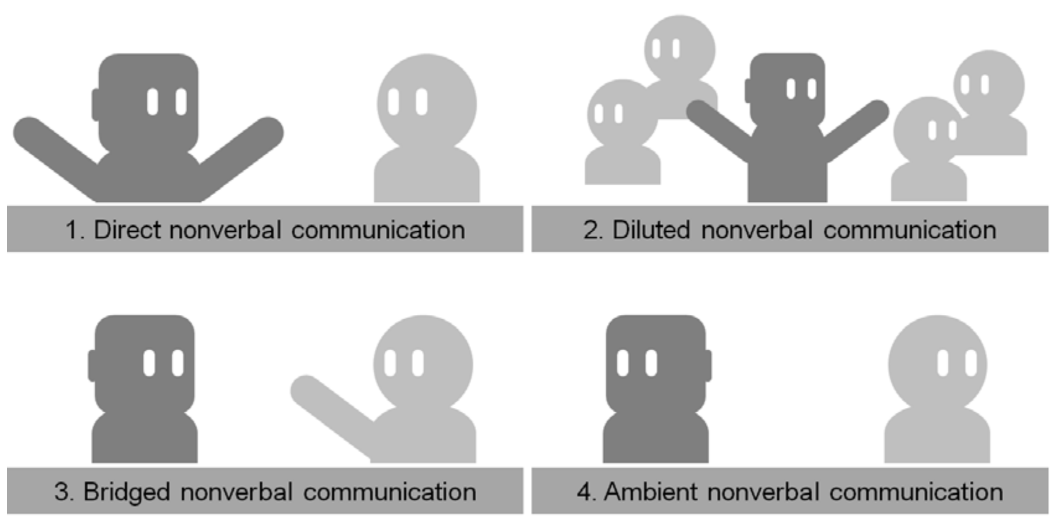

Figure 2 Four types of nonverbal communications with a humanoid robot

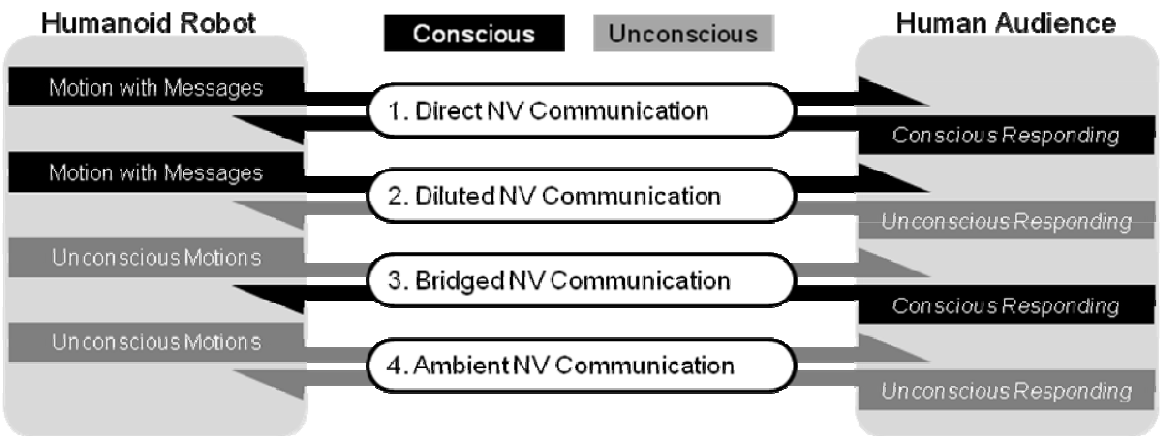

Figure 3 Responding patterns of human audiences for the four types of nonverbal communications with a humanoid robot

Survey to identify sharable user experience

In order to identify the relationship between the motion design attributes and types of nonverbal communication, we conducted a simple survey. The hypothesis was that some of the motion design attributes have significant tendencies in relation to a specific type of nonverbal communication. For example, most people might agree that the speed for ambient nonverbal communication needs to be slow. This is not for judging the validity of motion design, but for outlining sharable user experiences to design desirable motions for humanoid robots in various speechless contexts.

Survey Method

17 masters or doctoral students, 8 males and 9 females from the industrial design department of KAIST, participated in the survey. The survey was composed of four sessions. The first session was an introduction in which participants were acquainted with the purpose of the survey and signed a letter of consent. The second and third sessions were learning sessions. Participants were provided with handouts that explained the concept of nonverbal communication for the second session and motion design attributes for the third session (the content was the same as previous chapters). They carefully read the content so that during the last session they could define the relationship between the two concepts. Participants were provided with a 4x8 matrix (4 types of nonverbal communication x 8 design attributes) on a sheet of paper (Table 2). Each cross section had three possible choices. Two options indicated extreme opposite ends of each design attribute, for example Slow-to-Quick for the speed attribute. If the participants thought that the best speed for ‘Ambient nonverbal communication’ was slow, they circled the word ‘Slow’ on the paper. If the participants had no preference for either option, they could choose the remaining answer, ‘No inclination.’ Participants could refer to the handouts used in the second and third sessions.

Results & Findings

A Chi-square test was used to determine the distribution of the results. If the significant level is lower than $p<0.05$, it can be said that there is a tendency in the responses. If there is no tendency in the responses, it means there is no tendency toward one design attribute. But the tendency of an answer can be different from the tendency of a motion design attribute because ‘No inclination’ was among the three choices. Also, if the answers for an attribute lean toward 'No inclination,' then there is no tendency for that design attribute. In the results, 15 of the 32 cross sections were $p<0.05$ (Table 3). Three of those 15 cross sections had a tendency toward 'No inclination,' and therefore the remaining 12 cross sections contained the information we wished to identify. There were four more cross sections that we needed to look into even though they were not statistically significant. For 'direct-smoothness,' 'bridged-smooth,' 'ambient-accurateness' and 'ambient-direction,' participants showed no tendency for a specific choice. For example, no one selected 'stiff' for the 'direct-smoothness' relationship (Table 2). This can be interpreted to mean that 'not stiff' would be preferential for the motion design in direct nonverbal communication. The remaining cross sections did not show a strong tendency (Table 2). The participants shared their opinions about motion design for each type of nonverbal communication as follows.

1. Direct nonverbal communication needs to be designed with accurate, close motions and without stiff motions.
2. Diluted nonverbal communication needs to be designed with quick, large, repetitive, outward and far motions.
3. Bridged nonverbal communication needs to be designed with approximate motions and without stiff motions.
4. Ambient nonverbal communication needs to be designed with slow, small, repetitive, smooth motions and without accurate, outward motions.

Motion Design Attributes \ 4 Types of Nonverbal Communications		1. Direct NV Communication	2. Diluted NV Communication	3. Bridged NV Communication	4. Ambient NV Communication

Table 3 Chi-square test results

In the same way that we might appreciate and analyze works of art, we applied our own interpretation to the results. For direct nonverbal communication, accurate motion would be appropriate to express clear messages and close motion would make it easier to communicate without interference. This form of communication in particular should not have stiff motion, because the motion is observed at a close distance and thus the stiffness might detract from the communication. For diluted nonverbal communication, the robot is generally far from the human audience. Therefore, quick, large and outward motion, in other words, high-energy scattering motion, is advantageous to catch the attention of people in distracted contexts such as public spaces or wide-open areas. Moreover, a repetitive motion pattern is necessary because a scattered audience can hardly comprehend the intention of the robot in one instant when catching sight of it by chance. For bridged nonverbal communication, approximate motion would be more natural when presenting the robot as responding unconsciously. But the motion should not be stiff, because stiffness is exactly opposite to natural lifelikeness. In ambient nonverbal communication, the robot's motion should remain calm and minimized; therefore, low-energy motions (slow and small motions) would be proper. Additionally, smooth and repetitive motion suits the expression of life-likeness as an unconscious state. In that sense, accurate and outward motion is not appropriate.

In spite of the participants' choices, the statistical analysis and our own interpretation, all of which culminated in recommendations for motion design attributes for different types of nonverbal communication, it is not our intention to constrain designers to following these recommendations. Rather, this study suggests that the designer needs to refer to what people have agreed regarding nonverbal communication and about how memories can be shared, because both sharing information and the reinterpretation of meaning are important to shape a general user-experience.

Conclusion and future works

Knowledge of how to design motions for robots is increasing in importance. Humanoid robots are especially interesting and thus their motions need to be delicately designed to maintain their resemblance to humans. We reviewed related HRI studies about motion, and concluded that we lack knowledge in three areas: 1. nonverbal motion design, which is critical for HRI experiences with a physical humanoid robot; 2. motion design from a user-centered point of view; 3. practicality to help designers create motions for humanoid robots. To overcome these limitations, we turned to user-centered design approach. Based on the relationship between design attributes and nonverbal communication experiences, we suggest the concept of nonverbal communication gestalt to design a general user experience for interaction with a humanoid robot. To test our concept, a survey with 17 participants was conducted and it was found that participants shared a considerable amount of design preferences for desirable nonverbal communication with humanoid robots. Nevertheless, we do not seek to impose the relationships extracted here as a design guideline, instead preferring to leave open the possibility for reinterpretation, which is the spirit of art and design. As the HRI field grows, additional contributions to the study of robot design are required to bring robot technology into people's daily lives. This study aims to make synergetic knowledge about motion for robot engineering and design available so that people can have more desirable HRI experiences soon.

In this paper, we have introduced a concept user-centered motion design for humanoid robots. However, a real robot platform needs to be implemented for experimental verification of the concepts outlined in this paper. We plan to conduct a motion design case study with real humanoid robots so that we can identify deeper insights and inspirations.

Author Biography

Jinyung Jung

A Ph.D. candidate in the Department of Industrial Design at KAIST. Jung was trained as a product designer through the BS and MS programs in the same department and as an interaction design researcher through his involvement in various HRI design projects. His research interests lie in the fields of user experience design, user survey methodology. His Ph.D. research aims to establish a theoretical model to design motion of a humanoid robot for various speechless contexts.

Myungsuk Kim

A professor in the Department of Industrial Design at KAIST. Kim has been leading the Product and Environmental System Design Laboratory. His research interests are in the field of environmental system design, cultural design, emotional design, and robot design. He was the chairman of the Korean Society of Design Science (KSDS, 1997-2001) and Asian Design Congress (ADC, 1999-2001), which is a predecessor of the International Design Congress (IDC) and International Association of Society of Design Research (IASDR).

Design naturally, dealing with complexity of forms in nature & applying it in product design

Abstract

The aesthetic NORMs have formed some presupposes in designers' **minds** which don't let their eyes see the reality of forms in NATURE before their abstracting mind see. They usually reduce complex forms to their basic geometries and proportions, in order to find orders in their complexity and to harmonize them with their design paradigms. We believe that this common vision to the nature, deprive us from perceiving its reality. This paper proposes a new vision to the nature and thereby present nature's approach to the form issue, and some of its manifestations. These findings which are presented under the title of DESIGN NATURALLY would guide designers, one step closer to the complex reality of forms in nature to get inspired by. Our point here is that this approach takes us far beyond the law-bound principles of the geometry and traditional design aesthetics and would create a new aesthetic language to the world of products based on the real complex world.

Keywords

Abstraction; growth story; forces; complexity; natural forms; design naturally.

Human's perception from the world is obedient to his mind (Nasr, 1996) and his mind is obedient to platonic forms and metric proportions (Alexander, 1964, Arnheim, 1979; Rotzler, 1977); these prevent us from seeing the complexity of world and understand it in the way it is (Rampell, 2003; warthall, 2005). Being obedient to these kinds of presupposes have had obvious effects on different aspects of human life and has manifested in the world of design in format of geometric forms and abstraction. Regarding to the changing meaning of the beauty and growing need for renewing the aesthetic language (Akner-koler, 2007), this study is aimed to propose a new vision to the forms in nature. This vision is based on ignoring the traditional aesthetic language and presupposes in order to create new theory of form and go beyond the law-bound principles of geometry.

Phenomenology is a compatible conceptual framework to explain the approach of this paper. Phenomenology is about studying phenomenon based on direct and pure experience and observance from the world and by ignoring presupposes (Verneaux &wahl, 2009). Just as phenomenology question presupposes to study the reality of things, we questioned the aesthetic norms and conventions in order to get closer to the reality of forms in nature.

Therefore, by taking a phenomenological approach, it is tried to break down presupposes and re-observe the forms in nature. This kind of visions opens designers' eyes to the ignored qualities such as complexity, irregularity, asymmetry, etc. These qualities could be applied as tools of renewing the aesthetic language and to find freedom from conventions in field of design (Bois & Krauss, 1997).

Quantitative approach

Rationalism and humanism of renaissance enabled a scientific revolution, which let scholars look at the world in a different light and by reason & knowledge. In the 16th and 17th centuries, in contrast with medieval centuries, knowledge was strongly based on rational calculus, mathematics and quantitative measurements (Bertelsen, 2004; Nasr, 1996).
Galileo, in his famous phrase under the title of "*IL Saggiatore"* likened the nature to a math book with geometric shapes as its letters. He believed that this book could be merely understood by human's rational mind (Nasr, 1996). Descartes' mathematical definitions of time, place and substance, has had the deepest affects on the essence of the modern science structures. His reductionism went to extreme until he defined nature as a physical moving reality which is merely understandable via geometry and quantitative measurements. Scientific revolution reached its zenith by Newton. He in his essay called *Principia* certainly declared the beginning of the quantitative and mathematical approach to the nature (Frangmyre *et al.*, 1990).

By the efforts of some individuals such as Christian Wolff[1], mathematical and quantitative methods were gradually developed in other fields of SCIENCE too (Frangmyre *et al.*, 1990). In fact scientists were strongly motivated to impose order on all domains of nature via quantizing and reducing its complexity. *L'esprit Geometrique* (geometric sprit) is the French expression for this extensive approach which were shadowing on all European scientific activities of 18th century and also affected many aspects of the western culture up to 20th century (Nasr, 1996).

Geometric Spirit

Industrial revolution in 19th century and modern technology stimulated the penetration of quantitative attitude to different layers of human life (Nasr, 1997), such as DESIGN. By the beginning of the 20th century, the approaches of the modern art movements such as cubism, purism, futurism and constructivism were to turn to SCIENCE for concepts and models (Akner-Koler, 2007; Heskett, 1993). These attitudes were based on the Influence of Idealist philosophical traditions, and the search for Platonic ideal forms. Therefore the quantitative approach of SCIENCE appeared toward abstraction and in particular, geometric forms in modern world of art and design (Heskett, 1993).
Art historian Alfred Barr categorized modern art into two main movements: *geometric abstract art* and *non-geometric abstract art*. This emphasis on geometric abstraction shows how a big role geometric abstraction played in modern art movements (Akner- koler, 2007).
Although post-modern criticized the modernistic approach to define universal principles, genotypes and the search for "pure form" (Rampell, 2003), the major manifestations of the post modernistic styles were again toward abstraction and geometric forms.

1 German philosopher, (1679-1754)

Today, the aesthetic contributions of these movements have become the dominant aesthetic norms (Habermas, 1998) and they still dictate the conditions for beauty, at least for design and architecture (Akner-Koler, 2007).

The point here is that this tradition has also affected designers' visions to the FORMS IN NATURE. From a phenomenological point of view, it can be said that the aesthetic NORMs have formed some presupposes in designers' minds, which made them unable of seeing the reality of forms in nature before their abstracting mind perceive it. In fact, Designers usually reduce complex forms to their basic geometries and proportions, in order to find order in their complexity and to harmonize them with their design paradigms. The function of presupposes in human's mind is similar to the function of a red filter, which make a special wave length visible only (Gleick, 1988). In fact the filtering minds EXPECT to see geometric forms and patterns in nature and so reduce complex quality of forms to extract simple geometric patterns and proportions.

Deprivation from reality

Regarding to George Berkeley[2], the quantitative approach to the nature, abstracts its reality and presents the aspect, which is in our mind (Nasr, 1996).
Martin Heidegger explains that human usually escape from complexities and irregularities of universe. Reducing the infinite universe to understandable structures and models is equal with limiting it to our limited language also, taking this simplified model of reality as the reality itself, would surely deprive us from perceiving the reality of universe and would waste away its real values (Warthall, 2005).
In fact use of geometry entails a reductionism that excludes and "washes away" contact with the real world (Akner-Koler, 2007). Therefore, it can be concluded that abstracting natural forms in order to simplify their complexity, prevents us to perceive their reality. In other words geometric approach to the forms in nature deprive designers from seeing and perceiving many aesthetical values of natural forms.

Nature Inspired Forms

Deliberating forms in nature in order to receive inspiration from them is not a recent issue. The point is the way human represents his observations. We can categorize the human inspirations based on different degrees of abstraction. The more designers abstract natural form, the less the original properties such as asymmetry, irregularity, chaos and complexity would last. In this regard to 3 groups of Geometric, Geo-organic and Organic could be referred.

2 Irish philosopher, (1658-1753)

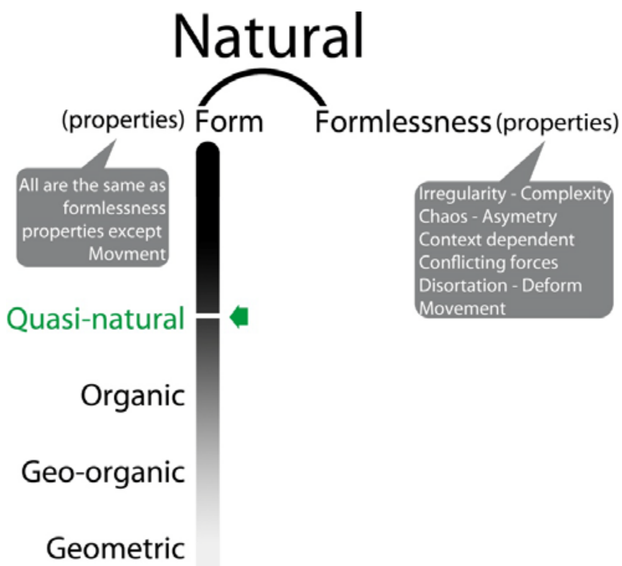

Figure 1 Different level of human inspirations from forms in nature regarding to the degrees of abstraction

Geometric

Golden section ratio and many of geometric patterns which are inspired by the nature are the result of geometric approach.

Geometric-organic Forms

This group refers to strong traditions in art and design, which merge geometric structural analysis with organic principles of growth and tension (Akner-Koler, 2007). By these traditions, Vladimir Tatlin and Mikhail Matiushin have been involved in studies of the efficiency and energy-conserving qualities of the anatomy of animals, which today might be called “bionic” approach (Tillberg, 2003). Many designers, engineers and biologists have endeavored in this field and have studied functional aspects integrated with morphological aspects of nature in order to receive inspiration (Trotto & Cianfanelli, 2006).

Bionic approach emphasizes on functional aspects and puts a great effort on harmonizing inspirations with design paradigms. Therefore, it always reduces natural forms to a general abstraction in format of products. Designers usually change natural forms in order to meet their design needs and so naturally they wash away many original qualities of natural forms in this process.

Organic Forms

As Waddington states:

"… We come then to conceive of organic form as something which is produced by the interaction of numerous forces which are balanced against one another in a near-equilibrium

> *that has the character not of a precisely definable pattern but rather of a slightly fluid one, a rhythm..."* (Wyte, 1968).

He also adds that: regarding the influence of man's intellectualizing, pattern-making habit of simplification, it is expectable that human's work of art would be a diluted version of the reality which has lost its unresolved complexity. Nevertheless, the problem starts when we equalize organic forms with natural forms; in fact we equalize a model or an aspect of reality with the reality itself which Heidegger showed that will deprive us from reality. It has become a kind of aesthetic norm that the result of studying natural forms to design things would be curved and smooth surfaces and circular shapes. But we have to consider that organic approach refers to just a level of abstracted natural forms with more attitudes to curves and fluid forms (figure 1).

In relation to these three types of approaches, we propose **QUASI_NATURAL** forms as the forms resulted by taking the approach of this paper to design. In figure 1 it is shown that this type of forms stand above the organic group of forms and closer to natural forms. It means that these forms have more properties in common with original properties of natural forms; it is because of less abstraction and more realistic approach to the natural forms (figure 1).

The Theory of Form

The approach of this study to the form issue is as follow.

- The first principle of this Theory is ignoring the traditional geometric-quantitative approaches to the nature. Therefore, the mind would ignore presupposes and traditional expectations for finding orders and patterns. Following this, the nature would not be limited merely to fluidic or curved forms or merely geometric and linear ones, but all types of forms would be considered and with their original properties. In other words it is tried to look at the nature as the way it is.
- Each of natural phenomena is considered as a designed one. It means that all details are important and has direct effect on final shape. Therefore, considering all details of forms as intentional created parts is another important principle.
- Although our observations have been based on non-abstraction approach, it should be mentioned that abstraction is unavoidable. Here we have just tried to apply less degree of abstraction in order to get closer to the reality.
- We do believe on the analyzing capacity of geometric reasoning and geometric forms, therefore geometric reasoning would be applied for analyzing the action of the forces (As it is explained in the following); but would not have apparent manifestation in Quasi-natural forms.
- Taking this kind of approach to the nature, complexity is the first quality appears to us. It is not tried to understand complexities of forms by finding and extracting patterns or orders in them. Instead it is tried to generate a clear and tangible definition about the logic of complexity. A definition which helps designers to think about the complexity as complexity.
- Gestalt was explained as "An arrangement of parts which appears and functions as a whole that is more than the sum of its parts" (Monö, 1997). The position of this study to

the gestalt is based on the interaction of all elements of form (Line, Volume, Color, etc.). Our studies showed that all elements of forms in nature affect each other bilaterally and the unity of final whole is the result of their interaction. All elements are exposed to the forces from each other and this is how the final unified shape appears.

- The involvement of this approach with different aspects of form theory is shown in figure 2. Visual aesthetics and emotional aspects are the most involved areas. In other words this approach would mostly affect these two areas in the sphere of form theory.

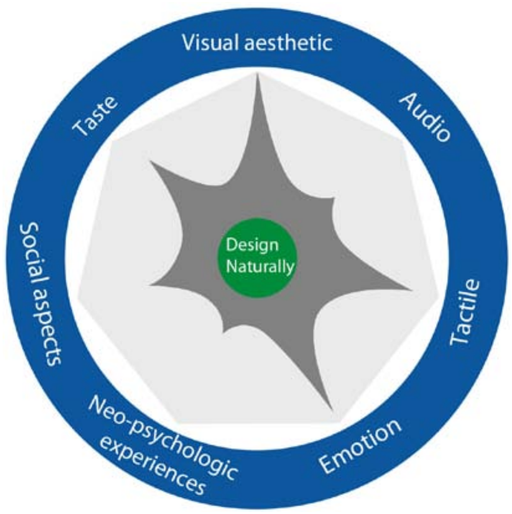

Figure 2 Different issues concern with form theory & involvement degrees of Design Naturally approach with each of them.

Objectives & hypothesis

This paper aims to

1. Study the reality of forms in nature, which is manifested towards complexity, by avoiding reductionism.
2. Present nature's approach to the form issue and its manifestations as applicable tools for designer.

Our hypothesis is that this approach would take us beyond the law-bound principles of geometry and would create a new aesthetical language to the world of products based on the real complex world.

Method

Case study

A case study was performed to study specific target group of natural phenomenon in order to find out nature's real complex approach to the form issue. The geometric reductionism, aesthetical norms, interests and presupposes were avoided and it was tried to see the forms in the way they really are. Thus we encountered with COMPLEXITY of forms and their relating characteristics such as, unpredictability, irregularity, asymmetry, etc. Apparently it was understood that nature's approach to the form is DIFFERENT from designers one. In fact, when we observe forms in nature we can follow some principles that are embedded in their design and it seems that they are not the same as the principles that designers use in shaping the artificial forms. These principles are those which produce visual complexity of natural forms. The target group was consisted of several types of birds and reptiles and few types of plants. The reasons for choosing such a target group was firstly due to the sake of birds' and reptiles' great variety in form and secondly due to the accessibility of plants for virtual study. We focused on principles behind the formation of forms in nature and the ways we defined them for designers.

The study started by observation and realistic drawings. In first phase, 10 types of birds, 6 types of reptiles and 12 types of plants were observed. The materials for observation were pictures, movies and also virtual observations. Some of the pictures were selected from the internet and books and others were taken by digital cameras.

The visual characteristics of each sample were carefully studied. Then detailed explaining notes and drawings from each of them were made (Figure 3). By this phase we could recognize some almost constant characteristics, which seemed to be common in all observed samples.

Figure 3 Drawings from birds

In Parallel with observations, a library search regarding the scientific aspects of form generation processes in nature was performed to find out the reasons behinds the visual qualities. It was also tried to obtain a general explanation for defining the observed characteristics.

The aim was to find out about the possibility of considering the observed visual characteristics, as constant principles, which nature applies to create forms. For this aim, there was a need for studying many samples. Statistical operations performed to determine the sample size of each of the target groups. High percent of common characteristics in first observations showed that studying 20 types of each of the birds, reptiles and plants would be enough to obtain decisive results about the final principles.

Results

The results are categorized in two parts.

1. Form Follows NATURAL Interaction of Forces: An explanation about how COMPLEXITY appears in natural forms.
2. Manifestations of this explanation in natural forms.

Form Follows NATURAL Interaction of Forces (FNIF).

This is our perception from how complex forms appear in NATURE. This sentence can simply and generally explain some complex qualities of forms in nature such as asymmetry and unpredictability. We believe that taking this approach to product design would cause these qualities to appear in products too.

The word "Force" refers to both Directional and surrounding energies. Directional forces refer to the energies acting upon the movement of the inner & spacial axis of form and its elemental parts. These forces increase the complexity and asymmetry in forms by affecting the surface from beneath and above and with different angles and intensities. The pressure or the tension of the force is absorbed by the positive element and then projected outward through the form and into space (Akner-Koler, 2007, 19). For instance they may cause curves, bends, concavity, convexity and wrinkles.

As a complement to directional forces, surrounding force is defined. Each element of forms in nature is surrounded by a type of energy which can affect the form of its adjacent elements. To some extent, it is comparable with invisible magnetic field of the magnet, which affects the iron filings around it or the layers of the energy surrounding every living thing (Figure 4).

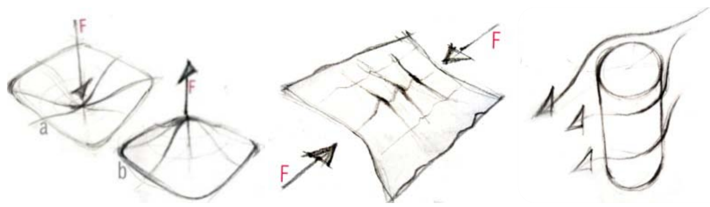

Figure 4 On the left: Directional forces cause concavity & convexity, in the middle: Directional forces cause wrinkles, on the right: Surrounding forces of the cylinder affect its adjacent axial forces.

Interaction of the forces refers to their bilateral relationship and its effects that shape the form. The quality of the interaction of the forces is defined by the word "Natural" which is the key word here. Longman dictionary has defined this word as "concerning, existing or happening ordinarily in the world (nature), especially not caused, made or controlled by people".

In conclusion, FNIF is pointing to "What ordinarily happens by bilateral relationship of directional & surrounding energies affecting axis & constituting parts of form". For example, crumpled piece of paper is the natural result of interaction of the forces applied by fingers to it. Also in figure 5 two forces contract a cylinder by asymmetrically pressing against the two base surfaces of it. It can be seen that two common traits of natural forms, chaos and asymmetry, has naturally appeared in this form via natural interaction of forces.

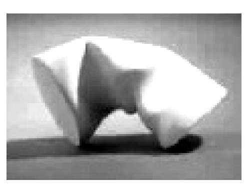

Figure 5 Complexity, the result of natural interaction of the forces

Manifestations-Design Naturally Principles (DNP)

FNIF has variety of manifestations in nature. Here they are categorized into 5 groups of line, plane, volume, color and texture. Each group explains how nature applies that specific element of forms regarding to FNIF dictum. These principles are like toolkit which can guide designers to apply elements of forms as nature do. Here they are presented under the title of DESIGN NATURALLY Principles.

The following principles are all based on one fact: Adjacent elements naturally affect each other and this bilateral effectiveness causes some changes in their forms. These changes which are mostly towards complexity, appears as the results of natural interaction of the forces.

Line

Line changes by form. These changes mostly appear in weight of line (thickness), its direction and sometimes, its color. The reason behind these changes is the forces from the context (plane) and other adjacent elements which affect the line through its path (Figure 6). Here two more common situations are presented.

Figure 6 Changing weight of the black line, regarding to its context

First is about the changes of line when it moves on different surfaces (e.g. concave or convex surfaces). When the line passes the concavity or convexity, naturally, the directional forces which have affected these surfaces and have made them curved, would affect the line too. So, naturally the line would become thick or thin (Figure 7) or temporarily get out of its direction.

Figure 7 Line on convexity naturally becomes thicker (b).

Second situation, is about the changes of line when it becomes adjacent with other elements through its path. For instance in figure 8. It can be seen how the surrounding forces of the bump on a tree have changed the direction of its adjacent lines. The form of the deviation depends on the form of the element, its size, the quality of lines and their distance from each other.

Figure 8 Surrounding forces of the bump on a tree have changed the direction of its adjacent lines.

Line changes the form. Regarding to the bilateral relationship of elements in nature, in some situations it can be seen that line affects its context and other adjacent elements too. For example in figure 9 the slight depression and change of color around the mid rib and each of the veins as lines, on the leaf, as their context (plane) are visible.

Figure 9 Line changes its context

It can be concluded that line changes freely by form and on the other side can change the form too. This dynamic and changing quality of line is what exists in nature but not in man-made products (Figure 10).

Figure 10 An unchanged quality of line when it passes a convex surface of a cylinder

Plane

Plane changes by its constituting parts. Plane prepares a field in which other elements can be defined. According to the bilateral relationship between the adjacent elements, we can say that plane is exposed to the directional and surrounding forces of the elements concluded. So the final shape of the plane depends on the result of natural interaction between all these parts.

Cutting, removing or adding an element, creating unevenness, or applying any other kind of change on a plane, is in fact equal with implementing a type of force to it (Figure 11).

Figure 11 It can be liken to effects of a drop on water.

Natural interaction of these forces would have some manifestations which depending on the forces' properties, would differ. An eye of a bird on her face can be a good example for this. In figure 12, some wrinkles and slight bump around the eye of bird on its face can be seen. These are caused by the directional and surrounding forces of the eye as an added element, on the face as its context.

Figure 12 The complexity of the white area

Regarding to the scope, angle and the strength of the acting forces, other manifestations such as depression or a bump, change in color or texture, wrinkle or even a dent are also expectable (Figure 13).

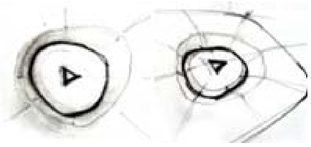

Figure 13 An added play button and its effects on a surface

As mentioned before, plane in nature freely changes by the forces acting upon it. The contour line of the planes also forms by the interaction of these forces. Figure 14 shows how surrounding forces of the inner elements have formed a complex and unpredictable contour line. This is why we rarely encounter with pure geometries of planes in nature.

Figure 14 Unpredictable contour line

Edges are specifically identified. Edges mostly form under the pressure or tension of the concentrated forces. Therefore according to FNIF dictum, it can be seen that in natural forms, these areas are almost always identified by some visual traits such as Wrinkles, constriction, change in thickness or the color and texture (Figure 15).

Figure 15 Change of color, texture and thickness on the edges of duck's bill.

Above-mentioned principles also apply to the "points" as scaled planes.

Volume

As volumes form by combination of the planes, all of the principles about the planes apply to volumes too.

- Volume changes by its constituting parts.
- Volumes don’t appear in their basic forms.

- Edges are specifically identified (Figure 15).

Joint areas are almost always identified by some visual traits. Joint areas in nature can usually refer to where one volume comes out of the other. Growing out a volume from the other one in fact means implementing force from inside, until the volume finds its way to get out. Interaction of pushing and opposite forces would naturally cause some changes to appear in joint area and in both volumes. Figure 16 shows how the petiole has grown out from its stem. Soft tonality of colors and constriction of parts which express contradiction of forces and also transformation of one volume to another can be seen in figure 16.

Figure 16 When a volume comes out from another one

Generally, when two volumes join together, it means that two or more opposite forces are interacting. Change in color, wrinkles, constriction, or a kind of puff are symptoms of this interaction. The changes in joint of volumes would differ due to the direction of axial movements, size and strength of the forces of the meeting volumes.

Texture

In nature texture changes by form and emphasizes on the quality of form. Texture is one of the characteristics of surface. It has a dynamic nature and should change by the changes of the surface. The directional and surrounding forces, which act upon the plane (surface), naturally affect its texture too. Therefore, for example the quality of texture of the concave surface surely differs from the same texture on convex one and also from the texture on the edges and joints (Figure 17). Designers mostly don't consider this point in their designs. Figure 18, is a picture of a product which presents texture that has covered a curved surface. As it can be seen, there is no meaningful relation between the texture and the curved surface beneath it. All elements of the texture are constant, no matter how the surface changes.

In conclusion it can be said that in nature texture changes freely due to the changes of its context. Therefore, it would find a dynamic characteristic which emphasize on the quality of form.

Figure 17 Dynamic texture in nature - All elements of the texture change by convexity and concavity of surface and also at the edges.

Figure 18 Texture in products

Color

Color changes by form and emphasize on the quality of form. Figure 19 shows the thorn of a rose. As the thorn gradually becomes sharp-pointed at the end, its color also changes softly from dark red to light yellow at its sharp end. This tonality emphasizes on the form of the thorn (sharpness) and is one of the other manifestations of the complexity in nature. Color has a dynamic nature and should change by the changes of the surface. Due to FNIF, the acting forces upon the surface naturally affect its color too. For instance, concave, convex, edges and joints are places which pressure and tension of the forces naturally cause changes in colors (Figure 20). We can also trace this phenomenon in some of our every day products, (Figure 21). Though designers mostly don’t consider this matter (Figure 22).

Figure 19 Thorns of rose bush

Figure 20 Mushrooms, Color changes on concavity

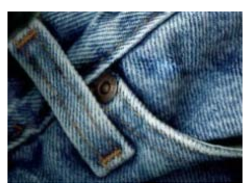

Figure 21 Blue jeans - Abrasion of the edges are the result of natural interaction of forces. Great relationship between form and color

Figure 22 A watch by Ross Lovegrove Plane color, No matter how the form changes

Above-mentioned principles are in fact the manifestations of complexity of forms in nature. Unpredictable contourlines, tonality of colors, dynamic textures, changing quality of lines, non-geometric planes and volumes, asymetrical compositions and so on, are all those visual items, which make nature complex in front of our eyes. FNIF dictum is an explanation which generally help us to understand these complexties and analayze them by the interaction of the forces. Besides, as you know, almost all of the above–mentioned principles are those items which have been ignored previously by designers because of their common geometric approaches to the nature BUT have values to be applied in product design.

Our point here is that Applying Design naturally principles would provide designres a vast realm of creativity and freedom in field of forms. It would grant a dynamic identity and new aesthetical values to all elements of forms, meaningful relationship between them and more sense of integrity to the whole complex.

To design naturally, first we have to think naturally!

As a complement to DNP we need to know about the process which by nature has applied DNP. This process is known as GROWTH. By the 'Growth Process' in nature we are referring to the process in which different parts of a phenomenon gradually appear till it attain to puberty. This is during the growth process which directional and surrounding forces work and so the above-mentioned manifestations appear (by the natural interaction of the forces).

In order to design naturally (apply the design naturally principles), we need to be able to think naturally. Transferring the concept of growth may help designers to do this.

Our studies are still in progress in order to generate a method based on the natural growth, to enable designers to:

- Think about the form-giving process as a growth process of natural phenomenon
- Analyze the acting forces and their natural interactions through the form-giving process
- Apply the DNP regarding to analysis of natural interaction of forces

Conclusion

After all it can be concluded that by looking through the complexity of forms in nature and by forgetting the geometric approaches, we would be able to get closer to the reality of forms to learn more and deeper from nature. Thus we would be able to go far beyond the law-bound principles of the geometry and traditional design aesthetics and create a new aesthetical language to the world of products based on the real complex world.

Author Biography

Parsa Kamehkhosh is student of master of industrial design at university of Tehran. His main research interest is chaos and complexity in form theory.

Alireza Ajdari got his B.A. and M.A. in Industrial design from university of Tehran, Iran and has got his Ph.D. in Industrial Design and Multimedia Communication from Politecnico di Milano in 2008. Since then he has been working as an assistant Professor in Industrial Design in University of Tehran, Iran. His main research interests are the role of Cultural Affordances in product Design and form theory.

Yassaman Khodadadeh is an Associate Professor of Industrial Design and Head of Department of Industrial Design of Kish International Campus of University of Tehran. She received her PhD from Keele University, UK. She is a member of Design Research Society (DRS) and an active researcher in field of Design.

Catching Wasps and Baking Dinosaurs: Experiences from Co-designing with Children

I.C. MariAnne Karlsson, Design & Human Factors, Product and Production Development, Chalmers University of Technology, Gothenburg, Sweden

Pontus Engelbrektsson, Design & Human Factors, Product and Production Development, Chalmers University of Technology, Gothenburg, Sweden

Abstract

User-centred product development and design can be carried out with differing degrees of user participation: for users, with users, and by users. A project characterized by a co-design approach, i.e. design 'with' rather than 'for' or 'by' users, was carried out during the spring of 2009. The co-design teams consisted of children (a total of 45, between 10 and 11 years old) and 10 product developers/designers (teachers and students from an industrial design engineering university programme). The overall theme for the co-design exercise was food, eating and health, a theme which the children had researched as co-researchers during the autumn of 2008. The design project followed a structured design process, including problem identification, idea generation, concept development, etc., supported by typical methods and tools such as various brainstorming techniques, formulation of evaluation criteria and concept screening. Working in teams of 3-4 children and one developer/designer, various problems were identified and solutions proposed. The problems included for example "healthy sweets", "keeping wasps away from the lemonade glass", and "how to make washing up more fun". The results from the process consisted of for example a healthy sweets advertising campaign, several "wasp traps", and a new type of dishwasher based on the principle of a record player. However, the results also encompassed experiences from co-designing with users. Some of these experiences were considered the consequence of the fact that the children were indeed children, and are thus considered relevant only for other projects involving children as co-designers. Maintaining focus and concentration, for example, was a key issue. Other experiences are considered more generic, i.e. issues which would emerge as important topics in any co-design process. Communicating an understanding of the product development process and the time required for the solution to develop from idea to prototype were regarded as such generic topics.

Keywords

co-design; participatory design; design with children

User-centred product development and design can be carried out with differing degrees of user participation. One way of categorizing these degrees is in terms of 'for users', 'with users', and 'by users' (cf. Eason, 1988). An approach 'for' indicates a fairly passive role for the user, that of contributing with, for instance, problem descriptions and experiences as a basis for product development. A 'by' approach, on the other hand, would reflect a very active user and a situation where the product developer's/designer's role is to operationalize what has already been specified as the 'design solution'. A 'with' approach, finally, would reflect a participatory design process where users and product developers/ designers bring their respective skills into a common arena and work in a collaborative process, acknowledging each other's contributions to the design process and its outcome(s).

The arguments for participatory design, or co-design, have been for instance that involving those who are affected by the outcome in creating the solution is a way to better fulfil their needs and requirements and for achieving sustainable solutions, i.e. solutions that will be accepted and adopted by the specific target group. The co-design concept embraces, furthermore, the notion that all people are (or can be enabled to be) creative and that this co-creativity will contribute to innovation.

Co-design has traditionally been applied in projects with the purpose of developing computer systems (e.g. Ehn, 1993; Grønbaek et al. 1993) and workplaces (e.g. Broberg, 2010; Garmer, 2002) but it has also been used in other domains, such as service development (e.g. Albinson et al., 2007) and development of urban design and planning (e.g. Shin, 2009). Co-design has also been carried out involving specific stakeholders, for instance children. Examples include the development of school environments (Ghaziani, 2008; Newman & Thomas, 2008) and new technology (e.g. Farber et al. 2002), as well as school-based intervention studies (e.g. French & Stables 2003; Prell et al. 2005).

Co-design raises, as such, a number of questions but these may be further emphasized in projects which involve children: What is actually the different participants' contributions to the design process? What are the contributions of children? What is required from the process in order to establish ”true” co-creativity and design? Will the children's voices be heard? How can the shift in power, from that of product developers/designers to that of users, be managed? Can and will the children and the adults be collaborating on equal terms?

The purpose of this paper is to present some experiences obtained in a co-design project with children. The project was part of a larger research project, “Children as co-researchers of foodscapes” (Swe: Barn som medforskare i matlandskap, BAMM) with the overall purpose to investigate the feasibility of involving children in searching for deeper knowledge on children's food consumption and their relation to and thoughts on food, eating and health. In a first phase of the project, during the autumn of 2008, the children had taken part in a co-research activity (reported in e.g. Brembeck et al. 2010). The co-design project reported on in this paper constituted the second phase and was carried out during the spring of 2009.

The Case Study

Object

The design object was “food, eating and related items and environments”.

Participants

The children came from two different classes in the same suburban school, a total of 45 children aged between 10 and 11 years. The product developers/designers were teachers and students from an industrial design engineering university programme. The teachers had differing backgrounds in that some were mechanical engineers and others were industrial designers.

Process and Process Results

The process involved seven sessions over a period of four months.

Session 1: Introduction

The first session was held in December 2008. The purpose of this session was to familiarize the children with the concepts of design problems and problem solving, i.e. the idea that it is possible to change things. A PowerPoint presentation was put together illustrating different ways of changing people's consumption of food, eating and related items through, for instance, marketing, information/education, and/or design and development of new technology. The children were encouraged to contemplate different problems that they would like to find a solution to in the next phase of the project.

Session 2: Identifying problems

The second session, held in February 2009, focused on identifying problems to be addressed. Approximately six children and one teacher/student formed groups which started to generate problems together. The method used was brainstorming, a method that was already familiar to the children. All problems were written down on Post-it notes (sticky notes), one idea per note, and placed on a large sheet of paper. The objective was thus to elicit possible problems to address. In some cases this was also achieved but the line between problems and ideas for solutions, or simply "ideas", proved to be thin.

When the ideas ran out, the Post-it notes were collated and grouped in 'problem areas'. A discussion was initiated on which problems were feasible to approach and which were not. The children had no problem in ranging the problems and ideas as realistic and unrealistic and were often more strict in their assessments than were the designer/developer. 'Cost', i.e. money, for instance, was an issue frequently brought up by the children. The result of the session was a reduced list of problems/ideas that were considered feasible to continue working with.

Session 3: Choice of problem

The problems considered feasible were listed, some additional "problems" were added by the teachers/students, and the completed list was distributed to the children. They were to make a choice of which problem(s) they preferred to work with. The final choices resulted in a total of six different "problems" and in 10 different design team.

- *Healthy sweets*. Sweets are desirable, but they are also "unhealthy". It would be desirable to develop a sweet which tastes as sweets should do, but is not unhealthy to eat.
- *A fruit protection kit*. When fruit is transported in a school-bag, it is often damaged why there is a need to protect the fruit.
- *A wasp (bug) trap*. When lemonade and similar drinks are consumed in the summer, a wasp may end up in the glass. It would be desirable to reduce this risk.
- *'Making washing up more fun'.* Washing up is boring and some solution should be found to make it more fun, something you want to do.
- *The school canteen.* The existing canteen was considered somewhat boring but also inefficient. Two groups worked on the dining area and two groups approached how to make it possible to serve at least two different alternatives every day.
- *The children's supermarket*, which later evolved into the *children's city*, specifically designed to match children's needs rather than adults' needs.

Session 4: Generation of ideas and choice of concept

The design teams were reformed based on the children's choice of problem. Working in teams of 3-4 children and one product developer/designer, ideas were now generated in order to solve the problem chosen. The methods used were some of the various methods taught on the industrial design engineering programme, such as brainstorming, Osborn's idea-spurring checklist, "extreme thinking", association exercises, etc. The result of these idea-generating exercises tended to be either "crazy ideas", such as "tame monkeys working in the school canteen" and "furniture made out of real fruit", or very down-to-earth, even pessimistic: "We could repaint the canteen, but it will probably be too expensive, (the head teacher) won't buy it". To end the session, a list of evaluation criteria was generated as a joint venture between the children and the developer/designer, and the various ideas and concepts were assessed accordingly in order to reduce the total list to one or a few concepts for further development. The method could be described as a simplified Pugh matrix.

Session 5: Concept development

In the next session, the work continued for an entire day in a large facility equipped with tables, chairs, paper, pens, paints, and an arrangement of materials by which physical models could be created. The goal for the day was to conceptualize the concepts, first in terms of sketches and second in terms of physical models.

- The group working with healthy sweets did not have the opportunity to develop an actual product since the premises did not allow working with different food ingredients. A basic concept was, however, a recipe based on corn flakes and chocolate, both considered ‘healthy’. One child devoted his time to carving tiny dinosaurs in foam, with the intention that this should be the shape of the sweets. The group worked on different packaging (an example of which is snown in Figure 1), which should contain the sweets, as well as commercial advertising campaigns by which the sweets should be marketed. It was noted that the children came up with ideas for different brand names, and the character and content of the advertisements surprisingly quickly.
- The fruit protection kit resulted in a solution which could be used for different fruits, folding and unfolding depending upon the size and shape of the fruit (Figure 2). Much time was therefore spent on producing models of fruit to try the principle out.
- The wasp trap idea was developed into several different solutions (Figure 3). In this design team, ethics became an important issue and the main goal for the group was to come up with a design that did not actually kill the wasp, but trapped it so that it could be released elsewhere.
- In order to make washing up more fun, the work of the design team resulted in a solution similar to that of an old record player. The idea was to place the dirty plate on a turntable dish and then allow the plate to rotate. A dish glove fitted with pieces of scrub-sponges attached to each fingertip would then be used to actually clean the plate (Figure 4). To the music played through the loudspeakers, the user could use the glove to “scratch” as a real DJ would.
- One of the groups elaborated the idea for a canteen with a jungle theme, with fruit-shaped furniture, lots of foliage, green plants, and jungle motifs on the walls etc. (Figure 5). A second group decided on a more ‘classic design’, spending their time on deciding on wall colours. A physical model was created (1:10 scale) and the effect of different choices could be studied by putting sheets of paper in different colours on the walls. A third group built a paper model of a conveyor system delivering plates of food (Figure 6) while the fourth group built a model of a more traditional serving station adapted for two main courses (Figure 14).

Figure 1. An idea for a packaging of healthy sweets. The brand name, “Krioxo”, is clearly identifiable as well as the elaborated “𝒦”-logo.

Figure 2. A basic concept for the fruit protection kit.

Figure 3. A model of a conceptual wasp trap created from a disposable coffee mug.

Figure 4. Prototyping part of a new type of dish glove to make washing up more fun.

Figure 5. Development of a jungle concept for the school canteen.

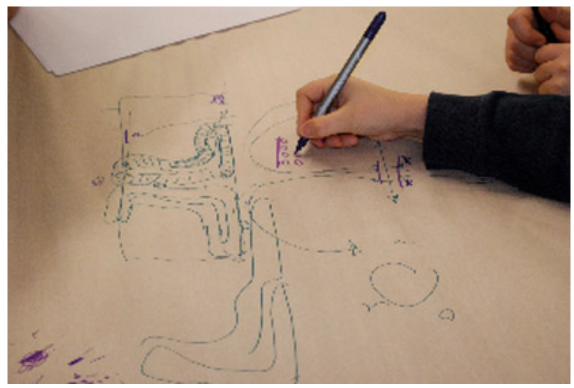

Figure 6. Sketching the conveyor belt solution for the school canteen.

- The children's supermarket became a shop on two floors, the ground floor for the parents and the first floor for the children only, offering an assortment of ice-creams and sweets. The children's consumption should be paid for by bonuses received on the basis of the parents' consumption. However, as a lot of sweets are consumed, this has to be offset by exercise. A sports hall therefore had to be added. The discussion in the design team ended in a children's city with a supermarket, a sports hall, a cinema, large parking areas, a roundabout (an important detail), and a place for events where, each week, a celebrity would turn up to sign autographs.

Session 6: Presentation of 'prototypes'

A week passed between sessions 2 and 3 and between sessions 3 and 4. After the concept development session had been completed, however, three weeks passed during which the product developers/designers continued to work on the concepts. The intention was to reach a 'prototype' level for at least some of the concepts. If a physical prototype was not feasible, a virtual prototype was created.

The final results included two dinosaur-shaped cookie cutters (Figure 7), posters for the different healthy sweets (Figure 8), a functional model (scale 1:1) of the fruit protector in ABS (by rapid prototyping) (Figure 9), computer models of the dish-washing device (Figure 10) and wasp trap (Figure 11), some CAD work on the canteen (Figure 12), a "fruit table" (scale 1:1) (Figure 13) and the city built in Google SketchUp.

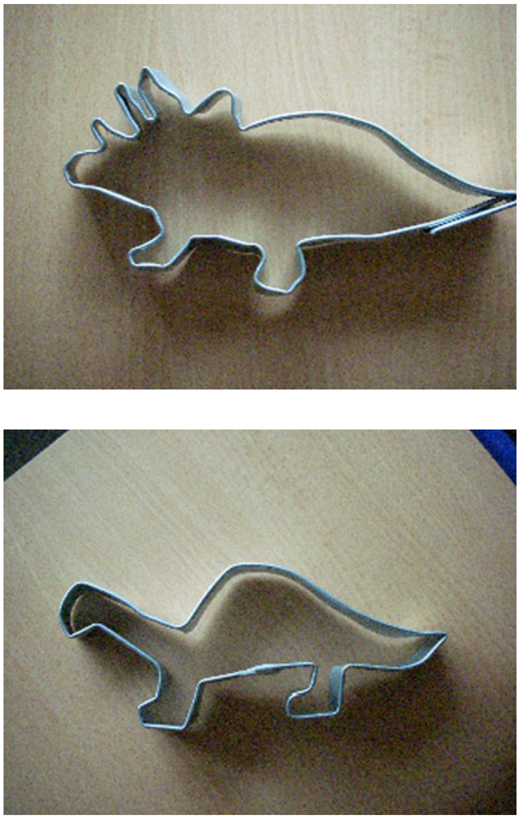

Figure 7. Cookie cutters shaped as a dinosaurs.

Figure 8. The advertising campaigns for “Rodeo”, “Rundat” (rounded), “Perstron” (a mix of “**per**sika” (peach) and “hall**on**” (raspberry), and “Krioxo”, argued to be “healthy sweets”.

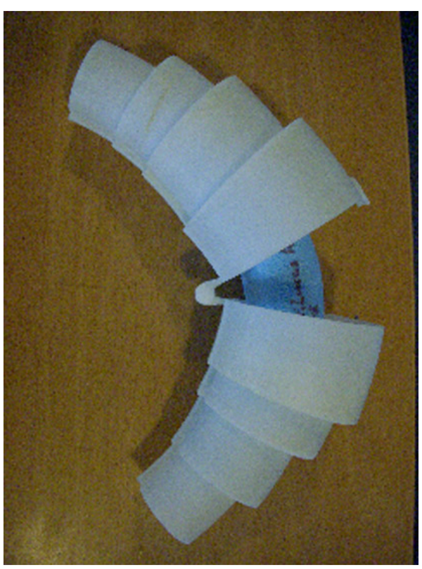

Figure 9. The foldable, and unfoldable, fruit protection kit.

Figure 10. The washing-up device in different versions.

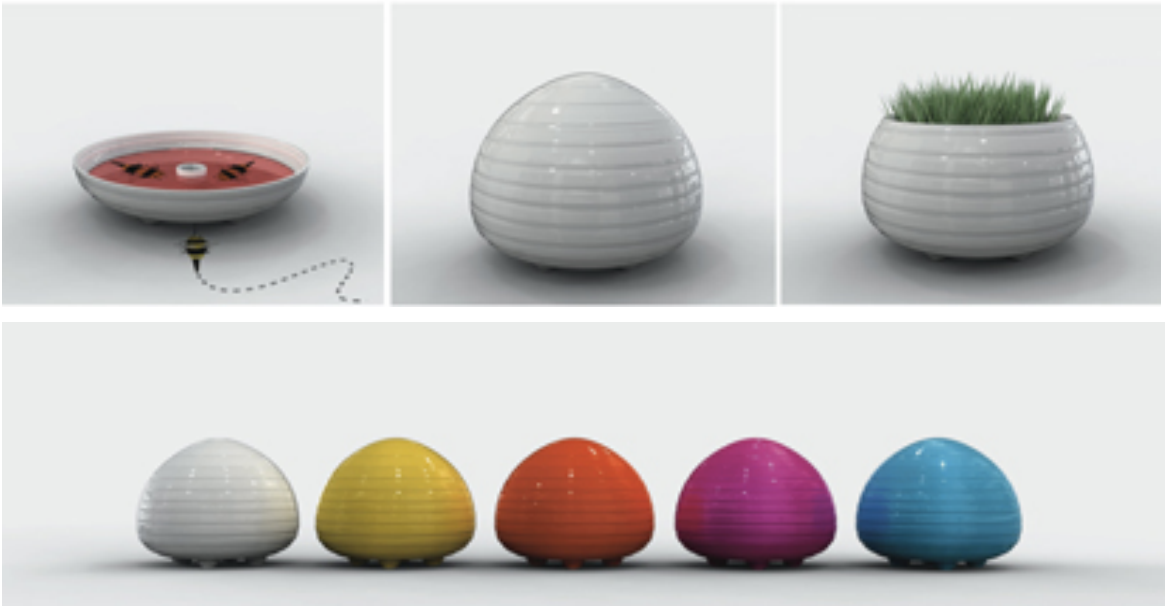

Figure 11. The wasp trap.

Figure 12. One of the design proposals for the school canteen had a jungle theme, here represented in CAD.

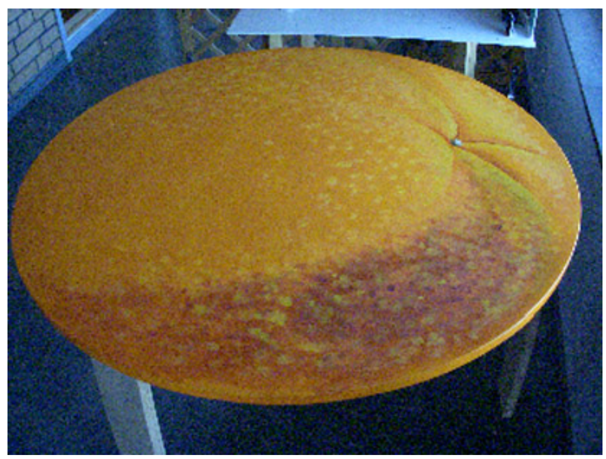

Figure 13. The “fruit table” produced in scale 1:1

The results of the prototyping work were presented to the children to gather their comments and impressions of the work. Did the concepts turn out according to their expectations? The discussion proved less dynamic than anticipated, however, and the children did not appear to relate to the prototypes as part of and/or the results of their work. The only prototype in which the children demonstrated a real interest was the virtual city in Google SketchUp which allowed them to interact with the software and make changes to the virtual representation for instance in terms of changing colours and perspectives.

Session 7: Communicating the project

Finally, in the sixth and last session, a small exhibition of the prototypes was arranged in order to communicate the results to other pupils at the school and to the children’s families. For the exhibition, posters were made illustrating the process in each design team, from ideas and early sketches to the final concepts. This time the children appeared more engaged than in the former session, taking part in completing the exhibition (an example shown in Figure 14) and even producing new product representations to further illustrate their work (Figure 15).

Figure 14. A model of the way food could be served in the school canteen.

Figure 15. A representation of one of the canteen solutions, the conveyor belt, produced by two children in GoogleSketchUp. The text reads approximately (with some spelling mistakes) "*The change of the food distribution in the school canteen"*

Evaluation

The project was evaluated and both children and product developers/designers were involved. The children were asked to write down their thoughts on the co-design project and what they had learnt. Overall the comments were that they had enjoyed taking part in the project as a whole (i.e. the autumn and the spring). Some children had preferred the earlier co-research activity, while others had found the co-design phase the most rewarding. Being able to "create" or "make" things had been "fun". However, there were also children who had found the co-design activity negative as they were not satisfied with their design solution (or the representation of the design solution).

The participating university teachers and students were interviewed regarding their experiences. Overall the response to participating in the co-design project was positive, but it had also involved some challenges. Excerpts from the interviews are presented below:

- " *… it was exciting. I thought it was fun to observe the creative ability of the children. ...// … They are very positive and unrestrained ...//…Then, of course, there are also problems associated with being unrestrained*."
- "*… The children could become extremely focused on a particular idea. …//…If this happened you had to put an end to it, well, I tried to broaden their thinking*."
- *"… I tried to capture their ideas as much as possible but at the same time one could feel that one was restraining them."*
- *"… to begin with it felt as though we have drifted away from the task and it felt as something negative as one is used to finishing a task if a task has been given. But then one had to say to onself that, well, what will this turn out to be? And if one doesn't end up with a store but with a house, I suppose that that is a result too."*

- *"I don't think they understood the process. I got the feeling that when they do something at school …//… you ask them if they have an idea. And then one tries to realize the idea…//… You move directly from idea to final product. One doesn't work in an iterative process, with evaluations, etc."*

Reflections and Lessons Learned

One outcome of the project consists of different problems and ideas for solutions to these problems. "Creating positive experiences" appear to be the "continuing thread".

Another result, which is the topic for this paper, includes experiences of co-designing with users. Some of these lessons learned are believed to be a consequence of the fact that the users were children, and may therefore be relevant only for other projects involving children as co-designers. How to maintain focus and concentration was, for instance, such an issue. Other experiences are considered more generic, i.e. issues which could emerge as important topics in any co-design process. Communicating an understanding of the product development process and the time and resources required for the product to develop from idea to prototype were considered such a generic topic.

Distribution of power and responsibilities

A first question to be posed is whether or not the project was, indeed, a co-design activity, i.e. a synergy of different skills. A related question concerns the allocation, or distribution, of power between the children (as users) and the adults (as product development/designers) in the project. The product developers/designer predominately worked with the children at their school, in the children's regular classrooms. It became evident that the adults, in the eyes of the children, were synonymous with "teachers" and hence the children accepted being told, but also to some degree expected to be told, "what to do". A slightly different relation was developed when the children and the product developers/designers during session 5 met on a more neutral arena. Hence, *the physical context should probably be considered* in these types of projects. The same concern has been raised, for instance, by Druin (2002), Jones et al. (2003) and Vaajakallio et al. (2009).

A factor contributing to the product developer/designer becoming the "teacher" or "supervisor" rather than the moderator was probably *the size of the team*. In the early phase of the project the design teams were fairly large with one senior product developer/designer and 7-8 children in each team. In the later phases of the project, the total number of product developers/designers was increased and the number of children per team therefore decreased. This not only helped balance the team, but also contributed to maintaining the design team members' involvement and focus. This issue has also been discussed by Druin (2002), Jones et al. (2003) as well as Vaajakallio et al. (2009), the concluding suggestion being that "*… a lot of resources including many adult facilitators … / /… are needed when working with children*" (Vaajakallio et al. 2009, p. 247)

Furthermore, a fundamental idea behind the project was that the children were to participate with their knowledge of, and with references to, being children. The product developers/ designers were to participate with their knowledge of design methods, skills in visualizing ideas etc. This could mean a drift in power, from the children to the developers/designers, a concern that was raised in the interviews with the product developers/designers. In co-design process it is, however, important that the respective participants are valued for and can play on their respective strengths. The designers' ability to sketch actually played an important role in facilitating co-creation in that the designers could rapidly visualize ideas, including the children's ideas, and these sketches could be used to discuss different issues within the team. The sketches thus became mediating tools, or enablers, for the design team as a whole.

Overall, the project proceeded as intended but not all design teams developed in the same way. It appeared unavoidable that the product developer/designer (i.e. the adult) took, or had to take, the role of “project leader” and/or “design team manager” but in doing so he/she also had to be aware of allowing the children's voices to be heard and to make a difference. The role could thus also be described as that of a moderator or facilitator. In the wasp trap team, the children participated actively and came up with different concepts. The designer developed the concept quite far from the early model in terms of how it looked but, nevertheless, the basic idea remained and the children recognized their “thinking” in the final product. The same holds true for the dish-washing device. In both cases the product developer/designer took control of the process, while still working hard to keep the children involved. In the healthy sweets team, on the other hand, the result of the process was that each child worked on his or her individual idea and the product developer/designer became the supervisor, or tutor, rather than a participant in the team. Hereby, the fundamental idea of co-creation was lost.

Maintaining focus and interest

Certain phases and tasks in a product development and design process require dedicated, focused labour in order to be successful. This can be assumed to apply also to the co-design process. The product developers/designers were, evidently, based on earlier experiences well aware of this and could consequently allocate the necessary resources. The children did not always manage, but there were large differences between the individuals. Some children were able to focus for a long time (even several hours) if they found the task interesting and meaningful. Two children, both boys, for instance spent four hours learning Google SketchUp and produced a usable drawing of their design concept, since they found that the product developer/designer had not accomplished this when developing the “prototypes”. Other children appeared to be able to focus for short periods of time, if at all, and the process had to be managed accordingly. Being able to understand the rationale behind a task, such as structured idea generation or assessment according to criteria, was identified as a key issue in maintaining the children's motivation.

However, in becoming unfocused or uninterested the children also communicated a self-projected inability to contribute to the work or contribute in a way they judged “good enough”. Most of the children appeared to face problems visualizing what they wanted, the way they wanted, on paper and in those cases where the model-making became too complicated for the children to be able to contribute substantially, their enthusiasm regarding the task clearly decreased. Evidently, the requirements on the participants in a co-design project must match their abilities and skills, and if the participants involve children particular care must be taken (cf. Vaajakallio et al., 2009). The question is, though, how much time should be dedicated to encouraging the participants of a co-design project if the process is based on the idea of ‘equal input’?

Focusing on and maintaining interest for particular design tasks were thus one issue. Maintaining the children's interest over time was another. The time lapses between the sessions were one to three weeks and each session, apart from session four, lasted for approximately 1½ hours. A week is most probably perceived differently by a child compared to an adult: a lot of things happened between weekly design activities, things which became more interesting and more urgent than the co-design project. In retrospect, more concentrated work where the teams had met every day or every other day but for a shorter time might have helped to maintain focus and interest over time.

Grasping process and methods

Various methods and tools were used for idea generation, evaluation of ideas, concept development, etc. These were examples of methods and tools typically taught to design students. The underlying thought was that children as a whole are no more creative than adults, and hence need support in terms of mediating tools. This assumption proved correct in that some children were very creative, while other children were not. However, based on the experiences obtained in the project, children and adults may have somewhat different needs when it comes to design methods. The children were noticed to, at times, become very focused on a particular idea and did not understand why further idea-generation was necessary why they needed encouragement to think further. However, methods devised to “free ones mind” and “think out of the box” did not always prove useful. A substantial number of “crazy ideas” emerged without any support and what was needed in these vases was instead methods and tools which maintained creativity but at a “working” level.

It was obvious that the children had, in most cases, very high expectations of what could be achieved during each session and in the few weeks allocated to the project. They did not appear to consider the results of the idea-generating session, or the concept development session, to be “results”. They had possibly expected “real products” or at least more realistic products to be the end result. This may be one reason why the computer generated images in general appeared to receive a better response than did the physical prototypes – the computer images probably looked more “real”. The fruit protection kit, on the other hand, did not impress the children at all even though it was developed into a working prototype in ABS, something that from an engineering perspective is quite impressive. It simply lacked the glossy plastic surface of injection-moulded plastic and it broke after half an hour.

It is most probably very difficult for someone not professionally involved in product development and design work to estimate the amount of time and technical problems associated with developing an idea into a completed product. Even though the development process, and its different stages, had been briefly introduced in session 1: Introduction, communication of the different design phases and their respective purposes and outcomes should probably have been given more time in order for all team members to fully grasp the progress. It is also possible that the co-design process per se should have been ”co-designed” to a greater extent in order for the different phases to be comprehensible to all those participating in the design work.

In conclusion, the project provided further evidence that co-design with children is a workable endeavour, with much the same opportunities and problems as co-designing with other categories of users. Nevertheless, some particular issues have to be considered: additional resources is needed in terms of adult facilitators, the requirements on the children as co-designers must match their abilities, and ways must be found by which focus and motivation can be maintained over time.

MariAnne Karlsson holds a Ph.D. in Consumer Technology. She is professor (chair) in Human Factors Engineering at Chalmers University of Technology, Gothenburg, Sweden. The main focus of her research is user-centred product development and design, in particular methods and tools by which users' requirements for products can be elicited and design solutions evaluated.

Pontus Engelbrektsson

Pontus Engelbrektsson holds a Ph.D. in Consumer Technology. He is presently employed as a researcher at Design & Human Factors, Chalmers University of Technology, Gothenburg, Sweden. His main research focus is on how to enable users to communicate their requirements to product developers/designers.

Knowledge Transfer from Designers to Home Crafts Makers: Negotiating Methods to Study Actions in Context

Cigdem Kaya, Istanbul Technical University

Chris Rust, Sheffield Hallam University

Abstract

This paper discusses the methodological problems arising in a dissertastion research project that investigates potentially productive relationships between professional designers and home based craft makers who have not received formal design training.

Informal observations by the researcher and other designers indicate that, when individuals from these two groups work together, in either professional or social settings, the craft makers' practices may develop in productive ways. We have observed that this can occur and be beneficial in traditional home craft work in Turkey (the main field of the research), post-industrial craft practice in Britain and small-scale industry in both countries.

In this research project, the designer-researcher is a participant observer dealing with non-verbal communication and the exchange of tacit knowledge stemmed from interpersonal relationships between the designer and the participants. In order to carry out a formal investigation of such a relationship a number of methodological issues must be addressed.

To develop a suitable approach we have examined theories with comparable features and explored the methods that would allow a managed programme of engagement between designers and traditional home craft makers to generate data and to process this data.

Since the knowledge transmitted or engendered in this research is tacit, it cannot be accessed purely by using language-based methods such as questionnaires and interviews although these can provide valuable triangulation. How to elicit the tacit knowledge transmission was the most important methodological question that we faced. That is why we reviewed methods for reflecting on the actions to elicit tacit knowledge transfer.

The questions we have explored include an evaluation of Action Research and Participant Observation, the advantages and challenges of observational video for capturing

spontaneous actions and reactions and the ways learning theories might help us to identify and characterise the essentially ‘silent’ tacit knowledge that is exchanged.

These methodological evaluations indicate the chain of methodological decisions that will be developed in this paper which will also speculate about how methods might develop during the practice in field work.

Since the aim of the project is to identify ways that designers and design researchers might act as enabling agents in developing the creative and professional understanding of well-motivated makers we will also discuss the nature of the methodology of practice that might emerge from this research as well as how we developed the hybrid research methods for this inquiry into knowledge transfer in informal production space.

The Research Context

The main question of this research is how to explain the gradual transmission of design knowledge in the works of home craft practitioners when they are exposed to designerly[1] thinking for a certain period. To explore this question methodological negotiations were made to design the research steps of a complex research question which involves capturing and studying actions that can only be understood via tacit knowledge.The ineffiableness of tacit knowledge has lead the authors to revise methods of research to develop strategies of eliciting reliable evidence by analyzing the making environment imbued with an intuitive understanding of the phonomenon. As a result of this elaboration the authors suggested a tentative methodology to study “concealed”, “silent” or “tacit” design learning in context.

To be able to work with tacit knowledge in this specific framework we have drawn on methods developed in recent practice-led research by Bowen (2009), Wood (2006) and Rahman (2010) as well as broader principles of exploiting tacit knowledge in design research previously developed by Rust (2004, 2007, 2009). In particular this work is guided by the

[1] “Designerly” way of thinking has been widely used in design research literature after Bruce Archer coined this term for the first time: “ There exists a designerly way of thinking and communicating that is both different from scientific and scholarly ways of thinking and communicating and as powerful as scientific and scholarly methods of enquiry when applied to its own kind of problems” (Archer, 1979). This ontological proposition has been widely cited and studied and it has also been the basis of some of the major works of Cross (2006,2007) and Schön (1983).

theories of Michael Polanyi (1958) who elucidated many of the fundamental concepts of how tacit knowledge is gained and used. This chain of arguement of methods can also guide further research in complex situated actions that embody design learning and tacit knowledge transmission.

Introduction

The reason for this inquiry is to observe how home crafts practitioners change their practice and attitude via exposure to design knowledge because the wide practice of home crafts might be a fertile ground to blend contemporary design practice and knowledge with local skills and knowledge particularly in Turkey: the field of the dissertation which is the source of the methodological argument that will be carried out in this article.

Another argument of this dissertation depends on how rapidly craft skills have been disappearing in post-industrial societies. Various research projects in post-industrial societies (especially the US and the UK) focus on ways of preserving hands on skills via contemporary media and concepts.

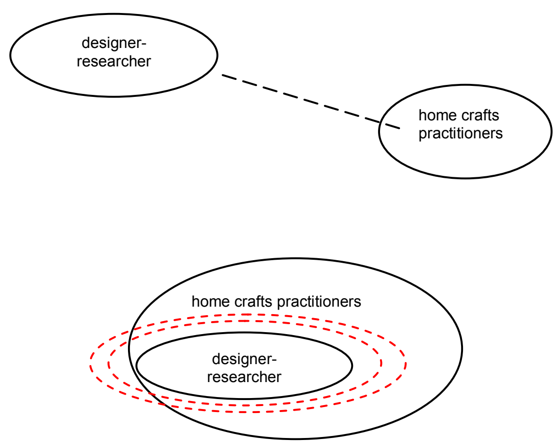

Figure 01. The designer-research joins a group of home crafts practitioners as a participant observer and studies the knowledge transmission that occurs during interactions with practitioners in workshops.

Having seen that these skills have been disappearing after a long history of industrialization in post-industrial societies, the dissertation also aims to build a methodology to understand and transform the minds of the practitioners of these skills and to explain this change with contemporary design theories.

This methodology could specifically be used as the initial step to enter a making environment by designers and design researchers who wish to engage with practitioners with hands on skills, particularly non-designers.

To study the tacit knowledge transfer from a designer to the home crafts practitioners we decided to organize three consecutive workshops where the designer-researcher is a participant observer. Each workshop is analyzed and the outcome of the previous workshop is used as data to structure the next workshop. The repeating analyses between the workshops have two aims: (1) Refinement of the designer-researcher's interventions (2) Elicitation of the transmitted knowledge, in other words measuring learning. The following sections of this article is going to explain how the research design represented in Figure 06 was devised depending on prior design research on tacit knowledge theory and situated learning theory.

Tacit Knowledge Transmission

As mentioned above the aim of the dissertation is to study the possible change in home based makers' practice and attitude when they work with designers for a while. The knowledge transfer that is expected to occur in this project is indirect, informal, unconscious and tacit.

In Personal Knowledge, Polanyi (1958) introduced the first concepts of tacit knowledge: that some part of our knowing occurs in relation to some *"unstated"* interactions among the various arrays of our prior knowledge in many fields. Thus, tacit knowledge embodies what we know but that we are not able to express with words (Polanyi, 1958). A popular example is riding a bike and not being able to explain how. This is highly relevant to crafts, design and all other making skills since we do not know how we make. And even when we make it we might not be able to explain how we made it with words. Yet, craft, design and other making is learned.

According to Polanyi (1966) tacit knowledge exists and is developed when the maker surrenders herself completely to the making. This process is defined as *"indwelling"* by Polanyi (1966) and it is cited by Rust (2004, 2007) as a crucial concept for design research:

> *"Polanyi was concerned with what he called the tacit dimension" in our knowledge. In particular he wished to give proper value to the process of recognizing, and making a commitment to, ideas and hypotheses, which may result from a rich understanding and*

> *knowledge but cannot be explained by tacit reasoning, in order to carry out the enquiry that will lead to them being more widely understood and accepted"* (Rust, 2004: 77)

Polanyi (1966) says that the apprentice unconsciously learns more than what the master thinks he is teaching: *"You follow your master because you trust his manner of doing things even when you cannot analyze and account in detail for its effectiveness. By watching the master and emulating his efforts in the presence of his example, the apprentice unconsciously picks up the rules of the art, including those which are not explicitly known to the master himself. "*(Polanyi, 1966, p. 53)

According to Lave and Wenger, this unconscious change that occurs over time might be called "situated learning". Lave and Wenger (1991) who are seen as the founders of situated learning theory suggest that learning occurs unconsciously within an action in a cultural context. Thus it is situated. According to Lave *"...learning is ubiquitous in ongoing activity, though it is often unrecognized as such."* (Lave, 1993) In other words, learning occurs everywhere during ongoing activity although we think that it occurs only in a teacher-student relationship. Since tacit knowledge acquisition is also impilicty embedded in actions, situated learning theory might also be able to guide a methodology to study tacit knowledge acquisition.

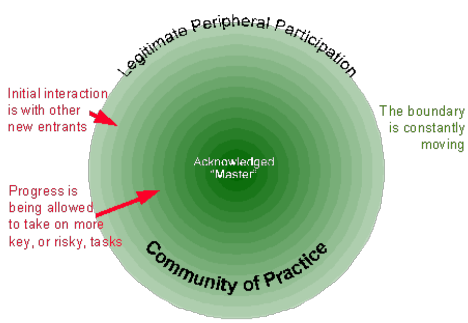

Figure 02 Graph of legitemate peripheral action theorized by Lave and Wenger, 1991.

The primary theory of situated learning defines how new learners learn more as they engage more with the learning context. According to situated learning a novice starts from a peripheral situation and progresses to the center towards the master in time. Figure 02 shows a basic diagram of how learning occurs according to situated learning theory (Lave & Wenger, 1991). In other words, newcomers to a community of practice are first in the periphery. As they keep working in the group they progress by feeling comfortable to take on more risks and experiment.

The vital point of moving towards the center from the periphery (also known as Legitemate Peripheral Action) for this research is that the movement is not *linear* but it is a *helix*. The "helix" movement towards the center- in other words "learning"- determines the duration of the research, the intervals between the workshops and the required analyses between each workshop.

Before each workshop the learner goes back to the previous action and reflects on the "learning". These are spaces between two circles in a learning helix. In other words, the transition intervals serve as check points where the novice looks back and acknowledges that she actually has made progress. Her perception of her work improves relatively from the previous cycle. Depending on this theory, we decided to structure several regular analyses with certain intervals to elicit the gradual progress in time as opposed to eliciting learning from the entire corpus of documentation.

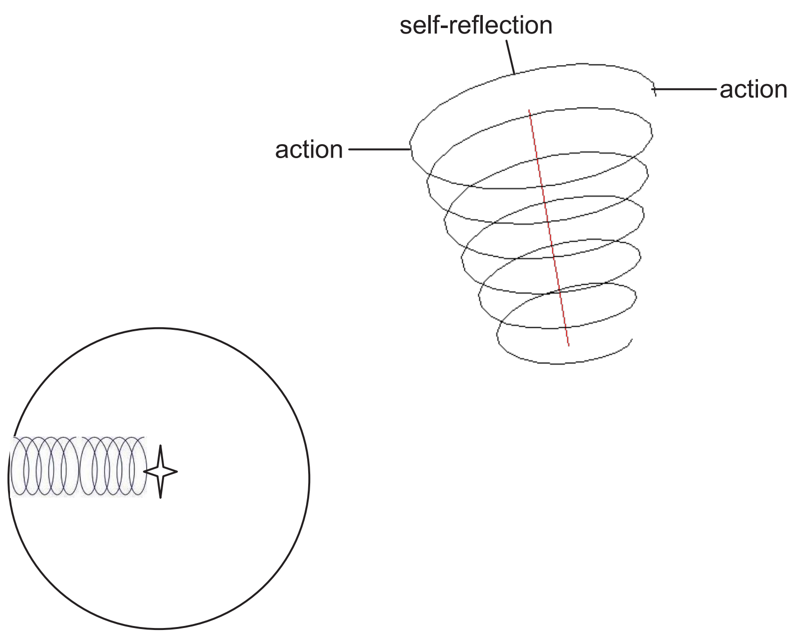

Figure 03. Graph of legitemate peripheral action theorized by Lave & Wenger, 1991. Learning occurs through a helix that moves from the novice to the master.

Capturing and Measuring Tacit Learning

To document the actions during the workshops observational video is going to be used because video captures sound and motion simultaneously and thus provides a rich resource for later evaluation. Having research data available to go back and re-evaluate is essential in this research because it observes gradual and subtle change. Wood (2006) explains this with an example in her research: When she was reviewing the footage with a master bowl turner Robin, he tried to catch up with the pace of the video footage and thus got frustrated due to lack of time and was not forthcoming. Having realized this Wood paid attention to the important matters that are being skipped and she rewound the footage again and again to provide enough time to open up the issues. Eventually, she noticed that the participants themselves opened up the issues when they were reminded that they could rewind the tape.

Being able to access video footage more than once is also important because it can be processed not only by the researcher but also by the participants. Measuring tacit knowledge transmission is complicated because the participants can not explicitly show what they have learned. This transmission can "partially" be traced from the designer-researcher's field notes and from her own analysis of observational video footage. That is why it is necessary to access what the participants think of the workshop experience by watching the observational video footage with the participants: in other words, to double check whether they agree on the researcher's findings. By asking the participants to reflect on their own actions might also help them acknowledge their progress consciously. This causes increase in self-esteem and self-confidence. This is how the participant internalizes the acquired knowledge (Schunk & Zimmerman, 1997). For this reason we planned to watch the observational video footage with the participants and analyze their verbal reports of self-reflection. To sum up, since it is not possible to explicitly identify tacit knowledge acquisition only by the researcher's interpretation we decided to "double process" observational video to see the interpretation of the participants of their learning experience. This can enable the participants to verbalize their interpretation of the knowledge acquisition process which can be called learning "bridges" (Wood, 2006).

Identifying Learning Bridges

Wood (2006) developed strategies for designing materials to help novices gain craft knowledge. She studies tacit craft knowledge to elicit knowledge that can be explicitly represented for learning resources. One of her findings in her research on transmitting craft knowledge, which is highly tacit, was a threshold where novices start communicating better with the craftsman. In other words, the initial interactions of the novices with the master can be painful and difficult. However, in time they develop a common vocabulary, understanding and communication. Wood (2006) explains the necessity of explicit information to form initial “bridges” to cover the gap of knowledge between the master and the novice during thet early difficult stage:

> *“The expert might start by demonstrating but, rather than leaving the novice to try and interpret what they see, the expert might provide a commentary, thus attending from his practice to his theory. The expert’s commentary will use explicit concepts in an attempt to bridge the gap, and the novice will need to undertake some form of action in response to this received knowledge, primarily imitating the expert, but in a reflective manner. The expert in turn should observe and reflect on the novice’s response considering revising his interpretation until a consensus of understanding is reached and the gap is bridged.”* (Wood, 2006, p. 131)

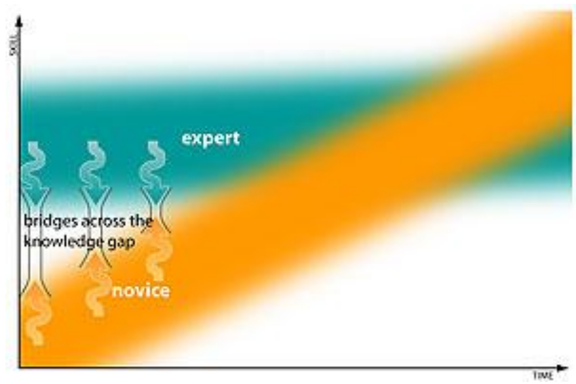

Figure 04. The knowledge gap between craft novice and expert. Wood, N. (2006) *Transmitting Craft Knowledge: Designing Interactive Media to Support Tacit Learning Skills*. Unpublished PhD thesis. Sheffield Hallam University: 147.

The mentioned treshold named as “bridges” during the tacit craft knowledge transmission process has been a compass to find out that there is indeed enough overlap between a designer and a home crafts practitioner to start a tacit learning process (Figure 04). Figure 05 shows where the participants of this research are in relation to the designer-researcher. In other words, home craft practitioners have enough exposure to the basic techniques of their craft and even enough motivation to work with institutions as individual entreprenuers. As shown in Figure 04 and Figure 05 in the beginning the makers might need some bridges to dwell into the overlap zone which is the locus of this research where they already have some similar skills with the designer to progress rapidly.

Looking at Wood’s theory and situated learning theory, we suggest that via this proposed methodology we can test that bridges are not only built in the intial phase of the master-novice interaction. Other bridges can be formed everytime the novice looks back at her work and reflects on it: in every turning point of the learning helix shown in Figure 03. For this reason, the analyses phases between in each workshop aim to explicitly define how new learning bridges have been built if not the bridges themselves.

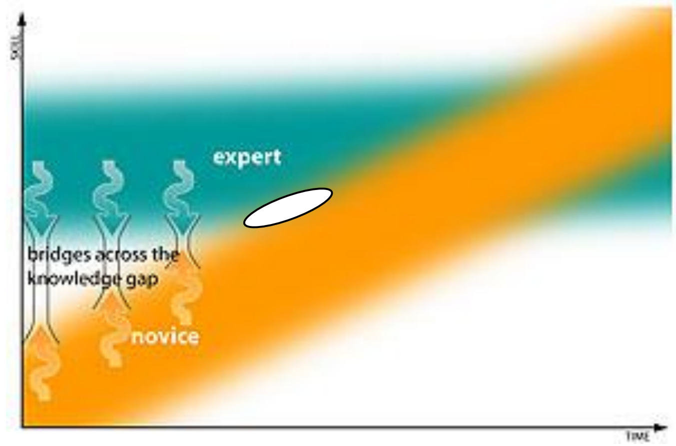

Figure 05. Locating this research on the theory of the knowledge gap between craft novice and expert. Wood, N. (2006) *Transmitting Craft Knowledge: Designing Interactive Media to Support Tacit Learning Skills*. Unpublished PhD thesis. Sheffield Hallam University: 147.

External Evaluation: From “distal” to “proximal”

The ways in which new learning bridges are built can be evident in the objects made in the workshops besides the interactions of the designer-researcher and the participant. The objects might also embody evidence of tacit knowledge that has been acquired from the designer-researcher by the participants. Analyzing what the participant might have learnt can be called looking (or *indwelling*) from “distal” to “proximal” in Polanyi’s words (Polanyi, 1958).

According to Polanyi (1958) tacit knowledge functions as an interrelation of two parts called *“proximal”* and *“distal*”. A simple example to explain this can be how a carpenter knows his hammer by its action on the nail and knows his muscles by the movement of the nail in wood (Polanyi 1958). In other words we cannot know of the hammer's use without the nail. To grasp the knowledge of the hammer we have to attend to the nail.

When looking from the proximal to distal, the proximal processing makes a leap towards the distal artifact as in the hammer-nail example. The relationship of the artifact to the process cannot be explained explicitly because it is tacit, yet can be validated through descriptive procedures. An example of this can be found in Bowen's (2009) process in his PhD thesis where he employed a tacit knowing relationship to *"process"* his experience of working with stakeholders (participants) by creating new design ideas. Bowen (2009) explains this processing as achieved through a tacit knowing relationship that has been creating by *"indwelling"*:

> *"In the case of my development of a critical artifact methodology, I suggest the comprehensive entity is the development of product ideas (as affected by the stakeholder activities). So, I can "process" my experiences of the stakeholder engagement activities by dwelling in them; by attending from these experiences (as the proximal term) to the designing of further conceptual designs (as the distal term)."* (Bowen, 2009, p. 173).

This proposition might work both ways. The other suggestion can be looking from the "distal" to the "proximal". In other words the artifacts (distal) can "*illuminate*" the reasons and aspirations (proximal) for which they were made.

Thus, in this research unlike Bowen's (2009) methodology the proximal and the distal are reversed as mentioned above: we will look at the artifact (distal) and track its motivation to be made (proximal). To achieve this, we are going to ask an external committee of experts with prior design research and practice background to evaluate the final work of the participants with reference to the initial work of the participants. This descriptive and comparative evaluation of objects will give us evidence about how the participants made progress.

The mentioned methodological decisions based on tacit knowledge theory and situated learning theory helped us shape the tentative methodology shown in Figure 06 to address our research question. Since we aim to observe tacit knowledge transmission we used situated learning theory because situated learning theory defines a structure for unconscious learning processes. This structure is a helix movement of learning from the periphery (novice) to the center (master). It is highly probably that the tacit knowledge is also acquired in a helix movement as it highly corresponds to the definition of situated learning: *"ubiquitous in an ongoing activity"* (Lave, 1993).

According to situated learning, the participant makes self-reflection on what she has learned in the initial step before moving on to the next step. That is why, the analyses steps have been placed at these points: between each workshop. In these intervals, the time between two consecutive workshops, the outcome of the previous workshop is analyzed in two steps. The first one is watching the video footage with the participants to hear their interpretations of their learning experience. The second one based on the two components of tacit knowledge:

tracing tacit knowledge transmission from “distal” to “proximal”. In other words external committee will be asked to evaluate the final work of the participants in comparison to their initial work (work documented before the workshop). Both steps aim to explicitly describe how learning bridges have been established.

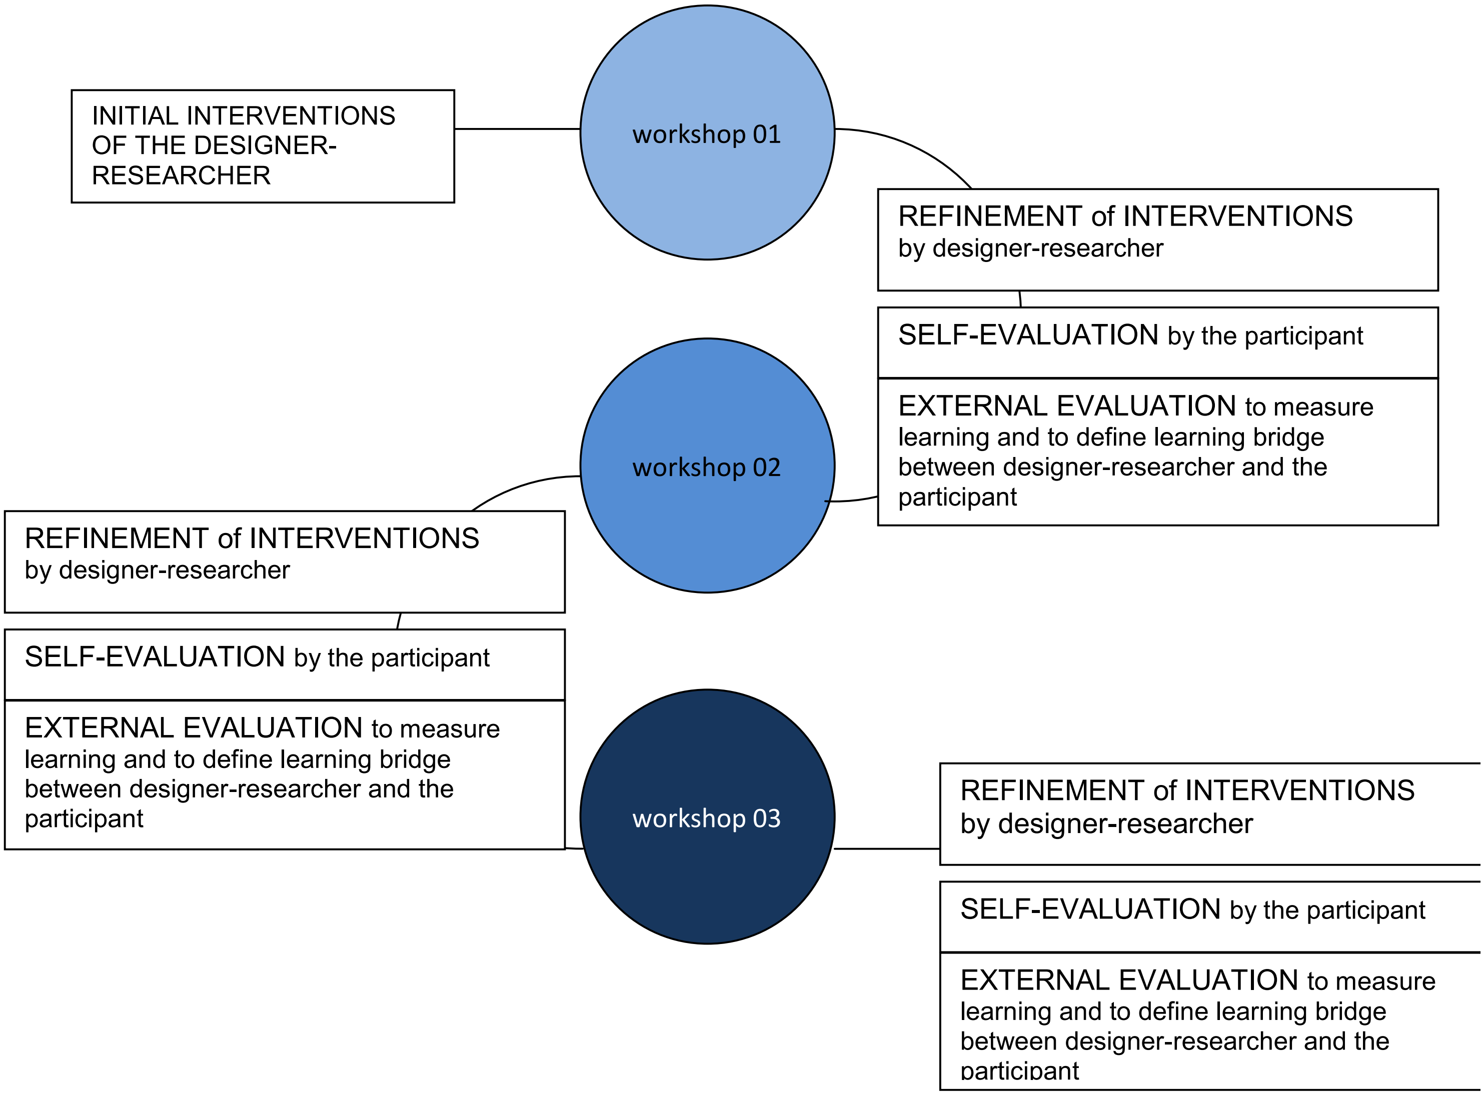

Figure 06. Research design to study how design knowledge is transmitted when a designer works with a group of home crafts practitioners.

Beyond Action Research

To study how a designer influences makers AR is essential for embodying action and reflection together during relationships.That is why AR is widely used in practice-based design research because AR focuses on incremental change (Pedgley 2007, Durling 2009). Although the methodology proposed above to study the mentioned specific research question highly resembles to AR it has some important differences. For this reason it is important to discuss why AR is almost but not exactly the methodology of this research. Although it illumniates the ideological roots of this methodology, it does not exactly correspond to the necessities of this research again mainly because the tacit nature of design are being explored.

In AR the researcher studies groups before, during and after an “action”, in other words “while doing things” to generate “change” and “understanding” consecutively: *“....It is thus an emergent process, which takes shape as understanding increases.”* (Sanoff, 2007, p. 214). According to McTaggart (2003) *“Fundamental to action research is the idea that the social world can only be understood by trying to change it.”* (cited in Brydon-Miller, Greenwood, & Maguire, 2003, p.15)

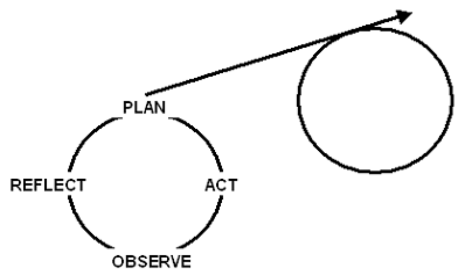

Figure 07. Steps of AR. Zuber-Skerritt, O.(1993). Improving Learning and Teaching Through Action Learning and Action Research. *Higher Education Research and Development, 12*(2), 45-58.

Although highly relevant, the method of this research is not exactly AR. While “following the problems” in a systemic cycle with respective logical steps shown in Figure 07, the subtle findings during the action might be missed because the elements shown in the cycle in Figure 07 (observe, reflect, plan, and act) have an integrated nature particularly in designing and in researching design (Swann, 2002). In this study it is not possible to identify these elements consecutively in cycles with certain logic because these processes are tacitly developed.

In her research on transmitting craft knowledge Wood (2006) indicates the same experience: *"....Whilst these elements are clearly identifiable in the research undertaken, they have not occurred as a sequence of separate and logically undertaken steps, rather the boundaries have been blurred and at times elements have been undertaken simultaneously."* (Wood, 2006: 14) Then, it might be discussed that some design researchers consciously use a non-identical twin of AR not to miss the tacit knowledge that is coming out during the action, like a good cameraman who might have to kneel down yet looking through the same frame.

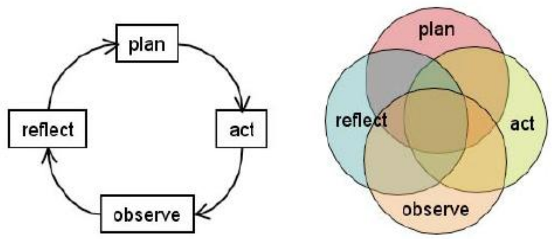

Figure 08. a. Action research b. Wood's (2006) interpretation of action research in practice lead research. Wood, N. (2006) *Transmitting Craft Knowledge: Designing Interactive Media to Support Tacit Learning Skills*. Unpublished PhD thesis. Sheffield Hallam University: 16.

Unlike action research, participant observation (PO) does not necessarily have logic of repeating steps of thinking and acting. Vice versa it is a method that tolerates blurry borders of planning, acting and reflecting to access entangled phenomena that cannot be accessed otherwise by other methods.

Participant observation is also appropriate for an iterative process where the researcher can go back to the event log (the notebook where the researcher writes down field notes) as frequently as she wants either alone or with the participants to revise it. This enables the researcher to pull the participants into the research. For this reason, the designer-researcher will work towards a specific methodology based on PO in consequitive workshops with intervals. This will constitute the field work.

Conclusion

This tentative methodology requires a relatively continuous long term study. First of all it is vital for the researcher to be present in every workshop, work with the participants and analyze workshops until a repeating pattern of the hypothesis is recognized. This is going to indicate when the research should be terminated.

Prior research most of which are practice-led dissertations have elicited, worked with and analyzed the tacit dimension of design knowledge due to their immanent connection to practice: “designing” and “making”. These researchers have been challenged by the difficulty of communicating their research because it is not possible to know how one makes. Yet it is possible to process the research through an argumentative analysis with detailed and clear procedures that document the entire process (Biggs, 2002; Durling, Friedman, & Gutherson 2002 ;Rust, 2004; Niedderer, 2007; Pedgley 2007). Prior research that document, analyze and synthesize tacit design knowledge also shows that the “tacit dimension” highly determines the methodology of the research as in this case.

In this article, we tried to explain how we reasoned our methodological decisions to adress a certain research question by the interrelations of learning theory, tacit knowledge theory and how these theories have been applied in prior design research. This methodology has been proposed to capture, measure and define tacit knowledge transmission during an action in a making environment. This chain of decisions can help design researchers who would like to study actions in context. The main argument of this article can be an example of how conventional research methods such as observational video and AR have been re-visited to address design-specific issues such as the tacit dimension of design.

Ontological Design Ways of Sustainable Intervention: A Conceptual Framework

Hyewon Kim, Indiana University Bloomington, School of Informatics, kim466@indiana.edu

Abstract
What is meant by the ontological way of sustainable intervention between technology and humans, and how can it be studied? This paper seeks to assist designers to structure their ontological reflection for sustainable intervention by discovering coherency in technological transformation. Grounded in the notion of ontological designing, this paper proposes a conceptual framework for sustainable interaction design. This framework imposes requirements on function, on behavior, and on meta-conjunction to reflect on and plan what a digital artifact is for; what the artifact performs; and what the artifact synthesizes. Four functional dimensions are highlighted: *Balancing* (B), *Prevention* (Pv), *Persuasion* (Ps), and *self-Motivation* (M). In each of the dimensions, the behaviors of digital artifacts are articulated as key design activities. Finally this paper attempts to justify the meta-conjunction process, which is established in each example of digital artifacts. Therefore, the results of these analyses show how ontological designs are shaped in a set of conceptual boundaries.

Keywords
ontological design; sustainability; conceptual framework; interaction design.

Our lives take place on the blurred boundary [18] between technology and the natural world. Today new technology systems are in need of sustainable intervention to address environmental problems. Designers' critical reflection can make the boundaries determinate and embody concepts of digital artifacts conscious and meaningful (e.g. a hybrid rather than a gasoline-powered car). Yet, if designers fail to carefully articulate the problem space of ongoing tensions, interventions may lead into unproductive directions. One possible approach is to envision ontological design ways in an alternative conceptual structure. This conceptual structure points out the reflective attempt to rediscover our connection with new technology systems and expose our true values.

Drawing on the questions, what is meant by ontological activity toward sustainable intervention between human and technology systems, and how can it be determined, this paper discusses the methodological approach of ontological designing [27]. This discussion lays the foundation for the role of designers in the ontological conversation with materials of sustainable interaction design [2], and how they perceive such activities. In this paper, the intervention seeks to discover possible context as the relation between the goal of human users and the behavior of a technology system. When interventions by designers are synthesized within a digital artifact, the digital artifact produces their functional behaviors, which are a useful set for leading users to reconcile their environment at micro and/or macro levels. Thus, this paper assumes the designer as a *critical agent*, whose concern is not limited to the explanation of the character of digital artifacts, but extends to the activity of producing design knowledge that transmits good design intentions.

In setting out the framework, this paper will use the term "*ontology*" in a sense that provides a systematic approach for describing the concept of a digital artifact and the synthesis, including functions and behaviors. By analyzing examples in current digital artifacts and future interaction scenarios that are vital to understand and predict complex human-technology networks, this paper highlights four functional dimensions, which are predominant purposes of sustainable interaction design: balancing, prevention, persuasion, and self-motivation. Each of the dimensions is modeled with the behavioral thread that provides key design activities of digital artifacts. These contexts and solutions imposed on the behaviors transform from the blurry boundary into critical design description.

What is Meant by Ontological Activities for Sustainability?

Willis's perspective on ontological designing [27], dealing with the nature of reflective thinking, contributes to designers' understanding of a subject matter of users. She asserts that "designing is fundamental to being human – we design, that is to say, we *deliberate, plan,* and *scheme* in ways which prefigure our actions and makings." The notion of ontological designing induces the purpose of advancing toward the intervention into interactions among humans, technology, and nature: The form of a digital artifact is an explicit formulation of ontological concept synthesized by designers. With radically different understanding of users' situations, reflection on ontological designing fits well with where/how a designer sees the focus of a particular formulation: on the role that his/her reflection plays in action, i.e. its effect on substantial intervention during the design process for solving ill-defined problems of the real world. While the designer explores the space of possible designs, ontological activity brings together interpretations of the current state of the world, effort, improvisation, and goals. The process of ontological reflection generates *coherence* for the expected world that the actions of the designer produce. This world is located within the interpreted world, as all goals and expectations can be viewed as interpreted representations of potential future designs.

For example, Oulasvirta [19] points out that people often have multiple digital artifacts and accessories tailored for specific tasks such as a mobile phone and a PDA. Although this current context of digital artifacts seems to provide such benefits as suitable display and manipulation choices, these benefits may not significantly change the user's practices of conservation: people might be asked to invest excessive attention and energy for operation as well as consumption of physical materials. Given that designers' reflective interpretations analyze where/how the advantage of a new technology system fits into and changes the existing practices, this ontological action help reach "a sufficient stage of maturity that information appliances are possible with adequate performance, high reliability, and reasonable cost." [15] If we would follow this path, then we would see the new technology aesthetic around us – wind power stations, hybrid cars, solar energy, and so on. Interaction designers consider their own intervention in the external world "not as an end in itself, nor as an artifact positioned to impact a situation" [21], but always as a challenge against accepted design knowledge. Ontological designing is re-creativity instead of mere analysis; autonomy instead of subordination; rationality instead of blind reaction; and intentionality instead of compliance.

The Conceptual Framework of Ontological Designing

An explicit formulation of how designers are intervening may help clarify expressions of ontological thinking, making possible coherency that could be effectively carried out. The so-called method of collection of *designerly* [6] activities for the formulation seems to offer a possible means for organizing discussion at the macro level, in which designers' thoughts are brought together and proceed to sub-classify the activities until, as one of the optimized decisions, the particular kind of activity emerges. The framework specifically aims to stimulate the constructive thinking by which interaction designers may modify current everyday practices with the advantages of functional systems of new digital artifacts such as smart materiality, intelligent architecture, wearable technology, persuasive technology, and ambient technology. (e.g., the shift of interface from the physical button of telephones to the intangible one in smart phones to decrease physical materiality) This framework imposes requirements on function, on behavior of digital artifacts, and on the meta-conjunction process to reflect and plan what a digital artifact is for; what the artifact performs; and what the artifact synthesizes. To categorize the most fundamental functions of the intervention, an analysis of over seventy papers in the sustainable design literature, in such academic disciplines as Eco Design, Industrial Design, and Human Computer Interaction (HCI), was conducted by the author from May to December in 2008. An investigation of ways to integrate the advantages of new technology systems into existing behaviors of digital artifacts was also conducted utilizing examples of advanced interaction scenarios and implementations as well as empirical studies.

This paper assumes that the ontological design activities represented can be viewed as describing requirements of *Function* (F), of *Behavior* (B), and of *Meta-Conjunction* (C) in developing a digital artifact. These aspects are the basic constituents of the ontological reflection that has been applied to various artifacts, including physical devices, software, and functional processes. By interchanging the variable factors of environmental issues and qualifications denoted, different compositions of functions and behaviors can be used to specialize a digital artifact interacting with the world. In this framework, the functional dimensions constituting a rectangle mainly explore these four functions as shown below. In Figure 1, each of dimensions is consistent with the behaviors of digital artifacts that enable designers to orient what they are doing in the synthesis process.

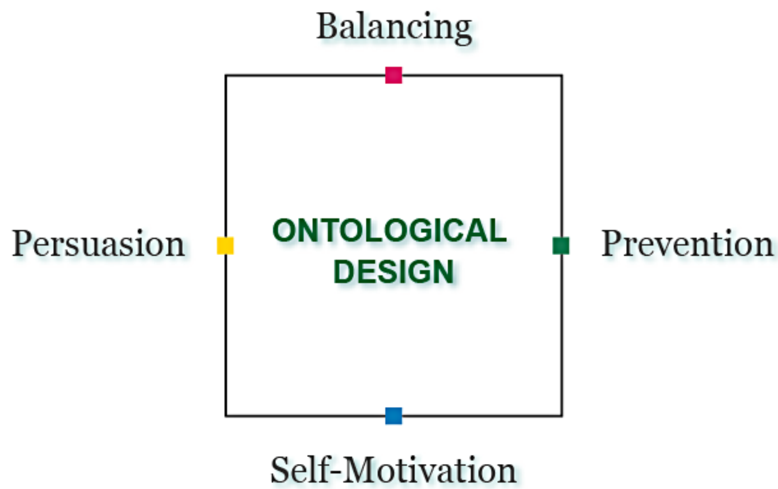

Figure 1 The conceptual framework of ontological designing

Function (F) of a digital artifact is defined as the purpose, "*what the artifact is for*". In this case of sustainable intervention, the indicated functions are "to balance between now and future", "to prevent environmental problems", "to persuade sustainable practices", and "to promote self-motivation of users".

Behavior (B) of a digital artifact is defined as the attributes, "*what the artifact performs*", that can be derived from its function. In the prevention example, behaviors include "using bio-degradable materials" and "using renewable natural materials (e.g., solar energy)".

Meta-Conjunction (C) of a digital artifact is defined as its components and their relationships, "*what the artifact synthesizes*". Components include those which are often specified by a set of variables, functions and behaviors described for a user community, time, environmental factors, constraints, technology, strategy, or materials. The notion of meta-conjunction can be applied at any level of designing. For example, depending on the class of an artifact and the perspective a designer chooses to take, he/she may imbue a radically different conjunction such as spatial conjunction, physical conjunction, information conjunction or organizational conjunction into a digital artifact: a designer's conceptual activity can be viewed as formulating a particular class of artifacts.

At the meta-conjunction level, all processes of design synthesis are unique, since individual designers' conceptual processes and perspectives crystallize the functions and behaviors of a digital artifact with the specialized mode of their understanding of users and environments. They internalize heterogeneous conceptual activities and produce design conjunctions as externalization. The design decision of each composition depends on the approach to synthesis which is used (e.g., synthesizing persuasion and prevention, or synthesizing behavior^1 and behavior^2). The resulting set of meta-composition is a way to position a key domain of design activities to see the relationships in how a digital artifact intervenes to address situational problems.

In the following section, this paper will define each notion of the four functional dimensions, and enumerate what behaviors each of the dimensions has. Each of behaviors is numbered to articulate the process of meta-conjunction.

Prevention of environmental problems (Pv)

The fundamental challenges of environmental problems involve not only improving the efficiency of products that guide consumption and human behavior, but also reducing the rate at which humans poison themselves and damage the world around them [9]. The primary concern of these immediate problems is related to avoiding toxic materials that cause environmental harm. The functional requirement in this dimension deals with the prevention of superfluous consumption of energy and materiality in the short-term. Designers may reflect on and contextualize behaviors of digital artifacts by considering what benefits of new technology can be integrated. This leads to products and services that can directly fulfill users' needs, deliver eco-efficiency, and decrease the materials and energy required to deliver the products' functions. Some of behaviors which designers can consider as the primary attribution in this function are:

Pv^1 Non-toxic material/noise pollution

Pv^2 Using renewable natural materials, such as solar energy, to create new functions

Pv^3 Dematerialization [8] in tangible and intangible products

Pv^4 Reduction of the materials consumed by both users and technology functions

Pv^5 Reduction of the needs of the manufacturing process

Pv^6 Usage of substitute technologies, such as nano/biotechnology, allowing the reinvention of old materiality, flexibility for users' contexts, longevity and durability

Pv^7 Multi-functionality that combines existing artifact capacity with the advantage of new technology without compromising the original functionality and performance

Pv^8 Bio-degradable organic user interfaces (OUI) [7]

Balancing between now and the future (B)

Ezio [13] points out that "good communication systems enable connections among people without the need for movement." As an example, effective communication system design can enable restaurants, along with other surplus food sources, to redistribute food that would otherwise have gone to waste. This averted surplus could be shared among those who need it, such as the homeless or impoverished. This is one possible way that information technology could satisfy the needs normally fulfilled through materiality. [8] Thus, design activity could not only conserve natural resources, but could also enhance balancing everyday practices of the current generation with the environmental interests of the future. In this functional dimension, obtained from eco-efficiency analyses, such factors as time, local resources, life style, production, disposal phase, life cycle [1], the network of product-information-service application, health, and socio-cultural patterns should be taken into account to mediate between the interests of current and future generations. By applying appropriate levels of technological benefits, this critical reflection will enable designers to facilitate the rebuilding of infrastructure and services in which everybody can easily participate. Some of behaviors which designers can consider as the primary attribution in this function are:

B^1 Exploring design activity to synthesize technological effect, user practice, and local environment

B^2 Understanding users' practices and local environments as an ever-changing complex

B^3 Observing vernacular design [20] developed by local community members

B^4 Searching for supply-chain management that uses minimal materials and resources, focusing on local sources

B^5 Applying appropriate technologies and services

B^6 Creating products and interactions that stimulate local employment and/or the local economy

B^7 Redistributing resources fairly within and between generations [18]

Technologies that persuade users to engage in sustainable practices (Ps)

Stegall [23] emphasizes "A profound role in making sustainability a reality is that a designer must persuade the general public to adopt sustainable behavior." In doing so, designers (as persuaders), may seek to discover the message that digital artifacts deliver to users and the distinct ways through which an individual's psychological world alters into an actionable social life. Thus, this dimension mainly stimulates designers to find ways to invite users to experience making consumption more meaningful. For example, these concepts of persuasive technology [11, 12, 13, and 26] discuss the communicative representations that use such clear metaphorical signifiers as words, images, acts, styles, narratives, sensory modes, emotions and/or music. Some of behaviors which designers can consider as the primary attribution in this function are:

Ps[1] *Understanding a digital artifact as a communicative possibility for transmitting sustainable meanings*

Ps[2] *Educating in regards to environmental issues, and indicating the efficiency of energy and materiality*

Ps[3] *Discouraging unsustainable behaviors and encouraging sustainable behaviors*

Ps[4] *Co-active persuading [22] in unobtrusive or obtrusive ways as needed*

Ps[5] *Achieving user friendliness that makes digital artifacts easier to understand and more fun to use*

Ps[6] *Supporting interactivity/user involvement that engages the user's abilities and skills in the artifact*

Ps[7] *Accommodating symbolic appeal, impact, and generative capacity that includes community agreement*

Ps[8] *Revealing a clear identity of sustainability such as in the visual style, the functions of a service agent, and materiality*

Ps[9] *Encouraging emotional connection to digital artifacts to support durability [4, 5] and longevity*

Ps[10] *Improving ergonomics/health and safety*

Empowering self-motivation (M)

Ehrenfeld [9] views the flourishing of immaterial notions like dignity, autonomy, freedom, and authenticity as fundamental in changing unsustainable behaviors. This humanistic and moralistic strategy is closely related to intellectual behaviors that users and community members as secondary producers can organize their own thinking and acting for ecological satisfaction. For example, design democracy, and alternative and self-help solutions (e.g., DIY products) inspire strong motivation, allowing users to manage their work and thinking. Design activity should discover how to empower and motivate users and communities to consistently participate in examining and implementing their identities and values. This design agenda may resonate with users' responsibility for social and environmental practices that protect natural resources. Some of behaviors which designers can consider as the primary attributes in this function are:

M[1] *Observing possibilities for creating empowerment*

M[2] *Creating a co-participatory opportunity as a primarily productive activity*

M[3] *Fostering creative/ontological thinking to enhance users' actions and thinking*

M[4] *Allowing democratic design [17] to help create good decision-making*

M[5] *Empowering community ownership*

M[6] *Universal design that allows the application of widely accepted practices, materials and technologies suitable for a wide range of end users and communities*

M^7 Improving the context-based wellbeing [10] of digital artifacts that serves their purpose better than previous designs

M^8 Eco-labels with improved identification of materials, energy, and production methods

M^9 Suggesting a social networking platform to share time, resources, and knowledge

Meta-Conjunction Process in This Conceptual Framework

The four functional dimensions are deployed as the initial statement made in Figure 1. Once a designer's ontological reflections explore possibilities with these functional purposes key behaviors can be synthesized to intervene in situational problems, and the behaviors can be selected depending on design perspectives or priority. (i.e., this conceptual design process metaphysically leaps among the requirements of functions and behaviors or edits some of them toward discovering most promising solution.)

The analysis of examples, derived from design processes or external results, shows justification of how the functions and behaviors would be synthesized to a certain creation of digital artifacts for any particular intervention into users' situations. This shows the centrality of functional behavior for categorization, which is in line with the adaptive view of design synthesis. The intentional view of ontological thinking also underlines the role intervened by the intention of designers of the artifacts. It should be noted however that the resulting set of processes do not represent any order of execution.

Applying wearable technology to existing artefact capabilities

In Figure 2, showing the Solar JKT from Zegna Sport [14], we can observe how wearable technologies have extended the basic function of everyday clothes. This interactive jacket was developed by Interactive Wear AG, in cooperation with well-known fashion and sports apparel manufacturers, to leverage a renewable resource, solar power. The main function of this clothing is focused on the prevention of environmental problems. To avoid the superfluous consumption of energy, the component of this artifact combines existing artifact capability with the effect of a new technology system, while not compromising the garment's original functionality and performance (Pv^7). In doing so, this artifact adopts the advantage of wearable technology that allows users to recharge cell phones, iPods or other artifacts through solar energy (Pv^2). The users can use the electricity generated from solar energy that is transmitted through conducting textile leads and stored temporarily in a battery or fed directly to a connected artifact. In turn, a conjunction of functional-behaviors in this interactive clothing demonstrates how ontological design perspective and development strategy applies appropriate technology system and service to current user practice (B^5). Figure 3 indicates the conjunctive relation with the two functions and behaviors: Prevention ^{2,7} and Balancing ^{5} synthesized in this example.

Figure 2. The wearable technology, Solar JKT

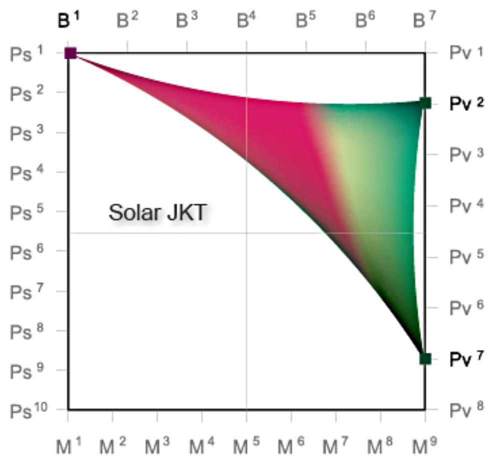

Figure 3. An ontological analysis of Solar JKT based on the framework

Reinventing a digital artifact with nanotechnology

In Figure 4, the Nokia Research Center has developed Morph [25], an elastic concept mobile phone. This concept scenario demonstrates the functional centrality for the prevention, that is, the possible usage of the substitute technology, nano-technology, which enables the reinvention of old materiality for longevity and durability (Pv^{6}). In this scenario, users can transform their mobile artifact into radically different forms—a keyboard, mobile phone or watch. This means that, by integrating the original purposes and performances which each of digital devices has, the components of the multi-behaviors offer users access to the technological variations in the same artifact (Pv^{7}). Users may then be fascinated by the interactivity for flexible accommodation of their different situations and needs (Ps^{6}). In doing so, to match the optimized point among spatial relations of information contexts, physical materiality and usage purposes of users, is a significant design factor here. In turn, this radical conjunction can fundamentally help reduce the consumption of physical materials used for both users' needs and technology functions with low-cost manufacturing and eco-efficiency in mind (Pv^{4}). Figure 5 indicates the conjunctive relation with the functions and behaviors: Prevention $^{4, 6, 7}$ and Persuasion ^{6} synthesized in this example.

Figure 4. Nokia morph concept phone

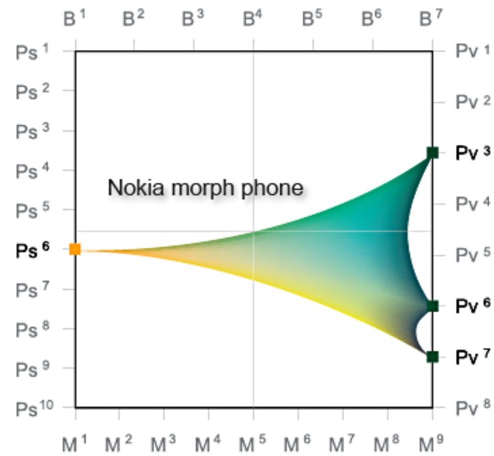

Figure 5. An ontological analysis of Nokia morph concept phone based on the framework

Understanding future sustainable habitat

In this future scenario [16], developed by the Philips's Design Probes Project (Figure 6), interaction designers can understand how new interactive architecture can be used in residential life to balance between the present and future environments. *The meta-conjunction* process of this interactive architecture is defined as the relationships that illustrate the possibility of a habitat as a dynamic eco-system, which deals with sustainable housing for an urban megalopolis in China in 2020. As seen on the right side in Figure 6, the interaction strategy enables the residents to live off the grid of the building while allowing the residents to retain their existing life styles. Regarding the behavioral performances, "the building surfaces, rather than being inert 'dumb' materials used only for construction and shielding, are sensitive skins that are 'alive' and act as membranes to harness energy.... [and create] a strong link between the exterior and interior of the habitat … collecting and channeling air, water, and light from the outside into the inside spaces." [16] In doing so, understanding users' practices in their local environments and constraints as an ever-changing complex (B^2) is fundamental. Designers should discover appropriate design activities to synthesize technological effects (the electronics and bio-chemical functionalities), user practices, and local environment in China (B^1). Searching for supply chain management of the natural resources available in the local environment is also a critical factor (B^4). In turn, this ontological design can improve the residents' current practices, ergonomics, and the welfare of future life (Ps^{10}). The conceptual activity of the design team can be viewed as formulating a particular class of organizational conjunction. Figure 7 indicates the conjunctive relation with the functions and behaviors: Balancing$^{1, 2, 4}$ and Persuasion^{10} synthesized in this example.

Figure 6. Off the grid: Sustainable habitat 2020

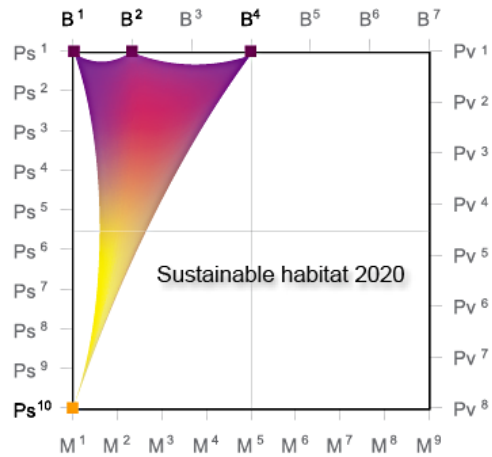

Figure 7. An ontological analysis of Sustainable habitat 2020 based on the framework

Unobtrusive persuasion of sustainable behavior

Both the symbolic and persuasive functions of the meaning of ambient technology have been discussed. In this Wattson energy monitor [28] in Figure 8, we see how the conjunction process applying symbolic expression of the digital artifact changes users' thinking and behavior by indirect persuasion. That is to say, by providing real-time feedback on total energy consumption, this digital artifact shows that the artifact can persuade users to keep monitoring consumption of energy within their home in unobtrusive ways as needed (Ps^4). A change in the intensity of color generated by the artifact gently helps users to understand the energy flow of all appliances in their home and to measure power consumption of each appliance. At this persuasive level of designing, the functional behavior enables them to try to reduce their total energy cost, sometimes by up to 20%. In doing so, designers need to understand the artifact as a communicative possibility for transmitting sustainable meanings (Ps^1). A persuasive strategy to alter users' practices of energy use should reveal a clear communicative message to save home energy in its visual style (Ps^8). Perhaps this persuasive component is also ultimately related to allowing democracy to create good decision-making by users (M^4). In turn, this design strategy can be viewed as formulating an information conjunction into a digital artifact in a certain user community. Figure 9 indicates the conjunctive relation with the functions and behaviors: $Persuasion^{1, 4, 8}$ and $Self\text{-}Motivation^4$ synthesized in this example.

Figure 8. The energy monitor, Wattson

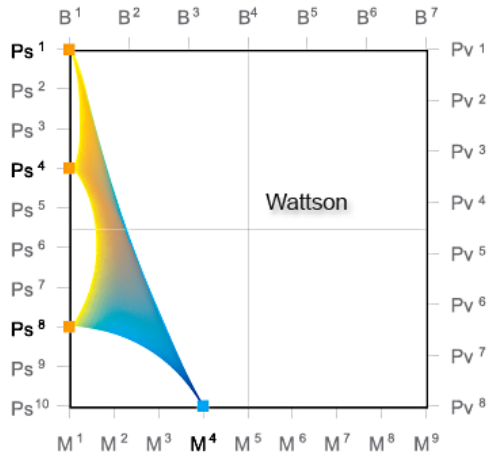

Figure 9. An ontological analysis of Wattson based on the framework

Eco-friendly approach for children

The ontological strategy of the interactive artifacts shown in Figure 10 is designed to communicate an eco-friendly message to children. The prototype toys developed by the "odo" design concept group, Sony Design Activities, [24] mainly aim to establish a sustainable function of self motivation through providing early education to children (Ps^2). To both instruct and make them engaged, the behavioral components of these artifacts tap into children's creativity as well as their curiosity about energy, introducing them to new levels of interactions (M^3). For entertainment while learning, some of these let children have fun moving parts, turning cranks, and using their bodies. This interaction between the children and the artifacts creates a co-participatory opportunity by which the children can be primarily producers to generate energy as they play (M^2). As a commitment to the environment, the behavior of the digital artifacts themselves will be made of recycled and vegetable-based plastics (Pv^8) to offer both new experiences for children and a sense of social consciousness. In pursuing such innovations, it is important that designers should consider universal accessibility that allows the widely accepted practices, materials and technologies suitable for a broad range of end users and communities (M^6). Figure 11 indicates the conjunctive relation with the functions and behaviors: Prevention^8, Persuasion^2 and Self-Motivation$^{2, 3, 6}$ synthesized in this example.

Discussion and Conclusion

This paper has discussed the design approach to guide designers to speculate on sustainable intervention between technology and human environments. This discussion established a design research foundation grounded in the philosophical idea of ontological designing. The conceptual framework proposed highlights the four functional dimensions of such intervention: balancing, prevention, persuasion, and self-motivation. Each of the functions features behaviors of digital artifacts, and these perform key design activities to stimulate designers' ontological thinking. These meta-conjunction processes in the framework radically delineate the different shapes in each of the digital artifacts. Each analysis of ontological views suggests that the capacity to infer a creation of digital artifacts depends on experience and prior knowledge of how to apply and use this conceptual framework. These analysis results provide designers with a uniform schema that could be configured as a goal-oriented, constrained, and decision-making activity; they can explore what variables and values might be appropriate for each ontological situation. The conceptual framework, therefore, helps provide a level of meta-conjunction that captures the designer's conception within the design situation to represent reflection in developing a particular digital artifact.

Although this paper suggests a conceptual framework to help implement ontological thinking within the four dimensions towards a more sustainable human civilization, it has only begun to construct the preliminary framework. A number of different digital artifacts and reflective interpretations of situations cannot be reviewed here. Moreover, designers might have different perspective in observing a design situation. There is still a long way to go for the framework to be improved for use in support of implicit ontological intervention, since sustainability is a loaded term in reference to ontological design. The current level should have more detailed ontological representations as a precursor to the designer's reflective conversation. This further development should be investigated with these categories: a wide range of target user groups or community members, various environmental contexts, design strategy, differing levels of user experience [3], stakeholders, and manufacturers. Development of the topologies of new types of digital artifacts is also important, since they can indicate the functional purpose digital artifacts perform.

This paper concludes that designers' ontological activity for sustainable intervention is an enlightened tool for re-conceptualizing the existing concept and functionality of digital artifacts, provoking meaningful reflection on new technology environments. Ultimately, the new structure of digital artifacts may not only emerge as set of additional, informal relationships, but also as a modified set of environmental components, eventually leading to new relationship with external design representation as if digital artifacts are part of organization of human technology environments. Designers may be able to structure their ontological determination by discovering coherency in technological transformation.

Author Biography

Hyewon Kim

Hyewon Kim’s work and interests have intersected across the following academic fields: industrial design, digital-media design, and Human Computer Interaction (HCI). She has been employed as a professional designer for several companies and a design researcher of Universal Design Research Center (UDRC) for the elderly in Korea. As a digital design theorist, she has explored design methodologies of HCI that not only include the relational processes of design, but also subjective processes that are not self-evidence. In doing so, she seeks to understand how to redistribute the communicative power between users and digital artifacts.

Speculative Visualization: A New Rhetoric for Communicating Public Concerns

Tanyoung Kim, Georgia Institute of Technology, tanykim@gatech.edu

Carl DiSalvo, Georgia Institute of Technology, carl.disalvo@lcc.gatech.edu

Abstract

Speculative design is an emerging rhetorical strategy in design practices and research to raise public awareness in social agendas that have been little explored. As a stream of this type of research, we propose *speculative visualization* that aims to achieve speculative design by utilizing techniques from data visualization and graphic design. Specifically, speculative visualization represents socially and politically meaningful data in aesthetic ways to provoke viewers' interpretation and further elicit discussions. In this paper, we report the diverse approaches of speculative visualization by demonstrating three exemplary studies and identifying their visual rhetoric. Based on the argument, we discuss research opportunities that speculative visualization can broaden its design sphere: the aesthetic adaptation of data visualization techniques, the methodologies of assessment, and the public's engagement in design activities.

Keywords
speculative visualization; speculative design; data visualization; visual rhetoric.

Over the past two decades, researchers have explored the capability and the role of design in increasing societal awareness, and motivating and enabling political actions (DiSalvo, 2009). This is evident in a diversity of endeavors, ranging from the work of individuals such as Natalie Jeremijenko,[1] design collectives such as Futurefarmers[2] and partnerships such as Dunne & Raby[3]. In their effort to empower the social and political actions, designers use visualization/graphics techniques to voice their and other's viewpoints though aesthetic displays.

We refer to this research paradigm as *speculative visualization*. In this paper, we begin by describing what we mean by speculative visualization and how it is connected to other disciplines, such as data visualization and graphic design. We also discuss its rhetorical power and thematic boundaries. Then, we present three studies of speculative visualization and exemplify how they invoke public awareness for the social and political issues that have been under-addressed. This paper contributes to the design community in two ways. First, it attempts to identify speculative visualization, the emerging phenomena across data visualization and graphic design, by identifying its core rhetorical aspects and breadth of topical diversity. Second, it provides researchers and practitioners with the opportunity to broaden their activity boundaries by opening a conversation on the potential of speculative visualization.

Identifying Speculative Visualization

Artists and designers often express their views on political and social agendas through their work. One way they do this is through *speculative design* — the use of design products and practices to envisage possible, often critical, futures. Despite the short history, speculative design comes through a wide variety of design activities including participatory design workshops with community members, the final results in forms of product, graphic, interaction design, and conceptual proposals. The most distinctive quality of this line of research is that it provokes issues that are unconscious and hidden in people's everyday lives. It means that the design does not aim for a specific solution to a problem, but rather an open-ended discussion that is less predetermined and more unanticipated.

Speculative visualization is a particular group within speculative design that tries to achieve the thought-provoking work by using visual representation methods. Certainly, it is more than a piece of art, or a public display that, for example, informs you of current stock market data. Speculative visualization combines multi-disciplinary qualities; encompassing the challenging perspectives of artists, the aesthetic representation of designers, the analytic ability of scientists to interpret data, and the love for humanity of philanthropists.

This section is structured as follows. First, we situate speculative visualization in the context of other disciplines. In particular, we discuss how data visualization and graphic design helped create the groundwork for speculative visualization with regards to the resources of deliverable, representational techniques they employ and the common aesthetic languages they share. Then we discuss of the rhetorical aspects of speculative visualization that takes a central role of communication as a today's important visual medium. In addition, not to make the terminology too inclusive, we limit the thematic boundaries that the term can embrace.

Beyond Scientific Purposes of Data Visualization

Once data visualization was regarded as an exclusive realm of, by and for scientists and engineers, since it mainly functioned as a technical tool to support accurate and fast data analysis. However in the past decade, the visualization community's interest in non-analytical uses has increased. The importance of communicative and illustrative aspects is now well known, mostly as sub research areas such as "social visualization" that seeks to convey social information in non-scientific forms (Donath, Karahalios, & Viegas, 1999), or "casual information visualization" that is used by non-expert users to depict personally meaningful information (Pousman, Stasko, & Mateas, 2007).

One simple but important catalyst that initiated those light-weight visualization domains is the fact that more data has become accessible. Data collected by government agencies, or by other parties paid for with taxpayer money, are now being made available (Kosara, Cohen, Cukier, & Wattenberg, 2009). The vast amount of the data is about demographics such as population change, economic growth, health related issues, and much more. These data seem more relevant to human life than any scientific data that used to be an interest of specific groups. Thus, they have potential to become "stories" when handed to creative people to become part of the cultural discourse when they are displayed to the general public. Thanks to the flourishing accessible data, recent years have witnessed the expansion of the creators who make the stories through data visualization. Beyond a simple bar or pie chart from ten by ten spreadsheet, journalists and their colleague data specialists and designers utilize much larger data and create information visualizations to fortify their reports. Politicians or activists also use visualization to strengthen their opinions.

The expanded access of data allowed us to categorize visualizations by its ultimate purposes, which are impacting on people's ways of thinking, believing and further acting. With the involvement of Human-Computer Interaction (HCI) and interaction design, visualization has become a research topic that is more omnipresent and proximate to everyday life. For example, if personal health data are represented in more graspable visualization rather than its apparently unrecognizable numbers, the visualization can help the person change their habits to favorable state. In addition, when visualizations are exposed onto journalism websites in a timely manner, they can function an editorial contents (e.g., NYTimes Visualization Lab).

Recently, more abstract representation of data is also loosely considered as information visualization. Several survey papers (Kosara, 2008; Pierce, Odom & Blevis, 2008) distinguished two general types of information visualization, namely pragmatic visualization and artistic visualization. The former is a reconceptualization of the more "traditional" types of visualization, which minimizes distortion and foster immediate understanding. Pragmatic visualizations may not seem to be correctly labeled "speculative", since they mainly support dispassionate data analysis. However, when accurate and possibly shocking data are exposed to viewers, it has potential to influence their mind by increasing awareness of what they have not had a chance to think about as deeply before (Figure 1) (e.g. Rosling, 2009). By contrast, artistic visualization presents enigmatic representation to express a point of view and further stimulate the target audience. Artists or photographers, previously thought to exist out of scientific visualization community, create artwork based on data. The goal of artistic visualization is not meant to be scientific or analytic, but rather interpretive and expressive.

Expression of Social Issues through Graphic Design

Graphic design aims to communicate intended messages to specific audiences in an aesthetic combination of text and pictures. Types of graphic design range from simple forms, such as road signs, logos, trademarks to complex information graphics and advertisements and the essential goals of the messages are diverse. In the history of graphic design, we can find numerous temporal and spatial contexts that were related to social issues.

For example, in the early twentieth century, graphic design functioned as effective delivery methods of ideas and arguments. Politicians created and manipulated print-based graphics (e.g., posters) in order to imbue people with their ideology in a similar way as radio and newspapers. Due to the omnipresence of visual images and the easy acceptance by illiterate people, governments used posters to appeal to laymen, and even to enlighten and raise awareness. Against governmental propaganda, counter-production of posters appeared as well. A distinguished figure of this appropriation is a Dadaist John Heartfield. He used photomontage as a potent propaganda weapon and his images met with immediate identification and comprehension by the working class (pp. 248-249, Meggs & Purvis, 2005).

In the contemporary design scene, it is not difficult to find many design consultancies and graphic design firms that are specialized in designing for non-profit organizations and activists (e.g. Another Limited Rebellion[4], Yippa[5], Zago[6]). Beyond client-driven or in-house design circumstances, individual artists and designers have started to express their voices on social issues utilizing their aesthetic skills. At professional conferences such as AIGA and IxDA as well as academic research (e.g Forlizzi & Lebbon, 2002; Dilnot, 1982) have paid attention to ethics of designers and socially responsible design.

A Rhetorical View of Speculative Visualization

Rhetoric is the art of persuasion. Beyond the classical Greek definition, which means public speaking for civic purposes, rhetoric exists in written, visual, and oral forms. Although visual communication does not function as a means of direct persuasion such as oral rhetoric, images are more vivid than text or speech and therefore more easily manipulated toward visceral responses. In order to fill the lack of the direct persuasion visual rhetoric requires visual “arguments” to “supply us with reasons for accepting a point of view” (p. 22, Bogost, 2007). The field of *visual rhetoric* explores the many ways in which visual elements are used to influence people’s attitudes, opinions, and beliefs through the analysis of photographs, drawings, graphs, tables, and motion pictures (p.2, Hill & Helmers, 2004).

A designed message communicates by effectively ordering and representing the common visual languages of society. Therefore, it possesses great potential to affect viewers (Buchanan, 2001; Forlizzi & Lebbon, 2002). To view a relationship between audience and visual communication, Tayler (1992) analyzed design within a theory of rhetoric. The audience is characterized not as a reader but as a dynamic participant in an argument. In this rhetorical view, visual communication attempts to persuade a specific audience through argumentation by referencing established or accepted values and attributing those values to the new subject.

The rhetorical view of communication design allows designers and viewers to actively co-construct meanings through visual messages. The common visual language is the medium through which differences are assessed, and ambiguities are reduced. The agents taking part in the dialogue can establish common frame of reference, and then build bridges to shared values. Effective rhetorical communication allows individuals to relate to each other, provides a vehicle for expression, freedom, and the discovery of truth (Buchanan, 2001; Forlizzi & Lebbon, 2002). We argue that real data added to communication design can strengthen the vehicle since it serves as an objective and more believable evidence over imagination-based visual elements. By the visual rhetoric of speculative visualization,

[4] http://www.alrdesign.com/
[5] http://yippa.com/
[6] http://www.zagollc.com/

we expect to communicate public concerns and further change perspectives, attitudes or behaviors by creating the possibility for social agreement.

Thematic Topics of Public Concerns

In visual and cultural studies, the discussion of *rhetoric by image* covers a tremendously wide range of activities and artifacts, from advertisements selling products to marketing, and even propaganda, promoting political candidates or causes. However, since we identified speculative design as a realization of designers' societal responsibility and its ultimate goal as promoting public awareness and engagement in social and political issues, we attempt not to include virtually all about human life.

The interdisciplinary nature of speculative visualization allowed us to establish the thematic guides employing the ideas of technological concerns. Fogg (2002) suggested a wide range of persuasive technology and application, which includes commerce, personal relationship and occupational effectiveness. We argue that these applications for personal interests and marketing should not defined as appropriate topics of speculative visualization. Instead, we include such areas that actively require re-realization from individuals' consciousness toward socially pertinent issues so that they are expected to increase awareness and further change attitude and behavior in favor of community's well-being. Some of the relevant topics are environment conservation/sustainability, disease prevent, political issues and social responsibility/solidity. As a sub domain of speculative visualization, Eco-visualization (Holmes, 2007) is tremendously popular among HCI researchers and designers. Themes about social responsibility are not as pervasive and materialized as practical applications as sustainability and disease issues. However there have arisen many design collectives such as NeMe[7], whose projects include visualization work representing human rights in general and community related data.

Case Studies of Speculative Visualization

In this section, we take three examples of photography, motion pictures, and media installation that can showcase how speculative visualization communicates public issues. These selected pieces all obtain the resources from the raw statistical data that may appear difficult for laymen to understand. In contrast, visualizing the data in aesthetical ways help connect the numbers to the making meaning.

Example 1: Running the Numbers: An American Self-portrait

First example is a series of visualization by a photographer Chris Jordan. His work looks at contemporary American culture through the austere lens of statistics. The photographer's belief is aligned with what we mean by speculative visualization: "My hope is that images representing these quantities might have a different effect than the raw numbers alone, such as we find daily in articles and books… I hope to raise some questions about the roles and responsibilities we each play as individuals in a collective that is increasingly enormous, incomprehensible, and overwhelming" ("chris jordan photography," n.d.). Each piece portrays a specific quantity of mundane artifacts. For example, in *Plastic Cups* he depicts one million plastic cups, which is the exact amount of cups used on airline flights in the United States every six hours (Figure 3). If we see the image from a distance, it appears as an abstract drawing of pipelines, but in a close look, we can notice the fact that it is composed of

[7] http://www.neme.org/

myriads of disposable plastic cups. At the moment people realize the minimal unit that makes up the massive image, they become overwhelmed and wordless, and sigh deeply.

Example 2: What is a Black Balloon?

What is a Black Balloon? is a series of motion graphic advertisement as a part of statewide campaign in Victoria, Australia (Figure 2). It is a simple way to measure and visually represent greenhouse gas emissions from domestic environment such as kitchen, laundry room, dining room, as well as an entire house. The video attempts to deliver an obvious but possibly unrecognized fact: using less energy will mean less greenhouse gas emissions, and will help to reduce the impact of climate change. In the video clip appear black balloons, each of which represents a unit of measurement, 50g of greenhouse gas. A balloon pops out from a single appliance at first, followed by many others that finally fill the upper space of a house. However people except a baby in the advertisement do not recognize the existence of the balloons, the metaphor of potential threat to environment. Viewers are not expected to count the specific number of balloons and calculate the total emission of greenhouse gas. Rather they may have visceral responses such as panicking or emotionally paralyzing through the abstract and aesthetized statistics.

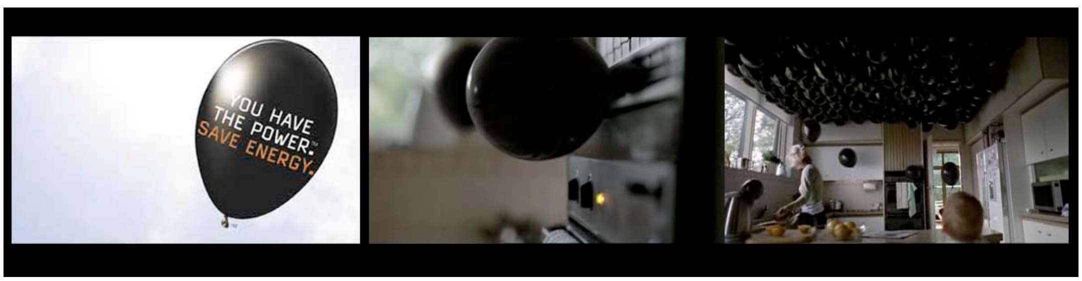

Figure 2 What is a black balloon? (http://www.saveenergy.vic.gov.au/)

Example 3: Smog is Democratic

Smog is Democratic is a digital media installation that explores air pollution and particulate matter through the medium of data and photographic visualization (Figure 3). As a subject, particulate matter brings together multiple themes in contemporary society: our concern with pollution, the relationship between urban living and hygiene; the tension between scientific representation and artistic expression of information; and the desire to produce techniques of measurement against the threat of the unseen. The visualizations in the installation are based off air quality, smog, and particulate matter data from for 2008, maintained by the Environmental Protection Division of the Georgia Department of Natural Resources. This database records both predicted and observed smog alerts as well as daily ratings of the air quality index. In the video visualization, the data are used to obscure the image by pixellating video of Atlanta highways—with the amount of pixelization generated from hourly air quality measurements in 2008. By obscuring the image, the visualization attempts to dynamically reflect the ways in which air pollution and smog obscure vision. This installation is interpretive and expressive, with the goal of considering how the sources and measurements of particulate matter might be rendered in order to generate reflection, discussion, and debate. The designer’s intention is to address the audience on an instinctive level and generate emotional responses that lie behind the data.

Figure 3 Carl DiSalvo and Jonathan Lukens, Smog is Democratic
(source: http://publicdesignworkshop.net/smog-is-democratic/)

Research Opportunities of Speculative Visualization

Because it is a nascent design genre and an interdisciplinary subject, speculative visualization has not been well investigated by design researchers. we suggest several opportunities and challenges for those who may potentially create speculative visualization and study it in a design research capacity.

Reimagination of Data Visualization Techniques

The information visualization (Infovis) community primarily comprises researchers from HCI, computer science, and statistics. Not attracting much interest from graphic designers, Infovis has continuously created various data visualization techniques, referred to as “visual styles” in designers’ terms. The endeavor to create visualization styles has continued for the purpose of representing a larger amount of data in a smaller area for more effective analysis. Therefore, one may consider such scientists’ suggestions not innately aesthetically pleasing. In fact, however, some of their innovative techniques have been inspired by modern art and graphic design traditions. For example, text visualization techniques such as Wordle and Tag Clouds were influenced by Soviet Constructivism (Viegas & Wattenberg, 2008). On the other hand, visual designers have attempted to manipulate scientific visualization techniques in aesthetic ways by blending color and typographic tactics with techniques. Among the myriad of techniques, radial graphs commonly represent networks or hierarchies, which have typically used by scientists (Figure 4). However, the graphs are being adopted to portray complex relationships between people and issues (e.g., NYtimes.com, 2007).

Beyond these relatively less complex techniques, interpreting the advanced formations of data visualization techniques with the touch of designers’ creative minds and hands will open opportunities for managing a greater volume of data and interactivity. Only a single datum can be impressive enough to generate viewers’ visceral stimuli as we earlier discussed in the case studies. Alternatively, we can anticipate that large data sets across regions and over periods may enhance complex feeling and in-depth discussion. In addition, supplementing layers of flexibility and interactions will provide audiences with more options to explore when compared with two-dimensional graphics. Several interaction techniques in formatted infovis such as Treemaps, Nodemaps and stacked graphs are now widely used to incorporate diverse data sets (Wattenburg, et al., 2008).

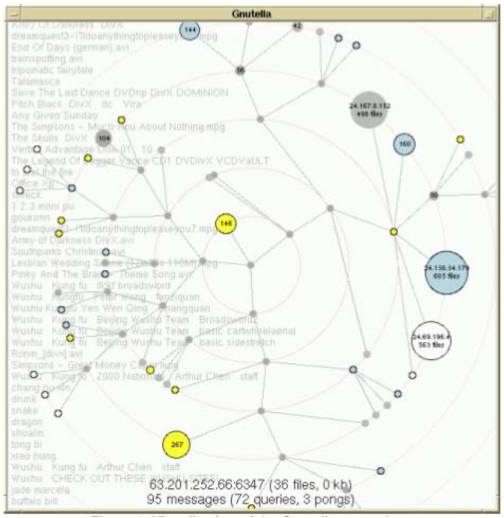

Figure 4 Example of Network Visualization on Radial Graphs
(Yee, Fisher, Dhamija, & Hearst, 2001)

Grounds for Assessment

When targeting visualization systems for analytical tasks, we have well established evaluation methods such as usability testing. However, evaluating the rhetorical aspects of visualization, even in collective and public situations can be challenging. The first impression of visualizations may be observed relatively easily through reading user comments or running simple surveys. For example, timely visualization of the stimulus bill passed by the U.S. congress led to some very emotional comments on a visualization authoring website, ManyEyes (Kosara et al., 2009). However, the influence on viewers' awareness, attitudes, perspective, and behavior was neither visible nor immediate. This situation opened up a new research opportunity: How do we design evaluation methods for a long-time experience rather than time and space constrained cognitive matters? In particular, how do we observe the social and cultural phenomena related to speculative visualization?

Engagement of Public in the Process of Design-making

It has been a rigid belief that the creativity of visual communication designers comes solely from personal intuition. However, if designers attempt to persuade audiences through visual messages without properly understanding whom they are designing for, inappropriate outcomes can result (Forlizzi & Lebbon, 2002). Understanding audiences does not require only traditional user research techniques. It also requires that designers envision methodologies that elicit the direct participation of the audiences. One possible way is inviting citizens in the process of data collection employing participatory design methodologies as discussed in a project by DiSalvo, et al. (2008). In this project, citizens engaged directly by collecting data from their local area, such as sound, air quality, humidity and temperature using sensing technology. Another manner of participation is people themselves becoming makers of the final artifacts as suggested by Gaver and Dunne (1999). Participating in the conceptual art work, senior citizens in a suburban city of poor reputation express their history of life, emotion, and the pride of the community. Finally the project acts as a socio-cultural intervention at personal, community, or political levels.

Conclusions

Visualization is what makes data accessible, intelligible, and interesting. When data visualization and graphic design meet together, each actively fills its absent traits with the advantages of the other; graphic design strengthens its arguments with objective and real data, while data visualization empathizes visual aesthetics adopting the principles of graphic design. Interconnecting the two realms in this way, speculative visualization makes data meaningful, insightful, and influential. To shed light on this emerging design research and practice field, we discussed its disciplinary traditions and rhetorical and communicative power with exemplary projects. Our attempt served to initiate a new research domain crossing visual design, rhetoric, and visualization community.

Kim is a Ph.D. student in Digital Media in the School of Literature, Communication and Culture at the Georgia Institute of Technology. Her research interest is design of persuasive digital media for citizen engagement. She holds M.S. and B.S in industrial design from KAIST.

Carl DiSalvo

Carl DiSalvo is an Assistant Professor of Digital Media in the School of Literature, Communication and Culture at the Georgia Institute of Technology in Atlanta, Georgia, where he directs The Public Design Workshop. He earned a PhD in Design from Carnegie Mellon University in 2006 and was a visiting fellow in The Studio for Creative Inquiry and The Center for the Arts in Society from 2006-2007.

Sensemaking and Framing: A Theoretical Reflection on Perspective in Design Synthesis

Jon Kolko, frog design & Austin Center for Design, Austin, Texas; jkolko@gmail.com

Abstract

Sensemaking is a constant process of acquisition, reflection, and action. It is an action oriented cycle that people continually and fairly automatically go through in order to integrate experiences into their understanding of the world around them. A frame is an active perspective that both describes and perceptually changes a given situation. A frame is, simplistically, a point of view; often, and particularly in technical situations, this point of view is deemed "irrelevant" or "biasing" because it implicitly references a non-objective way of considering a situation or idea. But a frame – while certainly subjective and often biasing – is of critical use to the designer, as it is something that is shaped over the long-term aggregation of thoughts and experiences, through the above process of sensemaking, and is therefore a larger way of viewing the world and situations that occur in it. Like a point of view, a frame too will change, but will change over the long-term rather than the short term.

Designers make explicit the normally implicit processes of sensemaking and framing during design synthesis, as they attempt to make meaning out of data through interpretation and modeling.

This paper offers a theoretical reflection on the relationship between design synthesis, sensemaking and framing. This reflection, based on professional practice in a world-class design consultancy, attempts to tie research from various disciplines to what many designers feel is an implicit part of their process – the ability to apply their own "intuitive" ability to find meaning in complex situations and solve complex problems.

Understanding Sensemaking and the Role of Perspective in Framing

Cognitive psychologists, social psychologists, and communication theorists all reference the word "Sensemaking" as an integral part of learning.

Robert R. Hoffman, Gary Klein, and Brian M. Moon are all cognitive psychologists who have been studying the connections between problem solving and intuition. They reference sensemaking as a way of understanding connections between people, places and events that are occurring now or have occurred in the past, in order to anticipate future trajectories and act accordingly. Their work positions sensemaking as an internal and reflective activity, where one is actively trying to solve a specific and contained problem, but also as an external and communal activity, where a group of people are trying to solve multiple problems in pursuit of larger, organizational goals (Klein, Moon, & Hoffman, 2006). Their view of the process is one shared of many organizational theorists [for example (Westrum, 1982)] where, in a large organization, various people may hold different pieces of data, and different levels of awareness of events, that are all critical to the success of a given project. Sensemaking is deeply related to a process of "socialization", whereby those with ideas and data share that with others in an effort to actively disseminate information and build consensus. Hoffman, Klein and Moon's view of sensemaking is a *process* that is both *personal and shared*, one that takes place *over a long period of time*, and one that is heavily dependent on a *perspective or point of view*.

Brenda Dervin, a communication theorist, describes sensemaking as a process that "reconceptualizes factizing (the making of facts which tap the assumed-to-be-real) as one of the useful verbings humans use to make sense of their worlds" (Dervin, 2003). As she describes, we make sense of complicated ideas by doing them, rather than studying them abstractly. The process of sensemaking is a process of learning, and it relies on and is subjectively dependant on the entire summation of knowledge, emotions, and prior experiences in the learner. This builds heavily on John Dewey's view of experience as being fundamental for education (Dewey, 1997), and implies that learning (and the process of solving complicated problems) must be an active process, and is always a subjective process. Dervin's view of sensemaking, then, is a *process* that is *personal* and *contingent on experience*, that *substantiates learning*, that takes place *continually and forever*, and is fundamentally based on each *participant's perspective or point of view.*

Daniel Russell and his team of researchers at Xerox PARC (and now Google) define sensemaking first as "the process of searching for a representation and encoding data in that representation to answer task-specific questions" (Russell, Stefik, Pirolli, & Card, 1993) and second as "the process of creating a representation of a collection of information that allows the analyst to perceive structure, form and content within a given collection." (Russell & Pirolli, An Overview of Sensemaking: A View from the Workshop CHI 2009, 2009) Both definitions describe the formation of a model – either a mental or actual, tangible representation – which can then be used as a hypothesis upon which to examine, test, and accept or reject specific questions and ideas. The representation is specific to the problem being addressed, and exists as a discrete model separate from larger "world views" or more abstract and general theories. Russell's view of sensemaking, then, is a *process* that is *personal*, that is *highly task specific*, that is useful for a *finite period of time*, and is fundamentally based on each participant's perspective or point of view.

David Snowden is a management scientist who has dedicated the majority of his career to understanding the complexity that exists in large corporations. In his work, Snowden frequently uses the word sensemaking as a descriptor to modify a noun. He's developed a framework that he calls Cynefin, and explains that "We consider Cynefin a sense-making framework, which means that its value is not so much in logical arguments or empirical verifications as in its effect on the sense-making and decision-making capabilities of those who use it. We have found that it gives decision makers powerful new constructs that they can use to make sense of a wide range of unspecified problems. It also helps people to break out of old ways of thinking and to consider intractable problems in new ways. The framework is particularly useful in collective sense-making, in that it is designed to allow shared understandings to emerge through the multiple discourses of the decision-making group." (Snowden & Kurtz, 2003, p. 468)

This implies that Snowden's view of sensemaking is on early and formative idea generation, and that the framework referenced supports the creation of mental models that can be used to think of problems, and solutions, in new ways. Snowden draws heavily on the use of narrative, and particularly fictional narrative, as a way of positing "what if" scenarios. His research has identified that participants who work backwards from a fictional end-state to reach a factual present-state are able to then identify the "sensemaking items", which he describes as the turning points inclusive of actors, communities, and factors in play (Snowden & Kurtz, 2003, p. 472). Snowden's view of sensemaking is a *quality* that can be applied to a framework or idea, is best embraced in a *highly collaborative environment*, has the most resonance during *early stages of problem solving* and for *a formal and finite period of time*, and embraces each *participant's perspective or point of view*.

Karl Weick, an organizational behavioural theorist at the Ross School of Business at the University of Michigan, ties sensemaking directly to organizational behaviour and particularly to the generation of organizational knowledge. As Weick describes, "… sensemaking is, importantly, an issue of language, talk, and communication. Situations, organizations, and environments are talked into existence… Sensemaking is about the interplay of action and interpretation rather than the influence of evaluation on choice." (Weick, Sutcliffe, & Obstfeld, 2005) From this perspective, sensemaking is a shared and communal activity that produces knowledge appropriate for action, but biased heavily based on the individuals doing the sensemaking – that is, each group of people who have the various sensemaking conversations will "talk into existence" a very different set of situations, organizations, and environments. Weick's view of sensemaking is a *process* that is *highly collaborative*, effective for *organizational growth and planning* in *both the short and long term,* and *highly dependent on interpretation.*

	Positions sensemaking as..	Style of engagement..	Effective for..	Length of engagement..	Highly dependent on..
Hoffman, Klein, and Moon	A process of problem solving	Both personal and shared	Long-term socialization of complex problems	A long period of time	Participant's perspective and interpretation
Dervin	A process of education	Personal and contingent on experience	Learning	Continually and forever	Participant's perspective and interpretation
Russell	A process of modelling	Personal	Specific tasks	A finite period of time	Participant's perspective and interpretation
Snowden	A quality of an artifact	Highly collaborative	Early stages of problem solving	Formal and finite period of time	Participant's perspective and interpretation
Weick	A conversational process	Highly collaborative	Organizational growth and planning	Both short and long term	Participant's perspective and interpretation

Thus, we see a landscape of researchers investigating sensemaking, coming to various (and abstractly consistent but specifically different) conclusions. Some of the views are tied to individual problem solving, while others focus on the abstract "organization" and its ability to make meaningful decisions. Some of the views describe sensemaking in an acute fashion, as an activity that has a start and end, while others view it is a long-term approach that serves as an underpinning for other activities.

Design Synthesis is a Process of Sensemaking

A fundamental consistency across all researchers above is the necessity of perspective, and an embracing of subjective interpretation as a fundamental aspect to both internal, reflective sensemaking as well as external, collaborative sensemaking. These are the same qualities that describe design synthesis – a part of the process of design found in all aspects of professional design work (including industrial design, interaction design, and service design) (Kolko, Information Architecture and Design Strategy: The Importance of Synthesis during the Process of Design, 2007). Design synthesis is an abductive sensemaking process of manipulating, organizing, pruning and filtering data in an effort to produce information and knowledge (Kolko, Interaction Design Synthesis: Translating Research into Insights, 2009). This process is used by designers during various parts of the larger design process, as they create new artifacts (used here to reference products, systems and services – both physical and digital).

While used throughout the process of design, synthesis is most commonly conducted at a precarious moment between research and definition. At this point in a project, a designer will have gathered large quantities of data from people, through a variety of primary research methods (such as contextual inquiry, interviews, ethnographic studies, cultural probe exercises, etc). They will have also gathered large quantities of data through secondary research methods (such as reading reports or journal articles). The intent of conducting this primary and secondary research is to inform the design of a new artifact, but the data itself does nothing to inform design, as data is inactive and lacking context (Shedroff, 2000). The designer must do something with the data in order for it to become active, and to actively inform design. They must "use" the data by extracting meaning from it or by generating meaning associated with it.

It is at this moment that design synthesis occurs, through an implicit and explicit series of actions. These actions are modified by the word "abductive": they all rely on a hypothesis as a form of inference (Peirce, 1998). Theoretically, these actions are limitless, as they are bounded by an infinite number of possibilities in both the specific domain knowledge being manipulated and in the experience of the designer performing the manipulation. There are, however, a series of common manipulation actions performed by professional designers; these actions include organization, pruning, interpreting, and reframing. All are driven by a personal perspective.

Organization describes the means by which a designer puts like items "near" each other, either physically (often by moving an index card around) or implicitly in their cognitive models of the data.

This nearness describes affinity, or likeness, and the intent of organization is commonly in identifying or deriving a series of patterns in the data – or in identifying opportunistic outliers, as these can act as stimulation for innovation. Organization also describes the ability for a designer to identify relationships and hierarchy, as is the case when creating a concept map, process flow diagram, outline, or tree-view of data. These relationships indicate prioritization and importance.

Pruning describes a selective measure of removing (and therefore both ignoring and implicitly prioritizing) data. Designers will prune data based both on popular similarity ("this was already captured once, no need to list it twice") and also rareness ("this was only captured once, so it's not important"), and in this manner, the pruning can be highly subjective and irregular.

Interpretation is the assignment of meaning to data (Holtzblatt & Beyer, 1998), thus extending (subjectively) the data and enhancing it.

This perspective from which interpretations are formed is in many ways synonymous with what Donald Schön refers to as a normative frame or appreciative system: "The very invention of a move or hypothesis depends on a normative framing of the situation, a setting of some problems to be solved… It is only within the framework of an appreciative system – with its likings, preferences, values, norms, and meanings – that design experimentation can achieve a kind of objectivity… Designers differ with one another, and change over time, with respect to particular design judgments, ways of framing problems, and generic perspectives manifest in their choices of problem settings, means, and paths of inquiry." (Schön, 1984) This frame is a bias, but one that designers frequently make explicit – and often put aside, shift, embrace, or actively reflect upon, through a process of design synthesis. In this process, a series of often subjective business, technological, decorative, or functionality constraints are deemed to be true, and this becomes the normative frame.

Reframing is the act of purposefully shifting the normative frame, often temporarily or in multiple directions at once, in order to see things from a new perspective. Designers may be able to manage multiple frames (commonly including "their own", "the user's", and "the business's") and realize tradeoffs when various frames are given precedent.

Synthesis actions are rarely mutually exclusive; that is, an action performed during synthesis might be both organizational and interpretative at once, or it might be an act of interpretation occurring in an effort to reframe from a new perspective. Regardless of the specific synthesis action that the designer takes, synthesis is always generative – it always produces more data, information and knowledge, than was present before the actions began. In this way, it is dissimilar to an empirical study that seeks to understand things that already exist (while remaining objective), and is dissimilar to a predictive behavioral study that seeks to identify causality and what people are likely to do (by remaining objective). Synthesis (and design in totality) seeks to understand the facets of things that do not yet exist by bringing them into existence, and the process of synthesis helps to guess what people will do, feel, or think once the thing that does not yet exists, exists.

A Need for Rigorous Approaches and Methods to Synthesis

While designers have historically referenced a period of design synthesis in their process, little has been done within the community of design research and design practice to formalize methods of synthesis or to describe a cohesive theory of synthesis. Instead, designers commonly performed design synthesis in the due course of solving a design problem, and it was rarely explicitly separated from forms of ideation and the "raw creativity" commonly associated with form giving. Additionally, synthesis was rarely conducted overtly – instead, designers would synthesize research through casual conversation in the design studio or – more commonly – through personal reflection, and much of the synthesis process was conducted "in one's head". However, it has become necessary to conduct design synthesis externally – publically – due to a number of factors:

1. **Design problems are more complicated**, and therefore, require a more rigorous and explicit process. Designers are increasingly enjoying a more prominent role in both large corporations and in creative agencies, and a result of this prominence is more responsibility for larger budgets and more in-depth projects (Brown, 2008). A typical design project in the 1970s might have been to define the way a chair or cup looked, or to define the identity

system (logo, letterhead, etc) for a corporation. A typical design project in the present day is to create a new software suite for a global brand, defining the features and functions, the way a user interacts with the system, and the manner in which the system changes when used on a laptop as compared to a mobile phone – arguably, today's activity is much more complicated, with more user-touchpoints, and certainly more complexity.

2. **Design teams have grown in size**, forcing processes to be externalized and formalized. In the past, designers may have worked independently, with a design review or critique (the "pinup" of sketches) occurring periodically in a formal manner. In-between these reviews, designers had no need to share their process with anyone except other designers. Integrated design teams, including engineers, marketers, project managers, consultants, software developers, and other constituents are now the norm, and designers are increasingly required to both describe and rationalize the decisions they are making, as they make them. Additionally, more members of the design team can claim to be "doing design work", as boundaries between disciplines on an integrated team may blur tremendously.
3. **Designed artifacts are increasingly invisible**, making discussion of in-progress ideas difficult without a formal, explicit, and descriptive process artifact to drive the discussion. A designer may be tasked with creating a system, service, or piece of software – things that have no physical qualities. In order to direct conversation, support decision making, and continually refine and expand ideas, the designer is forced to make their process explicit by creating diagrams, charts, models, prototypes, and other in-process artifacts.

The complexity of modern day design problems, the size of the design team, and the increasingly ethereal nature of designed artifacts has created a need for externalized, formalized synthesis of data.

Thus, design synthesis is presented as a fundamental part of the process of design, but a part of the process that lacks deep discourse and definition yet is increasingly both communal and complicated. This complexity demands a more formal theoretical understanding of synthesis, and designers require a better understanding of the cognitive and social structures that are used to support the various activities involved in synthesis.

The Role of Sensemaking and Framing in Design Synthesis

Sensemaking and Framing are the phenomenon that describe the process of design synthesis and begin to create a behavioral theory of synthesis both in and out of practice. These two theoretical constructs point to a structural framework upon which professional methodologies can be created – explicitly helping designers accomplish their work. Sensemaking, as presented above, is a process of making meaning that is highly dependent on unique perspectives and frames. In design, and particularly in design synthesis, this personal process becomes a communal and collaborative process and is used to create one or more working design frames. These frames are active, as they constantly change and adapt based on the circumstances of the project. Ultimately, these frames are the artificial boundaries of perspective, containing the scope of design work and acting as flexible constraints around a given design problem.

As both sensemaking and framing are normally internal mechanisms for understanding reality, design teams have begun to adopt technically rudimentary – but highly effect – methods and tools of sensemaking and framing externalization to create a shared "canvas" for synthesis.

Consider, for example, the following very brief snapshot of dialogue that occurred at frog design, a global innovation consultancy. The conversation took place between interaction designers who had just completed research for a new project, and were beginning the "concepting" phase of the project. They were tasked with simultaneously understanding a very vague business problem – "create a new competitive product for baby boomers and their parents" – and defining technical requirements for a supporting technology platform decision that was going to be made quickly.

> **Will**: "Let's try to get to a core concept and a set of high level constraints before we break for lunch."
>
> **Matt**: "Yeah, why don't you take the viewpoint of the older segment…"
>
> **Will**: "OK, I'll be my grandpa.. "

Matt: “OK; so, we know we have to use full and high bandwidth video transfer…” *(draws two big circles on the whiteboard, each labeled ‘mobile phone’, and draws another big circle on the whiteboard, labeled ‘cloud’. Draws a line from one phone, through the cloud, and back to the other phone, labeled ‘video – fast and HD’)* “…because it’s pretty awesome, and it’s basically the only known piece to the whole puzzle.”

Will, in character: “I don’t care about awesome, but I really want to be able to watch Junior at the soccer game…” *(grabs the whiteboard marker, and draws three stick figures. He labels one ‘grandma’, another ‘grandpa’, and the third ‘junior’)* “..because all I care about it being a part of his life.”

Grant, pointing at the figure labeled ‘grandpa’: “Yeah, but on your end, you don’t want to watch on a tiny screen. My grandma can’t even figure out how to use her answering machine, I think there must be messages on there from two or three years ago…” *(scratches out one of the Mobile Phones, and writes “TV”)*.

Matt: “Cool, so in our list of technical issues, I know we’re gonna run into some TV platform issues…” *(starts a list called ‘potential issues’ and write ‘TV platform – unknown, Microsoft? Open Source???’)*.

Will, in character: “If it’s going to be on my TV, I need an easy way to record Wheel Of Fortune, because it’s really pushing it to think I’ll miss the four o’clock game shows for little Will’s stupid baseball game.”

Matt: “Ok, so it has auto-DVR, and if you are watching streaming video, it automatically records…” *(writes ‘auto-DVR = cloud storage; Boxee?’)*

Will, as an aside: “God forbid he misses Wheel Of Fortune, and god help me if I ever get old and watch game shows…”

Grant: “A DVR seems really advanced for old people.”

Will, laughing: “What if there was a giant TV on wheels at the game instead of in their living room, and junior could see grandma and grandpa on the jumbotron, just like they can see him? *(draws a tv on wheels)*”

Grant: “Yeah, I mean, we add a low-fi version [of the software] that works with a webcam on the TV..”

Matt: “So we need bidirectional video, streaming?” *(writes ‘tons of bandwidth. 4G?’ in the ‘potential issues’ list)*.

In this brief portion of creative dialogue, three main synthesis techniques and approaches are used (albeit in a casual manner):

1. **Reframing from a new perspective, to empathize**. Will elects to represent the target audience, saying “OK, I’ll be my grandpa”. He clearly doesn’t intend to become his grandpa, but instead actively attempts to view the design space simultaneously as a designer as well as an older grandfather-like figure. He then participates in the discussion viewing the emerging design concept through at least three unique lenses, switching between them quickly and without much prompting:

    a. He contributes to the discussion as an older man, with particular wants, needs and desires related to television watching and inter-generational communication
    b. He offers colorful commentary of his specific grandfather, describing the idiosyncrasies that make his grandfather unique (the need to watch Wheel Of Fortune each night, the prioritization of a game show over a loved one)
    c. He offers contributions as a member of the design team, realizing that he can feel free to be provocative at this stage in the process by describing off the wall ideas (the TV on wheels) without fear of disruption or being called “inappropriate”

2. **Creative leaps, based on personal sensemaking**. Each team member offers ideas that change the nature of the design concept.

a. Matt has begun to add constraints related to technology capabilities, creating a list of more pragmatic issues, concerns, and features. His role, at least in this particular conversation, is one that is focused on technical realism. He translates the design and feature ideas into technological barriers, opportunities, and issues to warrant further discussion. This knowledge comes from his own personal interest and experience in technology; the knowledge is separate from the design problem that has been provided from the client, and it is up to Matt to bring this information to the problem.
b. Will has begun to add constraints and opportunities, related to his personal and intimate knowledge of his own grandfather. This is biased and highly subjective, yet Will clearly has a vivid mental image of his grandfather's peculiarities and uses these to spark new design ideas.
c. Grant offers statements that are practical, building on but simultaneously tempering the "blue sky" and biased qualities of Will's ideas. Grant clearly speaks from his own experiences with the elderly, as he describes his grandmother's inability to cope with technological complexity. He too offers new constraints and opportunities.

3. **Externalization, to create shared sensemaking**. Through the use of a whiteboard, and through the shared pooling and visualization of the ideas in a single democratic (and "unowned") dialogue and diagram, the team goes through a process of shared sensemaking. Grant and Matt have never met Will's grandfather, and neither Grant nor Will would have described the technological requirements that Matt saw from his unique perspective. But all three now have a shared view of the design space, the technological implications of design decisions, and the beginning of a central, high level, very conceptual design system idea.

Thus, the normally personal phenomena of sensemaking and framing are recast in a public light in the design studio, with the following outcomes:

1. The design team builds a shared understanding of the data that has been gathered, and acts on that data through organization, externalization, pruning, and interpretation. This is the beginning of design synthesis.
2. The design team collectively develops a series of artificial constraints, informed by but separate from the design space being studied and their own respective experiences. This is collaborative sensemaking.
3. These artificial constraints are applied in the context of the design problem as a flexible container, within which the designer can begin to solve a problem; this becomes the normative frame.

Perhaps the most exciting thing the design team could do next would be to "reframe" the situation, actively shifting the normative frame (the grandfather) and simultaneously shifting the design problem into the confines of the new container. The team might ask Will to play the role of the baseball-playing grandson, or the baseball coach, or a salesman at a consumer electronics store. Each of these new perspectives would generate a new frame of reference, and would result in new, innovative, and often ridiculous design outcomes.

Summary

Brenda Dervin describes Sensemaking with a rich and robust description:

… the human, a body-mind-heart-spirit living in a time-space, moving from a past, in a present, to a future, anchored in material conditions; yet at the same time with an assumed capacity to sense make abstractions, dreams, memories, plans, ambitions, fantasies, stories, pretenses that can both transcend time-space and last beyond specific moments in time-space. This portrait of the human subject… mandates positing as possible fodder for sense-making not only thoughts and ideas, observations and understandings, but emotions, and feelings, dreams and visions, pretenses and illusions, connections and disconnections. (Dervin 2003)

Dervin's point is apt: even a designer working on the most insignificant problem approaches that problem from a thoroughly complicated, unique, and both intellectual and emotional point of view, and this point of view is in a constant state of flux. This point of view forces a subjectivity on the design process and solution, and this definition of the "human subject" begins to illustrate how design solutions are deeply embedded in the culture of the designer themselves.

During synthesis, a designer simultaneously attempts to embrace *their own* unique experiences, emotions, and history – and to embrace *someone else's* unique experiences, emotions, and history. These are the elements that are crucial to making sense of the complicated design problem. Two designers may approach the same design problem in the same way and follow the same methods and steps, yet end up with a very different solution.

This difference points to the unique aspects of the designers themselves – their "style", or "design sensibility" – which is the collective and additive whole of their lives. It also points to the unique aspects of the designers in their ability to reframe and empathize – to consider what life is life from another perspective, and make logical inferences from this new point of view. In many ways, this is the unique skill of design: the ability to temporarily exchange or at least supplement one's own perspective with that of another.

Author Biography

Jon Kolko

Jon Kolko is an Associate Creative Director at frog design, and the Director of the Austin Center for Design. He has worked extensively in the professional world of interaction design, working around complicated technological constraints in order to best solve the problems of Fortune 500 clients. His work has extended into the worlds of consumer electronics, supply chain management, demand planning, and customer-relationship management, and he has worked with clients such as AT&T, HP, Bristol-Myers Squibb, Ford, IBM, Palm and other leaders of the Global 2000. The underlying theme of these problems and projects was the creation of a solution that was useful, usable, and desirable. His present research investigates the process of Design, with a focus on Design Synthesis and the creation of meaning.

Kolko's present work is heavily influenced by his prior role as a Professor of Interaction and Industrial Design at the Savannah College of Art and Design, where he was instrumental in shaping the Interaction and Industrial Design programs. He presently sits on the Board of Directors for the Interaction Design Association (IxDA), and is the Editor-in-Chief of interactions magazine, published by the ACM.

Kolko is the author of Thoughts on Interaction Design, published by Morgan Kaufmann, and the forthcoming text tentatively entitled Exposing the Magic of Design: A Practitioner's Guide to the Methods and Theory of Synthesis, to be published by Oxford University Press.

Interaction and Mediation in Preadmission Clinics: Implications for the design of a telehealth stethoscope

Ben Kraal, School of Design, Queensland University of Technology, Australia, b.kraal@qut.edu.au

Vesna Popovic, School of Design, Queensland University of Technology, Australia, v.popovic@qut.edu.au

Abstract

A telehealth stethoscope would make it possible for doctors to perform physical examinations on patients at great distances. In order to develop a useful and useable telehealth stethoscope we have conducted fieldwork observations of existing anaesthetic preadmission clinics to understand how stethoscopes are currently used. Both face-to-face consultations and videoconference consultations have been studied. Our results indicate that the stethoscope plays a minor role in the consultation and that consultations are mediated by the administrative work that is the reason for the consultation. We suggest that a stethoscope plays an infrastructural role in the consultation. The implications of considering stethoscopes as infrastructure are explored and considered in the context of a future telehealth stethoscope.

Keywords

interaction, stethoscope, infrastructure, telehealth, expertise

We are developing a digital stethoscope for use with a telehealth communications network in order to allow doctors to examine patients remotely (a telehealth stethoscope). A future telehealth stethoscope for remote examination of patients will mediate the interaction between doctors' nurses and patients. Understanding this mediation and enabling good collaboration to take place is important if a telehealth stethoscope is to be effective. Though some research exists on telehealth stethoscopes (Belmont and Mattioli, 2003; Fragasso et al, 2007; Wong et al, 2004) it does not focus on interaction and is based on existing products. To ensure that the new device we develop will be appropriate we are conducting field studies of anaesthetic preadmission clinics in a major rural hospital in Queensland, Australia.

An anaesthetic preadmission clinic is a consultation that takes place approximately a week before a patient undergoes an operation. They meet with an anaesthetist who assesses the patient's general health and suitability for anaesthesia. Most of the preadmission consultation involves the doctor interviewing the patient about their general health and about specific aspects of their health that may affect the patient's response to anaesthesia. A small but important part of this assessment in face-to-face clinics is the process of auscultation or the examination of the patient's chest (heart and lungs) with a stethoscope. In telehealth preadmission consultations the interview proceeds as it does in a face-to-face consultation but no stethoscope is available. Consequently telehealth consultations are only offered to people who are known to be "low risk" -- that is patients who are young, generally healthy and who will not undergo particular sorts of high-risk operations. Patients who are deemed "high risk", typically the very old or infirm, must travel to the main hospital, sometimes for several hours, to have a face-to-face consultation. This travel is expensive and time-consuming. A telehealth stethoscope would allow remote consultations to take place for many people who would otherwise have to make long expensive journeys in advance of their operation.

In the studies reported here, we observed both face-to-face and telehealth consultations.

Research Methods

In order to understand the context in which a telehealth stethoscope will be used we conduct field studies of anaesthetic preadmission clinic consultations. In these consultations, doctors and nurses examine patients about a week prior to surgery in order to assess the patient's suitability for anaesthesia.

Our data is collected through video-recorded observation, think (talk) aloud protocol and retrospective protocols, interviews and focus groups. Noldus' The Observer (2008) software aids our analysis of video data. We also conduct retrospective protocol with the doctors and nurses we have observed in order to clarify their actions. We use Atlas.ti (2008) to analyse verbal data.

The coding scheme (Kraal and Popovic, 2009) we used was developed through close examination of the videos of consultations.

Initially we sought to understand how the stethoscope mediated interaction in consultations and the coding scheme that was developed reflected this (Kraal and Popovic, 2009). That approach led to a deeper understanding of the context and the subsequent redevelopment of the coding scheme to better reflect how preadmission consultations are conducted. The next section briefly describes our previous research.

Communication between doctor and patient

In our earlier research (Kraal and Popovic, 2009) we saw that the way doctors conducted face-to-face consultations and telehealth consultations was very similar. We had expected that the different types of consultation would be different. Instead our research showed that there was no discernable difference in how the communication between doctor and patient was conducted. The only noticeable difference was that telehealth consultations did not include the use of a stethoscope. In contrast to the existing literature on telehealth video conferencing (eg Kaplan and Fitzpatrick, 1997; Li et al, 2006) in which communication between participants in remote interactions is sometimes difficult we have found that communication between doctors and patients was similar in face-to-face and remote consultations (Kraal and Popovic, 2009). We speculate that the similarities between the two types of consultation occur because the doctor's goal is always to assess a patient's suitability for anaesthesia.

The use of a stethoscope in the observed face-to-face interactions is largely perfunctory and serves a confirming, rather than specifically diagnostic, role. Only when a patient is elderly or has pre-existing medical conditions that may hinder effective anaesthesia do the doctors make detailed use of a stethoscope. The lack of a stethoscope in the remote consultations has shown that in cases where the patient is generally fit and healthy a stethoscope is not needed. Patients who are remote but whose poor physical health necessitates a detailed examination are always seen in person, which requires them to travel to the main hospital.

We also observed that the tools the doctors use in the consultations, both face-to-face and telehealth, are more extensive than the stethoscope. The primary tools that the doctors use in the consultations are the questions they ask patients and the patient's medical record. These tools are, obviously, available in both types of consultation. It seemed that the questions and medical record were mediating the interaction between doctor and patient in consultations. We collected more data and analysed it using the new coding scheme (table 1) to obtain further data on this aspect of the interaction between doctors and patients.

Mediating Artefacts in Preadmission Consultations

In preadmission consultations there are different stages of interaction. These different stages are (i) the initial interview between doctor and patient, (ii) the physical examination of the patient by the doctor and (iii) the end of the consultation when the doctor summarises their decision about the patient's anaesthetic needs and invites questions from the patient. We have examined all three stages in this research. We anticipated, and our analysis has shown, that the stethoscope mediates interaction between doctor and patient during the physical examination. The doctor's actions during the physical examination draw strongly on tacit knowledge. It is this finding that most significantly impacts on the design of a future digital remote stethoscope since such a stethoscope will require doctor, nurse and potentially patient to work together in a way that requires high use of explicit knowledge.

Further analysis of the entire preadmission consultation has shown that the administrative aspects of providing a patient with anaesthesia mediate the entire interaction, most significantly during the initial interview. The artefacts of the administrative aspects of anaesthesia are the patient's (paper) medical record, a form on which the doctor records their interview with the patient and, occasionally, the computer on the desk in front of the doctor which is used to look up parts of the medical record which are stored electronically. Most of the time, the doctor requests information from the patient to confirm or elaborate on information that is contained in the medical record. For example, doctors often ask patients about their previous experiences of anaesthesia. In two instances we have observed the patient does not have an extensive medical record and the doctor must ask them more detailed questions about their general health to obtain the same information that is normally in the paper record.

To describe these activities a coding scheme was developed (table 1) which sought to capture the activities that occurred in the preadmission consultation in a more refined way than that used by Kraal and Popovic (2009).

Code	Description
Examination	Conducting a physical examination of the patient
Medical Record	Doctor's attention is on the patient's medical record
Computer	Doctor's attention is directed at the computer
Writing	Doctor's attention is directed at writing
Patient Conversation	Doctor's attention is directed at the patient

Table 1: Coding scheme

There are five codes in the scheme. The Examination code was used when the doctor performed a physical examination of the patient. Three codes, Medical Record, Computer and Writing, describe activities where the doctor is focussed on administrative activities. If the doctor was speaking with the patient and engaged in an administrative activity, only the administrative code was used. The Patient Conversation code describes when the doctor was focussed on discussion with the patient.

Figure 1 shows the average times spent on different activities during the preadmission consultations we have observed. The activity that takes the longest is the conversation between doctor and patient with an average of 00:05:17 minutes. Writing the record of the consultation took and average of 00:03:44 and the other activities, the physical examination, using the medical record and using the computer took approximately two minutes each. Averages presented are calculated on times where the code occurred. For example, examinations only took place during face-to-face consultations so that average is calculated on 9 episodes.

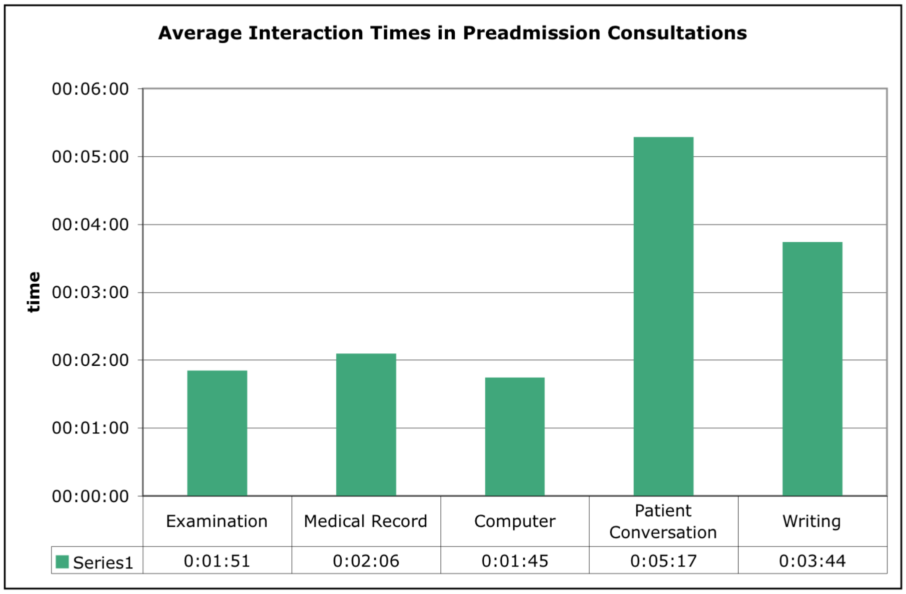

Figure 1: Average Interaction Times in Preadmission Consultations

There were some differences between the face-to-face consultations and videoconference consultations that were observed (figure 2). Patient examination times are not shown in figure 2 as no patient examination occurs during videoconference consultations. Additionally, doctors did not interact with the computer while engaged in videoconference consultations so that data is also not shown in figure 2. While the average amounts of time spent on patient conversation and writing the consultation record were similar between the two types of consultation, the amount of time spent dealing with the patient's medical record was different. In face-to-face consultations the doctors spent an average of 00:02:30 minutes examining and working with the patent's medical record while they spent 00:01:17 with the medical record in the videoconference consultations. However, this difference is likely a result of the limited number of videoconference consultations that have been observed.

As figures 1 and 2 show, a lot of time is spent on interacting directly with the patient. Exactly how much time is shown in figures 3 and 4 which combine the medical record, computer and writing codes in "administration". Figure 3 shows that, considered in this way, administration makes up the largest block of time during a consultation an average time of 00:06:05 minutes, followed by conversing with the patient, 00:05:17 minutes, followed by the short time spent on the physical examination, 00:01:15 minutes.

	Medical Record	Patient Conversation	Writing
Face-to-Face	00:02:30	00:05:01	00:03:50
Video Conference	00:01:17	00:05:53	00:03:32

Figure 2: Average Interaction Times for face-to-face and video conference consultations.

	Administration	Patient Conversation	Examination
Series1	00:06:05	00:05:17	0:01:51

Figure 3: Average Interaction Times in Preadmission consultations, all administration activities collated

Figure 4 shows the administration and patient conversation times split by consultation type. The differences in the average times for administration tasks and patient conversation activity are likely to be due to the relatively small sample size, particularly of videoconference consultations.

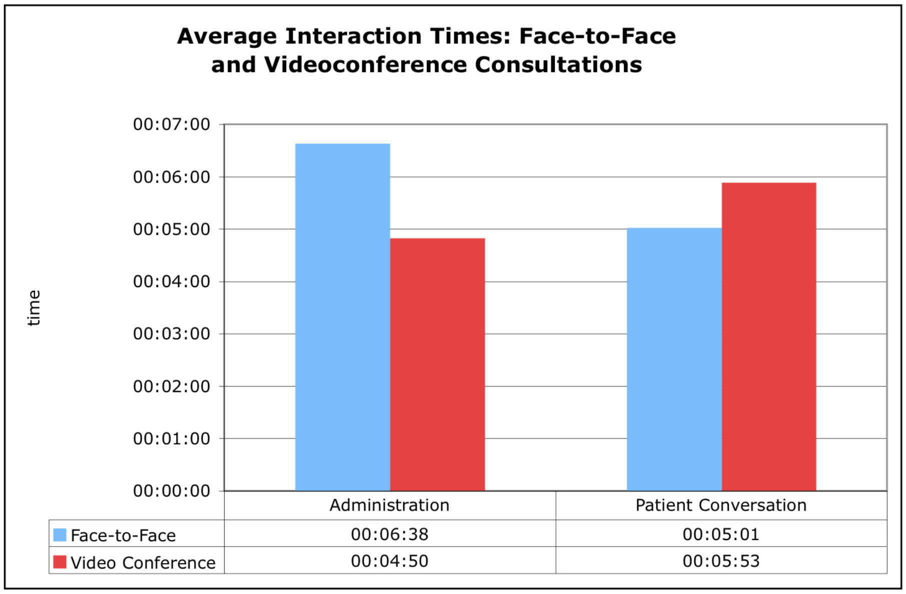

Figure 4: Average Interaction Times, all activities collated, by consultation type

These data show that in the consultations observed the doctors spend the most time dealing with the administrative elements of the interaction and that the physical examination is completed quickly. This is not to say that the physical examination is unimportant but that its importance, when measured by time taken, is not as significant as we had expected it to be. Only in cases where the patient is very high risk do the doctors spend a long time on the physical examination.

We have collected data from physical examinations of two high-risk patients. These patients requested that their entire consultation was not filmed, so there is no data on the length of the administration or patient conversation aspects of the consultation. In the high-risk consultations the examination lasted for 00:03:09 minutes in one case and 00:04:23 in the other. Stethoscope use was 00:01:11 and 00:02:32 respectively.

	Stethoscope Use	**Examination**
High-risk patient A	00:01:11	00:03:09
High-risk patient B	00:02:32	00:04:23
Average of other patients	00:01:06	00:01:51

Table 2: Examinations and stethoscope use in High risk patient consultations (Kraal and Popovic, 2009)

As table 2 shows, it is not possible to say that the doctors use a stethoscope for a significantly longer period of time during a “high risk” consultation than a “normal” consultation. However, it seems that the physical examination itself lasts for noticeably longer in the “high risk” cases than in the average of the other cases observed.

As these results have demonstrated, the interaction between doctor and patient is mediated by the doctor’s need to complete the paperwork that provides the record of the consultation and the advice to the doctor who will actually anaesthetise the patient. The stethoscope plays an important but subsidiary role in the consultation.

While the medical record always has a strong role in the consultation the stethoscope acts as a tool that is brought into use by the doctor as needed. Patients who are generally healthy receive a brief auscultation. Patients who are infirm or who have potentially dangerous existing conditions receive a similar length auscultation but a longer physical examination. The similar length of auscultation suggests that the skill of auscultation is in the interpretation of the sounds from the stethoscope and that very similar techniques are used to obtain the required sounds, regardless of the patient. The observations have shown that the doctors are able to use their stethoscope as it suits them and they use it with great fluidity, demonstrating great expertise. The fluid, natural, way that the doctors use the stethoscope and the subsidiary role it plays in a consultation has several implications for the design of a telehealth stethoscope.

Implications for the Design of a Telehealth Stethoscope

The results of this study, and our previous analysis (Kraal and Popovic, 2009), suggest that a good telehealth stethoscope will have two inter-linked properties. First, a telehealth stethoscope must be a good stethoscope and second, it must be as similar to an existing acoustic stethoscope as possible.

The first criterion, that a telehealth stethoscope be a good stethoscope, means that it must transmit sound from the patient's chest to the doctor's ears accurately. It is difficult to acquire the skill listen to the subtle sounds of the heart and lungs and doctors learn to expect to hear those sounds in particular ways. The second criterion, that a telehealth stethoscope be very similar to an acoustic stethoscope, means that the method of interaction with the telehealth stethoscope should fit with a doctor's existing experience with stethoscopes. A telehealth stethoscope should therefore look and feel similar to existing acoustic stethoscopes.

Different Stethoscopes Sound Different

The first implication arises because all stethoscopes have slightly different frequency response -- that is, they sound different. Callahan, Waugh and Matthew (2007) have shown that the sound reproduction of acoustic stethoscopes differs markedly and that accurate sound reproduction is not correlated with price. Dolan, Oliver and Maurer (2002) tested one acoustic and two digital stethoscopes and also found that each had a different frequency response.

As doctors tend to acquire a stethoscope and use it for several years it can be assumed that they become familiar with the way their stethoscope sounds. This familiarity makes up a significant part of a doctors expertise in auscultation. A telehealth stethoscope will almost certainly sound different from a doctor's own. It is unclear whether differences between stethoscopes result in less accurate diagnoses by doctors or even if the differences, while measurable, cause the doctors difficulties.

There seems to be no remedy to this problem. A telehealth stethoscope will necessarily sound different to any other stethoscope and as it seems there is no accepted or documented standard for what a stethoscope should sound like. Doctors will have to use the telehealth stethoscope in order to acquire expertise with it. However, even if it is carefully designed, it will be harder to acquire expertise with a telehealth stethoscope because it will be as much a system as it is an artefact.

Telehealth Stethoscopes are both Systems and Artefacts

An acoustic stethoscope, of the sort that the doctors we have observed use in consultations, is a relatively simple artefact consisting of a "head" comprised of a simple diaphragm that transmits sounds from the patient's chest to the doctors ears through a few lengths of tubing. The addition of a "bell" to complement the diaphragm, as the bell and diaphragm are able to transmit different types of sounds, is often the most complexity seen on a typical stethoscope. Various types of digital stethoscope also exist and these are usually variations on acoustic models usually with some type of amplifier and volume control available on the main tube of the device. Both acoustic-analogue and digital types of personal stethoscope are largely self-contained – that is they can be engaged with as artefacts. However, a telehealth stethoscope will be both a system and an artefact and this duality could be problematic, particularly with regard to the research findings presented in this paper.

The most relevant finding is that the interaction between doctor and patient is mediated by the administrative aspects of the consultation and not by the stethoscope. That the stethoscope can play a subsidiary role reveals that the doctor and patient treat it as infrastructure. Star (2002) describes infrastructure as that which is “part of the background for other kinds of work” (Star, 2002, pg 116). The stethoscope acts as infrastructure because it aids the doctor in their work of completing the administrative actions that are the reason for the consultation. However, the stethoscope can only act as infrastructure because the doctor is able to use it so easily. The relationship that the doctor has with the stethoscope is what makes it act as infrastructure. If that relationship were broken or changed in some way, the stethoscope would cease to act as infrastructure and would become a thing to deal with in and of itself. A telehealth stethoscope must therefore be able to operate as infrastructure, allowing the doctor and patient to interact for the consultation and largely ignore the stethoscope.

Ignoring a telehealth stethoscope will be more difficult as it will be a system of physical artefacts and software. All elements of the telehealth stethoscope must work correctly to allow a doctor to treat it as a stethoscope. In order that an acoustic stethoscope functions correctly it must simply be in good repair with no cracks in the tubing and a diaphragm that is intact. In a face-to-face consultation (figure 5), auscultation is mediated by a very simple artefact. In contrast, a telehealth stethoscope places a large number of artefacts and systems between the doctor and patient and also requires new relationships between people in order for auscultation to be performed.

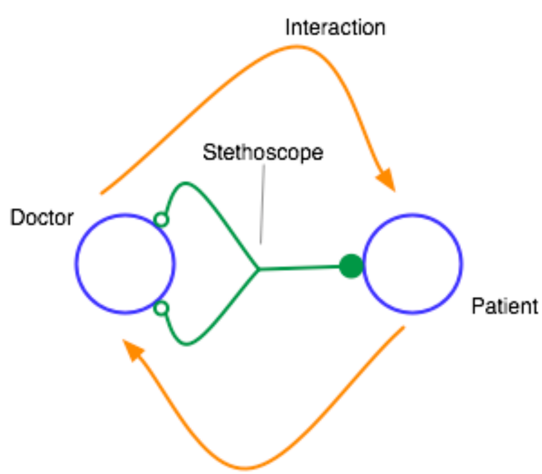

Figure 5: Face-to-face auscultation interaction

Figure 6 shows the mediations and interactions required for successful telehealth auscultation (teleauscultation). There are three participants in the teleauscultation shown, the doctor, the patient and the nurse. The nurse places the head of the digital stethoscope on the patient and has earpieces to listen to the patient’s chest. The digital stethoscope is also connected to the telehealth infrastructure to transmit the patient’s heart sounds to doctor. The doctor has earpieces that allow them to hear the patients sounds transmitted over the telehealth infrastructure. The doctor and the nurse must work collaboratively to listen to the sounds of the patient's chest. The additional interaction between doctor and nurse and the collaboration that is required to obtain good chest sounds is not currently taught to doctors or nurses and is something that will have to be learned in order to make a telehealth stethoscope useful. The collaborative work of using a telehealth stethoscope will need to become part of the infrastructure of the system in order to make the system work.

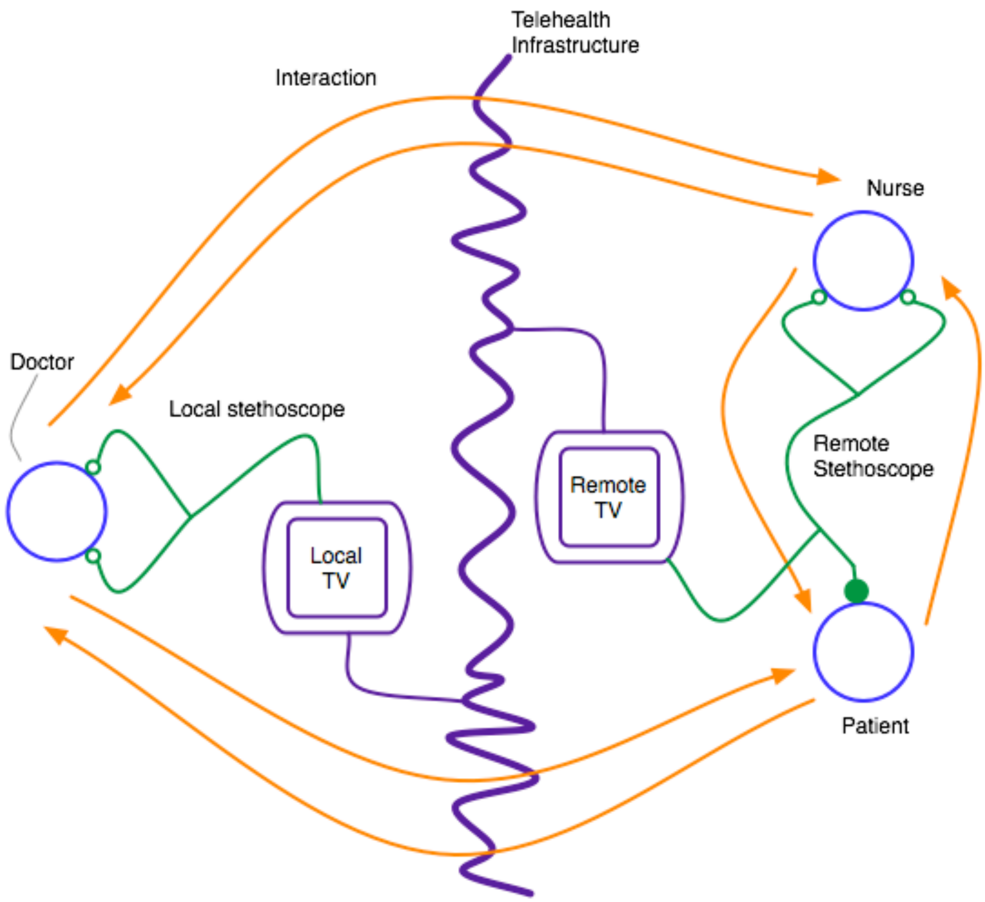

Figure 6: Telehealth auscultation interaction

Previous studies have shown that teleauscultation can be successful (Belmont and Mattioli, 2003; Fragasso et al, 2007; Wong et al, 2004). This research we have conducted has found that acoustic stethoscopes act as infrastructure in face-to-face consultations. The complexity of a telehealth stethoscope makes it more difficult to be used as infrastructure. The implication for design of this analysis is that designing the artefact of a telehealth stethoscope is not sufficient, what must be designed is the system that makes the use of the artefact possible.

In the context of our research, some elements of the system for teleauscultation already exist. The telehealth infrastructure is already in place. The findings described above suggest that the elements of the system that perform as stethoscopes should resemble stethoscopes. What must be designed is the interaction between the human actors in the system and the coherent functioning of the system as a whole.

Conclusions

The goal of this paper has been to examine how existing preadmission consultations are conducted, with a focus on how stethoscopes are used during such consultations. Analysis of the activity of doctors and patients during consultations showed that the majority of time during consultations is spent on administration and communication and that the physical examination of the patient is a minor aspect. We argued that the brief use of stethoscopes in preadmission consultations shows that doctors treat them as infrastructure, that is, as an artefact that allows work to be performed, rather than a site of work itself. We have then argued that if stethoscopes are infrastructure then that has implications for the design of telehealth stethoscopes.

The two implications for the design of future telehealth stethoscopes are related. First, a telehealth stethoscope will be a shared artefact, not a personal one. All acoustic stethoscopes reproduce the sounds of the chest slightly differently and doctors learn to interpret those sounds through their personal stethoscopes. A telehealth stethoscope will sound different to a doctor's own stethoscope and this may have an impact on their diagnostic and interpretative ability. Second, using a telehealth stethoscope will be much more complex than using an acoustic stethoscope because of the systems that must be created and sustained in order for a telehealth stethoscope to function. While some systems, such as the telehealth infrastructure, exist already, other systems and social protocols, such as how doctors, nurses and patients will interact, are yet to be created.

The conclusion of this work is that the design of a telehealth stethoscope must encompass the design of the artefact itself and the design of the systems that will make a telehealth stethoscope possible. Some of those systems exist already and will need to be appropriated into the design of the telehealth stethoscope. Others, such as the system that will allow accurate transmission of chest sounds, are yet to be created. And some aspects of the system that will make a telehealth stethoscope useful, such as the methods of interaction between doctor, nurse and patient, can be suggested but never truly designed.

These preliminary findings are significant because they provide new knowledge about the factors influencing the adoption of telehealth stethoscopes for remote patient assessment. If the systems that will support the use of a telehealth stethoscope are not adequate, then the telehealth stethoscope will not be able to be used. These findings allow a deeper understanding of what a successful tool will encompass and will ultimately lead to the production of an advanced telehealth stethoscope that will enhance the ability of doctors and nurses to conduct remote auscultation assessments.

Through careful analysis of current interactions we have been able to identify aspects of the new situation that must be carefully considered in a new design. This approach is adaptable to many situations and can contribute to the design of innovative systems and artefacts that can be readily inserted into complex situations. Our approach deals with important problems that are shared by significant application domains in rural health care. The new methods and techniques we are developing contribute to new knowledge within the domain of telehealth but also apply to other areas where the introduction of innovative tools must be studied. These methods and techniques are themselves new and contribute to the body of knowledge on conducting design research.

Ben Kraal

Ben Kraal PhD, is a Research Fellow in the School of Design at the Queensland Institute of Technology (QUT). He specializes in research about how people make use of technology in their lives. Dr Kraal's contributions to design research have included developing and extending scenario techniques to design for speech recognition interfaces; applying concepts from Actor-Network Theory to understand how users make speech recognition software useful on a daily basis; developing new ways to understand how expertise is demonstrated in physical activities, and; investigating passenger experience in airports from a passenger and object-centred perspective. He is a member of the Design Research Society and co-chair of the OZCHI 2010 technical program.

Vesna Popovic

Vesna Popovic PhD, is a Professor in Industrial design in the School of Design at the Queensland University of Technology (QUT), and she is the founder of the Industrial Design infrastructure in Brisbane, Australia. She has made an international contribution to product design research where she has integrated knowledge from other related areas and applied it to artifact design in order to support and construct design applications. In particular, she has been a forerunner of human-centred design research as applied to artefact, services and systems. The impacts of her work lie in the cross-fertilisation of knowledge across humanities and technology to design and produce humanised artifacts as well as to enhance our culture by facilitating understanding between professionals with diverse expertise and experience. She has published widely and is the recipient of numerous awards and research grants. She is a Fellow of the Design Institute of Australia and Fellow of the Design Research Society (UK). She was an Executive Member of the International Council of

Societies of Industrial Design (ICSID) from 1997 to 2001 and co-founder of ICSID Education Conference in 2001. Since 2001 she has been an ICSID adviser.

A Proposal for the Web 2.0 Revolution in Online Design Education:
Opportunities for Virtual Design Learning Using Social Networking Technologies

Karen Kwan, York University, Canada

Abstract
New Web 2.0 tools are enabling new avenues for online communication. Social networks that have sprung up from these tools are not only the basis of information dissemination but also a means of sustained learning. Educators are now able to investigate beyond traditional teaching pedagogies and student participation roles. By exploring learning theories and the philosophies of design education, this research proposes a framework for leveraging recent innovations in social networking technologies to facilitate these values in an online environment. Unlike many other subject areas, at the center of design learning is an underlying method of inquiry and dialogue that cannot be objectively transferred to students through typical learning management systems. The growth and popularity of social networking services has created a communications space that is distinct from the confines of the physical world. By taking advantage of the rich complement of applications that comprise this alternative communication space, educators can import the reflective learning approach essential to design education.

Learning; Reflective Practices; ICT

This paper examines the pedagogy of university-level online design education with specific emphasis on the utilization of Web 2.0 social networking tools. By exploring learning theories and the philosophies of design education, this research proposes a framework for leveraging recent innovations in social networking technologies to facilitate these values in an online environment. The goal is to open up the discussion of eLearning in design by investigating design education in conjunction with its virtual counterpart.

The area of design has been somewhat slow in adopting online eLearning formats. Perhaps because design learning is so tied to the tacit knowledge gained during the production process that forays into online design education has been somewhat tentative. There is now, however, a critical mass of data from which meaningful conclusions can be drawn as design vaults itself into the online realm.

With the advent of Web 2.0, the growth of eLearning has taken on a new complexion. Open source programs and application programming interfaces are now available to provide richer, more enhanced learning experiences. Web 2.0 has the potential to bring enriching experiences to online design education. A prototype design course environment using a selection of current Web 2.0 tools is presented in Appendix A; demonstrating the potential of these emerging technologies.

Current Online Learning
In general, online courses at universities are administered through one of several popular learning management systems. Typically, there is a personal homepage where general announcements are posted, courses are listed and tools such as calendars, task reminders and grade reports are available. On specific course pages, there is space for a syllabus as well as a medley of communication tools including email, forums and provisions for digital drop boxes. On the backend, instructors have a vast array of database-driven modules for building quizzes and lessons. Also available is a set of statistical tools showing student performance which can be used to generate learner profiles and help instructors prescribe remediation activities as needed on an individual basis (de Castell, et al., para .20).

Proponents of these systems have detailed a number of documented success stories and contend that the tools in these systems allow for engaged learning experiences. However, as Susan de Castell et al. explain in their article “Object Lessons”, despite the sophistication of the LMS environments with their powerful content management capabilities and integrated communication functions, the majority of courses do little more than utilize the display and distribution capabilities of computers and the Internet.

The argument continues that this pre-programmed approach to education is fundamentally rooted in textbook-based knowledge that encourages compliance above learning. Clearly, as advanced design education is a subject area that has few explicit textbooks of knowledge, the pedagogical constructs of current online learning would have limited application for design courses.

To address the needs of design courses we first turn to a consideration of the principles of design learning as it occurs in the design studio. This assessment will establish a concrete definition of design learning needs before attempting to evaluate how the unique capabilities afforded by new Internet technologies can be leveraged for online design courses.

Design Learning Defined

Particular to design education is the studio as an environment for instruction. The elements and philosophies of design learning were investigated with the following means.

1. An historical account of studio-based design learning

   Tracing the history of studio learning will provide a deeper understanding of the purposes and goals of this model of learning. This understanding would, in turn, provide guidance to the application of new methods and processes afforded by the current information age.

2. A close reading of the studio learning model as proposed by Professor Donald Schön

   Described as being “among our generation’s most influential philosophers of design and design education,” (Waks, 37) Schön’s detailed study on studio learning provides insight into the specific workings of design studios – the roles of students and educators and the interactions that constitute design learning.

3. The observations of a current studio-based class at the undergraduate level

   To understand the goings-on in the contemporary design studio and how design learning is imparted in such a setting, in-class observations of a studio-based design course were undertaken. The course description and project brief given to students at the beginning of the term is included in Appendix B.

Design Studio Origins

As a learning model, studio-based training can trace its roots to the guilds of the Middle Ages where apprentices learned under the direction of a master artist or craftsman. More formally in North America, the teaching system of the Ecole des Beaux Arts has been recognized as one of the standards under which studio-based education was founded. (Lackney, para. 2)

Beginning with a preliminary sketch of the “design problem”, then progressing to an interim critique (“crit”), the Beaux Arts system culminates with a final juried evaluation. Throughout the term, studio instructors guide students towards the completion of a final product. Although it has been over two and a half centuries since the adoption of this system, the essential elements within it has remained largely unchanged in present-day studios found at institutions of higher learning.

Donald Schön and Reflective Learning

In the 1980’s Professor Donald Schön put forth a series of essays that examined modern design studio learning in detail. After presenting the dialogue from a hypothetical design review between a student (Petra) and the studio master (Quist), Schön dissects the exchange to substantiate how learning in the studio environment is a reflective process. Reflection-in-action takes place on the part of both the studio master and the student. As Quist probes Petra about her design experiments he is testing (or reflecting upon) the effectiveness of his interventions and the student’s understanding of design. To the extent that Petra can translate Quist’s interventions and express them through design experiments demonstrates her process of reflective learning. Through a series of “telling” and “demonstrating” by Quist and “listening” and “imitating” by Petra, the master and student engage in what Schön refers to as “reciprocal reflection-in-action” until there is a convergence of meaning. (1985, 64)

Schön’s framework of the design studio has three implications: (Waks, 44)

1. Design can only be learned by experimentation. No explicit teachings can achieve the same results. Schön recognizes this dilemma by calling it the paradox of reflective learning whereby the student must start working on a design problem without adequate knowledge; the knowledge required can only be gained after working on the design problem.
2. Design cannot be learned in isolation. Each move or experiment undertaken affects the whole, which in turn affects subsequent moves putting constraints on possibilities. When Quist instructs Petra to make a move that can always be changed later, he demonstrates how design is to make new coherent patterns and meanings of all the components of the situation.
3. Designing depends on the ability to appreciate or recognize the desirability of outcomes whether or not they were intended. Negotiating the outcomes of successive experiments through operational moves and material back talk will develop a student’s ability to designate the quality of designs achieved.

This process is unique to the studio-learning environment and the fact that this learning model uses a conversational approach is significant. The dialogue is not only between student and instructor; it is also between students and their classmates and between students and their work. Social media that has expanded and enhanced the communication space of the Internet points to increasing possibilities for online design courses without compromising the core principles of design learning.

The Contemporary Design Studio

To explore how the traditions of the design studio and Schön’s model of learning have evolved, in-class observations of a current studio-based design course at the undergraduate level were conducted. Key features of the course revealed limited detraction from the studio system as it was adopted in the mid-nineteenth century and a close mimic of the descriptions presented by Schön.

As the course/project descriptions indicate, assignments are semester-long endeavours that start with an initial proposal, proceed through a series of “crits” before the final is submitted. In the sessions attended, the focus was on progress critiques for each student. Each week, classes were structured such that the iterations of student projects and work-in-progress was presented for class “pin up” reviews or one-on-one critiques with the instructor. This fostered “culture of criticism” akin to the imported model from the Ecole demonstrates this feature as a fundamental aspect to design learning.

In terms of the roles of the instructor and students in the course, interactions were a close match to those described by Schön. As the expert in the studio, the instructor’s role in the observed class was primarily centered on guidance and feedback. In fulfilling this role the instructor used a combination of lecture-style presentation material, group peer review or “pin-up” sessions and personal one-on-one critiques. To address the class as a whole, the lecture portion of the class concentrated on showing examples and highlighting areas of significance. The presentation was relatively short, spanning less than 20 minutes in a four-hour class. The remaining time was reserved for providing feedback to students. During the observed classroom “pin-up” session the instructor emphasized the need for all process work to be available in order to understand how different pieces of the same publication fit together to create a unified whole. While the session provided a non-confrontational opportunity for students to look at each other’s work and make suggestions, students were generally reluctant to show their work and hesitant in offering comments. Comfort for sharing ideas and sketches changed remarkably during the one-on-one critiques. The instructor was also the most thorough during this portion of the class. As Schön describes, through both classroom and personal critique sessions, the instructor guides students using a series of “telling” and “demonstrating” while students learn by “listening” and “imitating.”

Further to the instructor-student relationship described by Schön, the studio environment also allowed students to “tell” and “demonstrate” or “listen” and “imitate” amongst themselves. When not engaged with the instructor, students were observed to be actively helping each other, giving constructive feedback, answering “how to” questions and wandering about looking at each others' work.

By acknowledging that the process of design learning is predicated on a series of reflective dialogues and social negotiations, it becomes evident why online design courses have so far only shown moderate success. More often, successes have come in design courses where the objective is the acquisition of a design-related skill (i.e. software tutorials) that had little need for peer/instructor feedback.

What has changed? The online environment has evolved.

Advent of Web 2.0 Social Media

Background

Web 2.0 has brought a new set of principles on the use of tools available online. These principles, described by Tim O'Reilly, from whom the term was originally coined, include: (O’Reilly Media, para. 6)

1. The web as a platform
2. Harnessing collective intelligence
3. Data is the next Intel inside
4. End of software release cycles
5. Lightweight programming models
6. Software above the level of a single device
7. Rich user experience

These principles show that Web 2.0 was founded based on a platform of sharing and participation where users are in the driver’s seat and collaboration builds success. This essential aspect of Web 2.0 closely aligns with the established fundamentals of design learning. Continued growth and penetration of these tools has created fertile ground for offering online design courses in an increasingly accessible platform.

Growth in Popularity

The surge in the adoption of Web 2.0 tools, particularly social media, has touched nearly every facet of life. Marketing gurus dare not discount the feedback of online network groups; during the most recent election, political spin masters were abuzz on Twitter; and our daily vocabulary has been permanently expanded by the terms YouTube, Facebook and Wiki. A recent technology presentation by Morgan Stanley highlighted the fact that social network connections had 16% of worldwide online time, second only to the general category of communication at 22%. More astounding is that the category of social connections did not even exist four years ago. (Morgan Stanley, slide 9)

To visualize Web 2.0 in terms of the specific tools being used, a sample of 100 popular web services and applications were analyzed. Since Web 2.0 tools are in continuing flux with new applications being pushed out by developers on an almost daily basis, the larger sample of 100 services (out of 3,000) were surveyed to avoid bias or misrepresentation. The tools were chosen for this study by combining the popularity votes on various Web 2.0 directory sites[1] with the rankings and statistics from Compete.com.[2]

Statistics showing the number of unique monthly visitors for each site was mapped in the word cloud formation in Figure 1. The comparative size of each is provided in the top left-hand corner. From this image its can be seen immediately that the giants in the Web 2.0 universe are YouTube, MySpace, Wikipedia, Facebook, Amazon, craigslist and Blogger. A larger version of the graphic is available in Appendix C.

[1] These sites include: www.go2we20.net, listio.com, www.allthingsweb2.com.
[2] Much like the Neilson TV ratings statistics, Compete collects data from over 2 million Internet users and extrapolates their usage patterns to generate web domain analytics.

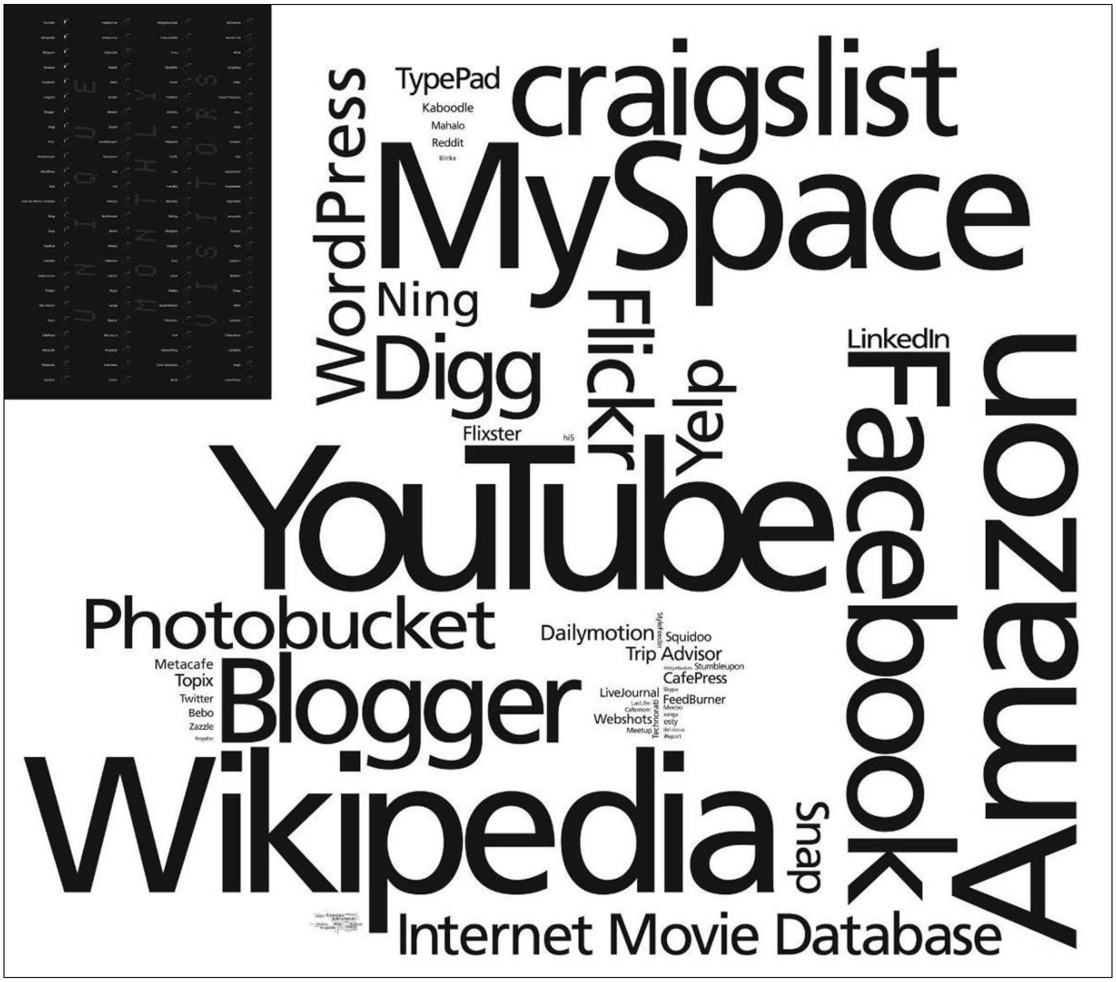

Figure 1 Word Cloud of Popular Web 2.0 Tools

Alignment with Learning Theories

As online learning via Web 2.0 tools begin to gain wider traction with mainstream institutions and students, this section evaluates these tools with established learning theories and how they align with the previously defined concept of design learning. Specifically, the learning theories examined are:

- Social Constructivism: where learning is an active and contextualized process of constructing knowledge rather than acquiring it. Knowledge is constructed based on personal experience, interactions and social negotiations.
- Cognitivism: where the focus is on the inner mental activities – opening the "black box" of the human mind. Learning under this theory centers on the individual and how they "make sense" of their environment.
- Behaviourism: a worldview that a learner learns by responding to environmental stimuli. With this school of thought the learner is assumed passive.

The "culture of criticism" handed down from historical models of studio learning and demonstrated in the observed undergraduate class is a close match to the social constructivist theory of learning. In the studio setting, the constant feedback from peers, instructors and invited guest experts all contribute to a student's learning experience. It can therefore be seen that in this model of learning, student students construct knowledge in a process that is mainly social.

Cognitivism delves deeper into the impact of the dialogues taking place in the studio setting. The progress of students relies heavily on their own interpretations of the materials and situations they encounter. Students will have different experiences in the course based on their ability to grasp a given lesson. Using this understanding, the learnings from a design studio mirrors Schön's reflection-in-action model where the focus is on the individual.

In contrast, behaviourism aligns with the view of education where textbook knowledge is emphasized. This learning theory is at odds with how design learning has been identified. The theory does, however, correspond to the characteristics of current online course offerings where the assumption is that student gain knowledge by reading the content on CMS portals. Without any additional form of participation required, this process of learning could be considered passive.

Distilling the three learning theories into the three factors of 'social', 'individual' and 'passive' and pairing them with their opposites – 'isolated', 'group' and 'active', these six factors of learning, result in a framework for evaluating the alignment of Web 2.0 tools against the three fundamental models of learning. The diagram in Figure 2 summarizes how these six factors were derived.

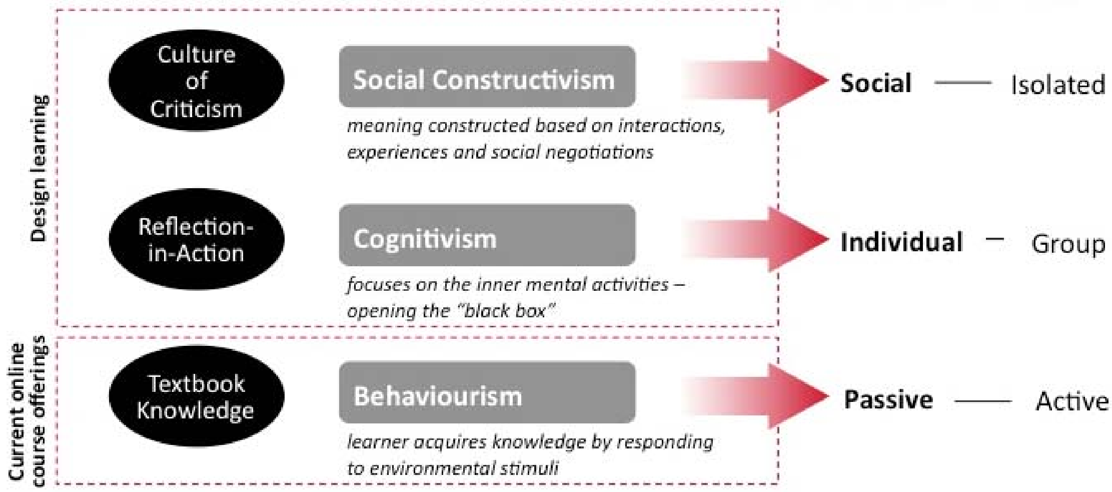

Figure 2: Learning Theories and the Six Factors of Learning

Taking each pair of factors, the 100 web services sampled previously were evaluated on a sliding scale from zero to ten, the higher the number the greater extent the tool displays that characteristic. In each case, the sum of the pair would equal ten. For example, if a particular web service rated 10 for passive, it would automatically receive a zero under the active column. This was done to control for the relative comparison between tools such that applications with multiple capabilities could be compared to a micro tool with only one function. If a site had eight functions and seven functions enabled interaction (bookmarking, commenting, sharing, voting, tagging, ranking, emailing), that web service would receive a nine for social and a one for isolated. Likewise, if a site had only one feature and it enabled interaction, that service would receive a ten for social and a zero for isolated. The result of this mapping is shown in Figure 3.

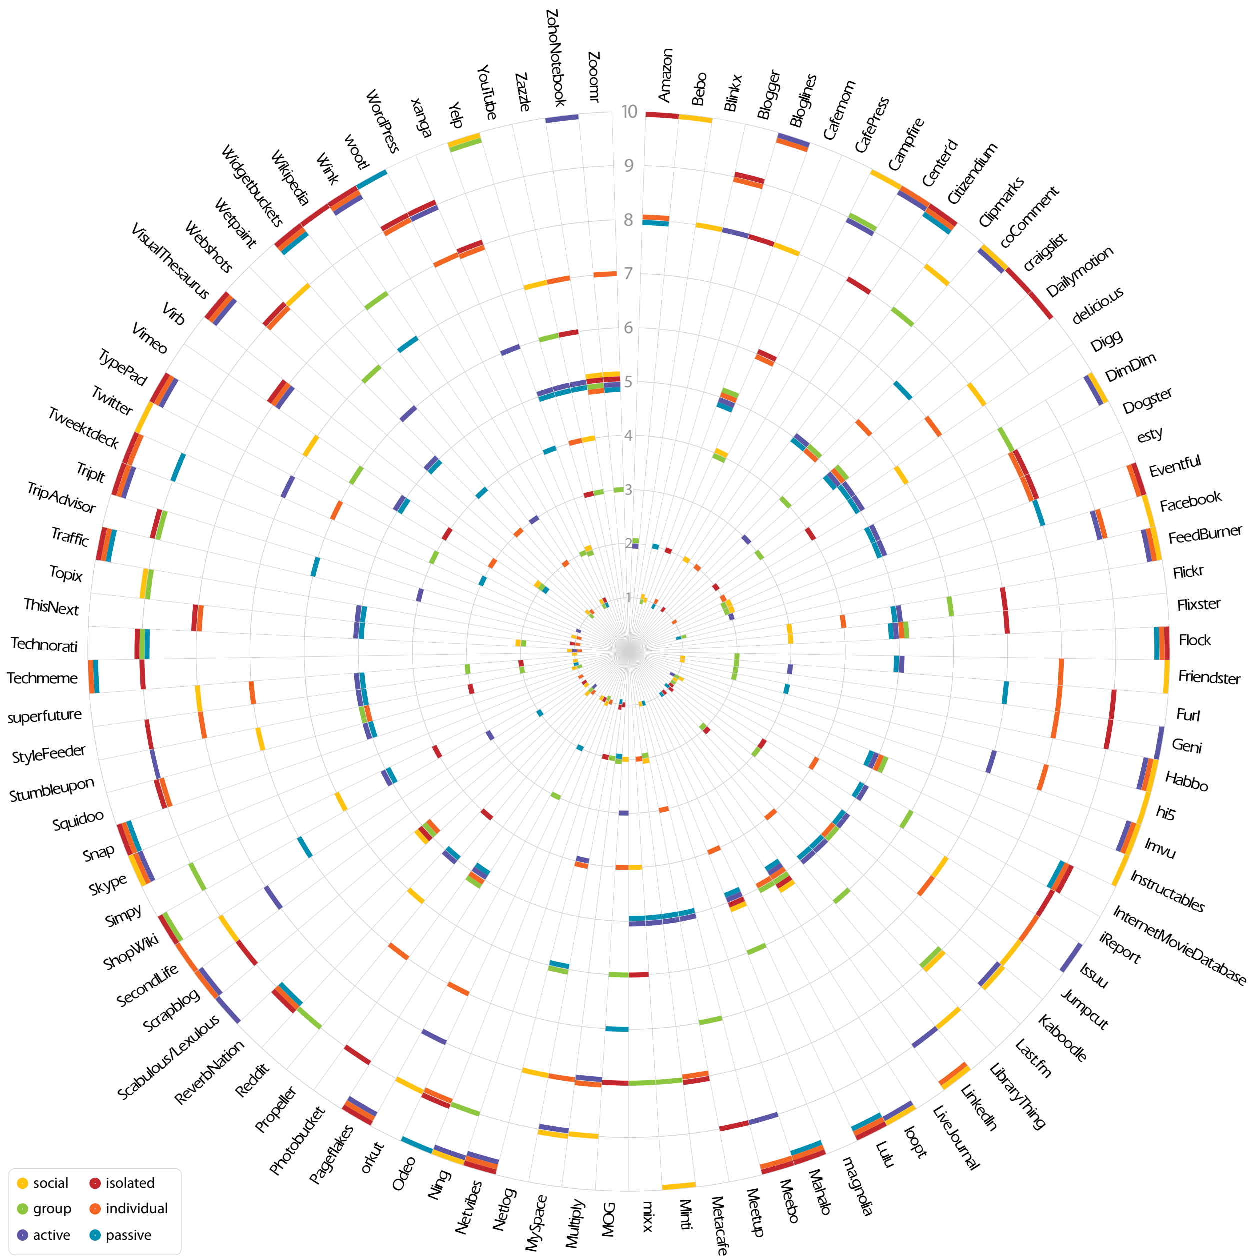

Figure 3: Mapping of Web 2.0 Tools and Factors of Learning

Taken as a whole, this diagramming of web services shows the range and diversity of the tools available in the Web 2.0 universe with its ability to accommodate a variety of learning situations.

To focus on the individual component parts of this visual, the six extractions shown in Figure 4 isolate each factor and represent them as “starbursts.”

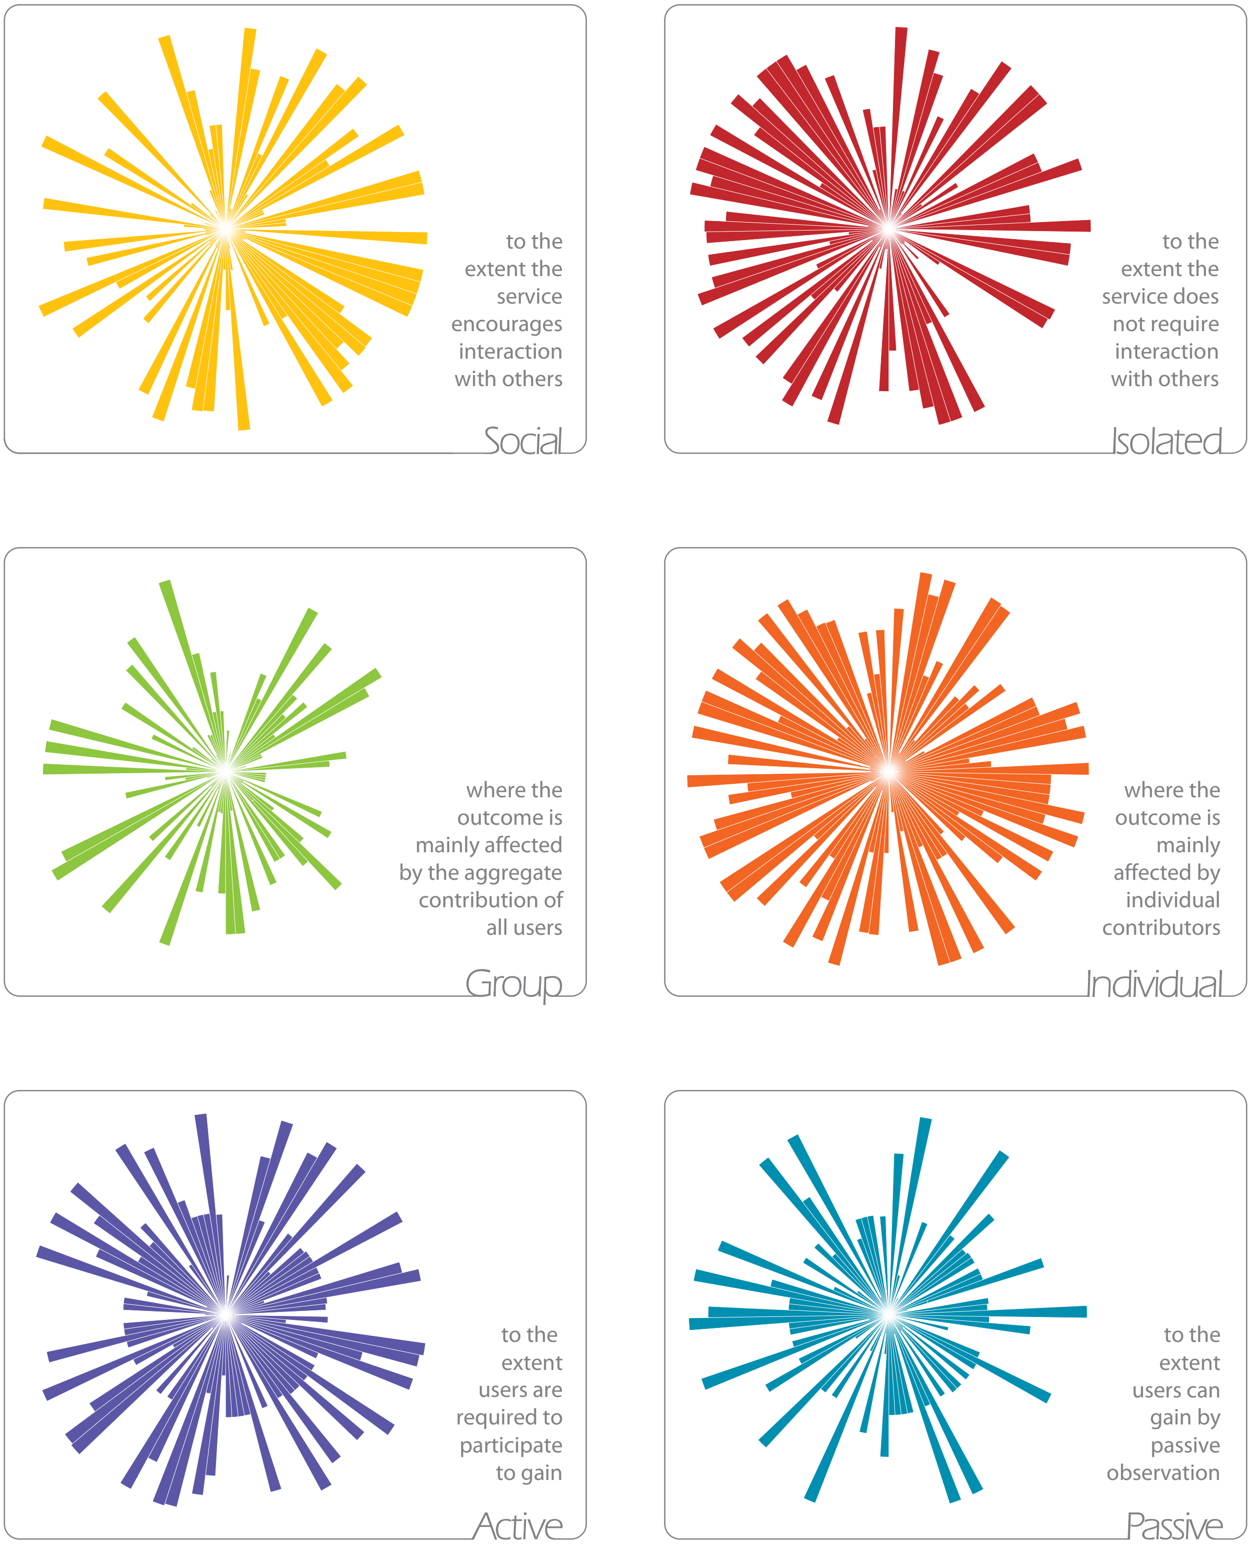

Figure 4: Individual Factors of Learning

Each pair of these “starbursts” represents the extent to which Web 2.0 tools facilitate the given learning theory.

Looking at the social constructivist pairing of “social” and “isolated”, the results indicate that there are a number of tools and services available to mitigate the physical isolation of using a computer. While the comparative sizes of the starbursts show that a slight majority of services do not necessarily require interaction with others, there is a growing trend towards encouraging more interaction.

Turning to the “group”/”individual” pairing that represents cognitivism, its can be seen that this is where online resources could be superior. The results illustrate that the vast majority of web services support an individualistic approach where there is ample space for reflective learning. Services like blogs or personal pages would be an example of these spaces.

Finally, when assessing how the behaviouralistic approach is applied to Web 2.0, the split between its two component factors “active” and “passive”, imply that users now have a choice as to whether they want to be active or passive – a departure from the traditional concept of Internet content which was mainly built on a “read-only” basis.

With this analysis, there is evidence of a close alignment between Web 2.0 capabilities and the principles of design learning. The results also present a plethora of tools available to build online course environments.

Change in Value Proposition

The advent of Web 2.0 social media tools has slowly changed the value proposition for online courses. Previously, the main advantage of online courses was its ability to transcend time and space. All knowledge was contained in neatly packaged modules that students could access whenever and wherever they pleased. However, since social media tools have created an alternative communication and learning space, the possibility of a fixed time and location for online courses is now available. The advantage of online courses, therefore, can now be expressed as a matter of technological relevance rather than mere freedom from temporal or physical limitations.

This shift in the perceived value of online courses has immense implications for online design courses. As established, the fundamental value of design courses is rooted in the various real-time dialogues that occur in the design studio. The non-location/time specific benefit of LMS-based online courses resulted in a dissociative and isolated experience that had limited applicability for design courses. Web 2.0 social media tools now present the possibility of truly offering virtual design courses that are both meaningful and engaging.

Tightly Integrated versus Loosely Coupled

Pre-packaged learning management systems have tools and resources are bundled and tightly integrated. These proprietary systems have highly developed tools that have been thoroughly tested by dedicated teams and function as stand-alone units. Their ability to interact with other resources on the Internet, however, is limited; most even have their own email repository that can only be accessed through their specific own portal. As visualized in Figure 5, these tools are neatly integrated into a tight package that constitutes an entire system. The tools in these systems are reliable and standardized but there is no option to customize functionality or “plug-in” external resources. By its very nature, the “closed-off” environment proposed by LMS products becomes a barrier in its adoption for studio-based design courses.

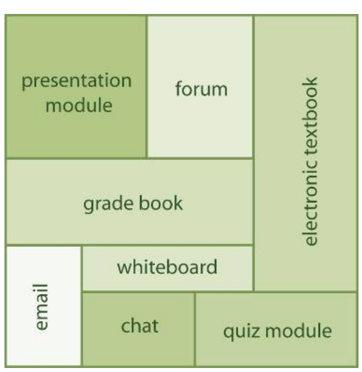

Figure 5: Tightly integrated course environment

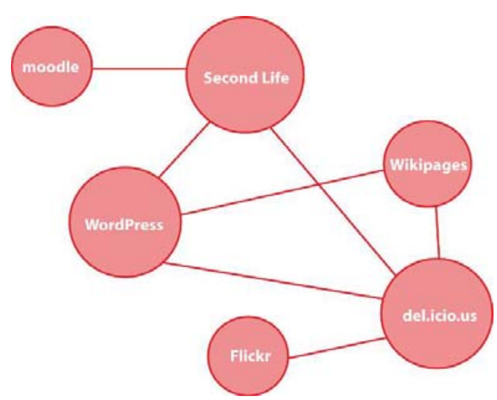

Figure 6: Loosely coupled course environment

In comparison, by looking at the individual tools available, rating their functions, popularity and propensity for educational value, the framework suggests a more flexible and somewhat ad hoc method of deciding which tools to employ for online design courses. Course environments, in this case, are built as networks of resources; they are loosely coupled to enable quick changes and flexibility. As an example, the diagram in Figure 6 shows numerous Web 2.0 tools connecting to one another to form a course environment. As different tools become available they could be incorporated into the network or even replace certain parts of it without disrupting other components.

The adaptability of this course environment model is in close keeping with the long tail development norms of Web 2.0. As rapid advancements in technology increases the variety, functionality and degree to which tools can be integrated, this nimble approach allows courses to be continuously enhanced and remain technologically relevant. In terms of design courses, instructors are at liberty to include or exclude tools as they build their virtual classroom. As the selection of the tools would be based on their usability, the tools themselves would be more natural and familiar, thereby eliminating the technology learning curve for both students and instructors. In addition, as the majority of these tools are independent entities that essentially provide one service, they are simpler to understand and their development is more responsive to user needs.

For the area of design, the growth of these tools has particular significance as the subject matter and the ways in which it is taught do not fit within the established structure of learning management systems. More importantly, these tools have also changed the way online courses are perceived.

Opportunities for Online Design Courses

There is a clear match between the capabilities of Web 2.0 social media tools and the priorities of design learning. While the pedagogy of existing online design courses belie the core principles of design learning, the prudent application of new Web 2.0 technologies can push beyond VLEs and create new opportunities for providing experiences that are as fulfilling as traditional studio-based design courses.

Social media tools provide a space for “show and tell” scenarios and reflective learning. As the previous analysis revealed, these types of tools are closely aligned with the social constructivist and cognitive theories of learning. Social media services enable peer and instructor feedback in a user-friendly graphical interface while the encouragement of individual contributions fosters reflective practices. Moreover, these tools promote the “pin-up” session behaviours that instructors try to create in a physical studio. As a computer network mediates this environment, the perceived risk is lessened allowing for a more productive learning situation. As observed in the studio class, students are inclined towards peer assistance where there is a heightened level of comfort and safety.

Virtual reality/3D services like Second Life and Imvu offer an additional level of interaction. Using a computer persona known as an avatar, these services provide the opportunity for design classes to meet classmates and instructors in a real-time environment. This environment fosters dialogue akin to the intimate conversations that occur in a bricks and mortar studio. While other disciplines like law and medicine have used virtual spaces to train students on required interactions within specialized settings, in design learning there are no special equipment or protocols. Rather, design educators can use the same tool to imitate and build the kind of atmosphere of communication uniquely available in design studios.

Conclusion

If design education is intent on using the Internet as a platform, educators must adapt their applications of technologies or risk becoming irrelevant. Controlled VLEs that are currently being used to house design courses may have their place in the management functions needed to administer a course but as this research as evidenced, there is a need to open up these environments to allow for effective learning conditions.

Unlike many other subject areas, at the centre of design learning is an underlying method of inquiry and dialogue that cannot be objectively transferred to students through typical learning management systems. There is a necessary amount of real-time interaction with instructors and peers in fostering a design “know-how.”

Web 2.0 tools and services have the potential to bring engaging experiences into a virtual classroom. The growth and popularity of social networking services has created a communications space that is distinct from the confines of the physical world. By taking advantage of the rich complement of applications that comprise this alternative communication space, educators can import the reflective learning approach essential to design education.

As Manuel Castells writes in The Information City, “[a] technological revolution of historic proportions is transforming a fundamental dimension of human life: time and space.” (1) It is now imperative that its implications be understood and explored.

Appendix A: Prototype Course

To demonstrate how an online course environment comprised of Web 2.0 tools could be conducive to online design learning, a prototype design course that integrates Second Life, Moodle and a variety of media sites was developed to show their potential.

For the course, Second Life, a virtual 3D social space is used as the main platform for interaction while Moodle, an open-source course management system, forms the administrative back-end to provide a secure repository for course-related paperwork. Additional media such as videos, images and web blogs are drawn into Second Life and are used as supporting material when needed.

Second Life was chosen to act as the interface component of the course because as an immersive social environment it can function as a close surrogate to actual face-to-face conversations. As Jim Blascovich describes in his study on social psychology and immersive virtual environments, social presence is a psychological rather than physical state where "the individuals perceives himself or herself as existing within an interpersonal environment." (130) Therefore, with virtual spaces and avatars the reflective dialogues so ingrained in design learning can be brought online without sacrificing the operational value of studio-based learning.

Moodle, meanwhile, was chosen because of its ability to connect with outside resources and its wide adoption rate. As an open-source program, Moodle can be modified and adjunct services added as required. That it has a high install base is an added advantage, helping to shorten the necessary learning curve.

The technology used to link the Second Life environment and Moodle comes from a UK-based research initiative called Sloodle (simulation linked object oriented dynamic learning environment) funded by Eduserv. Development and updates to their open-source work continues to enhance the collection of tools available across both applications.

Description

The prototype course environment consists of five key areas:

- Registration and course information area – for course enrolment and disbursement of course tools
- Auditorium – for general whole class meets and presentation-style lessons
- Student breakout rooms – for informal group meetings and peer gatherings
- Gallery – for the display of exemplar student work
- Office space – for one-on-one dialogues between students and instructors

The first two spaces, registration and auditorium, are areas that have would be typical of any course regardless of subject matter. The latter three were created based on the needs of design learning as discussed in this research.

Registration and Course Information Area

This will be the initial point of entry for the course environment. As shown in Figure 7, this area consists of a registration booth set up to allow for enrolment, an access checker that verifies enrolments, a vending machine (containing in-world tools) and an information dispenser (containing a folder of note cards with the course description, schedule and project briefs). Each resource is accessible by a simple touch from the avatar.

Similar to the administrative processes needed for physical classes, this area provides the requisite tools for students to enrol in and access the Second Life environment. More importantly, the initial in-world enrolment will link the students' avatars to their real-world identities.

The access checker, functioning much like lab access cards issued to students in the real world, enables an added level of security to ensure that only registered students gain access to course resources.

Finally, the vending machine and course information dispenser serve as convenient repositories for an unlimited supply of courseware. If students loose, corrupt or otherwise destroy their copy of the resource, supplicates can be obtained through these distributors.

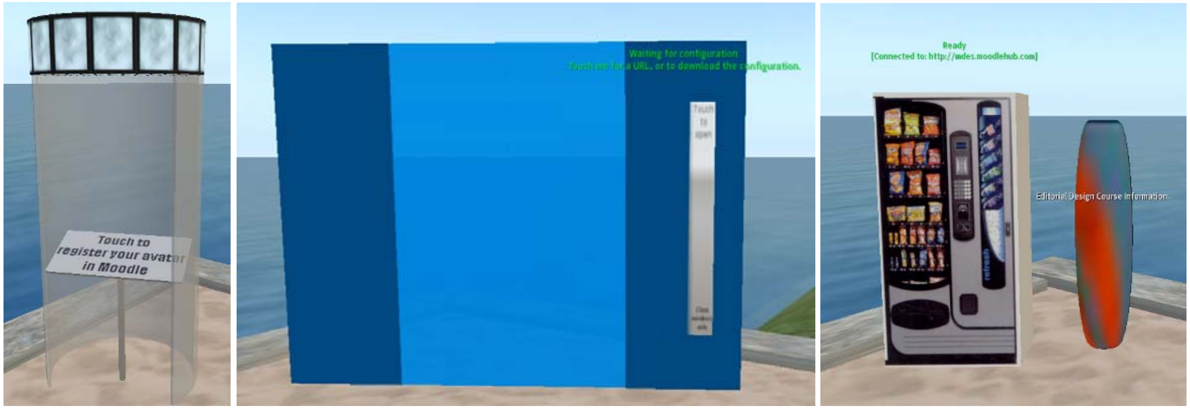

Figure 7: Booth, Access Checker and Courseware Dispensers

Auditorium

To address the component of learning where reference materials are needed, the course environment will have a lecture or theatre space where presentations, expert examples or pre-recorded movies can be shown to the entire class. As Figure 8 illustrates, this space would take the form of a familiar auditorium-style room. The only difference would be that students could return at any time to replay material.

Figure 8: Auditorium

This area is essential to provide a “home-base” for the course. Physical classes are structured such that there is an initial gathering space for the purpose of general announcements and lectures. Even in studio-based courses like the undergraduate course that was observed, there was an expectation that the instructor would address the class as a whole or give a lecture to mark the beginning of the class.

While this group meeting place defies the conventional “advantage” of online courses – freedom from time constraints – the comfort and psychological familiarity provided by this space would allow students a smoother transition into a virtual classroom.

Student Breakout Rooms

As a gathering place for students, the breakout rooms will have a number of tools for reference and to facilitate communication. Shown in Figure 9 are the resources students would have access to when visiting the breakout rooms. The flat-screen TV can be configured to stream videos or images from external urls, the “chat logger” box allows conversations to be recorded and stored in Moodle, the laptop is a pre-programmed tool that contains resources to for students to become more familiar with Second Life and the large book is an interface for accessing a Moodle-based glossary. Figure 10 shows the breakout room in its entirety. Also shown in Figure 10, on the outside of the breakout room, is the Adobe projector where students can load their work and gather around for discussion.

Figure 9: Tools in Student Breakout Room

Figure 10: Student Breakout Room

As a low risk environment to facilitate the social constructivist “culture of criticism” inherent in design learning, the breakout rooms allow students to learn from one another. As seem in the observed editorial class, students were more inclined to give open critiques of each other’s work when not in the presence of the instructor. The breakout rooms provide an informal space for that particular learning opportunity.

Gallery

In terms of space for displaying student work, the gallery, as shown in Figure 11, incorporates additional chat loggers to record any comments students wish to leave. The gallery space provides a continued arena for interaction as well as a place for individual cognitive development.

Figure 11: Gallery

Visiting the gallery in groups, students have the opportunity to record their comments about the various work displayed using the chat loggers placed throughout the gallery. Using the Moodle interface, students would be able to retrieve the logs for later reflection.

Because instructors are displaying exemplar work in the gallery, students can also view the space as a place of “demonstration.” As Schön describes, one of the roles of a design instructor is to show or demonstrate design know-how until students are able to “imitate” that know-how in their work.

Office Space

The office space (see Figure 12), equipped with a chat logger and reference materials make up the final distinct area in the course environment. Outside of the office, a drop box is available for project submissions using an interactive sketchbook.

Figure 12: Office Space

To emulate the one-on-one critiques observed in the undergraduate design class and the reflective conversation Schön described in his study on studio learning, the office space has a comfortable environment to facilitate communication. Students have space to show the instructor their work and the additional resource room allows instructors to reference external material as appropriate for each student.

This prototype course is one example of the many possibilities available for design education. By actively experimenting with Web 2.0 tools just as other subject areas have already begun doing; virtual design learning can become a viable reality.

Appendix B: Course outline and project brief from observed class

Information pertaining to contact information has been removed to preserve the anonymity of participants.

York University / Sheridan College Joint Program in Design

Editorial Design

Optional Practicum Course Fall Term 2008–2009
[redacted]

Contact information
[redacted]

Prerequisites
Communication Design 2 (ysdn 3004) and Typography 4 (ysdn 3003).
Basic working knowledge of InDesign. Intermediate knowledge of Illustrator and Photoshop.

Course Description
This course will focus on the design of print and electronic editorial documents. Students will investigate the relationship between type, illustration, photo and graphic imagery.

Students will research a range of editorial vehicles as part of an investigation into the nature of current editorial design practice. The projects in the course will give students an opportunity to practice the skills necessary to produce effective editorial print documents.

Topical outline
- Behavioral effects of visual communication design
- Typography / image relationships
- Print fundamentals & electronic page makeup/imposition
- Editorial style and typesetting
- Documentation of the work process
- Administrative and production positions in editorial design

Learning Outcomes
Upon successful completion of the course, students will have demonstrated their abilities to:
- Understand and apply the design process in the development of effective print-oriented and electronic design solutions
- Achieve both breadth and depth in concept and image development
- Visualize concepts with clarity and economy
- Perform cross-media research
- Organize and prioritize information and work flow
- Create meaningful and emotive relationships between words and images
- Communicate verbally and in written form about work process and intentions
- Achieve professional standards in the presentation of comps and prototypes

York University/Sheridan College Joint Program in Design

Editorial Design

YSDN3011

Fall Term 2008

Course Brief

Assignment
Students will be asked to conceive a new magazine, included name, identity, format, size, grid and typeface selection. Students can select from an array of genres such as cooking, politics, lifestyle, sports, music, fashion, the arts, literature, etc.

Procedure
This process will begin with a sophisticated critical analysis covering content, audience and visual considerations. This study will include both observations as well as a personal analysis and hypothesis report. Following this research study, students will execute and develop a new Identity for this chosen publication, thus creating a new visual voice based on their findings from the research study. After completing the logo/identity design, students will begin to develop and create specs for their publication ie. type styles, leading, grids, gutters, heads and decks and implementing these master grids in Adobe InDesign. The term project will consist of three projects; Project 1 will involve designing a feature story utilizing typography only and using type as a vehicle for self expression, Project 2 will involve utilizing illustration as the main design vehicle and Project 3 will involve utilizing photography as the main design vehicle. Students can use the same manuscript for all three projects.

Grading
Research study 10%
Project 1: Magazine format and design, contents page, department page(s) 20%
Project 2: 1st Feature story design 20%
Project 3: 2nd Feature story design 20%
Project 4: Cover and logo design 20%
Attendance, participation 10%

Deadlines
Meeting 4, Research study
Meeting 5, Magazine logo
Meeting 8, Project 1 (Typography)
Meeting 10, Project 2 (Illustration)
Meeting 12, Project 3 (Photography)

Author Biography

Karen Kwan has several years of experience as a graphic designer in the private sector. She has been the Course Director and Teaching Assistant for an online design course offered by the department of Design at York University. This research was completed in partial fulfilment of the MDes (Master of Design) program at York University.

Identifying Familiarity in Older and Younger Adults

Simon Lawry, School of Design, Queensland University of Technology, Brisbane; s.lawry@qut.edu.au

Vesna Popovic, School of Design, Queensland University of Technology, Brisbane; v.popovic@qut.edu.au

Alethea Blackler, School of Design, Queensland University of Technology, Brisbane; a.blackler@qut.edu.au

Abstract

This paper discusses empirical research into the familiarity of older and younger adults with contemporary electronic devices. Prior research into the field of intuitive interaction is examined, and the links between experience, familiarity and intuitive interaction are highlighted. An experiment is presented which investigated the differences in familiarity between older and younger adults. Overall the results suggest a negative relationship between age and familiarity, but exceptions to the rule are also demonstrated. This shows that age is not a determinant of familiarity, but it is often associated with a lower level of familiarity. This research also shows that older adults show verbal cues for familiarity far less frequently than younger adults, yet still display familiarity during task execution. The implications of these findings are discussed.

Key words

intuitive interaction; older adults; familiarity; prior experience; industrial design; interaction design.

Worldwide demographic shifts (with the exception of parts of Africa) are moving towards a model which has more adults over the age of 65, in terms of both absolute numbers, and the percentage of the entire population (Fisk, Rogers, Chareness, Czaja & Sharit, 2004; Lloyd-Sherlock, 2000). There are wide reaching social implications as a result of these changes. For example, it is expected that over 50% of the workforce in Australia will be over the age of 55 by 2018 (McDonald & Kippen, 1999).

People interact with a wide array of products on a day-to-day basis, and increasingly these products are electronic, with advanced technology, and more inbuilt functions and services (Heskett, 2002; Margolin, 1995). There is movement towards a more inclusive society, yet older adults often have difficulties using these complex digital devices which are now so prevalent (Djajadiningrat, Wensveen, Frens & Overbeeke, 2004; Docampo Rama, 2001). Devices such as mobile phones, which are firmly embedded in many younger adults' lives (Eisma et al., 2003), frequently baffle older adults (Lawry, Popovic & Blackler, 2009; Pattison & Stedmon, 2006). This can create frustration, which in turn can flow on to feelings of increased social isolation, reduced motivation, and even depression (Mynatt, Essa & Rogers, 2000).

It is becoming more important, on a societal, economical, and ethical level to address the usability issues that older adults are having with modern electronic devices. There are potential benefits, not only for older adults themselves, but also for society in general. Some of these benefits include improved social integration, higher levels of independence and improved health management (Mynatt et al., 2000). All of these benefits are likely to lead to a more fulfilling life (Fisk et al., 2004), and a more valuable contribution to society.

Incorporating intuitive interaction into user interfaces is one way of enhancing the usability of contemporary electronic devices for older adults. Intuition is a cognitive process that can be utilised in interactions with a product interface. Some typical characteristics of intuitive use include a lack of awareness of intuitive behaviour, and quick purposeful interactions (Blackler, 2008). Research into intuitive use and its application to interface is a new and emerging field.

Blackler, Popovic, and Mahar (2008; 2010) identified that intuition and familiarity are related, and that various elements of an interface design can contribute to intuitive interaction. Empirical investigations revealed that older people are less likely to utilise interfaces intuitively (Blackler, 2008). This research investigates and examines the differences in familiarity between older and younger adults with familiar contemporary devices.

Intuitive Interaction

There is no single concrete definition of intuition. Bastick's (2003) comprehensive examination of intuition and Klein's (1998) discussion of the role of experience in high pressure decision making situations have both assisted in shaping an understanding of intuition. Blackler (2008) has conducted an extensive review of intuition which resulted in the following definition: "Intuition is a cognitive process that utilises knowledge gained through prior experience…" (Blackler, Popovic & Mahar, 2002). Additional properties of intuition identified in Blackler's literature review include an increase in speed, higher levels of efficiency than other cognitive processes, and a lack of consciousness regarding what is taking place. For a full review of intuition, see Blackler (2008).

There is a difference between intuition, which is a cognitive process, and intuitive interaction, which is the use of intuition in an interaction. Blackler states the following definition, highlighting the distinction:

> Intuitive use of products involves utilising knowledge gained through other experience(s) (e.g. use of another product or something else). Intuitive interaction is fast and generally non-conscious, so that people would often be unable to explain how they made their decisions during intuitive interaction. (Blackler, 2008, p. 107)

The first empirical investigations into intuitive interaction by Blackler, Popovic and Mahar (2003) reached a number of conclusions. The most relevant conclusions from this research show that interface features which are less familiar are used less intuitively, older adults use products significantly less intuitively than younger adults, and interaction speed is affected by experience and familiarity with similar products (Blackler, 2008). Blackler (2008) suggests that further investigation is required in the area of age and intuitive interaction. Indeed, Blackler, Mahar, and Popovic (2009) have conducted further investigations focusing on exploring the effects of ageing on intuitive interaction. Their investigation included an examination of the role of cognitive decline, as a result of the ageing process, on intuitive interaction. Results show that both cognitive decline and the level of technological familiarity affect time on task, number of intuitive uses, and number of correct uses. Technological familiarity was measured using a questionnaire about relevant electronic devices and how familiar the participant was with certain aspects of the devices. Familiarity had a slightly stronger effect than cognition (Blackler et al., 2009).

Hurtienne and Blessing (2007) report on the definition of intuitive use developed by the Intuitive Use of User Interfaces (IUUI) research group from the Technische Universität Berlin: "A technical system is intuitively usable if the user's subconscious application of prior knowledge leads to effective interaction" (Hurtienne & Blessing, 2007, p. 2). Hurtienne is focusing his research on intuitive interaction with image schemata. Image schemata are knowledge structures that are based upon an understanding of the world developed through interacting with our environment (Hurtienne & Blessing, 2007).

The Engineering Design Centre at Cambridge University is investigating the role of prior experience within inclusive design. From their initial experiments they have concluded that “prior experience with similar products and product features is a strong predictor of the usability of products” (Langdon, Lewis & Clarkson, 2007, p. 190).

Experience and Familiarity

Examining the definitions of intuition and intuitive interactions, the central themes of knowledge and prior experience emerge. There is a close relationship between experience and familiarity. Blackler (2008) states that intuitive interaction is based on internal and external consistency, and that external consistency relies upon familiarity. Familiarity has been defined as “…an understanding, often based on previous interactions, experiences and learning…” (Gefen, 2000, p. 727). Gefen (2000) describes familiarity with a product as an awareness based on experience, where one has an understanding of the behaviour, function or action. Experienced is defined as “having become skilful or knowledgeable from extensive participation or observation” (Hanks, 1990). These definitions show the importance of knowledge developed through prior interactions and experiences to familiarity, and thus also to intuitive interaction.

New products are built upon old products. New products always make reference, in some way, to the previous generation of products (Lewis, Langdon & Clarkson, 2008). Users utilise the knowledge base they have built with previous products when interacting with new products and new interfaces (Docampo Rama, 2001). If the differences between the knowledge required to use the older product and the knowledge required to use the new product are too great, then the new product may be harder to learn, use, and understand (Singley & Anderson, 1985; Sweller, 1999).

Experiment

The purpose of this experiment was to examine familiarity with contemporary devices in older and younger adults. The aim of this research was to identify potential methods to extract familiarity from users in order to design intuitive interfaces.

Experiment Procedure and Analysis of Data

The experiment was conducted in the participant’s home, as it was easier and more comfortable for the participant, and it also provides a context which is much closer to a realistic scenario than a laboratory. The experiment also required the use of familiar products that are kept in the home. Four age groups were used for the experiment. The groups were 18 – 44, 45 – 59, 60 – 74, 75+. There were four participants in each age group, four male and four female. A total of 32 participants took part in the study.

The experiment was split into two parts, with each part addressing a different experiment question (Table 1). Part A utilised a semi-structured interview, to extract information about consumer and home-based devices that the participants used. Questions were asked regarding products such as televisions, microwaves, cameras, and blood pressure monitors. The questions varied in depth from frequency of use, to what the product allows the participant to do. Part B utilised a semi structured interview, an observation, and a retrospective protocol. The interview was used to identify a familiar product, and to identify a familiar task with that product. The participant also described the step-by-step process required to execute the task, from memory, with no prompts from the product itself. The observation then required the participant to perform the activity with the device. The participants were required to deliver concurrent verbal protocol while performing the activity. The audio/visual data from the observation was captured with a digital video camera. The video of the participant performing the activity was then transferred to a laptop computer. The audio was muted, and the video played back to the participant, while the participant delivered a retrospective protocol on the interaction.

	Part A	Part B		
Data collection method	Interview	Interview	Observation	Retrospective Protocol
Experiment Question	What products are the participants familiar with, and what role do the products play in everyday life?	What are the differences in description, execution and reflection of a task with a familiar product?		

Table 1 Experiment structure

By comparing the steps the participant described to perform the activity, with the steps that the participant actually undertook to execute the task, it is possible to identify the level of familiarity the participant has with the product, and with different parts of the interaction. A coding scheme was developed in order to define the activity and provide information regarding the steps taken (Table 2).

Coding Scheme

The coding scheme was applied to the participant's description and the participant's execution of the task using the video recording of the task. Each step performed by a participant during the task execution was coded. Steps are any action the participant makes which involves the product they are interacting with, such as picking up a remote, or entering a time on a microwave. Data input, such as entering a phone number, or time in a microwave was coded as a single step, rather than multiple steps.

Each step was first coded in terms of the matching description given by the participant before hand, and also the correctness and familiarity of the step. The codes used in relation to the description were: Accurate Description, Inaccurate Description, No Description, Incorrect Description, Grouping, and Failure to Execute (Table 2). The 'Accurate Description' code is used when the description of that step matches the execution of the process exactly. The 'Inaccurate Description' code is used when the step is not quite correct, or the step is performed out of order from the process given during the description. The 'No Description' code is used when the participant performs a step and there is no mention of that step in the description given by the participant before hand. The 'Incorrect Description' code is used when the step performed is contradictory to the description given, but still leads the participant closer to the required outcome. The 'Grouping' code is used when the step performed is described in a manner which includes multiple steps in a single description.

The codes which describe each step of the interaction are the Correctness and Familiarity codes. The correctness codes are: Correct, Incorrect, and Inappropriate. A step is coded 'Correct' when it takes the participant closer to the required outcome. A step is coded 'Incorrect' when the step takes the participant further away from the required outcome. The 'Inappropriate' code is used when the step is not required in the interaction. The Familiarity codes are: Very Familiar, Moderately Familiar, and Not Familiar. These codes have been adapted from Blackler's (2008) coding heuristics, where similar codes were used to help identify intuitive interaction. The 'Very Familiar' code is used when the participant performs a step quickly and fluidly, and with no obvious thought or reasoning. The ‘Moderately Familiar’ code is used when some uncertainty is shown in the performance of the step, and the interaction is slower, and is executed with some hesitation. If a step is executed very slowly, with indecisiveness and hesitation, then it is coded as ‘Not familiar’. The concurrent protocol also contributes to the identification of familiarity, through lack of verbalisation, and in depth descriptions of possible alternative actions for example.

Category/Code	Statement	Interpretation parameters
Step Description		
Accurate description	The specific step is described correctly before hand.	A specific step is described accurately and precisely.
Inaccurate description	The specific step is described incorrectly before hand.	The specific step is described before hand, but is not described correctly.
No description	The specific step is not described before hand.	No mention of the step before interaction.
Grouping	The step is described in a manner which groups multiple steps together.	Generalisations, including multiple actions in one sentence.
Failure to execute	Step is described beforehand but not performed.	Step is described before hand, but the participant does not perform during the interaction.
Correctness		
Correct	The step is correct for the activity.	The step takes the participant closer to the required outcome.
Incorrect	The step is incorrect for the activity.	The step takes the participant further away from the required outcome.
Inappropriate	The step is inappropriate for the activity.	The step is not performed at the right time.
Familiarity		
Very Familiar	The step is very familiar to the participant.	Quick use, no obvious reasoning.
Not Familiar	The step is not familiar to the participant.	Uncertain, slow interaction.
Intermediate familiarity	The step is moderately familiar to the participant.	Some certainty shown.
Procedure identification		
Procedure	Identifying groupings of steps.	Consecutive ‘very familiar’ steps with no interaction break.

Table 2 Coding Scheme

The final code used is the ‘Procedure’ code. The procedure code is similar to the grouping code in that it identifies where several steps have been grouped together. The procedure code is used to identify groups of steps during the interaction. This differs from the grouping code as the grouping code applies to the description by the participant, where the procedure code applies to the steps the participant makes during the execution. A procedure is coded when a participant performs consecutive 'Very Familiar' steps with no gaps or breaks in the interaction. A procedure is a very fluid interaction.

Procedures are coded as periods of time, as they are coding a series of actions executed during the task. Individual tasks are coded as being grouped, rather than being coded as periods of time. This allows the grouped steps to be coded for familiarity and correctness, rather than how long the grouping lasted for.

The coding scheme was applied to the observational data using The Observer XT 8.0 (Noldus, 2009).

Analysis

By examining the coded observational data, it was possible to identify the differences in familiarity across the selected age groups. The time-event logs (or data maps) display the data from individual participants (Figures 3 and 5), while the graphs (Figures 1, 2 and 4) display the mean of the data across age groups.

It is important to note that time is not a relevant variable for this experiment. Each participant chose a product that was specifically relevant to him or her, and performed a task which was also specifically relevant to him or her. Thus a comparison of time between individuals, or age groups is inappropriate. This experiment is investigating the differences in how people remember, execute, and reflect upon a familiar task, in order to identify experiential knowledge.

Figure 1 illustrates the mean of the percentage of total steps that were coded as grouped, by age group. The youngest age group (18 – 44) demonstrate the highest percentage of steps that had been grouped with 34% of executed steps coded as grouped. The 45 – 59 age group demonstrated the next highest percentage of executed steps coded as grouped with 25%. The next age group (60 – 74) had a much lower percentage of executed steps coded as grouped, with only 8%. The 75+ age group had only 4% of executed steps coded as grouped. This shows a negative relationship between age and the percentage of executed steps coded as grouped.

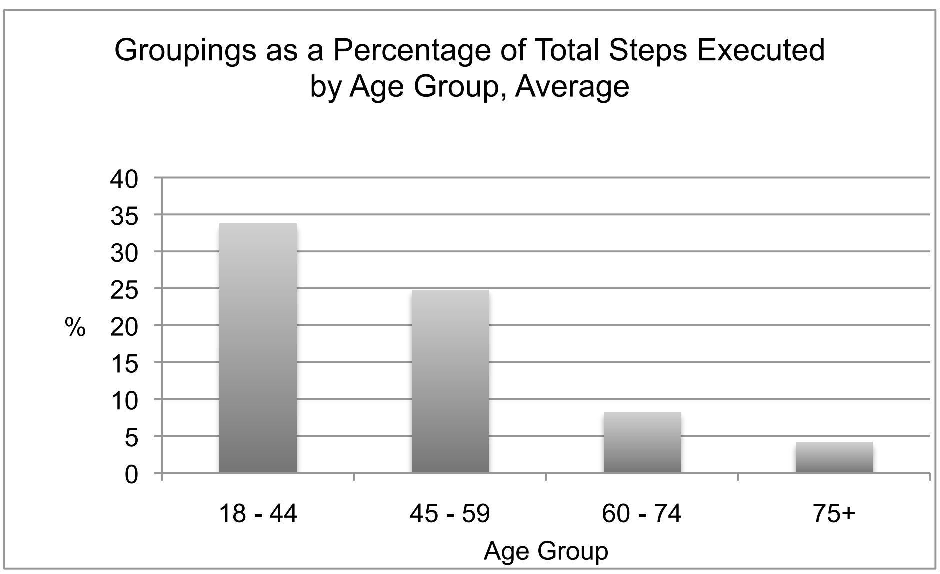

Figure 1. Mean by age group, of groupings as a percentage of total steps executed

Figure 2 shows the mean total time for which a procedure code was present during the task. It shows the mean percentage of the total task time which is spent in procedure. This illustrates that the 18 - 44 age group spends 66% of time using the product in procedure. The 45 – 59 age group spent, 44% of the total time on task in procedures. Time spent in procedure for the 60 – 74 age group was 24%. The 75+ age group spent 18% of the time in procedure. This demonstrates a negative relationship between age and percentage of time in procedure while executing a familiar task. Also, the 18 – 44 age group spends considerably more time (50% more) in procedure than the 45- 59 age group.

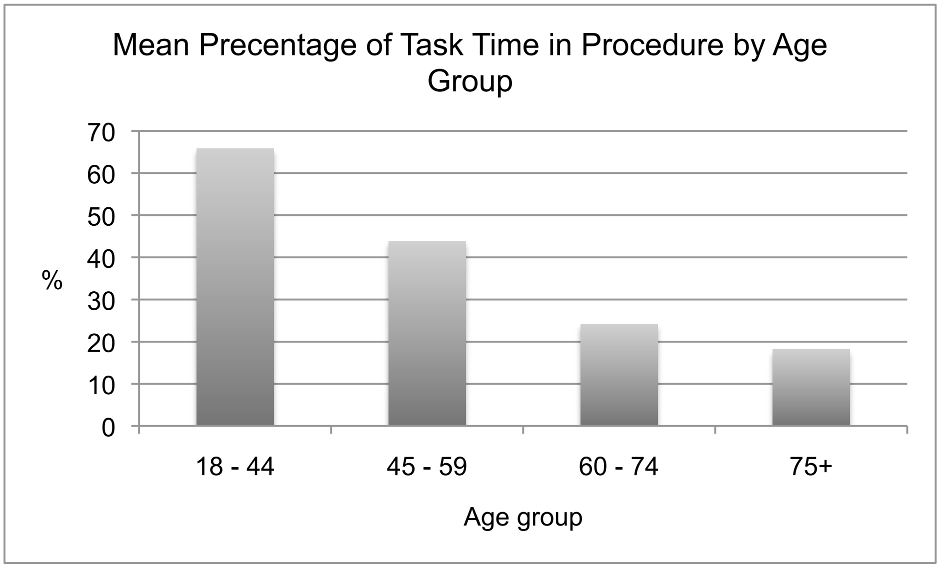

Figure 2. Mean by age group, of percent of task time spent in procedure

The time during the task execution where the participant was in procedure was isolated. The time in procedure was analysed in terms of whether grouping occurred with in the procedure or not, and by age, and step description. An example of the map created highlighting the time the participant spent in procedure can be seen in Figure 3.

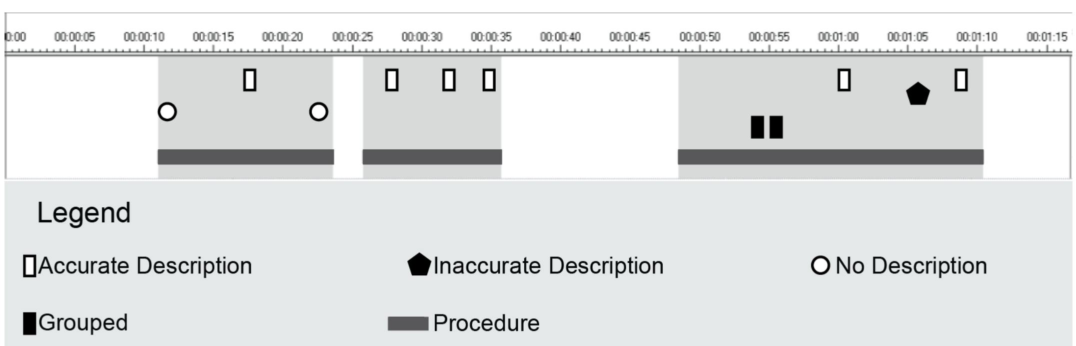

Figure 3. Example of data map showing procedures isolated

The light grey areas show the areas where the data is being displayed (Figure 3). Each vertical mark represents a coded step. In this example you can see that within the first procedure, the participant executed two steps that were coded as 'No Description' and one coded as 'Accurate Description'. The second procedure contained three 'Accurate Description' steps. The third procedure contained two 'Grouped' steps, two 'Accurate Description' steps, and one 'Inaccurate Description' step.

Figure 4 shows the percent of procedures that contained grouped steps. In other words, this displays the percent of performed procedures which were described beforehand as a grouping. The 18 – 45 year old age group had 71% of procedures conducted include grouped steps. The 45 – 59 age group had 50% of the procedures they executed contain grouped steps. The 60 – 74 age group had 22% of the procedures they executed contain grouped steps and 11% of the procedures the 75+ age group executed contained groupings. This displays a negative relationship between age and the occurrence of grouped steps within procedures. The data presented is the mean of each age group.

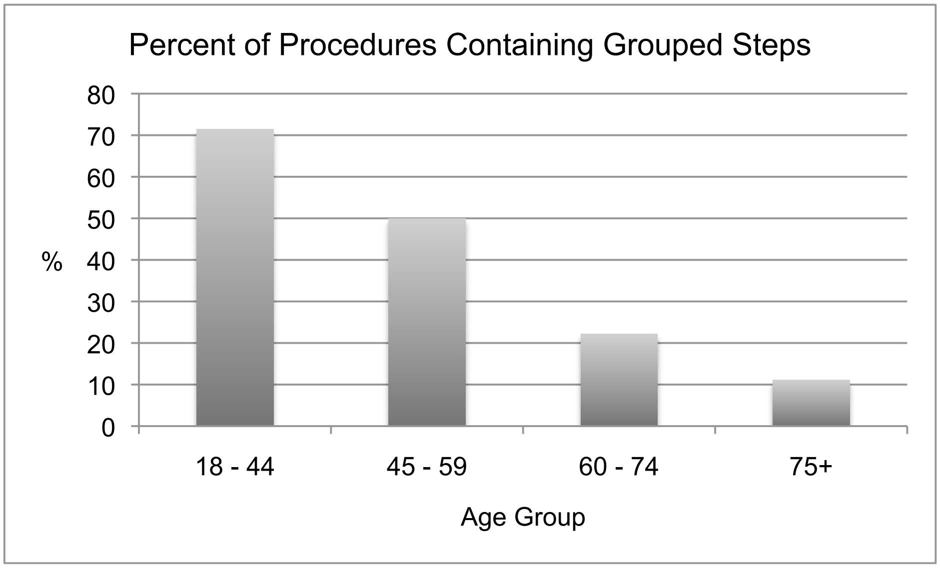

Figure 4. Percent of procedures, by age group, containing grouped steps by age group

The data presented to this point suggests that, generally, age has a negative relationship with familiarity. Figure 5 shows maps of three participants from different age groups. The following maps show that individual familiarity can be high regardless of age. The first is an example from a participant in the 18 – 44 age group. The second, a participant from the 45 – 59 who exhibited a high level of familiarity. The third map is an example from the 60 – 74 age group. The second and third maps demonstrate a high level of familiarity comparable to that of the participant from the youngest age group.

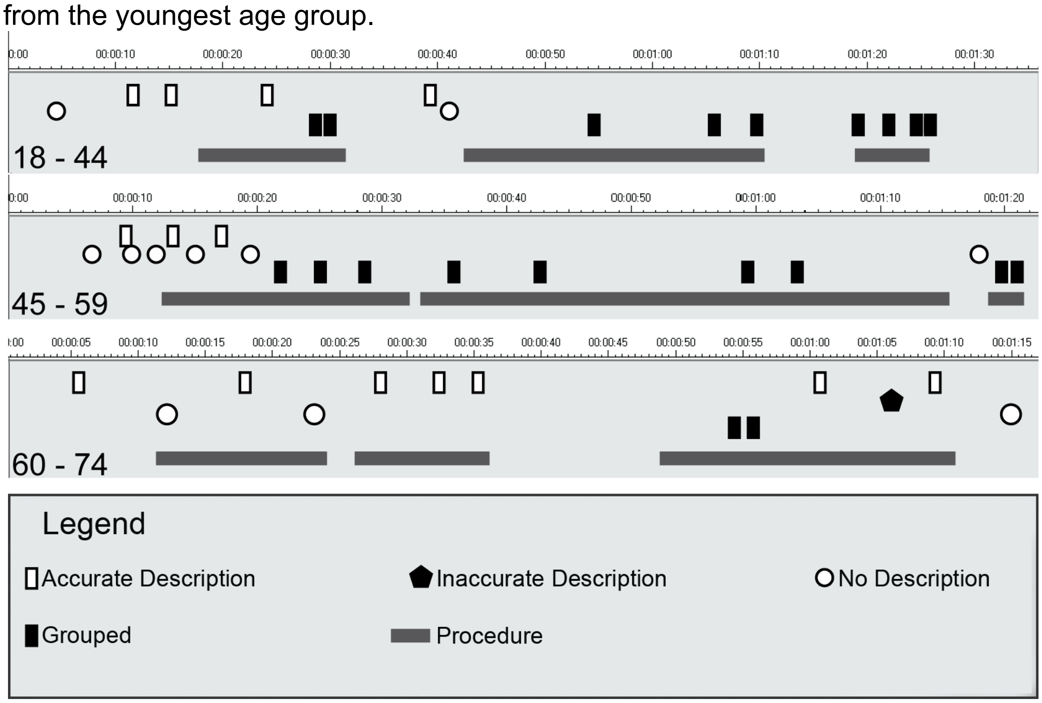

Figure 5. Examples of participants displaying high familiarity over different age groups

The levels of familiarity displayed are fairly similar. All three participants spend over 50% of their time in procedure. The 18 – 44 year old participant spent 50.4% of task time in procedure (mean for age group is 65.8%), the 45 – 59 year old participant spent 77.4% of task time in procedure (mean for age group is 43.9%) and the 60 – 74 age group participant spent 58% of task time in procedure (mean for age group is 24.2%). The number of grouped steps is the same between the 18 - 44 year old and the 45 – 59 year old at 9, while the 60 – 74 year old grouped only 2 steps together.

Discussion

There are some interesting results demonstrating the difference in familiarity across different age groups. In general, the results suggest that familiarity decreases with age, in the execution of a familiar task with a familiar product. The analysis shows negative relationships between age and the occurrence of both groupings and procedure. This suggests that age is a predictor of familiarity. Figure 5 shows that older participants can be just as familiar, if not more so, than their younger counterparts. Despite the analysis suggesting a negative relationship between age and familiarity, the findings in Figure 5 demonstrate that there are exceptions showing older adults who are just as familiar as younger adults, if not more so. Indeed, Fisk et al. (2004) say that age results in an increase in wisdom experience and knowledge. Vercruyseen (1997) states that age does not have to limit motor behaviour, and the use of adaptive behaviours of will put an older adult on par with younger adults (Bosman, 1993; Czaja & Sharit, 1998; Lundberg & Hakamies-Blomqvist, 2003).

Groupings

Groupings are the integration of a series of steps which would be executed during a task, into a single description. For example, a participant described the process of entering all of a new contact's data into his mobile phone as 'Input'. The participant condensed the six consecutive steps he executed when performing the task in to a single word description. It is suggested that this grouping occurs with a high level of familiarity. The participant knows the process so well that, in his mind, the series of steps required to execute that part of the task is only a single action.

The findings show that the 18 - 44 age group has a higher percentage of total steps as groupings compared to the other age groups (Figure 1). This ratio declines with each consecutive age group. This implies that, as age increases, a familiar task with a familiar product is less likey to be described using groupings.

Some possible explanations for these findings include declines in memory and recall functioning, and speech and verbalisation function, as a result of ageing (Gregor, Newell & Zajicek, 2002; Hawthorn, 2000; Klein & Scialfa, 1997). Reductions in memory and recall function could affect the ability of participants to accurately remember the task. Reductions in speech and verbalisation could prevent participants from communicating exactly what they are recalling.

Procedures

Procedures are the integration of a series of disparate steps executed in a task into a single fluid action. Some signs of a procedure displayed by the participant can include: no hesitation when starting a procedure, no or very little verbalisation during the procedure, brief verbalisation once the procedure is complete, fluid or flowing movements, and no pauses in between individual task steps. It is suggested that a procedure is a demonstration of familiarity, as procedures exhibit many of the characteristics of intuitive interaction that Blackler (2008) discusses, and as discussed earlier, familiarity is an important aspect of intuitive interaction.

Figure 2 shows the youngest age group spends the highest amount of time in procedure. It is found that the amount of time spent in procedure declines with each subsequent age group. The 75+ age group spends a mean of 48% less task time in procedure than the 18 – 44 age group. This could also represent a lower level of familiarity amongst older user with familiar tasks and familiar devices.

Some of these findings could be explained by a decrease in motor function (Vercruyssen, 1997) and visual and audio processing, increasing feedback processing time (Hawthorn, 2000), and cognitive load as a result of ageing (Korteling, 1994). It has been reported that delivering concurrent protocol can increase difficulties for older adults when using unfamiliar interfaces (Dickinson, Arnott & Prior, 2007). This could also apply to familiar products.

The Relationship Between Groupings and Procedures

There is a strong relationship between groupings and procedures (Figure 4.). They are very similar, in that they are the integration of steps into a process. The difference is that groupings concern the integration of the description of the steps of a process into a single descriptive word or sentence, while a procedure is the integration of distinct steps of a process into a smooth, flowing action. Groupings are descriptive, and thus they are based on the knowledge that an individual has of a device. This knowledge can be accessed without the device present, and Norman (2002) refers to this as “knowledge in the head”. Procedures, on the other hand, are context based and are always performed with the device. The device provides feedback and prompts, as the users interact with it, enabling easier recall. Norman (2002) refers to this as “knowledge in the world”.

Groupings almost always occur within a procedure. Of the steps that were coded during procedure, 94% were coded as grouped. This may occur as procedures have additional prompts and feedback from the device. This could mean there are more opportunities to recognise the next step. Groupings do not have additional prompts. The only prompt is what participants can recall from memory. Thus it is argued that it may be more difficult to form a grouping than a procedure, as the grouping has less prompts, and relies solely on memory (Norman, 2002). This could explain why groups fall within procedures most of the time.

The data shows that the younger a person is, the more likely a procedure is to have steps described as a group (Figure 4). The youngest age group had groupings in 71% of procedures, while the oldest group had groupings in only 11% of procedures. This shows that, as age increases, an individual is more likely to show familiarity through their actions rather than through the description of process. Thus older adults should not be considered unfamiliar with a particular product or task if they do not group the task description. This has implications for designers performing user research on older adults. This shows that verbal cues for familiarity and experience do not adequately demonstrate actual familiarity that older adults have with products. Observations allow the adequate identification familiarity, which can then contribute to the design of more intuitive interfaces.

Groupings almost always occur within procedures. This suggests that if people use a grouping when describing a task, then they have a high level of familiarity, as the grouping would also suggest a procedure would occur on execution of the task. Using a task description and groupings to identify familiarity is likely to demonstrate more familiarity for younger adults than older adults, as younger adults use groupings more than older adults (Figure 4). As groupings only identified a total of 44% of procedures, it is suggested that such a method is inadequate as a sole measure of familiarity, especially with older adults.

Conclusion and Future Research

The aim of this research was to discover methods that elicit familiarity from individuals regarding contemporary electronic devices. The findings of this research show that familiarity can be identified by determining if a user integrates successive steps of a task into a single step or process. This can occur in terms of both action, and the description of that action. It also shows that familiarity, both in terms of grouping and procedure, declines with age.

The data suggests that a process involving task description could be one possible way to quickly and easily identify familiarity. These findings suggest that if a participant was to use a grouping in the description of a task, it is likely that they would be very familiar with that part of the process. However, the data reveals a method such as this is likely to be less effective with older adults, as the older an individual is, the less likely they are to display their familiarity in the form of a grouping (Figure 4). Also such a method would exclude 66% of procedures, another indicator of familiarity. The analysis suggests that a method that incorporates the evaluation of both task description and task execution is required to get definitive insight into participant familiarity.

This research identifies characteristics of familiarity, such as verbal groupings and smooth interactions flow, that are present in different age groups. It also shows different ways in which individuals express familiarity. This research is significant because it demonstrates the differences in how familiarity is shown by younger and older users. The research techniques used also contribute significantly to the field by demonstrating some potential ways to identify that familiarity.

Further research will attempt to replicate the findings of this study. Additional areas of investigation may include comparing very familiar older adults with very familiar young adults, explorations of possible ways to identify proceduralised steps without the device present, and additional testing around the familiarity of older adults.

Simon Lawry

Simon is a PhD Candidate in the School of Design at the Queensland University of Technology, in Brisbane, Australia. His research focuses on the intersection of experiential knowledge, industrial and interaction design, and intuitive interaction. This aim of this research is to enhance the independence of older adults by helping designers create more usable products. He is in his third year of PhD.

Vesna Popovic

PhD, is a Professor in Industrial design in the School of Design at the Queensland University of Technology (QUT), and she is the founder of the Industrial Design infrastructure in Brisbane, Australia. She has made an international contribution to product design research where she has integrated knowledge from other related areas and applied it to artifact design in order to support and construct design applications. In particular, she has been a forerunner of human-centred design research as applied to artefact, services and systems. The impacts of her work lie in the cross-fertilisation of knowledge across humanities and technology to design and produce humanised artifacts as well as to enhance our culture by facilitating understanding between professionals with diverse expertise and experience. She has published widely and is the recipient of numerous awards and research grants. She is a Fellow of the Design Institute of Australia and Fellow of the Design Research Society (UK). She was an Executive Member of the International Council of Societies of Industrial Design (ICSID) from 1997 to 2001 and co-founder of ICSID Education Conference in 2001. Since 2001 she has been an ICSID adviser.

Alethea Blackler

PhD, is a senior lecturer in the School of Design at Queensland University of Technology. Her principle areas of research interest are the intuitive usability of products and design history and criticism education. She is currently working on intuitive interaction for older people and also design methodologies for intuitive interaction. She has received various grants and awards for her research and teaching, most notably an ARC Discovery grant of $280,000 for Facilitating Intuitive Interaction for Older People. She was the first to address intuitive interaction in any depth and the first to publish any empirical research in this area. She has now been working in the area for ten years and has applied her research to commercial projects. She is a member of the Design Research Society.

Complexité architecturale et assistance informatique

Caroline Lecourtois, Ariam-Larea, Ecole D'architecture de Paris le Villette, France, e-mail : Caroline.lecourtois@ariam-larea.archi.fr

Abstract

Depuis plus de trente cinq ans en France, un champ de recherche visant à expliciter la conception architecturale dans sa complexité se développe sous le vocable d' «Architecturologie». Aujourd'hui construit sous forme d'une connaissance scientifique, ce champ présente un langage théorique systémique dont le concept majeur a pour terminologie « *espace de la conception* ». Construit et décrit en tant que «*système complexe*», l'«*espace de la conception*» est posé par l'architecturologie comme lieu mental abstrait et théorique d'intrication de diverses opérations cognitives de la conception.

En tant que méta-savoir fondamental, abstrait de toute réalité concrète, l'architecturologie procède d'une pensée complexe et vise à construire une connaissance complexe de la conception prise comme activité cognitive elle-même complexe. De nos jours, cette connaissance fait l'objet d'une réflexion sur ses possibles applications. Elle est ainsi prise comme modèle pour une approche «clinique» de cas physiques et/ou scientifiques, concernés par la conception, tels que la perception architecturale et la modélisation informatique de l'architecture en projet.

Cette approche « clinique » amène, au regard de la complexité constitutive d'un «*espace de la conception*», à poser une complexité constitutive d'un «*espace de la perception*» et une complexité constitutive d'un «*espace de la modélisation*». Tandis que l' «*espace de la conception*» est descriptible en termes *d'échelles architecturologiques*, l'« *espace de la perception* » l'est en termes de *qualités* et l'« *espace de la modélisation* » le sera en termes d'opérations de modélisation.

La question posée ici, est celle d'un nouvel outil qui vise à produire une nouvelle assistance logique à la complexité de la conception architecturale : ESQUAAS. Produit de deux niveaux de programmation, l'un procédant d'une pensée simplexe et l'autre d'une pensée complexe, ESQUAAS interroge les «*reliances*» indispensables à l'assistance des opérations de la conception architecturale.

Architecturologie, conception architecturale complexe, assistance informatique

Abstract

A field of research that aims to explain the architectural design in its complexity develops itself, in France, under the name of "architecturology", for over thirty five years. Now manufactured as scientific knowledge, this field is constituted with a systemic theoretical language whose main concept is "space of conception". Built and described as a "complex system", the "space of conception" is posed as an abstract and theoretical concept which regroups intricacy cognitive operations of conception (design).

As a meta-knowledge, abstracted from any reality, Architecturology proceeds from a thought of complexity and aims to build an intricate knowledge of design posed as a complex cognitive activity. Today, this knowledge is the subject of a research on its possible applications. It is thus considered as a model for a "clinical" point of view that helps to approach physical and / or scientific cases, concerned by design, such as architectural perception and computer modeling of architectural project.

With this "clinical" approach, like the complexity that constitutes the "space of conception", it is possible to build other scientific concepts to describe the complexity of the cognitive mechanisms of architectural perception and computer modelling: a "space of perception" and a "space of modeling".

The complexity of the “space of conception” is described with the architecturological concept of “architecturological scales”. The complexity of the "space of perception" is described in terms of architectural qualities and, those of the "space of modeling" will be described in terms of modelling operations.

This article deals with a new computer tool that aims to support the complexity of architectural design: ESQUAAS. Proceeding from two levels of programming, one carrying a thought of simplexity and the other a thought of complexity, ESQUAAS conducts to question the necessary "reliance" to support the cognitive operations of architectural conception.

> « La *vérité scientifique n'est pas dans la certitude théorique. Une théorie est scientifique non pas parce qu'elle est certaine mais parce qu'elle accepte de se faire réfuter soit par des raisons logiques, soit par des raisons expérimentales ou d'observations.* »
>
> (Morin et Le Moigne 1999 : 37)

En France, un champ de recherche nommé « Architecturologie » - champ auquel j'appartiens depuis plus de dix ans - se développe depuis plus de trente cinq ans en vue d'expliciter au mieux la conception architecturale dans sa complexité. Ce champ a été proposé et « *structuralisé* » par Ph. Boudon et son équipe du Laboratoire d'Architecturologie et de Recherches Epistémologiques sur l'Architecture (LAREA), à partir de l'idée de constituer un *logos* de l'Architecture c'est-à-dire, un savoir universitaire qui soit propre à l'architecture. Posant à cet effet que ce qui caractérise l'architecture est d'être pensée, conçue et *mesurée,* ce champ de recherche produit, depuis les années 70, des connaissances scientifiques focalisées sur les opérations cognitives de la conception architecturale (Boudon et al. 1994).

Un des concepts majeurs de cette connaissance scientifique a pour terminologie «*espace de la conception*». L' «*espace de la conception*» est l'objet scientifique même que l'architecturologie se donne d'expliciter. Construit et décrit en tant que « *système complexe* », il est posé comme lieu mental abstrait et théorique d'intrication de diverses opérations cognitives de la conception. Ces opérations cognitives de la conception architecturale sont celles par lesquelles sont données formes et mesures au projet. Elles constituent une liste de vingt-et-une classes de manières de faire référence à un domaine particulier pour penser les mesures du projet. Ces manières sont conceptualisées sous le vocable de pertinences et ces classes sous celui d'« *échelles architecturologiques* ».

Chaque classe, chaque échelle se présente comme un micro-*système* complexe opératoire de possible description de cet « *espace de la conception* ». Elle renvoie à l'activité mentale du concepteur qui consiste, de quelques manières, à attribuer des échelles – au sens architectural du terme, c'est-à-dire de tailles relatives - au futur édifice ou espace.

Cette communication a pour objet d'expliciter la complexité que construit l'architecturologie de la conception architecturale. Interrogeant l'activité cognitive complexe de la conception, cette connaissance se développe sur le paradigme de « la pensée complexe ». Introduisant ainsi, de fait, un double jeu de la complexité, cette communication amène à questionner la complexité sous deux formes, une complexité théorique et une complexité empirique et, à investiguer les résistances de la dernière à être décrite par la première (Le Moigne 2007).

La première partie présente ce champ scientifique qu'est l'architecturologie en vue de préciser son potentiel à être « *mis en application* » pour l'étude d'une complexité de l'activité de conception architecturale que renouvellent les usages des outils informatiques. La deuxième partie présente une réflexion que nous avons en cours à l'ARIAM-LAREA et qui concerne un nouvel outil d'assistance informatique à la conception architecturale, nommé ESQUAAS : ESQUisse Architecturologiquement Assistée par Ordinateur.

Architecturologie et complexités de l'architecture

L'architecturologie est donc un champ de recherche qui porte sur l'activité cognitive de la conception architecturale. Il offre aujourd'hui un langage théorique *a priori* qui peut servir de grille d'approche de cas particuliers (Lecourtois 2005). La question que cette partie aborde est celle de la complexité que construit ce langage de la conception architecturale.

Complexité / pensée complexe

S'interroger sur la manière dont un champ construit une connaissance « complexe » d'un objet scientifique qu'il se donne, suppose de s'accorder sur ce que ce terme recouvre. Je m'appuierai ici sur E. Morin et J. L. Le Moigne qui proposent d'interroger la complexité non tant comme un phénomène que comme une activité scientifique d'approche qu'ils nomment : « la pensée complexe ».

« La pensée complexe » selon ces auteurs, consiste à s'interroger sur les relations entre le tout et les parties d'un objet, posant que la somme de ces dernières ne correspondrait aucunement au tout de l'objet. Autrement dit, « la pensée complexe » interroge les « *reliances* » au sens d'activation de liens (Le Moigne 2008) plutôt que les parties. La pensée complexe s'opposerait par conséquent à la pensée classique qui discrétise le savoir, en créant ou recréant des relations bref, en reliant.

Cette modélisation de la complexité s'appuie sur la célèbre phrase de B. Pascal - « *je tiens impossible de connaître les parties sans connaître le tout non plus que de connaître le tout sans connaître particulièrement les parties* » - ainsi que sur l'étymologie du mot complexité - "Complexus" - qui désigne le produit de ce qui est tissé ensemble. La pensée complexe a pour objectif de considérer les diverses interactions qui participent de la construction d'une contingence. E. Morin prend l'exemple du mot et de la phrase pour expliciter l'objet de « la pensée complexe », un mot ne prenant sens qu'au sein de son contexte syntaxique.

Penser complexe c'est, autrement dit, interroger les relations entre les objets et leurs contextes en vue d'en saisir le sens. La sémiotique Peircienne en serait un exemple. Penser le signe par un modèle triadique reliant un Representamen, un Objet et un Interprétant témoigne, en effet, d'une pensée complexe du signe (Peirce 1978).

Cette acception de la complexité se disjoint, me semble t-il, de l'approche essentialiste de la complexité que développe D. G. Emmerich : « *Aussi riche ou compliqué que soit, en apparence, une composition, le fait qu'elle possède un grand nombre d'articulations en soi ne permet pas de l'appeler complexe, car il est nécessaire que la structure soit décomposable en parties caractéristiques de sa constitution, autrement dit en sous-ensembles. Et si la structure de ces sous-ensembles est à son tour décomposable en d'autres groupes caractéristiques et ainsi de suite, on peut alors parler d'une complexité de plusieurs degrés*. » (Emmerich 1966-1967)

D. G. Emmerich pose la complexité comme un tout susceptible de faire l'objet d'une décomposition en sous-parties identifiables. « La pensée complexe » portée par H. Simon, E. Morin et J.L. Le Moigne se pose, quant à elle, comme une approche épistémologique, heuristique et logique dont l'objet scientifique est le principe d'organisation de « *reliances* » participant de la composition. D. G. Emmerich définit la complexité par la décomposition, les auteurs de « la pensée complexe » l'interrogent en termes de « *reliances* » écartant, de fait, de leur réflexion, l'identification et la nature mêmes des entités reliées.

Le point de vue de D. G. Emmerich se rapproche davantage de celui d'A. Berthoz, physiologue de la perception et de l'action, qui propose de s'interroger sur un phénomène d'adaptation qu'il propose de nommer *simplexité*. A. Berthoz (2009) distingue la *simplexité* de la simplification et place sous le concept de *simplexité* un mécanisme cognitif par lequel le cerveau traiterait des situations complexes suivant des principes simplificateurs. La *simplexité* serait un phénomène physiologique d'adaptation de l'être à la complexité de son environnement.

Ce concept permet, me semble-t-il, de poser une distinction entre complexité empirique et complexité théorique. A. Berthoz pose la complexité du côté de l'empirie et la simplexification comme mécanisme mental nécessaire à sa gestion. Dans son ouvrage "la simplexité", A. Bertoz critique l'architecture qu'il pose comme produit d'une réflexion simple et non simplexe. Cette critique amène à pointer une évidence pour les architectes : la complexité architecturale ne se voit pas tandis qu'elle participe des mécanismes de la conception qui la précèdent.

Conception / conception architecturale / espace de la conception

Revenons ici sur le terme conception qui peut porter à confusion lorsqu'on l'approche à partir de deux domaines franchement différents comme ici, la production de connaissances scientifiques et, la production de l'architecture.

J'ai, plus haut, fait référence à J. L. Le Moigne. J.L. Le Moigne est un scientifique qui a pour objectif de construire des connaissances épistémologiques faisant une disjonction majeure entre les sciences d'analyse et les sciences de conception. Il définit son activité comme suit : « *Modéliser pour comprendre et concevoir pour faire, voilà à peu près les deux devises qui jalonnent* *notre activité cognitive* » (Le Moigne 2007 : 343). Dans cette citation, l'expression « *concevoir pour faire* » ne concerne pas l'architecture tandis qu'elle concerne la science.

Par « *concevoir pour faire* » est ici entendue une activité cognitive par laquelle raisonner sur les modèles produits de l'activité de modélisation scientifique et, visant à *faire* de la science. Cette acception se distingue de la notion de "conception" posée par l'architecturologie en tant qu'activité cognitive visant à produire un nouveau projet (par la précision ses formes et mesures architecturales) en passant par la réalisation de modèles de représentation de ce dernier, qui , lui, n'existe pas encore.

Dans le cas de l'architecture, les modèles produits par les architectes, sont des artefacts, des faits de l'art qui ont pour objectif de simuler des objets qui n'existent pas encore. Si l'architecte comme le scientifique raisonne sur et à partir de modèles, ils ne le font pas de la même façon ni dans le même objectif. L'expression "observateur-descripteur-concepteur" forgée par E. Morin pour désigner le praticien en sciences, sied ainsi à l'architecturologue mais non à l'architecte. L'architecturologue vise la production de connaissances sur l'activité cognitive de la conception architecturale. Il en construit une description qui participe de la conception de son champ scientifique. L'architecte, quant à lui, conçoit de futurs artefacts. Si, en en prenant connaissance, l'architecturologie peut l'aider à comprendre l'architecture pour la faire, elle, ne fait pas d'architecture pour la comprendre. Son activité est autre, elle est de modéliser la conception de manière *a priori* pour la rendre intelligible, et non pour en faire.

Plus précisément et suivant Ph. Boudon, « l*'architecturologue ne se propose pas de connaître l'espace architectural, mais l'espace de la conception qui a présidé à sa « conception »* » (Ph. Boudon *in* Demailly A. et Le Moigne J.L. (dir.) 1986 :440). Autrement dit, l'objet scientifique de l'architecturologie est représenté par son concept premier : « espace de la conception ». L'activité architecturologique consiste alors à construire d'autres concepts élémentaires (seconds) en vue de décrire et/ou expliciter cet « espace de la conception ». « Echelle architecturologique », « propriété d'échelle » et « relation d'échelles » sont de ceux-là. Il s'agit donc de modéliser la conception, dans sa plus grande généralité, en désignant l'ensemble des opérations possibles de la conception, de manière *a priori*, et, en s'écartant d'une démarche d'observation de cas.

Pour préciser cette posture, Ph. Boudon s'appuie sur la distinction posée par H. Simon entre état et processus et, pose l'objet de l'architecturologie du côté du processus et non de celui de l'état. L'architecturologie n'a pas pour autant pour objet de décrire (ou construire) le processus de la conception architecturale ni d'en expliciter des diachronies processuelles. Le temps ou la description chronologique de la genèse de l'architecture résiste en effet au principe de l'architecturologie qui est de produire une connaissance générale valable quelque soit le projet. Le processus de la conception architecturale n'existe pas en soi tandis que des processus de la conception architecturale procèdent de contingences singulières et, de fait, participent d'expériences dont on ne peut construire de manière *a priori* (principe de l'architecturologie), une théorie.

L'« *espace de la conception* » constitué par l'architecturologie s'exprime donc en termes d'opérations de conception posées comme systèmes unitaires de l'activité de conception. La succession empirique des opérations en est volontairement écartée.

La modélisation architecturologique procède par ailleurs d'une *réduction* de l'architecture à l'activité cognitive qui la génère et qui est posée comme distincte (bien qu'y participant) des mécanismes du projet architectural. Cette réduction, qui peut paraître néfaste pour la connaissance complexe, permet d'éclairer et/ou de constituer des complexités opératoires intéressantes et riches d'enseignement.

Cette remarque peut choquer au regard des propos d'E. Morin : « *la complexité est invisible dans le découpage disciplinaire du réel. En effet, le sens premier du mot, qui vient du complexus latin, signifie : ce qui est tissé ensemble. Le propre, non pas de la discipline en soi, mais de la discipline telle qu'elle est conçue, non communicante avec les autres disciplines, fermée sur elle-même, désintègre naturellement la complexité.* » (Morin 2007 :29)

Il est un fait, l'architecturologie ne porte pas sur l'architecture en général. Elle se concentre sur un objet scientifique qu'elle construit en s'abstrayant de cet objet empirique. Pourtant, son objet n'est pas de simplifier mais de construire un objet scientifique, suivant les principes de la pensée complexe, en termes de « reliances ». Elle sépare son objet de l'empirie pour construire une complexité théorique de la complexité empirique de la conception architecturale, qu'elle nomme « espace de la conception ».

L'« *espace de la conception* » architecturologique est explicité par vingt-et-une échelles architecturologiques qui, chacune, représente une classe d'opérations de conception de formes et de mesures architecturales. Chacune de ces échelles représente, autrement dit, une complexité opératoire relative à un domaine de références. Par exemple, l' « *échelle parcellaire* » désigne l'ensemble des opérations de conception que l'architecte est susceptible de mettre en œuvre relativement à la prise en compte de la parcelle du projet. Une parcelle peut être caractérisée par ses limites, sa forme, sa surface, son orientation et sa topologie. Chacune de ces propriétés peut entrer en jeu dans la pensée de l'architecture. L'architecte peut s'y référer pour choisir la forme de son projet, positionner son projet, le découper, l'orienter et /ou le dimensionner. Positionner, se référer, découper, dimensionner, orienter, choisir une forme sont diverses opérations de la conception (autrement nommées « *scalèmes* » en architecturologie) qui peuvent être combinées pour penser le projet. J'ai ailleurs, à l'occasion d'un travail sur la collaboration en conception architecturale (projet Cocréa financé par l'ANR), mis en évidence dix opérations élémentaires de collaborations possibles qui peuvent également constituer des complexités opératoires pour la conception : 1) établir les propriétés d'un domaine de référence, 2) positionner le projet, 3) découper le projet, 4) établir des références architecturales, 5) énoncer des précisions programmatiques, 6) se référer, 7) hiérarchiser les domaines de référence, 8) orienter le projet, 9) Dimensionner le projet, 10) évaluer le projet.

Les « *échelles architecturologiques* » discrétisent donc la conception architecturale en domaines de références mis en œuvre par des opérations d'attribution de formes et de mesures à l'architecture. Des « reliances » de cette discrétisation sont pensées sous les vocables de « *propriétés d'échelle* » et « *relations d'échelles* ».

Les « *propriétés d'échelle* » (être initialisante, structurante, principale ou dominante par rapport au processus) spécifient les places et rôles des échelles relativement à l'ensemble du processus de la conception. Elles établissent des relations entre une classe d'opérations de conception et la conception dans sa globalité.

Les « *relations d'échelles* » (être surdéterminantes, co-déterminantes, juxtaposées, successives en cascade ou en relais), quant à elles, spécifient les relations temporelles et/ou spatiales des échelles entre elles. Ces propriétés et relations sont posées de manière *a priori,* au sens Kantien du terme*,* comme des concepts vides, qui ne prennent valeur que dans l'expérience de cas concrets.

L'architecturologie est donc une structure conceptuelle complexe qui prend la forme d'une modélisation systémique de la conception visant à expliciter la complexité de l'activité cognitive de la conception. Elle est une méta-connaissance (et un méta-langage) fondamentale et abstraite de toute réalité concrète.

Ainsi constituée, elle fait l'objet d'une réflexion sur ses possibles applications (Lecourtois depuis 2004). Cette réflexion amène à la prendre comme modèle pour une approche « clinique » de cas. Ces cas sont tant physiques que scientifiques. Le premier d'entre eux est la perception architecturale, le deuxième, la modélisation informatique de l'architecture en projet.

Espace de la perception

Cette partie fait état d'une réflexion menée à partir de l'architecturologie en vue de l'étendre à un autre domaine : la perception architecturale posée comme deuxième moment cognitif de l'architecture (le premier étant, bien évidemment, la conception).

L'objectif affiché par Ph. Boudon, dès les prémisses de l'architecturologie (Boudon 1971), est de construire une connaissance qui s'écarte de la description des édifices, pour spécifier une activité propre à l'architecture, la conception. Dans (Boudon 1990), il part de deux dessins de Steinberg représentant deux édifices aux aspects franchement différents (l'un semblant complexe ou compliqué et l'autre simple), pour marquer l'orientation de cette posture sur le phénomène complexe de la conception. Il s'aide par ailleurs de la fameuse planche aux quatre croquis de Le Corbusier pour pointer le caractère *invisible* de ce phénomène.

Dans cet article (Boudon 1990), Ph. Boudon situe la complexité de l'architecture à l'endroit de l'embrayage, action par laquelle un concepteur rend réalisable son projet. Poser ainsi l'embrayage comme lieu de complexité architecturale, consiste à penser cette action, l'embrayage, en tant qu'acte de « reliance » (Morin et L Moigne 1999) entre le projet et son contexte. L'embrayage serait ainsi un acte par lequel relier le projet à *la* réalité, en vue de rendre ce projet réalisable.

A cette complexité constitutive de l'embrayage, c'est-à-dire de « *espace de la conception* », répond, selon moi, une complexité constitutive d'un « *espace de la perception* ». La conception et la perception architecturales sont ici posées comme deux activités cognitives dont l'une vise à penser un futur espace ou objet architectural, et l'autre, un espace ou objet existant. On la vu ci-avant, l' « *espace de la conception* » est descriptible en termes *d' « échelles architecturologiques »*. L'« *espace de la perception* », quant à lui, l'est en termes de « *qualités* » (Lecourtois 2007). A l'instar des « *échelles architecturologiques* », les « *qualités* », perçues par les usagers, sont posées comme classes d'opérations de perception relatives à des domaines de références, propres aux usagers. Ce sont des classes d'opérations de perception par lesquelles sont attribuées à l'architecture, des qualités positives ou négatives.

Les études de cas menées sur la conception et la perception d'édifices, pointent la non-correspondance entre les *échelles* de la conception et les *qualités* de la perception. Prenons l'exemple d'un édifice qui fît l'objet de nombreuses controverses en France, le nouveau Palais de Justice de Caen. Du point de vue de la conception, les architectes ont particulièrement pensé les aspects de l'édifice suivant ce que l'on nomme en architecturologie, une « *échelle optique* ». Une complexité optique devait s'y établir : l'édifice devait être perçu comme intégré à son environnement et d'aspect clair dans une vision proche et, autonome, monumental et d'aspect sombre, dans une vision lointaine. Par ailleurs, l'édifice devait affirmer son unité le jour et sa discrétisation la nuit, par des jeux de lumière nocturne.

Figure 1: palais de Justice de Caen Photo C. Lecourtois 2002

Dans les faits, les citoyens et usagers ne perçoivent pas ce travail de conception. Une « *qualité optique »* négative est attribuée à cet édifice qui paraît noir, trop noir et non intégré dans sa ville. La vision de nuit est parfois appréciée mais rarement évoquée. Conception et perception s'affrontent donc, ici comme ailleurs, et créent des disjonctions entre leurs complexités constructives et/ou constitutives.

Espace de la modélisation

Le deuxième domaine d'application de l'architecturologique actuellement à l'étude est l'assistance informatique à la conception architecturale (Lecourtois 2008). De nos jours, les agences d'architecture ont quasiment toutes intégré de nouveaux outils, ordinateurs et logiciels, pour produire voire penser leurs projets. Ces outils informatiques sont divers et offrent des potentialités distinctes suivant les usages qu'en développent les agences. Le terrain privilégié par nos approches actuelles est celui des logiciels *dits* de CAO : autocad, archicad, allplan, Sketchup, Digital Project, Generative Components, Rhinoceros et son plugin Grasshoper, Cobald, etc. (Les logiciels d'évaluations techniques feront l'objet d'une deuxième phase de recherche).

Les usages de ces logiciels - de dessin, de modélisation surfacique et volumique et, de modélisation paramétrique - induisent une modification des habitudes de la conception et, par conséquent, un renouvellement des opérations et/ou fonctionnalités de la conception. La question qui occupe nos études consiste à identifier les relais entre les opérations cognitives de la conception architecturale et les opérations de modélisation informatique, en vue de savoir si la complexité de la conception architecturale en tant qu'activité cognitive est réellement assistée.

Il s'agit pour nous de développer une pensée complexe de l'assistance informatique en visant à identifier des liens existants ou à produire entre les opérations de la conception et les opérations de la modélisation informatique. Deux niveaux participent de ce développement : celui de l'interface et celui du mécanisme de l'assistance. Du point de vue de l'interface des outils ci-dessus évoqués, les menus présentent une hiérarchisation et un découpage des objets et fonctionnalités qui conduisent à penser qu'ils procèderaient d'une théorie de la simplexification plutôt que d'une théorie de la complexité. Les utilisateurs sont en effet guidés dans leurs usages par des déploiements diachroniques de menus qui ne laissent aucune place à une visibilité globale du système.

Mais là n'est pas l'objet majeur de notre interrogation. L'objet majeur de notre approche est de constituer un nouveau concept, celui d'« *espace de la modélisation* » que des classes d'opérations de la modélisation expliciteraient. La modélisation est ici entendue comme activité cognitive par laquelle penser et construire des modèles informatiques. Comment conçoit-on un modèle informatique qui puisse représenter et assister la conception d'un objet architectural en cours de conception ? en est la question principale.

Les opérations de modélisation développées par les utilisateurs dépendent, bien évidemment, des visées opératoires des logiciels empruntés. Les logiciels de dessin et/ou logiciels métiers conduisent les usagers à penser un découpage des éléments constitutifs des représentations en plan de l'objet. Ce découpage concerne les objets de la scène (murs, fenêtres, portes, etc.), des formes géométriques (rectangle, cercle, etc.) ou des textures d'objets à appliquer. Ces systèmes sont aujourd'hui capables d'interpréter ces éléments qui participent d'un modèle numérique souvent en 3D, pour produire une vue perspective ou axonométrique *dite* réaliste de cette scène. L'utilisateur doit, pour ce faire, indiquer l'emplacement du spectateur, l'emplacement du projet relativement à un système de repères géographiques et, éventuellement, préciser quelques informations sur des lumières artificielles et les qualités de certains matériaux.

Les opérations de modélisation de ces systèmes se disjoignent des opérations de la conception. Elles sont opérations de réinterprétation du projet suivant le découpage ci-dessus évoqué et, permettent de produire des modèles informatiques (souvent en 3D) à partir de modèles « *manuels* » d'objets nécessairement, au moins en partie, conçus au préalable. Choisir des objets, découper la représentation du projet en objets disponibles de l'outil, situer le modèle dans un système géographique, indiquer et préciser un système d'éclairage, situer l'observateur de la scène, choisir et qualifier des textures sont les opérations majeures induites par l'usage de ces systèmes. Force est de constater que les opérations de la conception architecturale mêmes s'en trouvent écartées et la complexité architecturale réduite.

Les systèmes qui aujourd'hui nous paraissent induire de la complexité entre l'activité cognitive de la conception architecturale et l'activité cognitive de la modélisation informatique sont, nous semble-t-il, les systèmes de modélisation surfacique et volumique qui passent par de la modélisation paramétrique. La modélisation numérique surfacique et volumique induit un renouvellement de la pensée des formes architecturales en offrant de nouvelles façons de les construire. La modélisation paramétrique offre des possibilités de programmation et incite à penser des relations entre des propriétés géométriques déterminantes de formes et, des variables indépendantes.

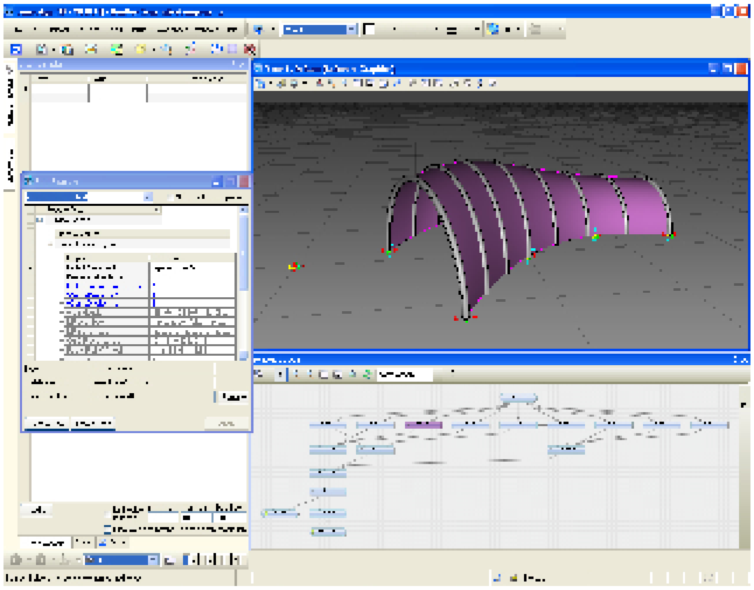

Figure 2 : image réalisée par F. Guéna avec Generative Components

L'image ci-dessus est un exemple des usages possibles d'un outil de modélisation paramétrique qui, ici, est Generative Components. L'opération de modélisation majeure, liée à l'usage de ce genre de système, peut, me semble-t-il, être posée en terme de « *reliance* » : penser le projet comme conjonction de relations participatives de la pensée des formes et mesures de l'architecture en conception.

L'expérience développée par Greg Lynn sous l'appellation d'Embryological House est emblématique du nouveau paradigme induit du recours à ces systèmes. A partir d'un modèle numérique unique, l'architecte propose une multiplicité de spécimens pour sa maison. Ces spécimens procèdent de la variation d'une valeur attachée à une dimension (propriété géométrique du modèle), elle-même liée à d'autres. Par prolifération, les valeurs des autres dimensions sont automatiquement mises à jour.

Greg Lynn lui-même identifie ce nouveau paradigme en termes d'intrication :

« *depuis deux ans, je tourne davantage autour de la notion d'"intrication".(…) Une structure intriquée ne comporte pas de détail. Ce n'est pas une forme faite de détails, mais un ensemble de composantes qui communiquent les unes avec les autres et évoluent en même temps. (…) Sans ordinateur permettant d'exploiter dès la phase de conception le calcul mathématique à un certain niveau créatif et intuitif, on ne peut obtenir l'interaction et la précision nécessaire. (…) L'ordinateur permet de concevoir des projets complexes, dans lequel le moindre détail est relié à l'ensemble, dans un dialogue continu et non discret.*»

G. Lynn (AA p. 104-106)

Il reste à étudier plus avant ces systèmes à l'aide de l'architecturologie en vue de préciser les opérations de conception qu'ils assistent ou induisent. Ce travail en cours permettra d'expliciter ce que nous nommons « *espace de la modélisation* »…

En parallèle à ce travail est actuellement à l'étude un système d'assistance informatique à la conception architecturale que nous avons nommé ESQUAAS (ESQUisse Architecturologiquement ASsistée), et qui participe de la réflexion que nous développons sur la complexité architecturale.

ESQUAAS :

En conséquence de ce qui précède, la modélisation paramétrique paraît être particulièrement intéressante pour penser des outils d'assistance à la conception architecturale et qui prennent en charge la complexité même du mécanisme cognitif de la conception. Le modèle de ce système nous aide à imaginer la poursuite d'un outil dont nous avons initié le développement, F. Guéna et moi-même, au sein de notre laboratoire l'ARIAM-LAREA. Cet outil a pour nom ESQUAAS et vise à assister les concepteurs par la création d'un modèle numérique transformable sous l'action d'opérations de conception identifiées par l'architecturologie (Lecourtois et Guéna, 2009 et, Guéna et Lecourtois 2009b).

Esquaas s'appuie sur le principe Simonien selon lequel il est préférable de viser la satisfaction plutôt que l'optimisation. Il se présente comme un outil visant à faciliter la proposition de solutions satisfaisantes plutôt que d'une solution optimale. Ainsi, cet outil n'est pas pensé comme un système algorithmique qui donnerait une solution unique mais comme un système d'assistance à la réflexion par des propositions possibles.

Deux phases de programmation composent le développement de cet outil encore en cours de réflexion. La première phase concerne la reconnaissance de traces graphiques. La deuxième concerne la signification et la transformation des traces relativement à des classes d'opérations de conception.

Reconnaissance de traces : simplexité

La première phase de programmation a consisté à produire un système qui permette de reconnaître des traces en vue d'interpréter une scène graphique. A partir du Modèle des Chaines de Markov a été mis en place un programme qui identifie des relations entre des traces graphiques.

Ce système analyse des relations entre des points en cours de tracé relativement à des points de la scène déjà inscrits. Il est capable de reconnaitre leurs propriétés - être proche de l'extrémité, être sur, être proche du milieu, être loin de, etc. - et de calculer les probabilités pour les traces de correspondre à des classes identifiées.

Cet outil s'appuie sur une classification des rapports binaires de traces graphiques identifiés par l'architecturologie sous le vocable de dromies. La figure 3 qui suit présente ces rapports de traces.

Nos hypothèses de départ sont :1) la représentation graphique est instrument de conception pour l'architecte et, 2) la trace graphique est porteuse de signification pour le projet. Le dessin est donc ici pris comme moyen de modélisation d'un objet ou espace qui n'existe pas encore. Aussi le modèle produit par le ou les concepteurs a-t-il pour visée d'assister la conception du projet par sa représentation. Il est ainsi d'une nature qui se rapproche, d'un certain point de vue et bien que son objet soit à produire, de la visée des dessins d'un Léonard de Vinci (*les carnets de Léonard de Vinci* ou P. Valéry, *introduction à la méthode de Léonard de Vinci*) c'est-à-dire, la compréhension, la représentation pour la compréhension et la conception. C'est une simulation pour la compréhension d'un existant anticipé….

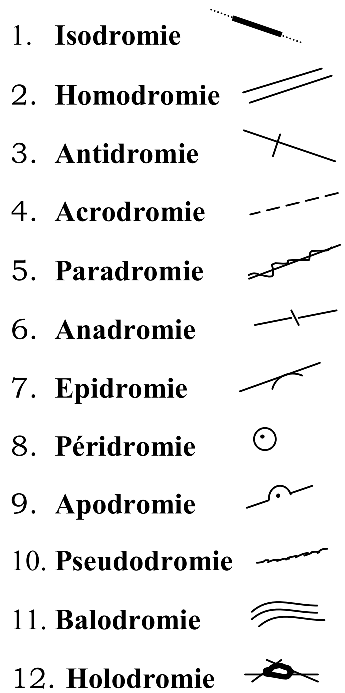

Figure 3 : liste des méta-dromies

Cette première phase de programmation procède d'un mécanisme de la pensée qui se rapproche de celui que décrit A. Berthoz par son concept de *simplexité*. Nous avons simplexifié la conception en en disjoignant deux constituants : des signes indiciels (traces graphiques témoins) et des opérations de conception (génitrices des traces). Cette posture s'appuie sur le modèle des systèmes informatiques experts qui impliquent deux types de modélisation de la connaissance : les connaissances énonciatives exprimées par un réseau sémantique, les connaissances procédurales exprimées par des règles de production. (Mathieu J. in Demailly A. et Le Moigne J.L. (dir.) 1986 : 75)

Cette première phase de programmation renvoie donc à une modélisation des connaissances énonciatives. La deuxième phase de développement d'ESQUAAS s'inscrit comme travail de modélisation des connaissances procédurales, qui implique la mise en œuvre de schémas de raisonnement (règles de processus de conception).

Opérations de conception assistées : complexité

Cette deuxième phase de programmation vise à constituer des « *reliances* » dynamiques entre les dromies et les classes d'opérations de la conception (autrement nommées « *échelles architecturologiques* »).

La trace graphique (décomposable pour partie en dromies) est ici considérée comme représentation ou témoignage d'un moment de conception procédant de la mise en œuvre de diverses « *échelles architecturologiques* ». Elle est un ensemble de signes indiciels de la mise en œuvre d' « *échelles architecturologiques* ».

La dromie (rapport élémentaire entre deux traces), en soi, ne possède aucune signification architecturale propre. Elle est en soi oppositive et acquière des significations suivant deux ordres : un ordre scénographique et un ordre indiciel (ou énonciatif). Du point de vue de l'ordre scénographique, la dromie acquière son sens par les relations qu'elle entretient avec les autres dromies de la scène graphique, autrement nommée trace. Cette signification de l'ordre scénographique peut être iconique et/ou métaphorique. Du point de vue de l'ordre indiciel (ou énonciatif), la dromie acquière son sens relativement à l'objet architectural qu'elle aide à concevoir. Elle procède alors tant d'opérations de la conception architecturale que d'opérations de la conception graphique. Ces opérations de la conception constituent, pour nous, le sens indiciel des dromies.

La trace est donc pour nous outil de conception qui relie un processus passé (1) à un processus potentiel (2) : processus 1) celui dont elle procède et pour lequel elle est modèle résultant, processus 2) celui pour lequel elle est modèle substrat et à partir duquel appliquer diverses transformations pour engager ou poursuivre le processus de la conception.

Dans ce cadre, chaque dromie est à étudier de manière à déterminer les possibilités pour elle de procéder d'une ou plusieurs classe(s) d'opérations de conception. Prenons le cas de l'homodromie en exemple. La question qui nous occupe est celle de savoir ce qu'elle pourrait représenter dans un croquis d'architecte. Interrogeons-nous à partir de la liste des vingt et une échelles architecturologiques : parcellaire, symbolique formelle, géométrique, de voisinage, géographique, de modèle, socioculturelle, d'extension, de représentation, cartographique, symbolique dimensionnelle, humaine, technique, de voisinage, optique, d'intégration, de visibilité, globale, de niveaux de conception, économique, sémantique.

Dans un croquis, l'homodromie désigne le phénomène selon lequel deux lignes se suivent, de tout leur long, selon des relations de voisinage quasi équivalentes. Dans le cadre d'une « *échelle parcellaire* », l'une de ces lignes pourrait représenter le contour de la parcelle et l'autre la volonté de suivre cette limite pour décider de la forme du projet. Dans le cadre d'une « *échelle géométrique* », l'homodromie pourrait manifester la volonté de créer des règles géométriques particulières entre deux éléments du projet. Dans le cadre d'une « *échelle de voisinage* », l'homodromie manifesterait la mise en oeuvre d'un lien entre un élément du voisinage, une hauteur, une limite, une direction et les mesures du projet à venir. Dans le cadre d'une « *échelle géographique* », l'homodromie jouerait un rôle similaire mais, dans ce cas, l'une des traces représenterait la topographie du terrain prise comme référence de pensée. Etc.,etc.

Ainsi, chaque dromie prend sens relativement à un domaine de références mis en œuvre dans la conception. Pour notre système ESQUAAS, chacun de ces domaines est pensé comme un contexte multi-agents déterminé par : 1) des propriétés (éléments déterminants le domaine de références impliqué, tels que, par exemple, la situation géographique, la topographie du terrain, l'orientation de la parcelle dans le cas de l'« *échelle géographique* »), 2) des variables dépendantes (éléments calculés par la machine relativement aux propriétés, tels que, par exemple, la course du soleil et la course des vents dominants dans le cas d'une « *échelle géographique* ») et, 3) des scalèmes (opérations élémentaires de la conception, telles que, par exemple, orienter, situer, découper, dimensionner dans le cas d'une « *échelle géographique* »). (Lecourtois et Guéna 2009)

Le développement informatique de ces contextes est pensé de manière à reconnaître le sens des traces d'une part et à permettre des opérations de transformations de celles-ci d'autre part. Il implique une pensée complexe à deux niveaux : 1) relative à la complexité opératoire des scalèmes des domaines engagés par le contexte concerné, 2) relative à la complexité opératoire entre les contextes eux-mêmes (« *relations d'échelles* » et « *propriétés d'échelle* »). Ainsi impose-t-il de penser un système opératoire de hiérarchisation des opérations de conception et de leur résultat qui ne pourra se faire indépendamment d'une pensée simplexe…

La conception de ce nouveau système d'assistance à la conception architecturale impose de revisiter la structure du langage de l'architecturologie. Elle conduit à poser l'action des « *échelles architecturologiques »* en termes d'hypertexte (Mahoudeau 2006 :40) par lequel sont créés des liens non linéaires entre les scalèmes des échelles mais également entre les échelles elles-mêmes, en vue de faire de cet outil une aide logique plutôt qu'une aide pratique qui prendrait en charge le mécanisme cognitif non-inférentiel (l'inférence pouvant par ailleurs être prise en charge par des systèmes bayésiens) des architectes….

En guise de conclusion

Cet article pose deux distinctions majeures entre : 1) complexité théorique et complexité empirique et 2) la « pensée complexe » et la simplexité. Partant de ces disjonctions, il développe une réflexion sur le statut du savoir constitué par l'architecturologie sur l'activité cognitive de la conception architecturale.

L'architecturologie est ici interrogée dans sa potentialité à s'offrir comme base de connaissance structurée à partir de laquelle développer des applications sur des domaines de l'architecture concernés par la conception, pour en constituer des complexités théoriques : 1) la perception architecturale posée comme deuxième moment cognitif constitutif de celle-ci et, 2) l'assistance informatique à la pensée et à la production de l'architecture contemporaine, posée comme lieu de nouvelles complexités opératoires empiriques.

La deuxième partie de cet article présente une réflexion en cours dans notre laboratoire et qui vise à produire une nouvelle assistance informatique portée sur la gestion de la complexité des mécanismes opératoires de la conception architecturale. Cette réflexion amène à ré-investiguer la structure complexe de l'architecturologie posée alors comme méta-connaissance de l'architecture. Ce système en cours de développement nécessite de développer puis de constituer des « *reliances* » entre des pensées complexes et des pensées simplexes…

Author Biography

Caroline Lecourtois

Architecte DPLG et Docteur en Urbanisme et Aménagement de l'espace (spécialité architecturologie), Caroline Lecourtois développe, depuis 1998, ses recherches au sein du LAREA (Laboratoire d'Architecturologie et de Recherches Epistémologiques sur Architecture) devenu, en 2005, ARIAM-LAREA (Atelier de Recherche en Informatique Architecture et Modélisation – LAREA). Elle a travaillé pendant près de dix ans sous la direction de Philippe Boudon. Elle est aujourd'hui également Maître-assistante des écoles d'architecture Françaises et co-dirige les thèses des doctorants de son laboratoire. Ses objets de recherche portent sur les opérations cognitives de la conception architecturale et leur assistance informatique. Ses travaux nourrissent deux des quatre axes du laboratoire : 1) activités de conception assistée par ordinateur et 2) modélisations précoces. Transformative Design: From Consultant to Clinician

Robert Lederer, University of Alberta

Ben King, Institute for Reconstructive Sciences in Medicine, University of Alberta

Heather Logan, University of Alberta

Abstract

The paper will describe how digital information gathered in medical diagnostic practices has been utilized in an area traditionally reliant on manual medical sculpting techniques. Working in conjunction with iRSM (Institute for Reconstructive Sciences in Medicine), the authors have participated in the development of systems and processes that have resulted in: enhanced surgical planning, elimination of surgeries and improved accuracy of prosthetics. As iRSM is the only centre in Canada to provide these services, it has attracted many international medical facilities and practitioners to use these digital workflows in their own practice.

Industrial Designers were originally consulted by iRSM on a project-by-project basis, consistently demonstrating the value of design research strategies. This demonstration of value resulted in the demand for a full-time designer within iRSM's interdisciplinary team, opening new insights and opportunities within the clinical environment. The integration of design into this area of medicine resulted in the development of a new field of design interaction, education and research. The collection of numerous case studies over an eight-year period provided the background for the development of a graduate program of study dedicated to this new field. The result of this work has been presented exclusively within the medical arena both at conferences and workshops. This academic year, the first student to be enrolled in a Master of Science in Rehabilitation Medicine with a specialization in Surgical Design and Simulation came to fruition. The creation of this new field of study is a continuation of this relationship, as the first candidate has a degree in Industrial Design, but will gain the necessary skills to become a clinician and researcher within a clinical practice. This new "species" of designer is at the forefront of new opportunities for design education and research with a focus on patient-centered health care delivery.

Keywords

Health care; Industrial Design; Computer Aided Design; Reflective practices; Visualization; Rapid prototyping.

Like many interesting research projects, the collaboration between the ID (Industrial Design) Program at the University of Alberta and the medical unit iRSM (Institute for Reconstructive Sciences in Medicine, formerly known as COMPRU - Craniofacial Osseointegration and Maxillofacial Prosthetic Rehabilitation Unit) arose from a series of unplanned coincidences. This paper will discuss the involvement of Robert Lederer as consultant; Ben King as a full-time member of the interdisciplinary team and the transition of Heather Logan from design student to clinician. Based upon the authors experiences' and observations, there is an increasing opportunity within health care for designers to define new roles that will have a significant impact on patient care.

Beginnings

In early 2000, Robert Lederer was appointed the coordinator of the ID program at the University of Alberta and sought to introduce various rapid prototyping (RP) systems into the undergraduate program. During the time Robert was investigating different systems, Rosemary Seelaus, an Anaplastolgist with iRSM, was also researching the integration of various technologies into her profession. Anaplastology (Fig. 1) is defined by the IAA (International Anaplastology Association) as a branch of medicine dealing with the creation of prosthetics to rehabilitate an absent, disfigured, or malformed portion of the face or body, typically caused by cancer, trauma or a birth defect. Anaplastology techniques traditionally rely on labor-intensive hand sculpting, physical impressions and mold making with very limited use of computer software of digital planning. Rosemary and Robert were introduced by a sales representative from a 3D printing company, as he felt the common interest in prototyping applications may benefit both parties. After discussing a potential collaboration with Rosemary, it became apparent that the opportunity to inject new technology driven techniques into the field of Anaplastology seemed plausible, but further expertise in Computing Science and a source of funding were major hurdles.

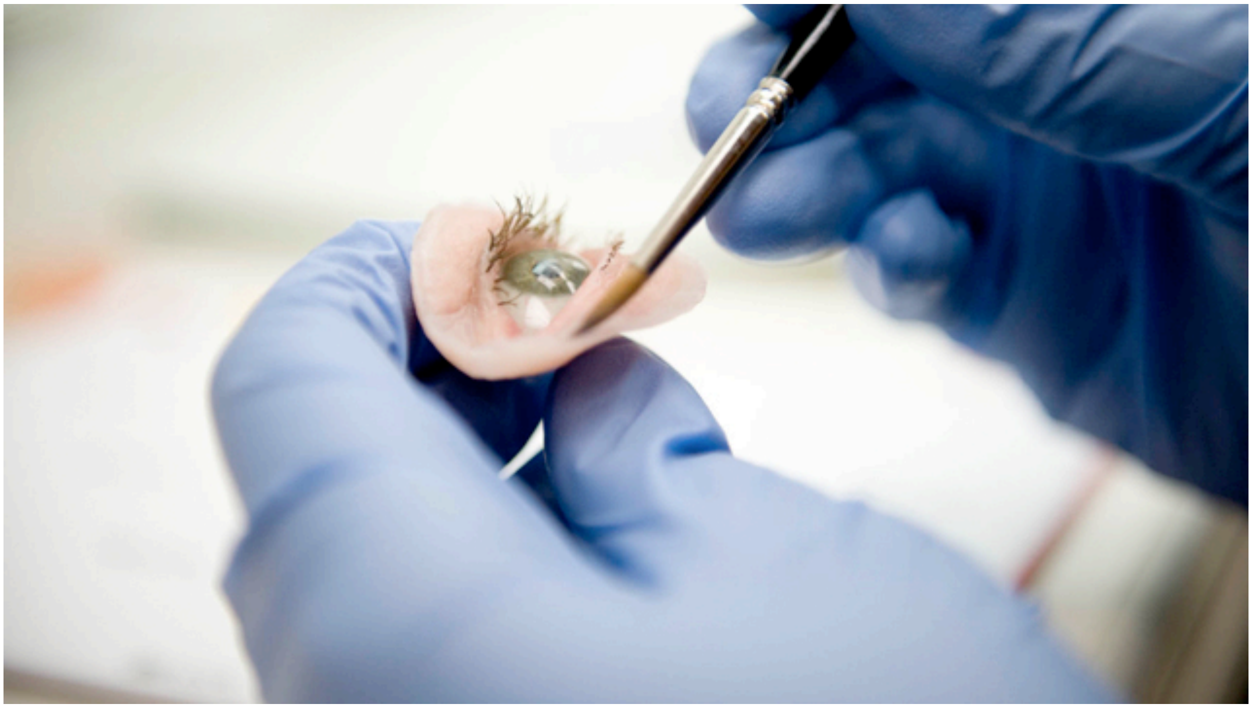

Fig. 1 Example of an Anaplastologist colouring a prosthetic eye

These hurdles quickly dissipated thanks to the involvement of Jonathan Schaeffer from Computing Sciences at the University of Alberta. Dr. Schaeffer received a large grant ($20 million MACI-Multimedia Advanced Computational Infrastructure) to develop digital data processing systems by linking PCs across Canada; it became apparent that a small part of the MACI grant was devoted to visualization. This potential funding source instigated research into various programs and input data from MRI (Magnetic Resonance Imaging), X-ray and CT (Computed Tomography) to comparatively assess the best means of acquisition, output and visualization for clinical applications. Once it became evident that CT could produce accurate and reliable scans that could be translated into 3D (three-dimensional) prints, an initial attempt at establishing a medical modeling process was formulated. As Bibb (2006) explains, medical modeling originates from the 1990s when it was realized that RP machines could potentially use a variety of 3D computer data, which included formats from medical scanners. Computer-Aided-Design (CAD) software served as the basis for medical modeling software, which can be used to translate and manipulate medical data and communicate with RP devices to print highly accurate medical 3D models (Fig. 2).

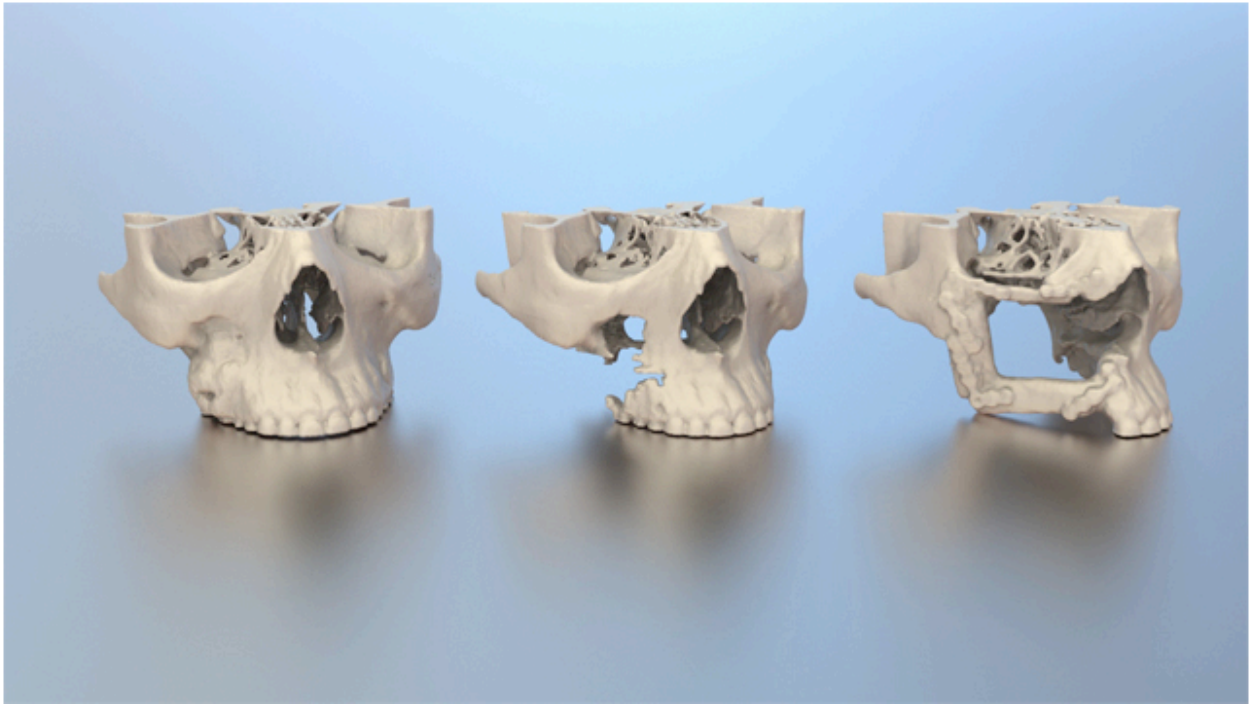

Fig. 2 Example of medical models used to identify, remove and reconstruct a maxillary cancerous tumor

The first 3D print generated was to be used as a surgical guide to reconstruct a patient's outer ear. The patient was born with microtia, which Medline defines as a congenital condition that causes an underdeveloped outer ear. The patient was going to have autogenous ear reconstruction, which is defined as the procedure of sculpting a new ear from the patient's own rib cartilage. Using a 3D laser scanner, the patient's fully formed left ear was scanned and a digital mirror image was produced to act as a template for the microtia affected right side. A 3D print was produced from this replicated ear as a guide for the surgeon in planning the shaping of rib cartilage as well as epidermis trimming and stitching. This visualization of digital information fit within the parameters of the MACI grant and funding was allocated to enable the purchase of a 3D printer.

The luxury of having a 3D printer and the freedom to experiment with limited parameters provided Rosemary and Robert the chance to explore numerous medical procedures. The first major project came after 6 months of exploring various medical modeling software and 3D printer applications and unraveling the true depth of change digital technologies could inject into the medical field. This first significant project dealt with a patient that had recently had a brain tumor removed; in order to access the tumor, a portion of the patient's skull had to be temporarily removed. Unfortunately, this section of skull incurred postoperative infection, resulting in permanent removal. The patient had undergone two previous operations to remove infected regions of bone and now required a prosthetic implant to cover the missing portion of skull to protect the brain. The medical procedure that was in place at the time required two operations; the first operation involved peeling the skin away from the affected area which exposed the skull. The use of a non-sterile molding material similar to putty was pressed into the cavity to form an impression of the defect. The incision was then stitched and the patient was provided with a protective helmet to wear while the impression was sent to a lab to be converted into a custom prosthesis for implantation during the next surgery. The second surgery, which normally occurs 2 weeks after the first, began the same way as the first surgery: by peeling back the patient's skin to access the cavity. The surgeon cut and cleaned the areas of both the patient's skull and the prosthesis to ensure a proper fit. The surgeon then had to decide where to place titanium attachment screws for securing the prosthesis to the skull while relying on the two-dimensional imagery provided by X-ray and CT scans to analyze the quality and thickness of bone. Unbelievably, all this work and decision making was being done while the patient was in surgery.

The challenge presented by Dr. John Wolfaardt (one of the co-founders of iRSM) was to find a means of improving this procedure using a digital workflow. Part of the earlier experimentation involved working with tolerances and accuracy related to processing digital medical information and 3D printing outcomes. With the knowledge accumulated from various experiments, there was confidence that the surgeon could be provided with a 3D print of the defect area. This model would presumably allow the surgeon to pre-operatively examine the bone structure around the defect and pre-plan where he would trim bone to allow a better fitting prosthesis. With input from the surgeon, alterations were made to ensure the prosthesis fit the defect area based on proposed surgical changes; the model also allowed the surgeon to examine areas for attachment and select the best sites. The 3D model and prosthesis were sterilized and brought into the surgical field for referencing and installation. To the relief of everyone involved, the procedure went incredibly smooth and the surgeon was able to install the prosthesis during one operation in significantly less time than it typically took for the traditional two-operation process. More importantly, the entire first invasive operation where impressions were made was eliminated. This resulted in less chance of infection for the patient as well as less operating time for the surgeon. The result was clearly an improvement in the quality of patient care and procedural outcomes as well as a reduction in operating time and costs. These models continued to be provided as visual aids for the next twelve months, while the 3D techniques continued to be refined. This case demonstrated incredible potential, which resulted in other researchers investigating the use of 3D modeling in surgical planning in areas such as: Maxillofacial Surgery, ENT (Ear, Nose and Throat) Surgery, Plastic Surgery, Prosthodontics, Pediatric Cardiology, Pediatric Surgery, Neurosurgery and Orthopedic Surgery.

Due to these successes, iRSM received a grant of $1 million dollars in 2005 from Western Economic Diversification Canada, which was supplemented by Caritas Health to setup the first Medical Modeling Research Laboratory (MMRL) in Canada at the Misericordia Hospital in Edmonton. It was outfitted with surface laser and probe scanning, a variety of CAD software, haptic stations (Fig. 3), Stereolithography prototyping, 3D Multi-jet Modelers in Acrylic and Wax, as well as CNC (Computer Numerically Controlled) milling. Previous to the setup of this lab, work was split between the prosthesis lab in iRSM and the ID studio; now everything was in one location. This consolidation also facilitated the ability to have graduate students work, learn and develop their thesis projects. Similarly, this enabled undergraduate students to take practicum courses to assist on various tasks and projects. This has led to a variety of results from tactile models for teaching plastic surgeons rhinoplasty surgery (Zabaneh, 2009), to developing and evaluating new digital workflows for a variety of medical processes such as mandibular reconstruction (Dziegielewski, 2010). The facility has also enabled a variety of medical product based projects such as concept designs for bone anchored hearing aids and otoscopes. Like the playful experimentation in the early stages of this collaboration, ID students at the University of Alberta will continue evolving and discovering while facilitating this beneficial relationship between medicine and design.

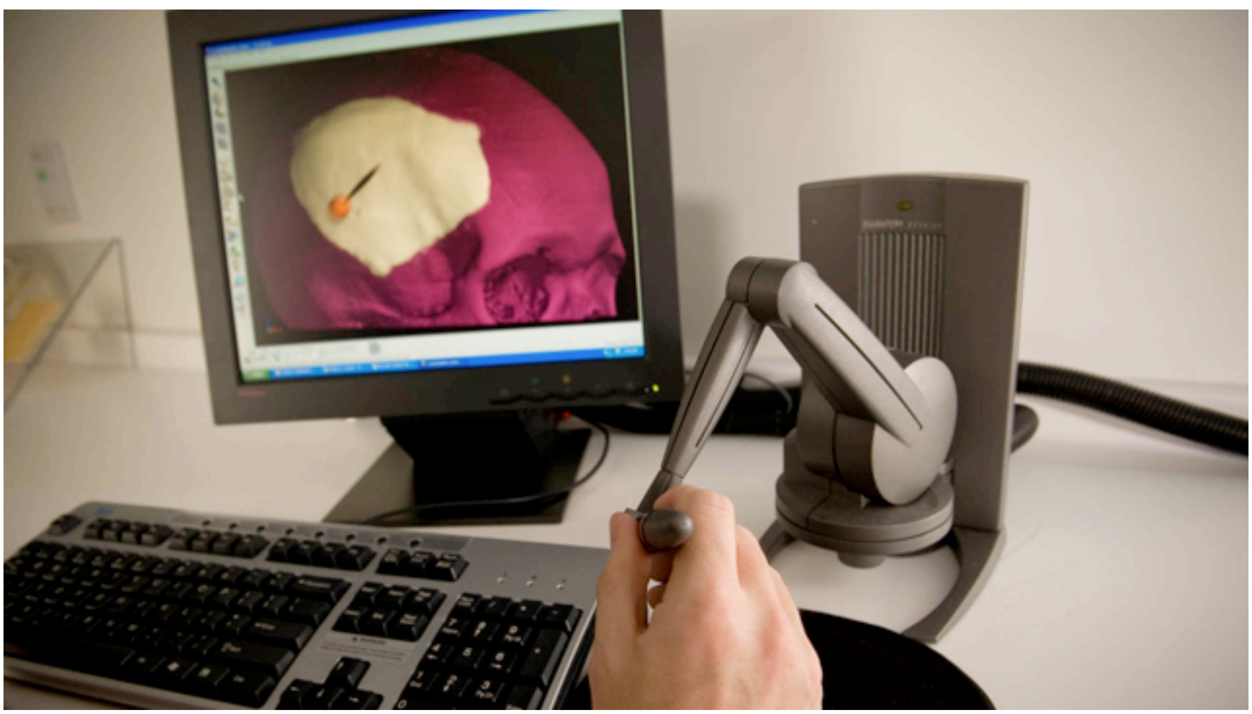

Fig. 3 Example of the use of a SensAble haptic device and Freeform software to virtually sculpt a cranioplasty implant

Infiltration

Ben King was one of the first students to take a semester long practicum in the MMRL, and was a willing guinea pig in deciphering potential future collaborations between ID and iRSM. His first visit to the MMRL was swiftly met with panic, as the clinician that was meant to introduce the practicum project had double-booked their first meeting with a patient consultation. Needless to say, the patient consultation was prioritized in this scheduling showdown and Ben was left alone in this newly assemble million dollar laboratory surrounded by shiny, futuristic devices. The clinician made the assurance that there "were instructions around somewhere" and that designers were perfectly capable of "figuring these kinds of things out". Instead of disintegrating into panic and frustration, this situation quickly revealed itself as a tremendous opportunity. Not many students are fortunate enough to stumble upon the design equivalent of Willy Wonka's Chocolate Factory.

The practicum project that was presented involved finding a way to measure facial volume changes in a patient pre/post surgery to aid in assessing facial reconstruction outcomes. Being able to reference quantifiable numbers instead of clinical assumptions and arbitrary opinions eliminates egos from this evaluation stage of patient treatment. This information would also improve outcomes of future surgeries by providing tangible reference material, as opposed to simply referencing anecdotal evidence from someone's surgical experience. Other than using a 3D scanner and a digital workflow, there was no structured handout or rules to follow. The clinical staff had all but abandoned this project and seemed amused that a student would be willing to spend the required time to repeat their missteps.

Like many challenges, this was a problem of process. Industrial designers are generally well-versed in the development of process and its application across multiple platforms. Once the medical jargon was deciphered, the project became a simple case of data acquisition, manipulation and output. Using available software and open-source programs, a set of work instructions were created that outlined a simple clinical workflow that would eventually be used in several clinical evaluative studies. These studies included titles such as "A Comparison Study: 'Proposed Digital Position' of Auricular Implant Retained Prostheses Using Computer Aided Design Versus the 'Final Position' of Fitted Prostheses" and "Free Tissue Transfer Flap Reconstruction of Parotidectomy Defects; A Paired Outcomes Analysis Using Three Dimensional Laser Surface Scans". These studies were presented at the 2008 Advanced Digital Technology Conference in Head and Neck Reconstruction in Cardiff, Wales; although the wording is complicated, the ability to perform these studies evolved from the willingness to ask seemingly simple questions. That is where designers hold a competitive advantage over many professions, both artistic and pragmatic: designers are often required to step outside of comfort zones to ensure a fundamental understanding of users, projects or processes.

By asking simple questions and providing not so simple results, iRSM was impressed enough with the potential of integrating designers into a clinical environment to offer a one year full-time Industrial Design position. During the interview process, Mr. King asked what the expectations were of the position, and was promptly told, "You tell us". Not very many clinical facilities have the fortitude to take risks and place such a large amount of trust into a young professional with no formal training in the medical field, but proof of concept resonates through all fields. A one year contract is a relatively small risk, but the reward of new collaborations can perpetuate for many years. In recognizing that creative professionals can blossom under less defined structures, iRSM has benefited from the eclectic array of designer skills. Industrial design has played a vital role in iRSM projects ranging from product development, branding and marketing, visualization, surgical planning, medical model production and surgical workshop development.

iRSM intentionally provided minimal training, and instead emphasized exploration. This puts the pressure on the designer but also allows for flexibility not typically found in the structured positions occupied by medical professionals. In fostering new ideas and skill sets, it became apparent that "we all have a creative side, and it can flourish if you spawn a culture to encourage it, one that embraces risks and wild ideas and tolerates the occasional failure” (Kelley, 2001, p.13). In addition to this creative freedom, the emphasis on interdisciplinary teamwork facilitated jargon related stumbling blocks. Individuals such as Andrew Grosvenor, a Maxillofacial Prosthetisist, acted as an invaluable resource in breaking down clinical jargon and explaining medical concepts and procedures. As Andrew recalls, once Ben understood the principles of medical modeling “he promptly tore up the instructions” and began writing new information so that it would be both usable and easier to learn. Medical modeling software is derived from Computer-Aided-Design, and like CAD software, desired results can be achieved from many combinations of steps and toolsets. A workflow was designed that would introduce new users to a variety of functions, and encourage non-linear thinking when using the software. This was intended to persuade the users to work around problems, as opposed to quitting when the established method did not work. The instructions were written in plain language to encourage researchers from a variety of backgrounds to learn how to use the software and hardware. Technology can be daunting, and if it is presented as exclusive and impossible to learn, an unnecessary hurdle has already been put in place. These instructions were used internally and later as the basis for a series of ongoing training seminars (Fig. 4) for both established clinicians and medical residents.

Fig. 4 Example of a web advertisement for one of a series of 3D modeling workshops

The dichotomy that occurs in these two groups is that medical residents express their lament that digital technologies were not introduced earlier in their education, and the established clinicians insist that although useful and interesting, technologies are too complicated to incorporate into everyday workflows. The simple deduction that can be derived from these two groups is that technologies that have proven to benefit patient care should be introduced much earlier in the education process for medical practitioners. Any new skill requires time and dedication; two ingredients that are particularly challenging when an individual has a full clinical workload. This leads clinicians to either plateau at an early stage of their career, or become reliant on information and training from workshops and conferences. This can work if an individual’s peer network is strong enough in technology research, development and communication, but clinicians are generally focused on addressing the sheer number of patient cases and not necessarily the process of their treatment. An unfortunate scenario involves clinical professionals attending conferences and being swayed by new technologies without realizing the associated costs and learning curve, all with the risk of the technology not addressing their needs. Simply put: medical professionals need a guiding hand with a deep-rooted understanding of technology that can interpret their needs.

Unfortunately, medicine is often guilty of projecting complication and red tape, which does not necessarily entice other professionals. Industries such as film and video games set the bar both creatively and technically for technological applications, and much can be learned or adopted by medical facilities. As Robert Lederer demonstrated in his early exploration, by researching RP for medical applications, surgeries have been eliminated, dollars have been saved, and patients receive safer treatments. The struggle is in promoting change and teaching medical professionals that it is both acceptable and encouraged to learn from professionals outside of their expertise, even though they may be from the ‘creative’ world.

Although the initial Industrial Design position held by Ben King with iRSM was upgraded from a one-year contract to full-time permanent (a first for an Industrial Designer in our Health Region), there will continue to be areas that are near impenetrable for designers. It seems that combining the inquisitive nature and technological savvy of designers with medical knowledge and clinical skills may result in a hybrid that will truly address the needs of patients. Dr. John Wolfaardt also recognized this potential value of design within a clinical environment and in conjunction with the faculties of Rehabilitation Medicine and Industrial Design at the University of Alberta initiated a new field of study to address these needs in 2009. Dr. Wolfaardt sees in designers what Pink (2005) details as the ability to empathize to ensure the patient is at the focus of care. Medicine has largely been “standardized – reduced to a set of repeatable formulas for diagnosing and treating various ailments” (Pink, 2005, p. 168). As Pink further details, this is reminiscent of a computer, but computers are essentially emotionally autistic. This has triggered changes at places such as the Yale School of Medicine, where medical students “are honing their powers of observation at the Yale Center for British Art, because students who study painting excel at noticing subtle details about a patient’s condition” (Pink, 2005, p.52). There is value in established rules and processes, but equally important is the recognition that human emotions play an integral part in the health care environment; patient-centered design and delivery of care will be instrumental considerations for the next (and current) generation of clinicians. An Industrial Designer can infiltrate quite far in the medical realm, but a clinician with the skills and empathy of a designer presents a tremendous amount of possibilities for new conversations, research and change.

Transformation

As an ID undergraduate student at the University of Alberta completing the last year of her program, Heather Logan was interested in gaining experience in the medical field. Heather has always had a strong interest in finding educational and professional opportunities that involved helping people. After speaking with several professors and peers about her interests, Heather was directed to contact Ben King at iRSM. A four-month practicum and design project ensued, with the task of redesigning a Bone Anchored Hearing Aid (an implantable hearing device). During this practicum valuable experience was gained in the clinical world while interacting with professionals of various backgrounds and learning about and interviewing patients with various conditions. Heather was also able to gain knowledge and insight into a new application of digital design and rapid prototyping. The experience inspired her to pursue a career in a clinical environment, which fortunately coincided with the opportunity to apply for a Masters of Science in Rehabilitation Medicine with a specialization in Surgical Design and Simulation. The program began in September, 2009 and Heather affectionately became known as the “new species”.

Program

The Masters of Science in Rehabilitation Medicine with a specialization in Surgical Design and Simulation program is designed to teach the necessary skills to become a clinician and a researcher within a clinical practice. It is composed of three main areas of learning: course work, clinical training and independent research. The course work is completed at the University of Alberta and includes advanced digital technology training, anatomy and physiology of the head and neck, issues in rehabilitation science and conducting rehabilitation research. The second area of learning is clinical teaching and training at iRSM. This section includes learning from a team of interdisciplinary health care professionals with a focus on surgical prosthetic care, research and advanced digital technologies. It is composed of clinical training, laboratory exercises and seminars. The final component involves independent research and completion of a thesis. Heather will be conducting research that will focus on advanced digital technology, and the value the technology brings to surgeons, their process and patient outcomes. There is a substantial array of research (Eggbeer, 2005) that discusses and describes advanced digital technology, including its accuracy and applications, but there is limited hard evidence that scientifically evaluates the surgical or patient specific outcomes. This type of evidence is what is needed to convince more medical professionals and health authorities of the benefits of incorporating new technologies. Unfortunately, most facilities do not have direct access to facilities such as iRSM, but with hard empirical evidence, this could change quite drastically.

Challenges

Although this new field of study was thoroughly planned, challenges developed in the early stages; it was obviously a shocking transition from an ID workshop to a clinical environment. Clinical environments are fast paced, continuously busy and people within that environment have strict methods to which they adhere to ensure team members can work in a smooth flow for optimal patient care. Injecting a student that requires frequent explanations slows down the intricacies of the activities going on in the clinical setting. It can be challenging for a student to feel comfortable asking questions and feel relaxed in a patient care environment. An expected, although none the less monumental challenge, has been absorbing and retaining medical terminology and vocabulary. Often designers have very little background in medicine and learning medical terminology, anatomy and physiology can be a tremendous learning curve. The course work that was initially planned to cover this material was joining a head and neck anatomy and physiology class with speech and language pathology students. Although this course presented important material that was of great value, there were areas of relevance that were not covered in the course. In order to acquire pertinent information, added readings, questions and an oral exam have been used as a supplement. The anatomy and physiology course work is essential to understanding and communicating with medical professionals and clinicians; an in-depth knowledge of these areas is critical for understanding and exchanging information.

Transferring from an art and design world, which is often qualitative and descriptive, to a scientific world that is more quantitative and evidence based presents a unique challenge for designers. Rehabilitation medicine and science has a strong relationship with empirical based research and methods; there are many strict methodologies that scientific research follows in comparison to design research. Scientific research focuses on experimental design, testing hypotheses and quantitative research; design research involves elements of scientific research, but it has a much greater focus on the user, user observation, user experiences, thoughts and relationships. Rehabilitation medicine has only recently begun to focus on quality of life and user experience. As troubling as it is, “current healthcare tends to be organized for the convenience of the organization and the clinical staff and most solutions are geared to the needs of these two stake holders” (Macdonald, 2007, p.27). The challenge as a designer is to explore new ways to implement design research skills and processes. Macdonald (2007) further discusses that clinical professionals often struggle to understand the role of design in health care, but eventually come to acknowledge the boundary-less approach of design as yielding incredible clarity to medical environments. As a designer, the understanding of human activity and human experience is an important focus, and can bring strong contributions to the clinical field. It is critical to bring new skills to a team and to add a new dynamic and perspective to clinical care. Advanced digital technologies have brought positive benefits to the design process and the design field. Exploring the benefits and applications of these technologies in surgical design and simulation as well as in patient experience and patient care is an intriguing area for future exploration. Rehabilitation Sciences is evolving and a fresh perspective adds a unique dynamic to established methods related to clinical care.

This journey as a designer transitioning into the medical world has brought positive and exciting experiences as well. There is a strong interest from medical professionals wanting to know more about the design world and what designers have to offer to the medical world, which has already stimulated greater understanding, learning and collaboration. There has been exposure to innovative and exciting ways in which the medical world has applied advanced digital technology and made great contributions to medical procedures and patient outcomes. Areas that Ben King mentioned in the previous section, such as head and neck cancer patients, craniofacial, orthopedics and cardiovascular surgery as well as preoperative and operative planning are greatly assisted using surgical design and simulation. Simultaneously, there is a lingering need for a greater universal understanding and awareness of technologies across all areas in the medical field. It has become evident that technology is a necessary and useful tool and in order to discover new areas and applications we must have a deeper and stronger evidence based understanding of its potential.

Conclusion

The roles of designers and the level of understanding regarding design from professionals outside of the field strengthens through collaborative efforts; the authors have experienced the benefits of such endeavors and the mutual value that medicine and design can enjoy. The current developments, advancements and growing collaborative potential between industrial designers and medical professionals at iRSM reflects a widening window of opportunity for aspiring designers interested in the medical realm. Whether industrial designers utilize their skills as consultants, members of staff, or clinicians, a beneficial relationship between medicine and design has created new opportunities of knowledge growth, research and collaboration within the two fields. As medicine continues to shift to technology driven workflows, there will be increased demand in a variety of areas such as user-centered approaches, interaction design and user interface design. New collaborations may arise from coincidence, but the hope of the authors is that medicine and design will work together based on a growing resume of results driven by patient outcomes.

Author Biographies

Robert Lederer

Has practiced as an Industrial Designer both as a staff designer and a freelance consultant in Australia and in Canada. He joined the University of Alberta as a sessional instructor in 1986 and as Assistant Professor and Program Coordinator in 1999. He is currently Associate Professor of Industrial Design. His research at present consists of a collaborative venture with the Steadward Center at the U of A developing exercise equipment for spinal cord injured persons, and more recently along with researchers at IRSM (Institute for Reconstructive Sciences in Medicine, Misericordia Hospital), examining “seamless technological interface” in patient treatment systems utilizing rapid–prototyping 3D imagery and other digital formats. A long term collaboration project with the Faculty of Rehabilitation Medicine in the development of student projects in the utilization of Universal design methodology and principles for the design of products for an aging population received a commendation by the American Society on Aging for Exemplary Program in Industrial Design (2002). Robert teaches classes in design principles, advanced industrial design practice and human factors.

Ben King

Is an Industrial Designer with iRSM (Institute for Reconstructive Sciences in Medicine, Misericordia Hospital) and a Master of Design candidate at the University of Alberta. He has extensive experience with Computer Aided Design and Rapid Prototyping for surgical planning as well as product visualization and development. Ben incorporates user-centered and participatory design strategies to achieve innovative approaches within interdisciplinary projects, which have included products and services for rehabilitation medicine, otolaryngology-head and neck surgery, audiology and pediatric medicine. Ben has experience designing and teaching courses on 3D modeling, and is dedicated to improving patient health care experiences and enhancing the abilities of health professionals while promoting the value of design within health care environments.

Heather Logan

Is a graduate from the University of Alberta Industrial Design Program in Edmonton, where she specialized in psychology and sociology. Heather is currently pursuing graduate studies at the University of Alberta and will be completing a Master of Science in Rehabilitation Science specializing in Surgical Design and Simulation. Heather will be conducting research that will focus on advanced digital technology, and the value the technology brings to surgeons, their process and patient outcomes. She has a strong passion to work with people and believes that the understanding of human activity and human experience is essential to design. Her seven years of experience working with people with disabilities and growing up in a family with a physically and mentally impaired brother has given her the knowledge and motivation to work as a successful and innovative cross-disciplinary designer. Her passion to work with people, learn from people and interact with people, joined with her knowledge and skills from her education gives her the greatest inspiration to design.

A Comparison and Analysis of Usability Methods for Web Evaluation: The Relationship Between Typical Usability Test and Bio-Signals Characteristics (EEG, ECG)

Haeinn Lee, St.Cloud State University, USA

Ssanghee Seo, Pusan National University, South Korea

Abstract

A usability assessment is now widely recognized as critical to the success of interactive interface design including web design. In this paper, our research team used a variety of different bio-signals such as Electroencephalogram (EEG), Electrocardiogram (ECG), and Electromyogram (EMG) to evaluate individuals' emotional reactions to different web interface designs. At the same time, we conducted typical usability testing of the same web interface design to compare the results of these two methods, and conclude whether usability testing using bio-signals is a good method to use for web evaluation.

Keywords

Web Interface Design; Usability Test and Method; EEG; ECG; ERP; Human Bio Signals; Visual Brainwork

On the web, usability plays a crucial role in user experience and is emphasized above anything else. It is an inherent design character and requirement, and closely related to various user errors (Rexfelt and Rosenblad, 2006; Latorella and Prabhu, 2000; Gramopadhye and Drury, 2000). Thus, usability testing is essential to create a well-designed web site that is highly usable, and measures a person's individual feeling and emotional satisfaction. Different usability evaluation techniques have been developed and incorporated into the design and development of web sites. Continuing study in this area, this paper shows a new and innovative method for usability testing, which classifies the emotional satisfaction of web interface design.

Typical user-based usability test and new method using bio-signals

Typical user-based usability test

Recently, it has been found that user-based testing is recommended to be the primary method in usability evaluations. The purpose of a usability test is to investigate whether a web interface design meets its usability requirements and problems it is addressing. Evaluating a web interface design helps to find out how successfully the design works, and what kinds of problems users have while using the interface design (Lee, 2006). This method is usually conducted in a scenario-based environment and includes user performance measurements, satisfaction questionnaires, interviews, and participator evaluations (Maguire, 2001; Gray and Salzman, 1998; Nielsen, 1993). With this method, the measures are easily obtained and can be used to infer problem areas in an interface design. This method, however, is too subjective and does not give any clear indication why a certain interface aspect poses a problem to a user or how to improve it (Jaspers, 2009). Therefore we focus on the strengths and weaknesses of typical user-based usability test.

New method of usability testing using bio-signals (EEG, ECG)

With advances in computer video display technologies, such as EEG, fMRI, PET, and SPECT, brain research has become a contemporary issue. Based on this issue, many different major areas, such as Medical Science, Engineering, Psychology, Biotechnology, Linguistics, Economics and Music explore diverse aspects of brain research. Hence, there should be many opportunities to study brain research relative to Art and Design.

When one makes the decision that something is good or bad, his or her decision is a result of the human thinking process. The brain works differently depending on a positive feeling or a negative feeling. In other words, the brain will answer in different ways when people look at effective designs or ineffective designs. One of my previous studies clarifies how the brain works when people look at good and bad design; it also comes up with an objective evaluation of how to judge the design value. Continuing this research, we are evaluating a person's emotion, mainly positive and negative feelings, by using a variety of different bio-signals such as EEG, and ECG.

Electroencephalogram (EEG): Many of the recent advances in understanding the brain are due to the development of techniques that allow scientists to directly monitor neurons throughout the body. EEG is the recording of electrical activity along the scalp produced by the firing of neurons within the brain (Society for Neuroscience, 2005). EEG has several strong components as a tool of exploring brain activity; for example, its time resolution is very high (on the level of a single millisecond).

Electrocardiogram (ECG): ECG is a transthoracic interpretation of the electrical activity of the heart over time captured and externally recorded by skin electrodes (Kumar). Electrical impulses in the heart originate in the sinoatrial node and travel through the intimate conducting system to the heart muscle. The electrical waves can be measured by electrodes placed at specific points on the skin. Electrodes on different sides of the heart measure the activity of different parts of the heart muscle. An ECG displays the voltage between pairs of these electrodes, and the muscle activity that they measure from different directions can also be understood as vectors. This display indicates the overall rhythm of the heart and weaknesses in different parts of the heart muscle. It is the best way to measure and diagnose abnormal rhythms of the heart (Braunwaid, 1997).

At the same time, we conducted a typical usability testing of the same web interface design to compare the results of these two methods, and concluded whether usability testing using bio-signals is a good method to use for web evaluation.

Methods

Participants and decision of web interface design

Ten healthy male college students in their twenties were selected for this experiment. After they agreed to the experiment, they completed questionnaires and we measured their brain waves and the electronic activity of the heart. The participants all consisted of persons who were right-handed and without brain-related diseases.

The websites evaluated were four different car companies' websites. Because of the subject issue, our research team chose all male participants who were interested in buying a car. In order to focus on design issues of web interface, the four websites chosen had brands of equal value and attractive design, but layout designs, navigation methods, and graphic elements were used in different ways. After the participants navigated the four websites, the preferred website was selected from the questionnaires given, and we compared them with the results of brain waves and electronic activity of the heart.

Usability testing procedure

The experiment included three main sessions: the user-based usability test, the EEG measurement, and the ECG measurement. Completing the usability test required approximately 60 minutes. All participants were involved in this research, and the scenario of the experiment is as follows:

1. Attach electrodes for EEG and ECG measurement
2. Show "+" on a computer screen for 4minute to ensure a steady state of participant's brain waves
3. Navigate Samsung SM5 web interface design and complete each task from the questionnaire during the next 10minutes
4. Show "+" on a computer screen for 1minute to ensure a steady state of participant's brain waves again.

5. Navigate GM Daewoo Tosca web interface design and complete each task from the questionnaire during the next 10minutes.
6. Show “+” on a computer screen for 1minute to ensure a steady state of participant’s brain waves again.
7. Navigate KIA Loche web interface design and complete each task from the questionnaire during the next 10minutes
8. Show “+” on a computer screen for 1minute to ensure a steady state of participant’s brain waves again.
9. Navigate Hyundai Sonata web interface design and complete each task from the questionnaire during the next 10minutes.
10. Show “+” on a computer screen for 1minute to ensure a steady state of participant’s brain waves again.
11. Participant chooses a mouse button (Yes: right button, No: left button) to decide whether he buys a Samsung SM5 car and we check event-related brain potentials (ERP).
12. Participant chooses a mouse button (Yes: right button, No: left button) to decide whether he buys a GM Daewoo Tosca car and we check event-related brain potentials (ERP).
13. Participant chooses a mouse button (Yes: right button, No: left button) to decide whether he buys a KIA Loche car and we check event-related brain potentials (ERP).
14. Participant chooses a mouse button (Yes: right button, No: left button) to decide whether he buys a Hyundai Sonata car and we check event-related brain potentials (ERP).
15. Participant fills out the user survey form for his preference of web interface design.

Procedure of typical user-based testing method

Usability assessment is now widely recognized as critical to the success of interactive interface design, including web design. Most common and typical usability testing is user-based evaluation that is based on user performance measurements, keystroke analyses, satisfaction questionnaires, and interviews. Using the four different web interface designs chosen, usability testing was conducted to analyze the user’s experience and performance. First, participants were asked for demographic information such as age, occupation, and their computer usage. Second, participants were asked to perform three tasks on the computer, and they had to finish all tasks navigating each car company’s website. Tasks were divided into specific questions such as checking each car’s model, shape, color, safety, performance, and price in order to find more accurate results. To accomplish these tasks, participants would navigate most of the websites. The software ‘Camtasia’ was used to capture a screen record and participants’ voices. Lastly, participants were asked to choose their preference of web interface design.

Procedure of usability testing using bio-signals method (EEG, ECG)

We also conducted usability testing using bio-signals, EEG and ECG, to evaluate individuals’ emotional reaction to different web interface designs in this research. Using the EEG method, electrodes placed on specific parts of the brain, which vary depending on which sensory system is being tested, make recordings that are then processed by a computer.

Our team has used the technique of EEG to address the question of how the brain answers while participants viewed websites. The most difficult decision when using EEG is which part of brain we need to place electrodes to measure the brain waves. Electrode location and names are specified by the 10-20 system for most research applications. This system is an internationally recognized method to describe and apply the location of electrodes in the context of an EEG test (Fig.1).

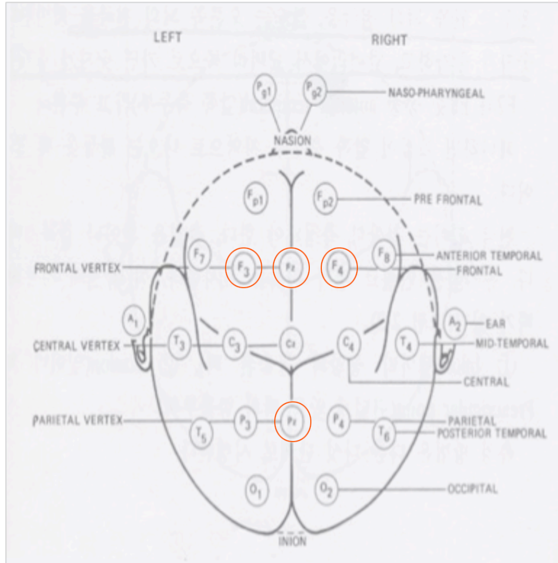

Figure 1 Electrodes location to check the EEG (10-20 System*)*

Brain waves were measured by QEEG-4 (LAXTHA) and 256Hz was selected for a sampling frequency. The position of electrodes went by the international 10-20 electrode arrangement, using the channels of F3 and F4 for emotional control area and Fz and Pz for decision making area. Standard electrodes were applied to Cz. The electrode arrangement plan is shown in Figure 1.

During the experiment, we used event-related brain potentials (ERP), which is a method in checking an electroencephalogram in certain moments when participants received the event, like choosing a mouse button to decide which car to buy. ERP is any measured brain response that is directly the result of a thought or perception. It can be reliably measured using the EEG, a procedure that measures electrical activity of the brain through the skull and scalp (Coles, Michael, and Rugg, 1996). There are four important components in the ERP waveform, which are P300, P600, P800 and N400. The N400 ERP component is described as a negative voltage deflection occurring approximately 400ms after stimulus onset, whereas the P300 component describes as a positive voltage deflection 300ms after stimulus onset. The presence, magnitude, topography and time of this signal are often used as metrics of cognitive function in decision-making processes.

Proper placement of the limb electrodes for ECG measurement is color coded as recommended by the American Health Association (Fig.2). Limb electrodes can be far down on the limbs or close to the hips/shoulders, but they must be even (left vs. right). Our research team attached electrodes like first figure and measured the electric waves of SDNN, the standard deviation of the normal RR intervals, and the ratio of high frequency (HF) and low frequency (LF) to check emotional status.

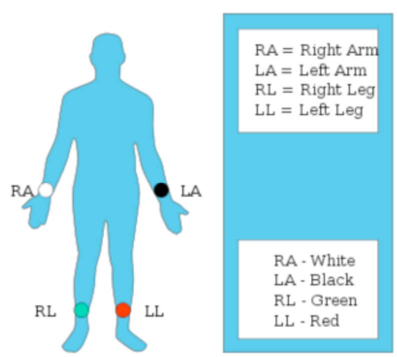

Figure 2 Electrodes location to check the ECG

Results

Analysis of typical user-based usability testing

Typical usability testing was user-based performance that was evaluated based on total time to complete tasks, number of errors, frequency of assists, and the percentage of completed tasks. Table1 shows the result of total time to complete task. The first column shows each participant and the first row shows the each website. Red texts show shortest time that participants had to finish all tasks from the websites.

Table 5 Estimated participant's preference of web interface design from user-based usability testing

Lastly, Table6 shows the results from the user survey that participants directly answered the one, which they liked most among the four web interface designs. The results of Table 5 and Table 6 are mostly similar with few differences; therefore the user-based usability testing was successful.

1	2	3	4	5	6	7	8	9	10
Loche	SM5	Loche	Loche	Sonata	Sonata	Loche	Loche	Loche	Tosca

Table 6 Participant's preference of web interface design from user survey

Analysis of usability test using bio-signals (EEG, ECG)

First, we analyzed the ECG electric waves of SDNN, the standard deviation of the normal RR intervals, and the ratio of high frequency (HF) and low frequency (LF) to check emotional status. The higher number of SDNN means the participant's emotion is more active and positive. The lower number means there is no emotional feeling change. The higher number of HF means the participant's heartbeat is stronger which shows more active and positive feeling. Therefore, the smaller ratio of LF divided by HF is their preference website.

Table 7 Estimated participant's preference of web interface design from ECG

Second, we analyzed the EEG data, which a frequency of 4~30 Hz was selected to remove the noise from raw data, and the values of RPS (relative power spectrum) were found in the frequency band of brain waves, theta (4~8 Hz) and beta (13~30 Hz), using FFT (Fast Fourier Transform). As we mentioned previously, brain waves were measured by QEEG-4 (LAXTHA) and the position of electrodes went by the international 10-20 electrode arrangement, using the channels of F3 and F4 for emotional control areas.

Higher numbers of theta mean that people are a in comfortable and positive status, while higher numbers of beta mean that people are a in nervous and anxious thinking status. Thus, the F3 position is located in the left side of the brain, an area that processes optimistic thinking, and the F4 position is located in the right side of the brain, an area that processes pessimistic thinking. Therefore, we need to focus more on analyzing the F3 area for decision of preference of web interface design.

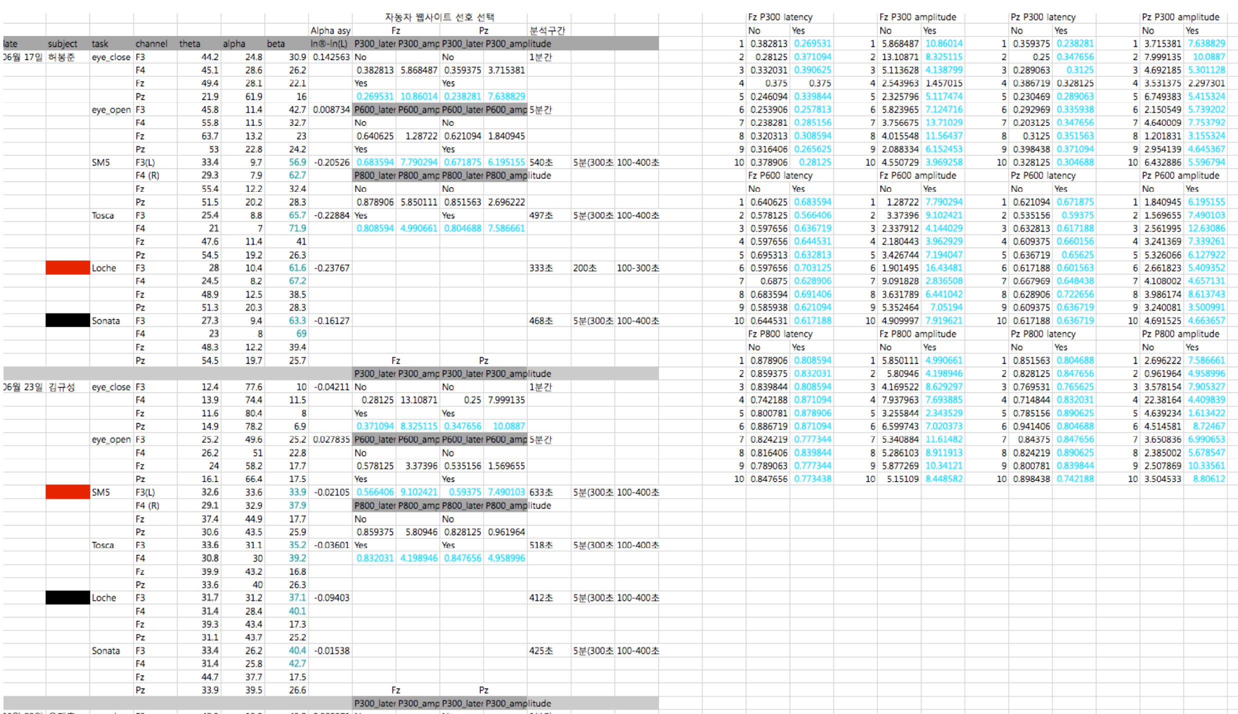

Figure 4 Example of analyzing EEG data

Figure 5 shows the result of beta power of F3 and F4. The red squares are the preference of web interface designs that participants chose from the user survey, and the black squares are the ones that they do not like. According to the figure of beta power of F3, most of their preference websites of beta power are lower than non-preference websites. As we mentioned previously, beta power shows the meaning of nervous and anxious thinking status, so this result is what we anticipated.

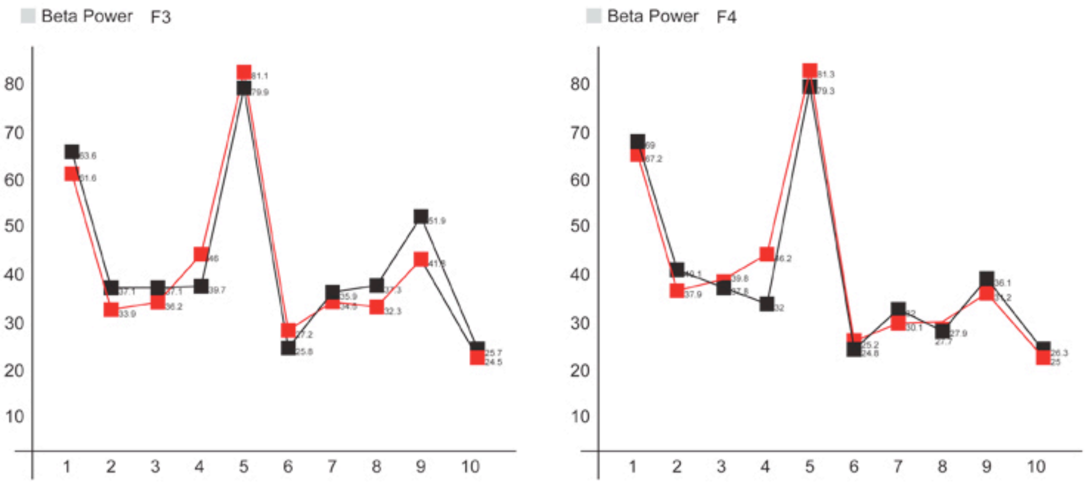

Figure 5 Result of beta power of F3 and F4

Figure 6 shows the result of theta power of F3 and F4. Again, the red squares are the preference of web interface designs that participants chose from the user survey, and the black squares are the ones that they do not like. According to the figure of theta power of F3, most of their preference websites of theta power are higher than non-preference websites. As we mentioned previously, theta power shows the meaning of comfortable status, so this result is what we anticipated.

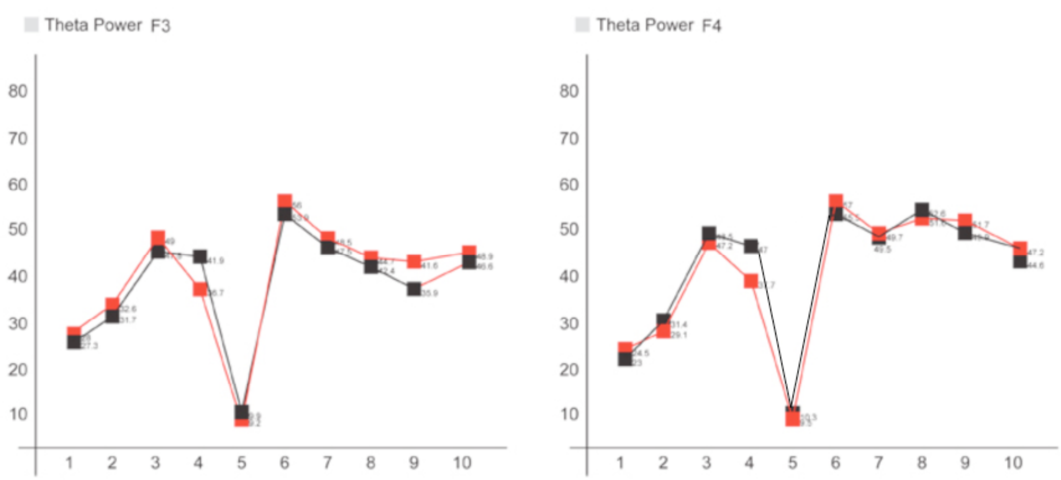

Figure 6 Result of theta power of F3 and F4

Additionally, we used event-related brain potentials (ERP), which is a method in checking an electroencephalogram in certain moments when participants received the event like clicking a mouse button (Yes: right button, No: left button) to decide which car to buy. Our research team attached the electrodes to Fz and Pz, which are areas for decision making.

Figure7 shows the P300, P600, and P800 of ERP results at the moment of participants clicked the preference of car. From the analysis, we concluded the amplitude of P600 shows the highest and strongest reactions when the participants chose preference of car.

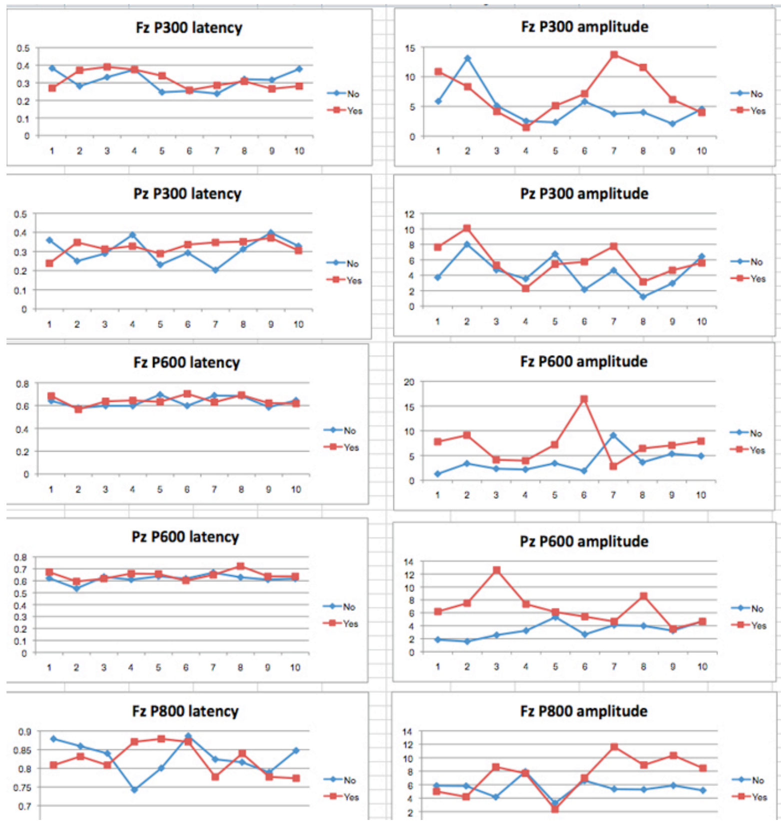

Figure 7 P300, P600, P800 of ERP result

Comparison and relationship of two methods

Table8 shows the results of the comparison between user-based usability testing, including the user survey and new usability testing methods using bio-signals (EEG, ECG). The final results of participants' preferences of car web interfaces consist through all different usability test methods, except the result of ECG (LF/HF). This result shows irregular choice of preference of car websites compared to other methods, and it is reasonable that we can eliminate it as final conclusion.

Table 8 Comparison of all methods

Conclusion

The purpose of a usability test is to investigate whether a web interface design meets its usability requirements and the problem it is addressing. Recently, it has been found that user-based testing is recommended to be the primary method in usability evaluations. With this method, the measures are easily obtained and can be used to infer problem areas in an interface design. However, sometimes it is too subjective and does not give any clear indication why a certain interface aspect poses a problem to a user or how to improve. To make up for this weak point, our research team used bio-signals (EEG, ECG) to evaluate individuals' emotional reactions to different web interface designs in this research.

Based on the result of typical user-based usability testing, we compared the result of new methods using EEG and ECG and it shows similar conclusion. Almost 70% of what participants chose the preference car website from typical-user based usability testing are the same result from the new method using bio-signals (EEG, ECG) which means reasonable and valuable method for web evaluation.

One of the most important issues in web interface design is a usability test to grasp a person's individual feeling and measure the emotional satisfaction. The web interface designs are also objectively assessed by measuring the degree of utilization of the design elements, clarifying how it affects their emotional feelings, and comparing it to the results of frequency from bio-signals. New design methods are required so web designers can grasp the proper emotion, impression, and feeling of a web interface, and reflect these elements to make better web interface design. In the future, the idea of this paper shows an innovative method for usability tests, which can classify emotional satisfaction of web interface design, also linked with ease of use.

Author Biography

Haeinn Lee

Haeinn Lee is an assistant professor of Graphic Design at St.Cloud State University where she teaches typographic design and information & interface design. She received her MFA degree in Graphic Design at Iowa State University. She has presented her research and design works in conferences both nationally and internationally. Her research interest focuses on experience design, typographic design, user research and brain works based on graphic design.

Ssanghee Seo

Ssanghee Seo is an associate researcher of BK center for U-Port IT research and education at Pusan National University. She received Ph.D. degree at Kyungnam University in 2000. She was included in MARQUIS Who’s who in the World 2010, IBC 2010 and ABI 2010 on brain engineering. Her research interest focuses on brain-computer interface and pain control using rTMS.

Design Research Methodology

Design research and the complexity encountered in people's critical thoughts

Yong-Ki Lee, Korea Advanced Institute of Science and Technology, ykl77@kaist.ac.kr

Kun-Pyo Lee, Korea Advanced Institute of Science and Technology, kplee@kaist.ac.kr

Abstract

This study focuses on the concept of "Critical Design", which describes the development and use of design objects for the discussion of social and technological problem areas. "Critical Design" provokes or puzzles the consumer. Instead of offering people merely optimized and constraint action patterns, open situations and questions are created. The arising reactions provide valuable insights for innovative product development and basic design research. This paper assesses the potential of "Critical Design" approaches to be utilized as novel research tools for future challenges to design. The main contributions of this paper are threefold. Firstly, it reviews various ways of user engagement to design that reinterprets the conventional relationship of user and designer. Secondly, it selects and evaluates specific qualitative research methodologies that accept and support the active involvement of the researcher as well as the importance of letting theories "emerge" out of data, in order to develop a methodological research framework specific and original to design. Finally, the study offers an assessment of "Critical Design's" potential, to understand and deal with people in a novel and richer way and to test it as a research tool that supports complex approaches. "Critical Design" illustrates the need for design researcher to deal with complexity encountered in the general dynamic of actors and in people's critical thinking.

Design and society, Action research, Social and cultural studies, Qualitative research methodology

1. Introduction

Before the consumer takes over possession by means of purchase, every product carries a specifically precast meaning of its own. Part of this meaning is the value model, which is attributed to the artifact by marketing's communication strategy. This model confers the aura of a brand or the corporation and consists of a defined image aimed at the desired target audience. Another part of the meaning is of rather practical nature: It consists of the definition of the intended purpose. It is the manufacturer or producer who determines this purpose of the product, i.e. the functions, which the product must fulfill, and the areas in which it shall be used. The determination of the purpose necessarily follows the needs of the consumer, while it remains to argue how these needs have been proven by empirical studies or rated as "natural" needs. In this condition, the product leaves the producer as an object, which is equipped with a number of invisible values, attributes, and definitions, or in other terms the product is equipped with a story. In recent years, the design industry has recognized these virtual values as a trend and has labeled it with the term "Storytelling" or "Narratives".

With the purchase of the product, the process of the product development could actually be completed. However, this is obviously not the case. Only at this point does the unfolding complexity caused by the design become apparent. As soon as the user unpacks the purchased product, she begins to undermine and manipulate the idea of precast image and purpose: The product generally is not used according to the exact notion of the producer. This disobedience of the user points out the shortcomings of such predefined interpretations and definitions and reveals their arbitrary and “user-unfriendly” nature.

2. Reinterpreting the relationship between user and designer

2.1 Subversion of the function

Brandes et al. coined the term “Non Intentional Design” or NID (Brandes et al. 2000) to describe the aforementioned reinterpretation of product functions. They describe this phenomenon with the “everyday redesign of the designed product”. Thereby, “Non Intentional” does not refer to the purpose, but rather to the process of design. NID in fact has an intentional goal or dedication: by inventing new possible applications and producing new narratives, the user satisfies unmet needs neglected by the original product design. However, it is not a deliberate design activity, since the change of the operation is carried out at a visceral level. More likely, it is a reflex, a reaction to the restrictions, which the object embodies.

“According to the motivation, no design results [...] since the impulse to consciously create design is missing. Non Intentional Design is not characterized or driven by the creative will.” (Brandes et al. 2000)

NID primarily happens in everyday handling of products, anytime the users change the predetermined purpose of an object. Turning a chair into a wardrobe could be one scenario to illustrate such a situation. Instead of using the hooks of a wardrobe, one uses the backrest of a chair to hang up the jacket. At that moment, the real function of the chair is reinterpreted. The chair turns into a wardrobe, because to the user it might appear to be the better satisfier to the need of storing one's clothes. The motives for this repurposing can be versatile and deliver information about the user's complex patterns of requirements: The chair might facilitate a better drying of the jacket, it might be closer to the user giving her a more secure feeling or it might allow the user to faster access things, which are kept in the jacket. Of course, these are only some possibilities motivated by the concept of NID. A deeper understanding of the processes during the use of objects is necessary to achieve a design that better considers the use situation and the complex needs involved. Thus, it is highly relevant to the quality of design outcomes to understand that the user's motives to handle a product in other than the “built-in” or designed ways are an attempt to remedy a situated deficit. The observations of the everyday redesign processes in the context of NID show that there are many deficiencies, which have to be addressed by investigations to inform design about novel necessities and unforeseen requirements.

Unlike NID, the so-called formation of “Beta-Tester” (Dunne, Raby 2001) intentionally confronts themselves with the redesign of objects. The term “beta” thereby is a well-suited metaphor for the processes of hacking and manipulating predetermined design concepts. The Beta as the second character of the Greek alphabet is used as an attribute to describe a second version of a Narrative or product meaning, which is not precast by the designer but interpreted by the user. Analogous, a similar meaning can be found in the field of software: the Beta-version is commonly a preliminary form of newer or advanced software, which is initially tested by the user before its market launch.

Similarly to the users involved in the processes of NID, Beta-Tester as well perform a repurposing. Yet, this misappropriation is conducted within a framework of an intentional design process and therefore it is a planned and conscientious act of designing by the user.

Beta-Tester, in a playful and exploratory way, redesign existing objects in order to utilize them beyond their initial purposes for their individually defined aims. As seen with NID, Beta-Tester also practice reformatting and overwriting existing Narratives by formulating and telling their own stories of use. In addition to this reappropriation, Beta-Testing involves a manipulation of physical forms and surfaces of the object, making it similar to hacking practices.

Fiona Raby and Anthony Dunne exemplify various Beta-Tester in their book “Design Noir”. For instance, they mention the “Anarchist Cookbook”, in which instructions are given to create sophisticated weapons out of everyday objects, or a group of athletes who with the deployment of radio antennas, receivers, and radio direction finders conduct some kind of urban orienteering where they try to recover electronic transmitter that have been hidden in the field. With the latter example, it becomes apparent that this extreme “disobedience” to the prefabricated world of consumption requires a substantial degree of technical knowledge and familiarity with the devices and the tools needed for the production of such equipment.

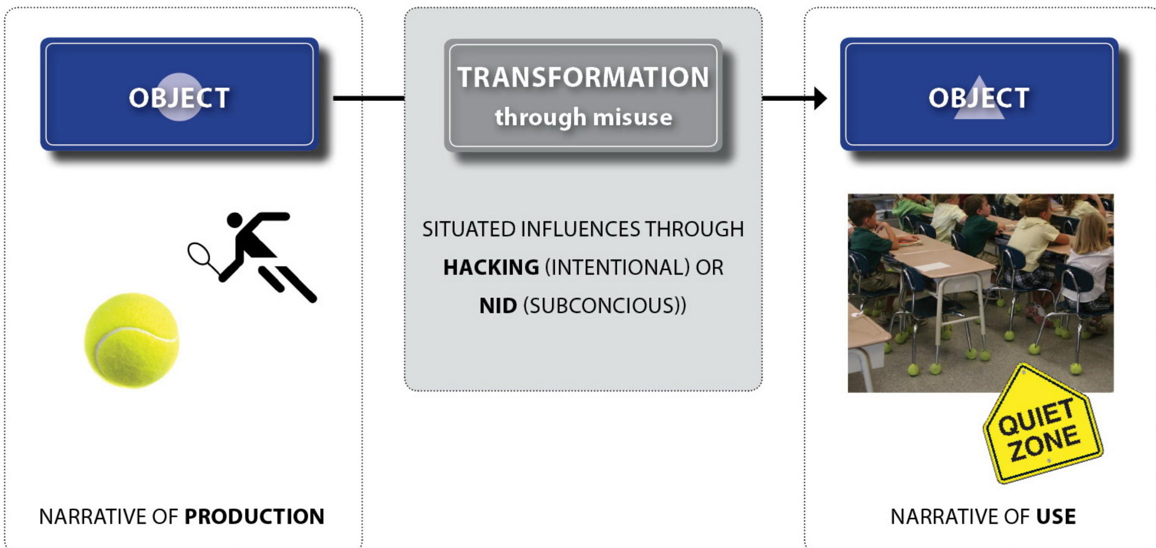

Figure 1 Subversion of the Function. Tennis balls serve as cushion to reduce the noise caused by moving school furniture.

2.2 From Consumer to Prosumer

The aforementioned phenomena emphasize the existence of reappropriation and redesign tendencies with narratives in the use of objects. Thereby, we are dealing with motivations that, driven by product deficiencies or dissatisfactions in the situation of use, aim at overcoming the status quo. Similarly, there are many other modification tactics in the world of consumer products: car-tuning, accessories in fashion, DIY, cooking, case-modding of computer boxes, just to mention a few. In most of the cases, the driving force to redesign is the desire for individuality: modifying, extending, recreating, or redefining oneself.

“Overall, making things is not an end in itself, but has to be regarded as a automatism of an incremental process of identity formation under the constraints of a progressing individualization. When there is an abundance of possibilities, orientation and thus identity can only be constructed piece by piece instead of one big cast.” (Liebl, Düllo, Kiel 2005)

Be it of a purely functional or individualistic nature, the user obviously has a fundamental drive to design. Taking a glance at today's Open Source cultures and noticing the flourish of Blogs, the efforts of autonomous design activities in the digital and virtual world are already highly advanced. In this way the roles of producer and consumer converge to a new role which Alvin

Toffler in his book from 1980, “The Third Wave”, has called the “Prosumer” (Toffler 1984)

The development of consumers actively participating in the design should not frighten the designers. Surely, there is no trend towards a society without designers. It rather shows that the effort is worthwhile to pay more attention to the use-situation. Considering the phenomena of the participating consumer, interesting and useful insights can be collected to inform product development from specific use-situations. It must therefore be the aim to understand the circumstances, mechanisms and goals related to the use-situation to better analyze the underlying psycho-social factors.

“It is astonishing that despite this problem statement, which dates back far into the eighties there is still no qualitative Design Research and the Study of the everyday life in the field of design.” (Brandes et al. 2000)

The aim of this study will thus be to describe the processes involved in the transformation of artifacts, from the designed object to an object of use, and how this alteration or translation process could be specifically utilized in design research, in order to better understand people’s motivations, behaviors, and “Complicated Pleasures”. In the end, this will lead to a qualitative improvement of design outcomes.

In the following, specific qualitative research methodologies that accept and support the active involvement of the researcher are reviewed. Those approaches are crucial to portray people’s motivations and behaviors, and they recognize the importance of letting theories “emerge” out of data to develop methodological research frameworks specific and original to design.

3. Design as a research tool

In his article “Research in Art and Design” (Frayling 1993), Christopher Frayling classifies design research in three distinct directions: research INTO art and design, research FOR art and design, and research THROUGH art and design.

The design aspects within this classification are as follows.

1. Research INTO design: e.g. Design History (operates in a scientific-observing manner, i.e. observing from the distance without influencing the subject.)
2. Research FOR design: e.g. Market Research or Consumer Research (provides necessary insights for the design process. Designers can deliver those results. However, those can be of varying use to others due to the specific constraints applied by the design methodology.)
3. Research THROUGH design: Design Practice as Research (allows the researcher to design the subject of study as well as the study context with all its elements.)

The vast majority of the Anglophone design research emphasizes the two first categories as central part acknowledging design as a scientific discipline. Looking at the slow advancements in higher theoretical design education, the existence of research through design still seems to lack credibility. Yet, possibilities of scientific methodical approaches towards design do exist. They are from the sociology-based area of qualitative research and are already applied in design:

- *Action Research*: as a method for changing the practice
- *Grounded Theory*: as a method to develop a theory
- *Mode*-2 research: as a method with inter-relationships between science and society

These methods accept and support the active involvement of the researcher as well as the importance of letting theories "emerge" out of data. Theories are no longer considered mere verifications of previously stated hypotheses just to affirm existing coherences. Rather, they are understood to openly interact with an instable study area, and always being flexible to change. Immediacy to the subject of study and ways to cope with inexactness and uncertainty are new challenges with this approach. Therefore, when talking about design research it is impossible to reduce its methodologies to the first two categories of researching into and for design. They might offer scientific innocuousness, however they do not lead to what design research could become: a self-contained and original research domain that is closer to the real world. Hence, the challenge is to look for a method specific and original to design, which orients itself to the aforementioned areas of qualitative research and emancipates itself from rigid and traditional Mode-1 research, by introducing new methodologies that are more adaptive to current challenges and problems.

3.1 Action Research

During his time at MIT in 1944, Psychologist Kurt Lewin coined the term "action research". In a paper published in 1946 titled "Action Research and Minority Problems" he described action research as "a comparative research on the conditions and effects of various forms of social action and research leading to social action that uses a spiral of steps, each of which is composed of a circle of planning, action, and fact-finding about the result of the action" (Lewin 1946).

Action research in its origin primarily saw itself as criticism to traditional social research through which it not only made a methodological but also an epistemological contribution. At the level of methodology, Lewin denounced the increasing estrangement between sociological theory and practice. The aim was that science could and should change the field of practice. Therefore, action research was considered a study within the social domain where there should be no more strict separation of the researcher and the participant and where social change as well as the activation of the participant should be the main goal.

At the level of epistemology, Wadsworth considered action or participatory research not only as a method but also as a general paradigm for research. He claimed that action researchers are simply conscious of the unavoidable fact that they influence the object of research by their examinations:

"Action researchers, it seems to me, are really just researchers who have come to understand the practical and ethical implications of the inevitability of the value-driven and action-effects of their inquiry, that is:

- *the effects of raising some questions and not others,*
- *the effects of involving some people in the process and not others,*
- *the effects of observing some phenomena and not others,*
- *the effects of making this sense of it and not alternative senses, and*
- *the effects of deciding to take this action as a result of it rather than any other action." (Wadsworth 1998)*

Through action research, the researcher is intentionally integrated as a stimulating actor.

3.2 Grounded Theory

In Grounded Theory, (Glaser, Strauss 1967) the relationship of theory and empiricism consists of the principle of openness and of the communication. The principle of openness states that the theoretical structuring of the object of research is held back until the structuring of the object by the research subjects has taken shape. To avoid any pre-knowledge and prejudices at the beginning of an examination, a clarifying discussion by the means of brainstorming or analysis is required. The principle of communication refers to a communicative research concept which considers the interaction between researcher and participant and suggests the communication rules and interaction forms.

3.3 Mode 2 Research

Another concept from social studies is the so-called Mode-2 research (Gibbons et al. 1994). Gibbons et al. argued that a new form of knowledge production started emerging from the mid 20th century which is context-driven, problem-focused and interdisciplinary. It is closely related to the methods of qualitative social research, however, seeks for an approach to bridge from classic science methods over to application-oriented methods. Instead of special academic interests, real problem definitions from practice are the motivators of the research. The following table shows a comparison of the research approaches. It summarizes features of the approaches discussed here and mentions possible characteristics of design oriented research, which is transformed from the subject-object relation of conventional social research into a subject-subject relation.

Table 1 Comparison of qualitative research approaches.

	MODE 1	MODE 2
Problem statement/ solution	In the academic community	In the situational context
Aim of research	Fundamental principles and their integration into theories	Contextualized result and their application
Research content	Bound to disciplines	Trans-Disciplinary
Research structure	Hierarchical und homogenous	Transient, heterogeneous
Quality control	Fixed to expert judgment	Multidimensional/use-oriented
Communication	One-way Information transfer from science to society	Diffusion process/interactive relationships between science and society

4. “Critical Design” as a research tool supporting complex approaches

4.1 Conservative Products

In his book “The System of Things” (Baudrillard 2006) Jean Baudrillard talks of how nowadays products force their rhythm upon people instead of people determining their rhythm by themselves. This surely applies to many products. For example, there are automatic error corrections in computer interfaces, ergonomic regulations in furniture, assisting “wizards” in cars, etc. that are all supposed to simplify things by spoon-feeding the user. It is all about the apparent optimization of use. Yet, in the actual use, these optimizations are often perceived as restrictions and thus are consciously or unconsciously ignored. Even if, as a designer, one detects something about the true, complex desires of users, there still is the client with her wishes and her cost-benefit calculations, which hinder the development of better products. This inevitably results in even more so-called “Conservative Products” (Auger 2005), which go by the dominantly established understanding of supposed optimal user satisfaction, and thereby jam developments in new directions. Design that orientates itself to existing markets and its products without analyzing them cannot bring any change. Dunne & Raby describe this uncritically confirming design as “Affirmative Design” (Dunne, Raby 2001).

4.2 Wondering Products

What could be the counter balance to these conservative products, which exclusively affirm the status quo and which embody the normative or official standpoint?

“Beneath the glossy surface of official design lurks a dark and strange world driven by real human needs. A place where electronic objects co-star in a noir thriller, working with likeminded individuals to escape normalism and ensure that even a totally manufactured environment has room for danger, adventure and transgression. We don’t think that design can ever fully anticipate the richness of this unofficial world and neither should it. But it can draw inspiration from it and develop new design approaches so that our new environment evolves; there is still scope for rich and complex human pleasure.” (Dunne, Raby 2001)

In accordance to Dunne and Raby, we argue that the counterparts to conservative products are artifacts that raise questions. It has to be products that are subject to uncertainty, which suggest open ways of use, and which question existing use patterns. On the one hand, this is a reaction to the lessons learned from the NID concept, on the other we are supporting the required reorientation towards more qualitative aspects of design research that adapt to the users’ improvised behaviors.

In their free play with things, users steadily test the boundaries of new values and norms creating unforeseen situations. This uncertainty must be turned into strength. Anthony Dunne claims, designers cannot expect to be able to dictate users’ behavior with absolute rules and fixed structures anymore.

“All he or she can offer are the contents of his or her own head, where internal imagination meets the external world of reality. Design is used as a strategy for linking these two worlds. Its outcome consists of conceptual design proposals offering a critique of the present through the material embodiment of functions derived from alternative value systems” (Dunne, Raby 2001)

Those conceptual design proposals stand between the imaginary and reality. They relate to Values and behavioral patterns, which are hypothetical or just made up, resulting in so-called “Value Fictions” (Dunne, Raby 2001) that are the basis of further designs. As we are moving around in this fictional world, we as designer are able to act like authors of stories. Fictions allow us to imagine any kind of condition, to ask questions, and to turn possibilities into subjects of discussion. Treated as actual possibilities, those fictions serve to make concepts and imaginations subjectively graspable for the reflection of our individual narrative. Hypothetical objects and products therefore contain some poetic aspects that allow us to experience imagined concepts closer to reality.

At this point, provocations and irritating objects are able to be reappropriated to enable new experiences far beyond usability. The Experiences are all about situations that evoke reactions. Furthermore, stimulating products are intended to play a crucial part in the analysis of those reactions. This kind of design facilitates to create wondering products, objects that ask questions, which can be used to address, illuminate, and even produce research-topics.

This kind of design is what Anthony Dunne calls “Critical Design” (Dunne 2006) as opposed to the earlier mentioned affirmative design. It offers the design-inherent qualities of mediating and illustrating complex problems and gives the user deeper insights to implications of current societal and technological developments. In this sense, “Critical Design” fulfills the educational responsibility to inform people, to communicate contemporary issues, and to offer the designer an opportunity to dive into the research field during the early stage of the design phase. The user’s reception therefore becomes a productive part of the design process.

"Critical Design needn't be judgmental of any particular technology, it simply asks for a more complete debate on how it is applied, who is applying it and how we could be affected by its mediation of our lives. Successful "Critical Design" comes about from good balance and application of three things:

1. *The application and usage of technology should be relatively feasible, i.e. the concept cannot easily be dismissed as science fiction.*
2. *The design concept, product or service needs to be desirable in both form and function.*
3. *Communication is of fundamental importance. This is why the written word usually reaches such a limited audience; a page of complex text does not encourage the average person to read on. A sophisticated "Critical Design" proposal can utilize props, newspaper articles and other means to entice and coax the audience into the discussion." (Auger 2005)*

"Critical Design" demands for dispute, enlightens researches, mediates and communicates through design.

Table 2 "Critical Design's" impact in project-works

MODE OF ACTION	PROJECT EXAMPLES
Stimulation (of the research field)	Stimulating: "Iso Phone" (James Auger), "Social Mobile" (Crispin Jones)
Simulation (of discussions)	Discussing: [all "Critical Design" projects raise discussions]
Measurement (for analysis)	Observing: "Placebo" (Dunne & Raby)
Comment (as a statement)	Commenting: "Huggable Mushroom" (Dunne & Raby)
Mediation (of complex topics)	Mediating: "Bio Jewelry" (Tobie Kerridge)

4.3 "Critical Design" as a research probe

Is "Critical Design" suited as a means of research? The table describing "Critical Design's" impact in project-works shows four modes of action that illustrate its versatility as a research tool. The first two are "stimulation" and "measurement". The metaphor of probe is an interesting approach to describe how "Critical Design" accomplishes these two modes. In its original meaning, a probe stimulates and at the same time senses. Both procedures of stimulation and measuring influence and change the study-objects simultaneously. The Heisenberg Uncertainty Principle already described this phenomenon that it is impossible to observe without changing the observed. This universal rule leads to the notion that fuzziness or blur are inseparable parts of nature that have to be accepted and dealt with. By including the aspect of uncertainty, the focus shifts on qualitative aspects of research that incorporate the idea of instability. Action Research and Grounded Theory, the two established methods of qualitative research discussed earlier, strongly relate to this principle of observing in the field and stimulating through interventions. "Critical Design" thus shows a natural affinity to those qualitative research methods.

The remaining two modes, "comment" and "mediation", emerge from Dunne & Raby's original concept. They stand for the development and use of design objects to raise discussions about societal and technological issues. Objects of "Critical Design" challenge the user by provoking or irritating them. The resulting reactions provide valuable insights for the product development that, for instance, could be revealing implications of new technologies. Projects like Dunne & Raby's Huggable Mushroom or Auger and Loizeau's IsoPhone exemplify how objects turn into critical comments on technology and mediate the issue in ways of embodying the statement, so that it can be discussed. They try to test the psychosocial limits of the user by questioning usages of technology.

Hence, "Critical Design" proves to have high potential to pick up debates on relevant issues in order to test them for further research and to inform early design processes. It is a useful research tool for the designer, which lets people substantially benefit from it: The mediation of technology and the probing of unprecedented possibilities in everyday life give people a useful tool that empowers them to self-engage with previously unnoticed issues and shape a personal attitude towards the same.

About the work of Dunne & Raby, who have pioneered this design approach, there is one crucial thing that is still missing in their practice. They only conduct a limited empirical analysis of people's reactions. Like the aforementioned probe, which provides observation data as well as stimulates the study object, "Critical Design" could sense and assess the importance, acceptance and integration of technology in everyday life.

4.4 The detachment from technology

The areas that Auger and Dunne mainly focus on are discussions about the implications of new technologies and their influence on everyday life. People as anti heroes of the quotidian life are confronted with invisible technologies such as electromagnetic radiation, radio waves, or other forms of data transmission. Many disclosed aspects, which design can make accessible for experience and vision are found in these topics, so that thinking about these technologies can be designed more effectively.

At first, the important aspect is to make the ability for critique possible, by avoiding any readymade opinions or fixed statements, and permitting future technologies to enter the personal sphere as a possible part of one's everyday life. The mediations of invisible or fluid technologies through physical interfaces is especially important to those people who are not so familiar with newer technologies, since they do not belong to the young, technology oriented, early adopters who have the money to buy e.g. the latest gadgets. In contrast to those, older and poorer people need a different access to technology. Thus, objects conceived as an interface to technology are the medium with which the particular and the society are able to recognize and identify themselves. In other words, in the industrial society there is a gap between the ability to use technology and the ability to integrate that technology personally and socially so that it becomes meaningful and individually relevant.

What do we get as we define these two positions as extremes? In the first case of early adopters, there is an uncritical and barely reflected relationship to technology, while in the second case of the elderly or the poor there are fears of contact and lack of understanding. For the first group the affirmative design develops gadgets with increasingly more functions and steadily growing usability as sign of a rising optimization. The affirmative design however does not develop those gadgets in the light of a meaningful integration to our everyday lives, but rather to bring them closer to or even into our human bodies. For the second group existing products are generally simplified to keep the people away from the real potential of the technology. In conclusion, technology is either invading and conquering or isolating and discriminating us through affirmative design. It is to question whether this quantitative outlook on the future relationship between humans and technology that is caused by affirmative design a desirable one.

A qualitative access to technologies must produce a necessary distance to them, so that other opportunities get visible, and that the optimization of objects does not simply happen based on a pure interface improvement between man and machine. Interface theorists like Donald A. Norman may have pioneered concepts of user-centered designs, yet those may fail to provide deeper values to people, as they do not pick up the social integration, meaning, and the development of new use-possibilities for products as the central theme.

4.5 A new prospect: Heterotopia

Utopia is always about escape and dream, as mystical scenarios filter the present real-world. Yet, how can we achieve that the desire for improvement in the world will not be exhausted in naive wishing? Design's credibility as a research discipline has always suffered from being too illusory. Consequently, the time for Utopia and utopian designs has to be over, since today's challenges do not demand for unreal and readymade visions that are inaccessibly rooted in the ideal world. However, what are other options to Utopia? Within the limitations of this paper, the authors introduce a fundamental notion to a methodology based on "Critical Design" that sits between science and art and that replaces utopian designs.

Such a design methodology would have to clarify aspects of its mode of engagement to avoid two common pitfalls. These are first, how far design manages to aestheticize without getting egocentric and unratable so that it would become Art, and second, how design activities gain accountability without losing their inspirational autonomy so that it would become Science. Since we are talking about design, one too obvious mode of engagement would be that of spreading utopian fragments through tangible objects and enactable scenarios in order to refresh our perception of the presence, to confuse the people and to provoke their reflection. This is partially happing already, however with little impact. Another more subtle mode would be the formation of a sense for possibility, which pushes aside pointless dreaming by promoting debates about the possible and the desirable and introducing a complementary model called "Heterotopia". It stands for actual 'places' integrated in the real society, in which autonomous rules of their own are valid, but also in which the social values of the real world are mirrored. Michel Foucault says:

"There are also, probably in every culture, in every civilization, real places - places that do exist and that are formed in the very founding of society - which are something like counter-sites, a kind of effectively enacted utopia in which the real sites, all the other real sites that can be found within the culture, are simultaneously represented, contested, and inverted. Places of this kind are outside of all places, even though it may be possible to indicate their location in reality." (Foucault 1967)

Foucault exemplifies such places as hospitals, prisons, elderly homes, cemeteries, or even travel journeys. Despite their reality, these places offer a large projection surface, which design can use. The garden, the theatre or the ship as metaphors provide us a "reservoir of imagination". We can utilize this "reservoir" with heterotopian products inspired by a "Critical Design" approach.

The concept of Heterotopia, which Anthony Dunne also describes in his book "Hertzian Tales", might become clearer through the help of a medical definition. Medically speaking, Heterotopia stands for a shift of healthy body tissue to an unusual or wrong place, where it causes vivacious activation. In accordance, a heterotopian concept of design could be understood as design being within society to which it brings constructive unrest, whereas the conventional utopian concept of design would locate it outside society, where it rather has a mesmerizing and even narcotic effect. Unlike science or the arts, which stand outside society to merely comment on it, industrial design has always been deeply rooted within popular culture and the everyday life and has always been commented on. This position of design bears great potential for a design research that emancipates itself from the shortcomings of overly rigid scientific approaches as well as from unaccountable artistic outbreaks. Design having an intrinsic heterotopian potential can inspire researchers across the disciplines for more ‘designerly ways’ in research. Would the true question even be whether science and art are not becoming design in the moment in which they leave their utopian position?

5. Future work

“Design is not engaging with the social, cultural and ethical implications of the technologies it makes so sexy and consumable.” (Dunne, Raby 2001)

Besides a first impression of the opportunities and potentials of “Critical Design” as a research tool, questions have primarily resulted from this study. There is a necessity to investigate following questions in further researches:

- *Which roots and parallels are there in art history and other past practices?*
- *To which areas can “Critical Design“ approaches be applied?*
- *In which context (research facilities, teaching, product development etc.) can “Critical Design” be established as a method?*
- *Is the arising discussion that is activated by “Critical Design” measurable through empirical studies?*
- *Are there alternative concepts for the technological economic understanding of efficiency and rationality?*

6. Conclusions

The world today is incredibly complex and our social relations, human desires, personal fantasies, hopes and fears are very different from the beginning of the 20th century, when design began to emerge as a disciplined activity. Since then the general image of humans has matured, becoming richer, messier, and increasingly down-to-earth. Most areas of culture have accepted that humans are complex, contradictory, even neurotic, yet design has not. Still, abstruse or complex emotions are mostly ignored in mainstream design. Instead, many designers keep considering people as predominantly obedient, predictable, and rational users/consumers, while neglecting those “complicated pleasures” that arise from the darker, puzzling side of human nature. In this world of increasing complexity, Anthony Dunne and Fiona Raby explain that the focus in design shifts to products, which pander to the side of people that is complicated, irrational, and contradictory. For that purpose, they introduced the concept of “Critical Design”, which so far can be described as the development and use of design objects for the discussion about social and technological problem areas. “Critical Design” provokes or confuses the user to elicit thoughts and attitudes that are subconsciously hidden or held back within the people’s mind. Instead of offering people merely optimized and therefore constraint action patterns, open situations and questions are created. The arising reactions provide valuable insights for product development and especially for design research. “Critical Design” emphasizes questions to complex pleasures and existential design. Therefore, this study has assessed the potential of “Critical Design” to be utilized as a novel research tool by utilizing conceptual products as a "medium that fuses complex narratives with everyday life" (Dunne, Raby 2001).

“Critical Design” illustrates the need for design researcher to deal with complexity encountered in the general dynamic of actors and in people's critical thinking. As Elizabeth Sanders and Pieter Stappers noted that, „What is being designed will change. Larger views across space and time will be needed. New tools and methods for design research will be needed to address increasing scope, scale and complexity.“ (Sanders, Stappers 2008), it is becoming apparent that sticking only to its existing knowledge, design might not tackle future challenges. On this Background, the goal of this paper is to explore novel and suitable approaches to deal with and conceptualize the complexity that is involved in the interplay of design and people.

An Investigation into Features of Design Thinking in Fast Moving Consumer Goods Brand Development: Integration and Collaboration

Younjoon Lee, PhD student, Lancaster University, UK

Martyn Evans, Senior Lecturer, Lancaster University, UK

Abstract

Most companies and researchers have no doubt now that design envisages a way toward future products, services, and systems. Recently, however researchers have started to highlight ‘design thinking’ to ensure that design becomes the next competitive advantage in companies. They acknowledge that design thinking enables companies to develop differentiated products, services and systems which consumers and users need. However, there is little research which reports how design thinking can be embedded and fostered in different business contexts, especially in FMCG (Fast Moving Consumer Goods) brand development. This paper investigates what features of design thinking are employed in FMCG brand development via stakeholder interviews in three domains: agencies, companies, and retailers. This paper concludes with suggestions of how design thinking can be embraced in FMCG brand development.

Keywords

Design thinking; brand development; Fast Moving Consumer Goods; design integration, and collaboration

Branding is a key strategic asset for organisations in an increasingly competitive retail environment (Lincoln & Thomassen, 2007; Thomassen, Lincoln & Aconis, 2006; LePla & Parker, 2002; Southgate, 1994). Brand development is a complicated process in which stakeholders have different needs and expectations of the development process. Hence, to ensure that brands can be both competitive and sustainable, an understanding of integration and collaboration between different disciplines is of prime importance to the various stakeholders involved (Olins, 2007; Mozota, 2003). Literature suggests that design can assist in the development of competitive advantage in an integrated and collaborative way and support effective brand development (Brown, 2009, 2008; Mozota, 2003, 2002; Vazquez & Bruce, 2002). The manner in which this could be achieved has not yet been described within the literature. There is less research discourse detailing the interaction of design within brand development. This in part can be attributed to current working practices in organisations and associated resistance to change as well as the lack of awareness of the potential added value design can bring to this development process.

Many researchers affirm that design envisages a way toward future products, services, and systems (Berger, 2010; Martin 2009; Brown, 2009, 2008; Neumeier 2009; Mozota, 2003, 2002). Recently, ‘design thinking’ has received attention claiming that design can help companies to create competitive advantage such that they can develop differentiated products, services and systems which consumers need and desire. However, research has yet to focus upon how design thinking can be embedded and be fostered in different business contexts. Many researchers (Kimbell, 2009; Fraser 2006) also claims that design thinking research in design disciplines needs to consider approaches employed in design practice in more detail.

While FMCG brand companies compete in fast changing markets, they also call for new approaches to communicate with consumers and to develop brands effectively. In these contexts such challenges faced are not easily described, and this is not discussed in a meaningful way. Such problems currently faced by these companies are ‘wicked problems’, where neither the problem nor the solution is known (Buchanan, 1992). Recent discourse has likened wicked problems to design problems (Berger, 2010; Martin, 2009; Brown, 2008, 2009; Neumeier, 2009). Neumeier (2009) claims that the central problem of brand building is getting a complex organization to execute a bold idea so that design thinking helps organizations to appreciate fast changing markets and to find opportunities or solve undefined problems. Design and designers are well placed to tackle wicked problems that companies face and design thinking gears up for what FMCG brand development needs. Martin (2009) illustrates how P&G could avoid downturn in activities by adopting design as a core driver for a company. As organisations involved in the FMCG sector experience a competitive and fast changing market, it is imperative to employ design thinking in order to explore new brand ideas. This investigation aims to address the above needs for new approaches to both branding and design thinking research.

There has been limited research which outlines design thinking in FMCG brand development. This paper aims to investigate the role and features of design thinking in FMCG brand development and compare these identified features to more broadly defined concepts of design thinking.

The central research questions are:

1) What is the role of design thinking in FMCG brand development?

2) What features of design thinking can be identified in FMCG brand development?

1.0 Research Design

To provide a brand effectively to a market, brand development has to embrace diverse stakeholders from different disciplines supporting appropriate and effective communication. Companies who traditionally develop and produce FMCG brands (known as national brands) now face competition not only from other companies but also from retailers' own brands. In some instances, retailers' own brands are even taking over national brands (Lincoln & Thomassen, 2007; Thomassen, Lincoln et al, 2006). Since the growth of own brands, companies not only employ design thinking internally but also collaborate with external specialists to keep bringing new thinking into the development process (Martin 2009). Many companies, besides retailer, tend to collaborate with external agencies. It is more efficient to work with them in terms of time, money and creative efficiency (Berger, 2010).

As has been illustrated, it is crucial to study design thinking of three dominant stakeholders, who play a critical role within FMCG brand development: companies; retailers; and agencies. This research framework investigates the three stakeholders in Korea and in the UK in order to generate general features of design thinking in FMCG brand development.

2.0 Research Methodology

A qualitative research methodology was employed to explore the main research questions and included a series of semi-structured interviews with a range of stakeholders within FMCG brand development within companies, retailers, and agencies. The research aims to understand various perspectives upon FMCG brand development. These interviews informed a series of case studies that explored FMCG brand development processes and the role of design and design thinking within this context.

Communicating design thinking terms with interviewees is difficult because design thinking is not defined yet as a broadly understood concept. Due to the lack of awareness and the variety of interpretations of design thinking, interview questions explored terms associated with design thinking (design, design approaches, and creative design) rather than design thinking as a term itself. Therefore, interview questions are development to investigate design integration and collaboration through their project processes and their value to design.

Researchers (Berger, 2010; Brown, 2009; Neumeier, 2009) recognize that collaboration with external specialists is a way to foster design thinking. Design integration and collaboration are also important to embed design thinking into projects both internally and externally to an organization. Interviews investigated how agencies and their clients (companies and retailers) conceive and foster design thinking depending on perspectives of agencies, companies and retailers.

2.1 Rationale for interviewee selection

Interviewees of a company and a retailer in Korea were selected based on ‘Best Brand Award’ and ‘Brand of the Year’ by Korea Advertising Society. Participants were selected based on ‘design of year’ from ‘Design’ magazine, which specializes in brand and packaging design or have an independent team of packaging in the agencies. Packaging design is substantial aspect of FMCG brand development in contrast other brand development such as cars, electronic products, luxury products and so forth. Agencies that undertake packaging design were considered important to the study due to the relationship of packaging design to FMCG brand development. In the same way as in Korea, agencies and company in the UK were selected from the DBA’s (Design Business Association) ‘Design Effectiveness Award’.

3.0 Design Thinking

Before presenting the analysis of the interviews, it is necessary to discuss the term ‘design thinking’ to convey an understanding of its features and characteristics. Even though researchers have studied concept of design thinking from 60s, the term design thinking is ambiguous and confusing when used in design (Simon 1996). Definitions refer to the way in which designers think as part of the creative process (Brown 2009, 2008; Lawson 2006; Cross 2006; Rowe 1987); and a design attitude (most current researchers work in this area). In contrast to earlier design thinking research which studied that design thinking was analytical thinking or inductive thinking (Rowe, 1987), recent research argues that design thinking is synthetic and abductive thinking aligning with ways of approaching wicked problems as applying design thinking to whole organizations (Martin 2009, Brown 2009). Currently, Brown’s (2009, 2008) claim that the concept of design thinking is thinking like designers is accepted and broadly applied to other disciplines.

Successful cases employing design thinking can be found in pioneer design driven companies from design-related companies like Herman Miller and Steelcase to technology- related companies like Philips and Apple. Previous companies embrace design thinking to solve ill-determinate problems and to find a way toward undefined goals (Brown 2009, 2008; Martin 2009; Neumeier 2009). Research has started to investigate what these successes are derived from and design thinking becomes highlighted in other disciplines: business, organizational studies, and non-profit organizations. Researchers (Berger, 2010; Martin 2009; Brown 2009, 2008; Kimbell 2009; Neumeier 2009) start to delineate ways of applying design thinking at general strategic level. Even though, their concepts of design thinking are slightly different, most researchers claim a balance of thinking: integrated thinking; systematic thinking; balance between analytical thinking and intuitive thinking or abductive thinking, balance between divergent thinking and convergent thinking so that currently design thinking can be adopted to other disciplines beyond design practice. There is also the prime claim among researchers that design thinking helps organizations transform to implement innovation.

Research has sought to clarify characteristics of design thinking to help people to embed it into their organizations and develop competitive and efficient products, services and systems. Early research which investigated design, delineated some design methods and designers’ techniques like visualization, sketching, drawing, and so forth as attributes of design thinking (Rowe 1987; Cross 2006). On the other hand, recent research seeks to characterize design thinking as design attitude (Berger, 2010; Brown 2009, 2008; Martin 2009; Owen 2007; Lawson 2006; Dunne and Martin 2006). These attitudes can be interpreted as features of design thinking. Research identifies how design thinking is employed, and thus embeds design thinking beyond traditional design contexts and establish pervasive design thinking culture, incorporating this into business strategy (Porcini 2009) or non-profit organizations’ goals.

Research has emphasized different features and methods for design thinking. For examples, Brown (2008, 2009) makes emphasis on prototyping and user-centred approach in *industrial design*. On the other hand, Neumeier (2009) highlights agility, collaboration, and approaches to wicked problems and so comes closer to *branding*. So, there can be different acknowledgements of what stakeholders conceive for design thinking methods in FMCG brand development.

4.0 Interview Analysis

Interview data was been clustered in three groups: 1) agencies, 2) companies and 3) retailers (Table.1). The research data was analysed by thematic analysis utilising theoretical codes to link together the features that arise from the interview data and the concepts from literature. Thematic analysis is appropriate to provide a potentially rich and detailed account of data across theoretical and epistemological approach (Braun and Clarke 2006). Flexibility in thematic analysis bestows no limit so that a researcher can find essential and flexible themes from complex data without bias. Through reviewing data, latent codes arise and this provides the following themes.

Through using thematic analysis without any bias to data collection, three themes are distilled from agencies interviews: 1) features of impacting design integration and collaboration in FMCG brand development, 2) features of impacting FMCG brand development, 3) features of impacting own brand development. Two themes are in companies and retailer: 1) features of impacting design integration and collaboration in organizations, 2) features of impacting brand development or own brand development.

	In Korea		**In UK**	
Agency	Agency K1	CEO Specializing in FMCG brand development and packaging design development.	Agency UK1 Agency UK2 Agency UK3 Agency UK4.1 Agency UK4.2	CEO Co-founder and creative director Senior client team manager Director of brand valuation Creative director of FMCG Specializing in brand development and packaging design development. Whereas agency UK 3 and 4 are global agencies, agency UK 1 and 2 are based in the UK and work cross the countries. And comparing initial ones, companies are small.
Company	Company K1	Manager for design planning and packaging design A Korea leading FMCG company. Company K1 has a lot of brands in different businesses.	Company UK 1	Head of creative Starting from a SME company and now a leading company in category section
Retailer	Retailer K1	Brand manager for furniture and storages Being established as joint venture.	None	

Table1. Summary of respondents' organisations and roles [K=Korean; Agency K1=1st interviewee of Korean agency; UK=United Kingdom; Agency UK1=1st interviewee of United Kingdom agency]

4.1 Agency

Design thinking in agencies can be found in both internal projects and external collaboration. However, their role in FMCG brand development is limited and performs generally in identity development. Through their workflow and cases, features were extracted and analyzed. Approaches of agencies to FMCG brand developments are different depending on client processes, timing of agencies' engagement, types of brand development, their budget and so forth. Because as previously noted, problems which clients face are undefined or wicked problems, so if they have proprietary processes, agencies tend to tailor their process. If there is no proprietary process, the reason is that they build up an appropriate process and adapt it toward each different task. Especially in agencies UK 4 interview one respondent stated that projects and associated processes are "depending on clients" and emphasized flexible approaches.

	Features of impacting design integration and collaboration in FMCG brand development	
	+Encouragement	-Barriers
Agency K1	**+Clients' understanding of design** **+Consensus of what agencies and clients are doing** **+Early engagement** **+Long term relationship** **+Communication**	**-Clients' understanding of design** -Lack of money -Lack of time

Agency UK1	**+Consensus of what agencies and clients are doing** **+Communication** **+Working together as one team with clients** **+Early engagement** **+Building relationship**: long term relationship, strategic partnership **+Integrated work processes** **+Understanding consumers** +Challenge mindset: challenge +Proprietary processes +Key decision maker involvement +Combination strategy and execution +Clients attitude working with agencies +Articulated design brief +Keep providing good works +Who handle projects	**-Poor clients' understanding of design** **-Client mindset: cautious** -Clients attitude work with agencies -Lack of money -Who handle projects -Poor design brief -Consumer's reaction -Focused group
Agency UK2	**+Consensus of what agencies are doing and how ideas work** **+Communication:** Working at the same places for communication **+Early engagement:** early involvement on product development **+Integrated work processes** **+Building relationship**: providing good experience with clients **+Understanding consumers** **+Client mindset**: Brave, design leadership **+Working together internally** +Cover whole spectrum of brand development including campaign +Challenge to change the way of perception +Working with right people +Develop new research methods for consumer research +Changing clients recruiting systems +Consistent creative ideas	**-Poor clients' understanding of design** **-Client mindset:** anxious -Client internal politics -Wrong ways of consumer research -Recruiting systems
Agency UK3	**+Consensus of what agencies and clients are doing** **+Understanding consumers**: observing consumers and their lives +**Building relationship**: trust, long term relationship, partnership and credibility **+Early engagement** **+Agency's attitude: passionate, confident, and strong rational argument** **+Working together as one team** **+Integrated thinking and process** **+Clients mindset**: respect an agency, Clients' value design and design thinking **+Key decision maker involvement** +Cover whole spectrum of brand development +Proprietary process +Structure and processes of clients' companies +Providing what clients want +Collaborative work processes +Collaborative strategic design +Tailoring agencies' processes +Part of Global company +Rigor for creativity +Fusing client's confidences	**-Poor clients' understanding of design** **-Client mindset:** nervous -Structure and processes of clients' companies -A lot of clients' background work and agencies late involvement
Agency UK4.1 and 4.2	**+Agency's attitude: passionate** **+Consensus of what agencies and clients are doing** **+Communication:** informing clients **+Integrated approach and processes** **+Clients' understanding of design** **+Understanding consumers** +Flexibility +Interaction with clients +Designers' intuition +Diagnose situations +Inspiration: by environments, materials and so forth	**-Clients' understanding of design** -Rigid structure and processes -Insufficient knowledge -Wrong information that clients have -Time consuming convincing stages

Table 2. Summary of agencies' Interview: features impacting integration and collaboration in FMCG brand development (items mentioned more than three times from different interviewees are in bold)

The goal of FMCG brand development in agencies is to find opportunities, to find the optimum arena for the focus of their activities, and to change consumers and clients perceptions. When agencies and clients seek to find a way to achieve goals, they need a consensus about (re)defining problems and establishing frameworks to solve them. In agency interview UK 3 the respondent stated that “using design and design thinking helps actually to find out what‘s the optimum arena for brand and to load this presences”. This evidence suggests that agencies seek to achieve these strategic goals by employing and adopting design and design thinking.

As demonstrated in Table 2, there are nine common features to be found about encouraging design integration and collaboration: 1) clients understanding of design, 2) consensus, 3) early engagement, 4) building relationship 5) communication internally and externally, 6) working together internally and externally, 7) integrated approach and process, 8) understating consumers, 9) clients and agencies’ mindset. Each common feature has different details depending on interviewees. In contrast to the above common features, there are opposite opinions about some features. Whereas, Agencies UK 2 and 4 point out proprietary processes for encouraging features, Agencies UK 1 and 4 mention that these processes sometimes are avoided due to lack of flexibility. They account for developing flexible proprietary methods and then depending on projects, they prefer adopting appropriate methods in response to the specific requirements of each project. This difference is influenced by the nature of each organization, such as vision, size, structure and so forth. Above all, it depends what they value in brand development. The latter two agencies tend to value intuition, creativity, and disruptive thinking.

Features of encouraging design integration and collaboration in each group are interlinked and dependent each other. For example, building relationship between clients and agencies determines design integration and collaboration to cultivate effective design thinking. Communication between clients and agencies is necessary to build strong relationship and consensus of overall aims. Conversely, better relationships determines that agencies and clients communicate with each other well and that agencies can have more engagement with clients at a strategic level. This leads clients and agencies to have strategic partnership with trust and credibility. Through working with agencies interplay and integration issues enables design thinking to embed clients businesses and have more chance to identify consumers’ need and desire. It can be concluded that communication is a key factor in fostering design thinking within FMCG brand development

As demonstrated above, whether they are common or not, a variety of factors influence both national and own brand development. In their experiences, most interviewees noted that there are different design integration and collaboration approaches because the goal of brand development, and associated organizational structures, are different. Whereas national brand development is a matter of independent brand and is normally handled by a design manger, designer, or marketer, own brand development is a matter of developing brand architecture of category and is carried on by a marketer. Features of own brand development overlap with features of national brand development but there are also differences. Therefore, features seen in FMCG brand development in table 3 can be considered as developing own brand.

	Features of considering in FMCG brand development	**Features of considering own brand development**
Agency K1	• Emotional approach rather than marketing approach • Time consuming marketing research	• Communicating value rather than price
Agency UK1	• Providing new opportunities • Combination strategy and execution • Developing independent brand • Defining what brand stands for • Design development for building brand equity • Client’s project design brief • Consumer reactions • Changing consumers’ perceptions • Macro and micro consumer researches • Projects handled by a design manager, a designer or a marketer in client side	• Understanding brand differently • Developing architecture of categories rather than each independent brand • Different structure from national brand companies • Valuing product (category) not brand • Mostly In-house design team involvement • Projects handled by a marketer

Agency UK2	• Providing new opportunities • Wit and humor • Higher risk in national brand development • Contribution by design • Developing brand itself • Role of packaging in FMCG brand: the voice of brand, entertaining consumers to engage them, differentiation from competitors	• Low risk in own brand development • Developing own brand with corporate statements • Tactical advantage • Challenge with innovation
Agency UK3	• Providing new opportunities • Holistic approach • Creative ideas or disruptive thinking to change design • Brand engagement • Emotional residences • Decision's effect sales • Different approaches depending project types: new brand development and existing brand development • Role of packaging: embodying brand essence through packaging, differentiation of brand, communication of brand, change consumers' perception and lives	• Different creative approach but similar brand development process • Brand architecture process: communicating hierarchy of architecture on packaging • Navigating consumer to find own brand products: providing category cues • Changing consumer's perceptions: letting consumers feel pride to buy good quality
Agency UK4	• Holistic approach • Broad consumer target • Getting maintenance on shelves • Providing new opportunities	• Approach localizations: understanding what local consumers want

Table 3. Summary of agencies' Interview: features of considering in FMCG brand development and own brand development

4.2 Company

As previously mentioned in agency analysis, how companies value design determines design integration and collaboration between companies and agencies in order to develop a competitive and sustainable brand. Company K1 has many brands in different businesses and all design activity relating to their brands is carried out in-house a design centre in the company. However, the role of design centre seems to be limited in companies' strategy such that design thinking is not pervasive to other departments. Above all this company is a big organization and to achieve time and financial efficiencies, every stage is executed through computer-systematized processes. There seems to be a lack of communication to share ideas and opinions. In contrast, company UK 1 has two category lines but it is to be a leading company. The organisation has a flat managerial structure so its culture is appropriate to share ideas about problems. In addition, the mindset of company UK 1 stimulates challenge new opportunities rather than cautious attitude that company K1 has. The reason that this company can achieve leading position in around a decade is communication for sharing problems and finding a way together.

	Features of impacting design integration and collaboration in organizations	**Features of impacting brand development**
Company K1	+Updating new knowledge for design and design management +Sending designer to other countries to research their design and learn how other companies manage design +Design team supported by CEO in organizational hierarchy +Confidence of design +Developing design tool kit or library +Developing process for design -Strong sales team power -Reward for big profit -Stage gate process between teams -Brand mangers and category mangers handle design projects -Complicated process system -Every stages counted by money	+Design center for whole design spectrum +Planning tool -Sales person attitude: cautious for changing design to lose brand loyalty

Company UK1	+Entrepreneurship: entrepreneurship in design +Open space and mixed placement +Space (office place) itself: creative space for employees +Horizontal hierarchy +Whole employees engagement to solve problems +Whole employees involvement in generating ideas +Get problems and ideas from consumers +Commercially intelligent +Finding right external agencies: agencies' understanding problems +Taking about ideas freely +Simple decision process +Keeping finding great people +Keep learning -Wrong definition for problems	+Keep consistence of what brand stands for +Keep nature of brand +Great products +Brand engagement with consumers +Find what consumers want and then engaging them

Table 4. Summary of Companies' Interview: features impacting design in organizations and features impacting brand development

As can be seen in table 4, ways of finding and sharing problems in organizations affect approach to projects. Therefore, companies seek to find a way, which stakeholders can be engaged in order to find opportunities to meet consumers' unmet needs.

4.3 Retailer

Through this study, it is clear that retailers have started to value design to enable the development competitive advantages. They develop new ways to bring design in their organizations and own brand development such as collaboration with star designers and developing premium brands. However, they confront barriers, for example, complicated decision system and insufficient resources such as budget and people. The retailer seeks to adapt design for competing with competitors. The retailer employs design to develop differentiated own brand from other retailers and take a leading position in a market.

	Features of impacting design in organizations	Features of impacting own brand development
Retailer K1	+Collaboration with a star designer +Value design for competitive advantage to shift to premium line +Starting to hire designers in each different category line +Own brand test room -Structure complication -Complicated decision stages	+Brand development guideline +Packaging guideline +Using consumer panel and data +Benchmarking +Specific step guideline for developing own brand -Guideline and policy without considering capacity

Table 5. Summary of Retailer's Interview: features of impacting design in organizations and features impacting own brand development

5.0 Findings

Firstly, perspectives of design thinking from companies and retailers can be found in their interviews and agencies interviews. The role of design in FMCG companies is not to act as a catalyst and facilitator for design thinking, but to supporting other departments and to add aesthetical touches. Specially, the role of an agency is limited in developing brand identity. Thus, collaboration and integration between companies and agencies tend to take place at the latter stages of brand development. However, there are some approaches in companies and retailers to adopt design thinking consciously and unconsciously.

In Company UK 1 interview, they do not explicitly set out to employ design thinking but the organizational culture already has important features of design thinking. Employees from different departments share problem-solving approaches and collectively find ways to define problems in consultation with consumers. The space of the company is open and designed to communicate conveniently. In contrast to this, Company K1 has a different organizational culture in relation to design thinking, having rigid processes and roles within each department. This represents a barrier to effective communication and prevents integration of processes across departments.

Secondly, features extracted from three groups of interviewees are integrated and interlink with each other. Thus, it is necessary to conceive these features integrally. As can be seen in agencies' interviews, most interviewees argue that clients' understanding and valuing design has an impact on collaboration and integrated design process between companies and agencies. Most features, which are described in table 2, are determined by agencies' clients (companies and retailers), hence agencies need to build good working relationships for design thinking to pervade projects. In FMCG brand development, unlike in industrial design, evidence suggests that agencies do not foster design thinking within client projects and more broadly their strategic planning processes. It can be claimed that agencies are preoccupied with pleasing clients rather than engendering creativity and questioning the status quo. However, there is another stream of design agency. Agency UK 2 was the smallest within this study nevertheless they ranked in the top 5 agencies in UK (as published in Design Week, 2008). They are broadening their business activities from packaging design to brand campaigns. The respondent claimed that their agency needs to dominate projects rather than pleasing clients, and their intention is to strongly promote design thinking. In conclusion, it is crucial that agencies seek to find ways to collaborate and integrate with clients without losing their creative abilities.

Thirdly, retailers have potential to create a new way to develop own brands. Retail K1 collaborates 'star designers' to reinforce their brand and infuse creativity into their brands. Interviews with agencies demonstrated that retailers have a lot of potential to develop own brands in an innovative way. There is opportunity to implement design thinking and develop own brands with lower risks than national brand companies. There are some barriers to this, namely a lack of understanding of the value of design, rigid hierarchies, and focus on sales profit for example.

Data analysis (Figure 1) illustrates the features of design thinking for FMCG brand development between clients and agencies. This is divided into two groups: i) agencies, and ii) companies and retailers. Features identified in bold have a substantial impact. In first column, organizational culture has to be fortified as a foundation stone, and features in the second column need to be cultivated for design thinking to penetrate into projects. The third column provides further details. The features in the third column do not take place in a linear manner and these are iterative and integral in processes and further more organizations.

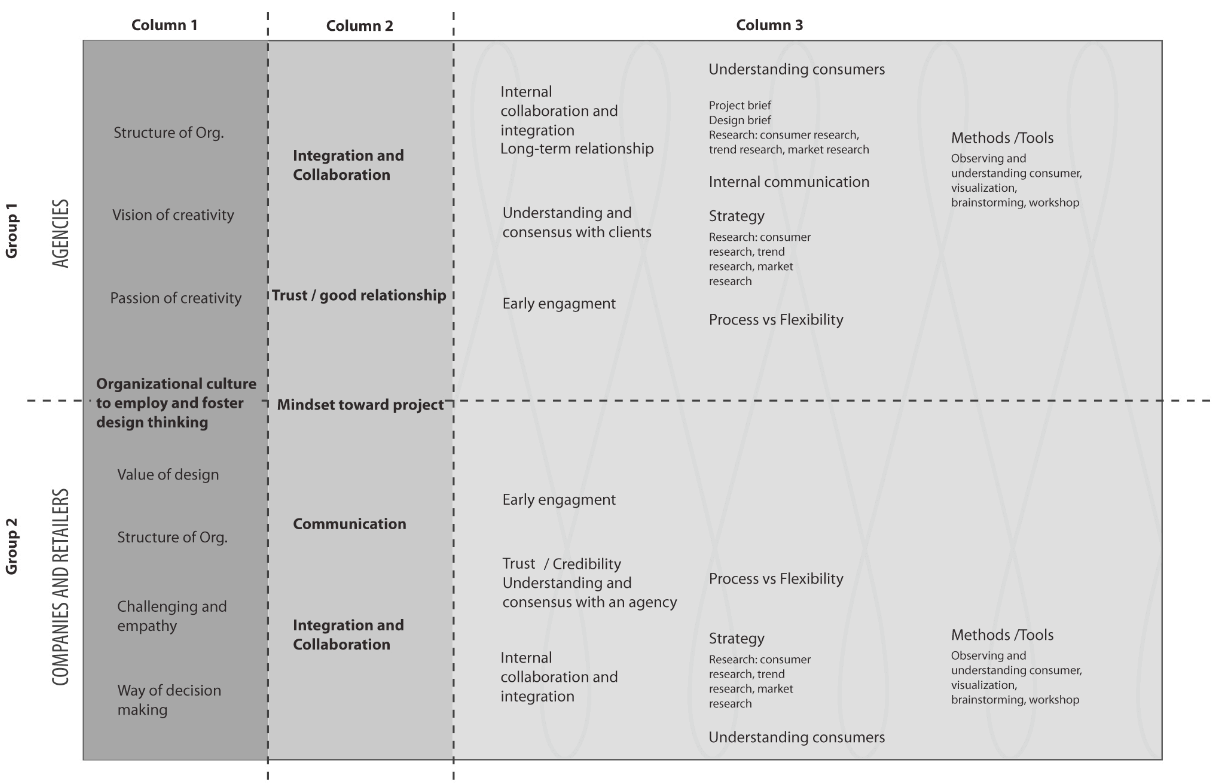

Figure 1. Design thinking features map in FMCG brand development

The empirical data collection via the research interviews has identified features of the role of design thinking in FMCG brand development that has not previously been identified in research literature. These features include lack of money to devote to a project, lack of time to undertake design thinking related activities, and the need to please clients. There is a clear implication of resource availability and the ability for organizations to undertake design thinking-led FMCG brand development. Many features identified within the interview analysis correlate with published literature upon design thinking. However, features such as prototyping and user-centered approaches (Brown 2009, 2008) which are noted in design thinking in industrial engineering design, is less pronounced in FMCG brand development.

Most companies and agencies still maintain traditional management styles and while FMCG industry operates in fast changing markets, associated strategies are not long-term. Agencies are often engaged in the latter stages of the brand development operating under compressed and unrealistic timescales. Therefore, agencies build long-term relationships with clients to engage with early stage of brand development, however the nature of these relationships results in agencies seeking to please rather than question clients. For this reason, disruptive ideas may not make it into presentations agencies make to clients.

In summary, the following are three important reasons for differences between design thinking in the literature and design thinking in FMCG brand development practice:

- FMCG industry context: fast changing market, a short-term brand strategy, value of sales, different stakeholders' involvement;
- Conventional relationship between agencies and clients (companies and retailers): the role of agencies is conceived as carrying the last stages of development of the aesthetical part of brand;
- Conventional approaches for developing FMCG brands: late design engagement, conventional consumer research methods, rigid roles of individual departments.

6.0 Conclusions and Further Work

It can be concluded from the interviews that design thinking is not yet a core aspect of FMCG brand development, but there are instances where its value is recognized and its use is increasing. Respondents identified the role of design thinking in the FMCG brand development process, where design is already valued and recognized a core activity. Where literature provides evidence of the value of design thinking across the functions of an organization, there was little empirical evidence of its adoption in organizations involved in FMCG brand development. Thus research undertaken within this study suggests that design thinking has not yet been adopted into broad processes of FMCG brand development organizations. Although literature claims that to develop competitive and sustainable brands it is imperative that features of design thinking are employed and fostered, there is a requirement to communicate this in an effective and concise manner to FMCG brand development organizations. The ongoing debate regarding design thinking – its meaning, value, and role in both design process and more broadly in business contexts – contributes to this communication challenge. There is a need for stakeholders involved in the use of design thinking (in its various guises) to provide concrete examples to stakeholders in the FMCG brand development process.

This research provides evidence that it is necessary to frame the role of design thinking in FMCG brand development while recognising the fast changing market context and the complexity of stakeholder accountability. Further work is planned that seeks to develop the initial work in this study by engaging with a much larger audience of stakeholders in FMCG brand development.

Author Biography

Younjoon Lee

Younjoon Lee is a PhD student in design at Lancaster University. Before she started her PhD, she worked at Interbrand Seoul as a senior designer and Gaid Associates for six years. She has experience working a lot of big Korean FMCG companies to develop brand and packaging design.

She also graduated with MSc Communication Design from Pratt Institute and gave lectures in Woosong University in Korea.

Martyn Evans

Martyn Evans is a Senior Lecturer in Design at Lancaster University and Director of its MA in Design Management. As a trained product designer, his research activities explore the approaches designers use to consider the future. His PhD investigates the role of future thinking in design and has published over 30 peer review articles in this area. Martyn is external examiner at a number of UK institutions and have acted as an academic advisor for curriculum development both nationally and internationally.

Resonance rather than Solo: Shaping a Regional Image with Soundscape

Yu-Chiao Lee, Department & Graduate School of Computational Design, National Yunlin University of Science and Technology, yu.chiao430@gmail.com

Li-Shu Lu, Department & Graduate School of Computational Design, National Yunlin University of Science and Technology, luls@yuntech.edu.tw

Abstract

As times change, industrialization and urbanization transform the structure of traditional rural society and result in imbalanced development between urban and rural areas. Then, as a result of population outflow and change in industries, rural distinctiveness gradually disappeared. Given that visual text was normally used to shape a regional image, this study further added audio text to enrich rural expression and also adopted the soundscape concept proposed by Murray Schafer (1973). Other than artificial sounds and natural sounds, soundscape also covers memory sounds, image sounds, cultural sounds and social sounds. The study incorporated the ecological triangle developed by Tilly (1974) – humans, space and activities, to analyze the urban and rural social structures; as well as the soundscape triangle developed by Schafer (1978) – soundmark, signal, keynote, to analyze the sounds in the environment.

This study utilized environmental marketing to transform sounds that are regarded as noises from negative exchange phenomenon to positive exchange of environmental resources. By using in-depth interviews, the study filtered out the scenic spots of Tongshiao Town, Miaoli County featuring mountainous or oceanic uniqueness and conducted a field survey to collect visual and audio text data. The text analysis method was used to analyze the data contents and meanings, and explored the derived interactive relation between humanistic emotions and the rural image. The study designed a soundscape shaping region prototype- Sonic Vison, which blended visual and audio test data into audio-visual interactive creation, in an attempt to help the study subject better promote the region's tourism industry and reinforce marketing applications. The results can also be used as a reference for future research on shaping a regional image in other rural regions.

Keywords

Soundscape; ecological triangle; Soundscape triangle; regional image

Introduction

Following its economic growth, Taiwan is now experiencing an imbalanced development between urban and rural areas. The lack of job opportunities in rural areas, the replacement of labor force by agricultural machines, and the shortage of social resources, have caused the widening gap between urban and rural areas, the outflow of rural population, and the gradual disappearance of rural features (Ding, 1999). Besides, many rural towns, which used to maintain traditional agricultural life due to restrictions of landform, location and transportation, have shifted the developmental focus to the tourism by means of the rich resources well-preserved because of difficult exploitation in the past, as the social structure changes in the rising tourist tide and now are gradually forming into famous tourism towns (Chen, 2000). It is necessary for these towns to build new images to attract tourists. Chiang (2001) pointed out that the "Image of the City" refers to the "memory" and "meaning" resulted from the "knowledge" of these urban and rural areas. Given that visual text was normally used to shape a regional image, this study further added audio text with local distinctiveness so that the image could be perceived and remembered both visually and aurally and then be transformed into special regional memory. The early industries were predominated by agricultural society and handcraft industries such as straw mat weaving and wood carving once thrived in the 1930s, which, however, declined soon due to the changing time and population outflow, and the characteristics of rural towns gradually disappeared. The high audience rating of the Taiwanese idol drama, Lavender, broadcasted in 2001, successfully marketed the Flying Crow Ranch in Tongshiao, which caused a whirlwind at that time and indirectly made the Flying Cow Ranch popular overnight and gradually promoted the development of scenic spots in the vicinity of Tongshiao Town, and the unexploited natural landscape of Tongshiao Town was developed into agricultural recreation areas in recent years. The town has shifted its developmental focus to tourism industry, which further attracts artists who brought to the town an artistic and cultural atmosphere. The disintegration of traditional social and urban structures causes the confusion of the image of the city, and since people gradually lose their "memory" and "emotion" about the urban environment, it is actually an important step to value and rebuild the image of the city (Chiang, 2001).

Wang (2001) views the city as an organism and studies the city expression with five-sense association method: soundscape, tastescape, smellscape, touchscape and mindscape. The research on soundscape, a concept proposed by Murray Schafer in 1973, launched a series of world soundscape projects, which paid special attention to the auditory feeling under the contemporary visual current. The soundscape of a city is an important environmental reference of quality of life in the urban setting (Pereira, 2003). Since each region owns special soundscapes of its own, this paper selected a rural region, whose tourism industry just getting started with its tourism resource of mountains and sea, as the study subject, and shaped the regional image by means of the soundscape triangle proposed by Schafe (1978), and the ecological triangle proposed by Tilly (1974). Then via the sounds and images created by the local landscape, this study aims to discover local characteristics from the perspective of environmental marketing and shapes a local image. In addition to establishing self-awareness and a sense of identity among locals, this study can also be served as a reference for future researches, and thereby successfully markets Tongshiao Town.

Literature review

The soundscape is any acoustic field of study. We may speak of a musical composition as a soundscape, or a radio program as a soundscape or an acoustic environment as a soundscape. We can isolate an acoustic environment as a field of study the characteristics of a given landscape (Schafer, 1994). The concept of soundscape was originally developed by Murray Schafer, a Canadian composer, in early 1970s, who launched a series of survey researches with the "World Soundscape Project" as the core. The idea of soundscape is "to employ the natural sound, the urban rhythm, the memory of artificial sound, and the sound within impression on this planet to take the image of landscape while catching its sound". This can be viewed as a special emphasis on auditory feeling in the contemporary visual current. Each region owns its special soundscape and since the sight and sound coexist with each other, and the missing of either will render the environment unnatural, the visual representation shall not be the only one employed to shape the regional image. Schafer (1977) proposed that other than artificial sounds and natural sounds, soundscape also covers memory sounds, image sounds, cultural sounds and social sounds, and since environmental sounds influence the locals imperceptibly, the analysis of environmental sounds can be applied to discover those of positive values, which can even serve as regional marketing strategy. Besides the sound as physical phenomenon, soundscape also covers the environmental space that transmits sound and the feelings of recipients; that is, soundscape is a method and an idea to study the interrelation among sound, environment and human and therefore, the harmony among those three is absolutely necessary for good soundscape (Shi, 2004). Among human, sound and environment, they supplement and complement the others and it is human that feels, thinks and remembers the sound and environment and then feeds back to the sound and environment. In other words, sound and environment transmit feelings to human, who will unconsciously returns sound and create environment of the same quality. (as shown in Fig. 1)

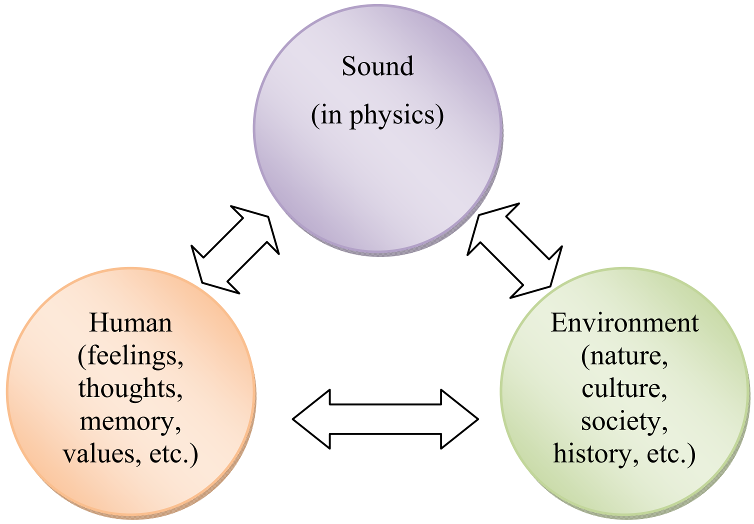

Figure 1 Relationship between sound, human and environment (Data Source: Shi, 2004)

The majority of soundscape studies in recent years focus on environmental noise, human perception about environmental sound and sound management. In such studies, noises are typically described by a quantitative metric such as sound pressure level and people's responses to noises are represented by a single evaluation of annoyance (Kawai, 2004). The point is to master its physical characteristics and analyze via the quantitative methods such as the measurement or calculation of decibel value, sound frequency characteristic and reverberation time, rather than its social, historic, environmental characteristics (Shi, 2004). The study on sound from the perspective of soundscape shall conduct comprehensive consideration about the multiple characteristics of sound and attach different values and cultural contents based on individual differences. Therefore, soudnscape is not only a pure physical concept resulted from acoustic measurement and spectral decomposition, but also a social and cultural existence attached with distinct personal emotions.

The image of a city is based on its residents' memory and meanings resulted from long-term observation, use and knowing about certain region in the surrounding environment (Chiang, 2001). The urban and rural citizens develop not only memories but also emotions about the place, and only the combination of urban appearance and personal and communal ideologies will form the image of the city. In the city, different groups develop different images based on their own social lives, and thus it is a must to master the nature of social experiences in order to know the structure of mutual urban and rural images. Kevin Lynch has published a classic work concerning the image of the city, The Image of the City, which simplifies the urban imagination into the physical form of the city, focuses on the readable spatial factors (such as paths, nodes and edges), proposes meanings of obtaining the urban experiences with mental map and represents the main tool for contemporary studies on urban connotations (Hsia, 1989). Since social practice plays a more important role than perception in form does, it is improper to apply the perception method to study the image of the city due to its incapability for symbol analysis of the image, and this study, besides using the perception method to discover images, applies soundscape triangle and ecological triangle in an attempt to find the environmental sound with local characteristics, and views soundscape as a non-physical exchange object for the urban environmental marketing according to the concept of soundscape proposed by Wang (2001) in the hope of transforming sound into positive exchange phenomenon of "environmental resources", rather than negative exchange phenomenon of noise, and applying the concept of soundscape as a special product for urban and rural marketing.

Method

Subject

This paper selected a rural region, Tongshiao Town, as the study subject, whose tourism industry is just getting started. This region is rich in tourist resources of mountains and sea. Taiwan lies on the right side of mainland China and on the left below Japan(as shown in Fig. 2); and Tongshiao Town lies in the northwest of Taiwan (as shown in Fig. 3) predominated by hills descending from the southeast to the northwest, which forms a gentle slope to the coastal line so that it is characteristic of mountains and sea. The unexploited natural landscape of Tongshiao Town was developed into agricultural recreation areas in recent years, and the town has shifted its developmental focus to tourism industry, which further attracts artists, who come and bring the town with artistic and cultural atmosphere.

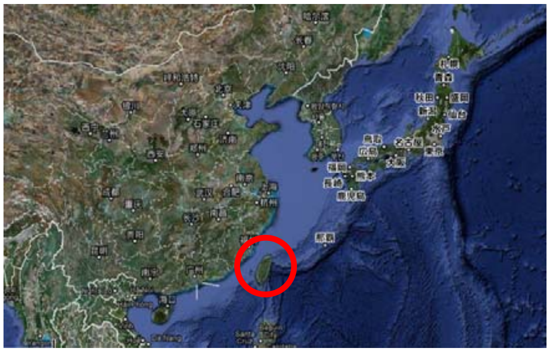

Figure 2 Location of Taiwan

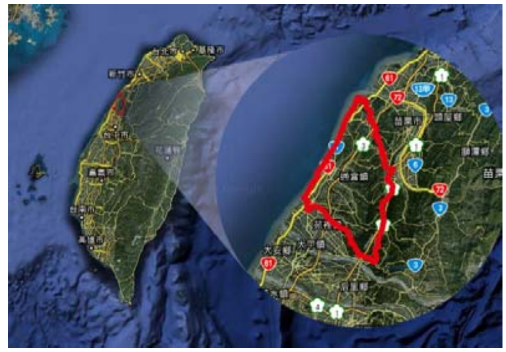

Figure 3 Location of Tongshiao Town

The scenic spots of Tongshiao Town were decided through two means: questionnaire and online statistics. The semi-open questionnaires were given to local seniors in order to find out the scenic spots of local characteristics, and meanwhile the scenic spots survey is also conducted on hot tourism websites; and the most representative scenic spot is concluded from the statistics of those two means, and then the collection of sound and image started officially. The questionnaires were distributed to 30 local residents and seniors who have lived there for more than 20 years and the distribution of questionnaire was conducted on the street in a convenient sampling manner. Three representative tourism websites were alos selected as the hot websites for survey (Taiwan Travel Information Net, Miaoli County Travel Information Net and Miaoli Travel Net). According to the result, the representative scenic spots are Flying Cow Ranch, Tongshiao Beach Resort, Mt, Hutou, Qiumao Garden, Salt Path, Tongshiao Shrine, Gongtian Temple, Taiwan Salt Factory, Tongshiao Thermal Power Plant, Flower Filed, and Coastal Windmills. Because of limits to environmental sound recording, only 8 of them obtained complete audio recording: A. Flying Cow Ranch, B. Tongshiao Beach Resort, C. Flower Field, D. Coastal Windmills, E. Tongshiao Salt Factory, F. Mt. Hutou, G. Qiumao Garden, H. Gongtian Temple. (Fig.4)

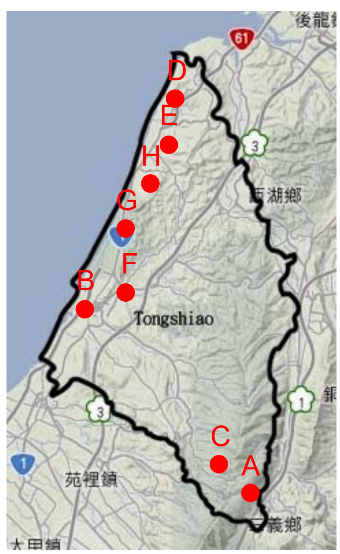

Figure 4 Location of Field Survey

Process

This study, mainly through means of literature analysis and interview, filtered the scenic spots of Tongshiao Town, Miaoli County and conducted field survey to collect visual and audio data in order to explore the interrelation between derivative human emotions and images of urban and rural areas, and proposed tourism promotions and marketing applications about the study subject's area employing characteristic text to create soundscape prototype, which can serve as a reference for future research on shaping the image of other urban and rural areas. The study's process is as follows:

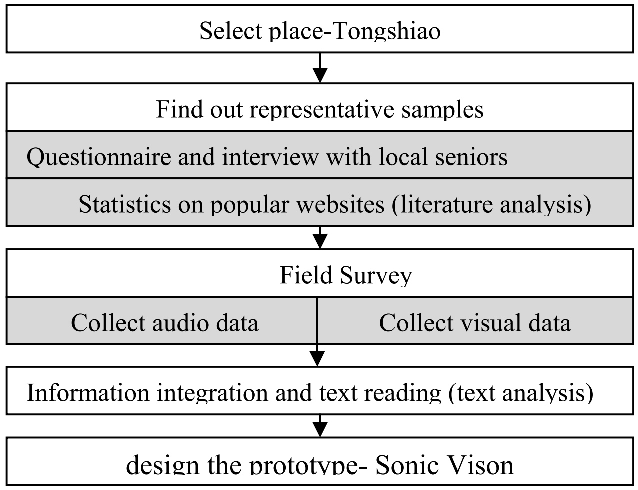

Figure 5 Structure of the study process

Analysis structure

As to the collection of sound and image, this paper directly observed and recorded in a manner of live field survey, where recording pens and digital cameras served as the collection means for this study to conduct collections of audio and visual data.

The study structure of soundscape proposed by Wang (2001) served as the analysis structure for data analysis. The ecological triangle of environmental ecology of Tilly (1974): human, space and activities, is employed to analyze social sound structure. Human serves as social actor, space serves as social container, and activities serve as social output. Since it is too narrow for human to serve as social actor of environmental sound, the data analysis structure of this study transformed the naming of human into social actor. Space stands for environmental sound in nature. Sound resulted form activities does not come from itself, a media is necessary for producing sound. This study employed social actor, space and activities as the horizontal axis for data analysis. The soundscape triangle developed by Schafer (1978) served as the vertical concept: soundmark, signal and keynote. The soundmark is a derivative word of landmark, which refers to the sound resource, and signal refers to the message transmitted by sound, and keynote refers to the representative sound or keynote sound in the environment. This is shown in the following table.

Visual Image	Ecological Triangle / Soundscape Triangle	Social Actor	Space	Activities
Fig.	Soundmark

	Keynote			

Table 1 Soundscape study structure

Data Analysis

This study employed social actor, space and activities as the horizontal axis for data analysis. The soundscape triangle developed by Schafer (1978) served as the vertical concept: soundmark, signal and keynote. The soundmark is a derivative word of landmark, which refers to the sound resource, and signal refers to the message transmitted by sound, and keynote refers to the representative sound or keynote sound in the environment. This is shown in the following table.

Ecological Triangle Visual Image	Soundscape Triangle	Social Actor	Space	Activities
 A. Flying Cow Ranch	Soundmark	tourists, children, ducks, insects and birds	stream and forest	mowing, moving car, human activities and goat activities
	Signal	sightseeing area, recreation area and rural area	open, rivers and leisure	liveliness, human stream
	Keynote	tourists' voices, sound of playing children, duck quacking, insects chirping and birds singing	wind, stream murmuring and tree leaves rustling	sound of car, sound from mobile loudspeakers, sound of walking on the cobbled road and jingling of goat bells
 B. Tongshiao Beach Resort	Soundmark	tourists	rivers and sea	tide splashing
	Signal	sightseeing area	leisure, open, peaceful and comfortable	*
	Keynote	tourists' voices	wind, sound of sea, and river murmuring	tide splashing
 C. Flower Field	Soundmark	tourists, children, birds and dogs	wind	old motorcycle, moving car, mobile loudspeaker
	Signal	sightseeing area, recreation area and rural area	open	rural area, high mobility, liveliness and human stream
	Keynote	tourists' voices and birds sound	wind	old motorcycle sound, sound of car stream and mobile music
 D. coastal windmill	Soundmark	tourists, children, peddlers, insects and birds	Sound of wind and sea	spinning windmills, motors of peddlers, tourists walking, car moving, locomotive and camera
	Signal	sightseeing area, recreation area and rural area	open, broad, peaceful and comfortable	liveliness and beautiful scenic spots

	Keynote	tourists' voices, sound of playing children, of cries of peddlers, sound of insects, and birds singing	sound and wind and sea	windmills spinning, mechanic sound of windmills, sound of peddlers' motors, tourists walking, sound of cars and chugging-by locomotives
	Soundmark	tourists and children	thermal spring	*
	Signal	recreation area	leisure	*
E.Taiwan Salt Factory	Keynote	tourists' voices and the sound of playing children	murmuring of thermal spring	*
	Soundmark	tourists and insects	Wind	*
	Signal	sightseeing area, recreation area and rural area	open and mountains	*
F. Mt. Hutou	Keynote	tourists' voices and sound of insects	sound of wind	*
	Soundmark	tourists, children and peddlers	sea and wind	swing
	Signal	sightseeing area, recreation area and rural area	open, broad, peaceful and comfortable	happy tourists
G. Qiumao Garden	Keynote	tourists' voices, children's voices and peddlers' cries	sound of sea and wind	Swinging swing
	Soundmark	tourists, disciples and residents	*	people waking, sound of moving car, cup-dropping and paper-money burning
H. Gongtian Temple in	Signal	pious pilgrimage	*	sacrificing ceremony

Baishatun	Keynote	tourists' voices, disciples' praying and residents' talking	*	people waking, sound of moving car, cup-dropping and paper-money burning

Table 2 Study analysis of soundscape

In the table above, some blanks marked with * represent the state of silence rather than being drowned out by other louder sounds, which may render human unaware of its existence. In the following, the rural village soundscape of Tongshiao Town is summarized with characteristic illustrations of social actor, space and activities.

Soundscape of social actor

The social actor may cover orientations of ethnic group, class, sex and organization (Wang, 2001) including residents, tourists and the sound of animals. According to the background mentioned afore, since the population of Tongshiao Town outflows severely, only business talk is available in the scenic spot where collection is conducted, for example, the cry of peddlers. The tourist group is predominated by small families and lovers, and happy tone and sound of children's playing stand for the signal of sightseeing, which brings vitality and liveliness into the town. The sounds of insects and birds are the keynotes of the mountain area of Tongshiao Town, and as Tsai (2002) has proposed that people has a preference for sounds in the nature such as that of birds, cicadas, frogs, winds, stream, springs and stirring trees. Just as the relationship among sound, human and environment proposed by Shi (2004), Tongshiao Town possesses rich natural soundscapes, which will directly bring comforts to the locals and tourists, and then people will also feed back their happy feelings to the environment.

Soundscape of space

Space, as social container, covers natural or artificial structures, and the main study object is the soundmark of this place, which includes the sounds of sea, wind and stirring trees. The sound of water and sea is one of those important elements of soundscape in Tongshiao Town, and the connection with water is of quite an importance because that Tongshiao Town leans against the mountain and faces the sea with Taiwan being surrounded by sea, for example, there are murmuring streams in the mountain area, and the sound of sea and splashing tides in the coastal area. In the recent years, the beautiful coastal line has attracted many tourists and businessmen, which also invigorates the coastal line. In Tongshiao Town, the keynote of wind sound is loud and clear and the open rural area, comparatively low constructions and broad rural landscape together make it as reference note. And this broadness brings people with feelings of peace, leisure and comfort, and these special soundscapes of space have become unique to Tongshiao Town.

Soundscape of activities

Activities, as social output, cover various high-divided social interactions. The keynote of soundscape of activity in Tongshiao Town is the sound of human activities, such as traffic soundscape, tourists' walking, mobile loudspeakers, broadcast and so on. This activity soundscape refers to those continuously changing sounds in the environment, which bring the environment with different sound features. Besides, there are still other special sounds in the soundscape of activity such as sounds of spinning windmills and wind and sounds of cup-dropping of praying in the temple and paper-money burning. The windmill belongs to the wind power system established in recent years in a response to environmental protection, and there are about tens of windmills built off the shore of Tongshiao Town making special marine sight-construction. The cup-dropping sound and paper-money-burning sound transmit the local culture and belief and a grand sacrificing ceremony will be held annually in Gongtian Temple in Baishatun, in which the soundscape is much more multiple and abundant such as the firecracker sound and drumbeats. The traffic soundscape and the mechanic sound of motors are always classified as noise in the urban soundscape, however, the sound of car stream of traffic soundscape reflects the existence of mobility and vitality in urban and rural areas transmitting the signal of "sightseeing", and from the perspective of environmental marketing, the soundscape, a non-physical exchange object, will transform the sound deemed noises from negative exchange phenomenon to positive exchange phenomenon of environmental resources so that the environmental noise will be of a positive image. The continuously changing sounds in rural activities beautify the countryside just like the cosmetics do.

Prototype design of soundscape for shaping regional image

This study designed the prototype with an attempt of shaping regional images with soundscape concept surpassing previous regional image shapings, which only employed vision-oriented products, and soundscape researches, which only employed auditory perception. The making of this prototype combined senses of sight and hearing so that the regional image shaping products can make the browsers experience personally, provide the region of study object with sightseeing promotion and marketing application and serve as reference for future researches on shaping the image of urban and rural areas.

The elements for making this prototype are divided into two groups. One is audio elements and the other is visual elements, which are kept as original as possible. The audio elements come from the live recording of field survey, and although the field recording of one scenic spot is conducted in several places, the representative sounds of each scenic spot mentioned afore are mixed into one sound track during the making of prototype sound, which will become the representative soundscape of that scenic spot. The visual elements are constituted of pictures of field photographing without many special effects added or other treatments and they are shown through revolving playing.

The form of presentation of prototype design employed the website as the platform in order to attract more browsers through its convenience and interaction. The map of Tongshiao Town is used as the background of the page with specific scenic spots scattered in different areas and there are guide buttons on scenic spots for the browsers to click upon and on clicking, the sound of the scenic spot is played first and then the revolving play of visual pictures followed. The creation of prototype is dedicated to timeliness and spatiality and the browser can not see the regional image immediately as the webpage opens so that with the timely combination of hearing and sight on clicking, the total impression during that time can become the image of that area. It is difficult for people to experience personally because of the usual depth of field of flat vision; however, with the key characteristic of spatiality, the sense of space is created by sight and sounds.

Table 3 Design of image commentary

Conclusion

Because of the preference for visual culture, more attention shall be paid to auditory feelings, and the missing of either will render the environment unnatural and audio orientation and visual orientation shall coexist with each other in the study of urban and rural soundscape. In the city, different groups develop different images based on their own social lives and it is a must to master the nature of social experiences in order to know the structure of mutual urban and rural image and the urban and rural citizens develop not only memories but also emotions about the place and only the combination of urban appearance and personal and communal ideologies can make the urban and rural image. It may require three important variables to explain the difference in environmental perception: social group values, life-style and culture, therefore, the discovery of urban and rural images must start from the viewpoint of human and then study the reflection of values of local groups and humanity history on the perception and image of the environment. As the study developed, it found out that the study subject, Tongshiao Town of Miaoli County, although being a town “leaning against the mountain and facing the sea”, does not view this characteristic as a focus of marketing in the urban promotion and this paper has revealed the characteristics of mountains and sea in order to make marketing effects.

Since the image and characteristics of one region shall be jointly shaped by the locals and external tourists, it is suggested in this paper that in the future, the opinions of the locals and tourists be considered, and to discover the urban and rural image through the integrated analysis of residents and tourists. To sum up, the future executive direction of this study will be: to verify and modify this prototype with depth interviews with the residents in the hope that the soundscape shaping, through the effort of this study, the plan of local governments and cooperation of associations in place, will actively conduct the marketing and promotion in a direction suitable to the town itself and show a better urban and rural environment after follow-up implementations and this paper can also serve as the reference for future researches on shaping of other urban and rural images.

Consultancy designer involvement in new product development in mature product categories:

Who leads, the designer or the marketer?

Abstract

This research sets out to uncover how design is contributing more intensively to new product development. More precisely, it aims to understand the growing involvement of designers, and in particular consultancy designers, in NPD in mature product categories. The study seeks to build on recent evidence of design taking a greater leadership and strategic role in new product development, particularly in embracing the theory and praxis of the discipline of marketing.

The research methodology involved a quasi-ethnographic case study within a medium-size, internationally focused design consultancy undergoing significant transition. Three key areas/themes mediating designer involvement in new product development emerged in the findings: (1) a broadened designer remit, (2) the importance of consultancy-client relationships, and (3) a performance-design tension. If design consultancies take greater leadership in NPD, new marketing-related competencies will have to be adopted by designers, designers will have to be more sensitised and knowledgeable about the types and intensities of consultancy-client relationships, and designers and managers will have to actively manage the sometimes contradictory tensions between design integrity and commercial hard sell.

Keywords

New product development; design strategy; design process; consultancy design

Product design has its roots in industry (e.g. Heskett, 2001; Sparke, 1983), yet the role of design and designers in new product development (NPD) has always been problematic and complex in its approach, and in the extent of its involvement (Jevnaker, 1998; Leenders et al., 2007; Murray and O'Driscoll, 1996; Veryzer and Borja de Mozota, 2005). Recent evidence from the literature suggests that the role of designers in NPD is becoming more strategic and that design is taking a leadership role (Perks et al., 2005). That reorientation is the focus of attention of this article.

Design involvement in NPD

The integration of industrial design in business practice has been empirically examined extensively, especially over the last decade, in a range of domains: for example, (1) its impact on company performance (e.g. Gemser and Leenders, 2001; Hertenstein et al., 2001, 2005; Olson et al., 1998), (2) international performance (e.g. Ughanwa and Baker, 1989; Walsh et al., 1992), (3) management of (e.g. Borja de Mozota, 2003; Cooper et al., 2003; Leenders et al., 2007), (4) as strategy (Liedtka, 2000), and (5) its link to other functions (e.g. Bruce and Daly, 2007; Jevnaker, 2005; Martin, 2007). Of particular note is Jevnaker's (2005) study of 'outlying' design-business relationships in innovative companies whose success is concluded to owe much to their championing of design. These studies drive to understand the contribution of design to business: all point towards design as a 'strategic tool' (Kotler and Rath, 1984) of increasing value.

Despite these credentials, the disconnect between the design and business pairing runs deep (Martin, 2009), partly down to design's interest in the future and the unknown, versus the preference for predictability and logic in the commercial context. However, it has been suggested that the couple are more convergent than divergent (Borja de Mozota, 1998) – both are concerned by people, and must creatively solve 'wicked' problems (Rittle and Webber, 1973). Their methodological approaches, however, are fundamentally different. Designers generally work intuitively, while managers seek systematic logic and minimisation of costly NPD risk. A recent trend has championed the harnessing of design skills ('design thinking') for business (Boland and Collopy, 2004; Brown, 2008; Martin, 2009).

While the product development and design management literature remain divided between 'systematic' and 'intuitive' approaches to design, neither the systematic nor intuitive paradigms alone are responsive to the requirements of designer and manager alike. Martin (2007; 2009) suggests the optimum solution is a 50/50 balance between managerial 'reliability' (consistent, replicable outcomes founded on methodological rigour with the goal of risk minimisation), and designer 'validity' (meeting the objectives of the future, using judgment and bias in order to produce relevant products).

As design becomes more prevalent, organisations are increasingly turning to it to add value to the basic product offering. It is not novel that design can add value at levels greater than solely product aesthetics (Cooper and Press, 1995; Murray and O'Driscoll, 1996), yet few organisations are adopting a product strategy which integrates design from the outset of NPD.

Since paths of NPD are underpinned by firm focus and strategy, this focus determines who has the definitive input in NPD: the designer or the marketer. In 'evolutionary' firms (Borja de Mozota, 1998) a traditional genre of business leaders are dominant, and consider design an 'add-on' to existing practices, even despite the modes of integrative NPD fashionable during the 1990s (e.g. Hart and Baker, 1994). In the quest for reliability, design expenditure must be justified to eliminate risk. In contrast, in 'revolutionary' firms, design is wholly recognised and integrated. Design processes are less quantifiably rigorous, and more dependent on designer intuition. A review of the literature suggests two polar modes of NPD: marketing/business-led NPD, and design-led NPD (Table 1). This classification develops Borja de Mozota's (1998) distinction between the evolutionary and the revolutionary organisation.

Table 1: Polarity in NPD

Marketing led / business led NPD	Design led NPD
Systematic approach	Intuitive approach
Design as a functional specialism	Design in leadership role
Designer is a 'small' player in a multidisciplinary team	Designer has pre-eminent role in a multi-disciplinary team
Idea sourced from consideration of business issue/emergent technology on behalf of trained designers	Idea generated from unknown depths of designer mind
Combined effort of team of specialists in a range of fields	Design has final say
Product functionality is key	Functionality and aesthetics balanced
Planned structured process	Intuitive, serendipitous discovery path
Solution emerges from problem definition	Co-evolution of problem and solution
Detailed market research	Serendipitous, experiential research
Later designer engagement to solve pre-determined problem	Early design engagement
Limited designer involvement	High designer involvement

Source: Developed by the authors from relevant literature

Both NPD and modern day industrial design are extremely complex and multifaceted, involving increasingly large numbers of stakeholders. While a recent study describes a move from marketing led to design led NPD (Perks et al., 2005), there is shortcoming as to design's role in the NPD and design management literature. Jevnaker's (2005) research laid the foundations of comprehending how designers work for manufacturing firms and identified relational and activity-based capabilities embedded in the firm side. However, empirical data on how design plays a role in NPD remains limited (Kim and Kang, 2008).

Perks et al. (2005) suggest that industrial design is gravitating to the role of NPD leader. Whilst traditionally design is a final, surface-deep NPD add-on, since the 1990s design has transitioned to player in a multidisciplinary NPD process. Moreover, a handful of companies, the authors suggest, are becoming led by design from the outset of NPD. This can be mapped on a continuum (Figure 1). This research, therefore, seeks to better contextualise the developing right side of the continuum. To understand the nature and level of changing design and designer involvement in NPD, the research focuses on the design side involvement.

Figure 1: Design involvement continuum

NPD in mature product categories

Processes of NPD differ depending on the type of product category being created (Trott, 2001; Veryzer, 2005). Classifications of product categories have been offered by, for example, Ansoff, 1965; Booz et al., 1982; Hart and Baker, 1999; Johne, 1995; and Trott, 2005. The Booz, Allen and Hamilton (1982) classification proposing six grades of product development is widely accepted in the NPD literature: just one of the six categories – new to the world products – involves radical innovation. Trott (2001) identifies 'discontinuous' (high-tech, innovative and radical products) and 'continuous' (additions and repositioning of mature products), and notes that only ten percent of all products can be considered discontinuous and technologically innovative. Hence, the majority of product development that takes place is not 'new', but falls into continuous, mature classifications.

The development of continuous products requires the revision of existing products, or replication of an existing technology (Veryzer 1998). Unlike high levels of risk in discontinuous NPD, due to sudden leaps of intelligence (Kim and Mauborgne, 2005) and the collaboration of a range of disciplines (Veryzer and Borja de Mozota, 2005), continuous NPD is the result of incremental progression, and gradual accrual of market research and intelligence. Development of these products is less reliant on frame-breaking technological innovation and scientific know-how, and more so on marketing and design, and the interactions between these disciplines. Thus, this research focuses on the role of design and designers' involvement in NPD in mature, continuous product categories, rather than in discontinuous ones.

Consultancy design and NPD

In-house versus outsourced

When it comes to the role of design in NPD, such design activity can be carried out in-house, or it can be outsourced, or a combination of both (Bruce and Morris, 1995). The choice of approach has been suggested to affect courses of NPD and product success. Outsourced design, external to the firm, is the most common approach (Press and Cooper, 2003), and can occur where a lack of resources or belief prevents investment in design (Walsh et al., 1992). However, the outsourced approach is generally considered to be more dynamic: consultants external to the firm have the ability to continually input fresh ideas (Bruce and Morris, 1998a; Lorenz, 1990; Walsh et al., 1992).

In contrast, although in-house design connotes top management support, buy-in and design recognition, specialised design teams can be weak, bureaucratic, and suffer from stagnation (Bruce and Morris, 1998a). Internal design usually exists attached to R&D and engineering teams: where many disciplines have input, NPD can be complex and problematic (Veryzer and Borja de Mozota, 2005). However, analysis of external consultancy design offers the potential to isolate the richness of interplay between the design and marketing functions. This isolation of the design-marketing interface makes for a more interesting dynamic which is rapidly evolving since consultancy designers must pitch for new work.

Types of exchange

Evidence from the literature suggests a spectrum of types of consultancy-client exchanges. For example, the relationship between client and consultancy can be enduring and close (a ‘family’ approach), more distant (‘arms-length’) or one-off (Bruce and Docherty, 1993). Bruce and Morris (1998) distinguish types of client-designer relationships based on duration and proximity variables. Since proliferation of many small, specialised design consultancies (Press and Cooper, 2003) has extended the reach of design expertise, firm focus can determine the use of one-off exchanges with a range of suppliers, or the construction of a more enduring partnership with one consultancy. Issues of trust affect the client-designer relationship: the withholding of sensitive information on the part of the client affects the course of NPD (Bruce and Morris, 1998b). However, where partnerships and trust build over several projects, research suggests that switching costs can become high. That long-term relationships evolve on a ‘learning by doing’ basis (Jevnaker, 1998) means that long-lived exchanges can become a competitive advantage (Bruce and Morris, 1998a).

This research, in focusing on consultancy designer involvement in NPD, gives the potential to look at a range of design situations, and design-client interactions, and renders it a rich and valid context in which to explore the role of design and designers in NPD. Jevnaker’s (2005) influential research, cited earlier, of the design-business relationship, studied companies using consultancy design. This research therefore focuses on the involvement of consultancy designers in NPD in mature product categories.

Methodology

That empirical evidence on this phenomenon is limited has implications for the research methodology. Since extant research is thin, an interpretivist, discovery-driven approach was necessary (Brannick and Roche, 1997) to be able to address the research issue (Easterby-Smith et al., 2002). The interpretivist paradigm, it is suggested, is more applicable to the discovery-driven research aims of the study in hand: its focus lies in being to understand what is happening in a given context (Carson et al., 2001). As such, a case study, with its naturalistic setting, quasi-ethnographic stance, and ability to offer contextual richness (Yin, 2003), was considered the best methodological approach for this exploratory research: the case approach enables an evolutionary development over time (Carson et al., 2001). It also holds the capacity to build theory (Eisenhardt, 1989), and therefore to enhance research contribution. The collection of context-rich, empirical evidence can assist in improving design practice (Tzortzopoulos et al., 2006).

An industrial design consultancy, Design Partners, was selected as the central research site. The consultancy was known to be in an interesting time of transition as it sought to reorient itself in the challenging economic climate of the post-Celtic Tiger. Established over 25 years, and employing 30 design professionals, the consultancy is the largest of its type in Ireland. It has prototyping and workshop facilities on-site, as well as office and meeting space. The consultancy works with a range of well-known international clients in consumer products, including Palm, Terraillon and Logitech. Designers often travel internationally to meet with clients, prospective and existing, as well as to suppliers and manufacturing facilities.

The lead researcher spent six weeks embedded in the firm in summer 2009, carrying out quasi-ethnographic observation and semi-structured interviews with designers and management. A rich qualitative dataset was collected from the case notes and diary kept by the researcher. It is based on quasi-ethnographic observation, informal conversations, and attendance at company and client meetings. Eleven interviews with staff were recorded and transcribed. Interview topics were accounts of participation in recently completed projects, liaison with clients and colleagues, and changes in job description. The firm was found to be in an interesting period of transition, between marketing led and design led. A studio in this position has yet to be empirically examined in the literature.

Findings

The consultancy was found to be in a period of significant flux, moving from a situation where the client ‘called the shots’, often based on uni-dimensional market research, towards one where the design studio sought to win greater involvement in NPD. Reorientation from a passive, and often late, role in NPD towards one of fuller leadership and greater input is a central feature of this research, and marks the shift from ‘evolutionary’ to ‘revolutionary’ (Borja de Mozota, 1998), and from marketing led NPD to design led NPD.

The findings corroborate Perks et al.'s (2005) proposition of the increasingly influential role of design in NPD. In charting the shift from designers as followers to designers as leaders, three major themes emerged steering the transition: (1), the broadened remit of designers, (2) the impact of client-consultant relationships, and (3) the design-performance tension. The effects of each of these are described.

Broadened designer remit

A significant amount of conventional design work was gravitating towards business analysis and marketing conceptualisation. To that end, the consultancy team, previously comprising only design and administrative staff, was tentatively recruiting marketing and business development personnel. The company's new mantra was to "manifest our clients' brand through great product design", signifying an underlying business-driven purpose.

This shift in direction marks the movement from the designer's role as a mere service provider to one of design authority. As such, the remit of the designer was broadening to encompass a complex cross-fertilisation of the activities of design and marketing.

The designer-marketer

Designers were *au fait* with the language and craft of business, and in particular marketing. In a number of ways, the designers used this accruing expertise to strategically take a greater degree of responsibility for the development process. This meant that design roles were greater than just the functional and the aesthetic: designers also imbued commercial and strategic value in concepts and products.

The reorientation towards strategic, conceptual, analytical work was evident in many ways. Designers commonly dissociated their work from simply product form, adamant that their task was more than just having ideas; or as one junior designer put it: "our job isn't just to draw pretty pictures" (D2:7). Rather, all design concepts were accompanied by 'stories'. Stories were the marketing propositions around which the design became valid in its commercial context. A senior designer described his job as being to create a tangible marketing vision:

> we're being asked for the emotion and the spirit and the big story, and the strategy to link much more with marketing so that the vision that marketing have for a product, that doesn't exist yet, is embodied when the designer starts to make the product tangible (D6:11)

In conceiving a story, designers engaged in a high level of analysis on product, user and brand, and in doing so, again exhibited the skills and tasks normally adopted by the marketer. Moreover, that the designers themselves undertook research enabled further immersion in the project. Presentations showed that brainstorming normally yielded around four keywords which designers used to encapsulate the ‘spirit’ of the project. This meant that all concepts followed a specified set of values, and this was important for designers.

Identification of customer segments and their needs was another area for which designers took responsibility in concept development. These studies were so in-depth that clients listened as designers explained their propositions. Target user groups and their motivations to purchase were dissected, accompanied secondarily by design ideas and sketches. In this approach, the designer’s natural instinct to create directly according to user needs is enhanced by an entrepreneurial approach to product development. In the quest for relevant product design, the designer’s attention to market segmentation extends the traditional scope of design training.

Designers manoeuvred strategically to guide clients. At concept selection, guidance was offered by tactical selection and ordering of the presented ideas. For example, ‘sacrificial concepts’ were included to emphasise relevance and features in other ideas. By having identified and created a vision for the product, concepts were so honed that rarely were more than six presented. Noticeable also was the reliance upon verbal communications in ‘selling’ the vision encapsulated in each concept – models and sketches were only an aid in convincing the client.

However, that strategic manoeuvring was required at all was down to the design-marketing disconnect. Designers usually possessed intimate knowledge of the client brand, having participated in its creation. However, where advice based on sound judgement was rejected, designers were left frustrated. In some cases, client preference for hard data, choice, and extra research resulted in reluctance to buy-in to ‘spin’. Tensions arose when the designer felt he/she was merely fulfilling a service providing role, rather than being considered an authority on design, design process and brand.

By embracing, and adopting the culture, language and activities of marketing, the designer attempted to foresee and combat this disconnect. For instance, that no sketches were produced without having a marketing story was intended to assert, and make palatable for the client, the product’s market relevance. Designers still found hardship in justifying gut-instinct, and this was often frustrating.

However, the strategic, tactical and analytical aspects to the role, described here, show that designers are assuming extra responsibility in product development, and are fulfilling part of the traditional role of marketing. Ironically, the consultancy’s embracing of the culture of business was enabling the clients’ NPD processes to become more ‘design-led’. By default, designers have an enlarged sphere of influence, and move roles from service provider to design authority.

Consultant-client relationships

The consultancy has two significant, global clients with whom the relationship had begun in the 1980s, along with a number of smaller, newer international and local clients. The extent to which extra responsibility, leadership, could be successfully assumed depended, in a large part, on the relationship between designer and client. These relationships were tailor-made, and determined the extent and timing of involvement of designers in NPD. Different types and intensities of relationships were observed.

Importance of ‘chemistry’

That a firm is only as strong as its people is a philosophy resonant at the consultancy. Great caution was exercised to ensure that the ‘right’ designers were assigned to the ‘right’ projects. Personalities and chemistry clearly influenced the course of product development, corroborating the research by Bruce and Morris (1998a). Designers were all client facing, even those most junior members of staff.

The consultancy’s approach to business was transparent and honest, built on warm personal relations – a ‘family’ approach (Bruce and Docherty, 1993). The consultancy ‘courted’ its clients by, for example, organising extended business trips for bonding. This fostered repeat business, and positive recommendations, and had allowed the business to grow. Relationships were ‘marriages’, one manager pointing out that the clients ‘love’ the consultancy for its approach: for the client, a smooth, efficient development process is as memorable as a successful product outcome. The designers’ quest for ‘great’ product design ultimately underpinned their goals for relationship formation. For them, relationship quality was linked to the product outcome. The closer the ties, the easier the process of communications, the better the product outcome.

Relationship asymmetry

Relationships were of paramount importance due to the typical closeness of collaboration. However, relationship intensity had the capacity to blur the boundaries between design teams and client teams, and the parties became interdependent. This had repercussions for the nature of the collaboration: in some ways, designers were more liberated to take control of the design process. For example, where relationships were intense, warm and enduring, designers understood the client brand so intimately that it was not uncommon that briefs were written by the consultancy to be vetted by the client.

However, the symbiosis was, on occasion, asymmetric: the consultancy was treated as an in house resource by significant clients, and in this instance, was taken for granted. For instance, the consultancy regularly undertook extra work for the same fee, agreed to unfeasible deadlines, and designers were always available by telephone or IM (instant message) contact.

Naturally, the development process was affected by these relationships - some designers considered that these blurred boundaries produced the best design results. However this considerate, honourable and respectful approach exposed a sense of ambiguity within the consultancy. That design was ‘selling’ was regularly reinforced by management at company meetings, yet relationship asymmetry prevented greater self-assertion on the part of the consultancy design team. This was often a source of internal tension.

The design-performance tension

The extension and increasing complexity in the role of the designer is accompanied by a set of designer and consultancy tensions. Designers acknowledged and actively embraced their adoption of the role of marketing. However, the consultancy’s state of ambiguity – service provider versus design authority – caused tension.

Designers were meticulous, almost to the point of being pedantic, about the miniscule detail of their designs. One senior designer confided that his colleagues “really care about what they’re doing, and they love what they’re doing” (D4:12-13). Designers managed their own time and budgets and were therefore responsible that projects came in on time and on budget, and this work-integrity meant that working hours regularly stretched beyond 6pm, sometimes into the night. Compromise of design ideals therefore becomes a dimension of the job.

Necessity of compromise meant that the ingrained passion and quest for ‘great’ design appeared to only to last so long. For some, often more senior, designers, there was little attachment to the hundreds of designs churned out. One senior admitted to not owning anything he had designed. In contrast, for those more junior, projects and completed products were compared to offspring.

Designer salesman

As previously noted, designers sought to convince clients of concept validity, and models and sketches were only one tool in achieving this objective. More and more, the idea of the sales aspect of design was becoming of paramount importance. The ‘sales pitch’ was a performance, crystallised during client contact. One junior designer described his job as equivalent to sales:

> basically what we do every day is sell our insights, sell our thoughts, our designs our sketches, our renderings and our skills (D2:14)

To that end, designers were savvy about the world of business. Many spoke in the language of the marketer, and demonstrated an acute understanding of the hierarchies and political processes common in large corporations. Yet the job was regularly compared to artistic performance - musical, sporting and theatrical. The nature of the design performance is troubled in its paradoxical quest to marry, by process, a fusion of the irrational aesthetic and functional, with the rational business objectives.

Tension and disillusion

Recognition of the client quest for increased revenue from design resulted in an uneasy tension between the business of design, and the creative, liberal, right-brain attitude of designers passionate about the work that they do. A senior designer was disillusioned about the notion of being 'design-led':

> Sit in on client meetings and you'll see interaction of how things become design-led…but it's actually money led (case diary, 9/4)

Frustration regarding compromise and short client reins resulted in jadedness and intense disappointment, not in their current positions, but in the nature of the profession as a whole. It manifested in the realisation that clients recruit them not for the sake of 'great' design, but for the purpose of revenue and increased profit margins. The bottom line was that design is business.

That the individual is responsible and personally attached to the work is a characteristic of the service provider. However, the firm sought to meld, depending on client, both service providing activities and exercise authority as a consultancy, which brought a lack of clarity in internal and external perceptions. In some ways, designers were essentially service providers, and engaged in an elaborate performance, orchestrated to convince the client of validity of propositions. However, in other regards, the designer was a consultant, and acted with authority, guiding the client based on respected expertise.

Conclusions

This research seeks to examine the growing involvement of consultancy designers in NPD in mature product categories. The paper's subtitle asks who leads this new development process – designer or marketer. In an era when design, its uses, its tools and its organisation are taking on an increasing complexity, there is emerging evidence of design embracing a greater leadership role in new product development. Three important areas mediating designer involvement emerged in this study.

First, across the NPD process, designers regularly undertook tasks beyond the traditional realm of design, in line with the conclusions of Perks et al. (2005). More and more, however, they encroached upon the role of the marketer. By adopting these tasks, designers assumed a crucial role in NPD, and extended their responsibility: designers guided clients, and this meant increased control of NPD. Such was the scope of change in the remit of the job, designer competencies had to evolve in line. Fluency in communication and management skills were becoming a necessary complement to traditional design training.

Second, the constellation of the consultant-client relationship emerged as a significant factor mediating designer involvement in product development, developing research by Bruce and Docherty (1993). This chemistry also had the scope to influence quality of the design outcome. Relationships of varying closeness and intensity were observed, and in some cases, an asymmetry – where the relationship became overbearing and ambiguous – left the consultancy in a weakened position.

Third, the reorientation often left designers frustrated, even disillusioned, as they struggled to come to terms with their new role. Designers were required to at once provide a service, and exercise design authority. As they sought to pander to the client's business sense, the personal goal for 'great' design was compromised. This brought tension, especially for those more experienced, in the new direction of the profession.

The seemingly contradictory opposites in the designer's remit – design versus marketing; synthesis versus analysis; doing versus thinking; leading versus following – indicated the challenges to the discipline in its state of flux. While paradox is often interpreted as imposing a simple 'either-or' choice between polar opposites, a more inclusive notion posits that, in a 'both-and' approach, we can acknowledge and better cope with the ambiguous, complex and diverse nature of business and organisations (O'Driscoll, 2008). For design, with its multitude of facets and new challenges, this is a valuable proposition. The early embracing of the language and craft of marketing has enabled designers to reorient themselves into a more powerful and increasingly knowledgeable position, and in doing so, they have assumed a degree of ownership and responsibility outside of the traditional sphere of influence.

However, to fully utilise the potential of this transition, to assume greater credibility and recognition in business and NPD – for example, design representation at board level – these tensions need to be fully addressed, managed, and resolved. Where relationships are crucial, where designers are marketers, the researchers suggest an urgent and widespread need for designer (re)training to be able cope with new and increased demands. As the design-thinking literature suggests, the discipline has a widespread applicability, and potential (Borja de Mozota, 1998; Martin, 2009), and the task now is to educate and enhance its reach. Further research – charting greater designerly contribution to NPD, comprehending how designers may have a more holistic impact upon both product strategy and product function, and exploring how design activity may be more usefully integrated into organisations – is required.

When artists and designers inspire collective intelligence practices: Two case studies of collaboration, interdisciplinarity, and innovation projects

Isabelle Mahy, Université du Québec à Montréal, mahy.isabelle@uqam.ca

Mithra Zahedi, Université de Montréal

Abstract

Current mainstream collaborative processes and practices are not always fit to deal with the complexity of our society and the problems it generates. The lack of complexity-based practices for empowering collective intelligence conditions makes it difficult to address and solve intertwined multi stakeholders situations. As a disciplinary attitude can rarely succeed to solve complex and wicked problems, there is relevance and a need to question today's mainstream approaches to collaboration and innovation. We explore this issue by asking how design can be of help to lead this reflection and to translate collaboration into pragmatic activities. We propose that by focusing on a constructivist paradigm and an interdisciplinary approach, collective intelligence can be constructed. It will then generate new ways to address complex situations.

To support this, we draw from two interdisciplinary projects done in two organizations where collaborative design has translated into various social practices. In one case the creative process involves artists and managers, in the other, collaborative reflective practice within an HCI project brings stakeholders to focus on a human-centered approach to design and sustainability. We examine how design has in each case been of help, and finally, we conclude by presenting pragmatic ideas easily translatable into guidelines for fostering collective intelligence.

Keywords

Collaboration; Interdisciplinary; Complexity; User-centered approach; Project-grounded approach; Collective intelligence; Innovation.

The issues the world has had to face in the last decade have become increasingly complex, global, and interdependent. When social, political, economical, or organizational problems prove to be intertwined, the communities at stake still largely address these issues with abilities based on XXst century disciplinary methods and tools.

In such a context, counting only on disciplinary problem-solving approaches is thus inadequate to address the complexity of the global and emerging issues in a long term, responsible, and sustainable perspective.

This decade has also seen an increase in social movements claiming for recognition, expecting to take part in the reflection, and in the design of solutions as recognized stakeholders. Groups have become active, exercising ownership and willing to commit. This call for participation from various lobbies and communities has become vocal, putting pressure not only on governance but also on methods and tools to negotiate participation and problem solving. Thus collaboration has now become mandatory and unavoidable. Consequently, the abilities required to engage in this perspective of collective intelligence are becoming central to foster innovative solutions for complex problems.

While short-term, narrow sighted solutions are still often privileged over long-term commitments, the complexity and pervasiveness of today's issues call for questioning XXst century methods, as well as their underlying epistemology, which have shown their limitations.

Encompassing collaboration, shared goals, and processes, the concept of collective intelligence is a helpful paramount construct, useful to translate what we pose as being a desired outcome and a nurturing context to address complex and wicked problems from an interdisciplinary perspective. This being posed, what are the core practices that can be associated with it? What are the conditions that support the emergence of collective intelligence and, more specifically, how is collaboration embodied? While technology, organizational and interpersonal communication, creativity and facilitation skills come to mind as some key dimensions to consider, for the purpose of this paper, we limit the scope of the exploration to the contribution of design. The central question of this paper then becomes **how design can be of help to lead this reflection and to translate collaboration into pragmatic activities**. To answer this question we will explain how we relate 'collective intelligence' to 'design' and 'innovation', considering collaboration as the key process leading to the construction of collective intelligence, in an innovation context. We will illustrate this by drawing from two interdisciplinary projects done in two organizations where collaborative design has translated into various social practices. Before providing answers to the research question, we will examine how design has in each case been of help, and finally, we will conclude by presenting some pragmatic ideas easy to translate into guidelines to foster collective intelligence.

Is collective intelligence something to design?

For Morin and LeMoigne (1999), complex thinking is essentially dealing with uncertainty by providing clarity to the strategies human beings put forward to address today's world. Complex thinking is able to *design* complex social, human and technical systems like organizations. Complexity is also the ability to bind, bridge, and connect, to put in context, to globalize while recognizing singularity, uniqueness and the concrete aspects of a phenomenon. Based on this definition, design can naturally be considered a relevant approach to address the collective phenomenon of collaborating. With the development of information technology, an interest in the active user and in activity theory also grew. The designers of human computer interfaces (HCI) found themselves confronted with new demands of users, which were created by the evolution in Information Technology (IT), and by the lack of performance of the classic engineering-type interfaces (Linard, 1998; Norman, 1988; Winograd & Flores, 1986).

While multidisciplinarity addresses the study of a same disciplinary object by different disciplines or domains, interdiciplinarity aims at transferring methods from one domain to another. Nicolescu (2002) shows how interdisciplinarity triggers innovation inside and across domains by making possible new applications, epistemological reflections, and even the emergence of new domains. By considering design as the method shared between domains we are able to see how collaborative practices are enacted in different domains, as the two cases presented hereafter will illustrate.

For the purpose of this paper, innovation is seen as the key motivation and context, and we refer to Lawson (1984) who compared students from architecture (design discipline) and science (non-design discipline) and concluded that designers are 'solution-focused' whereas scientists are 'problem-focused'. In other words, innovation is seen as new and creative solutions found by design teams when attempting to solve complex problems.

Practice-based knowledge differs largely from academic theory-based knowledge in its production process. Where academic knowledge is mainly mono disciplinary, practice-based knowledge is multi and inter disciplinary, and co-created by the communities to whom it is relevant. Focused on finding complex solutions for complex problems, practice-based knowledge assumes a close collaboration between all actors. Many (Carroll 2000, Löwgren & Stolterman 2004, Findeli 2008) suggest that design focused on human beings could constitute an ideal collaborative research mode to create innovative systems.

Considering complexity, humanism, and action based learning as the grounding epistemology for the research presented here, the concept of design translates itself into methodology, problematic, products, and impact (LeMoigne, 1994; Findeli, 2001, 2008). Accordingly, collaboration embodied as practices -which are enacted through an inner posture, attitude, and processes- is the conjunction and meshwork of talents from different fields and disciplines. These practices are anchored in an asserted humanistic perspective, valuing collective and personal responsibility and ecosystemic sustainability. Thus, collaboration is a process where individuals and groups engage in collective thinking and action for the common good.

In a variety of fields, such as building design, human computer interface, artistic-creative processes, it is recognized that to solve complex problems an efficient form of collaboration among all actors involved is needed; the knowledge for problem solving lies in the interaction between actors rather than in a collection of many individual expertise. Thus, collaboration depends largely on social skills, the ability and the will to share knowledge, leadership skills, and the aptness to act collectively in an intelligent manner, as birds in a flock do, in synergy, contributing to the knowledge flow. This flow (Csikszentmihalyi, 1996) is neither planned nor conducted, it emerges from a collective body sensing situations and reacting to them organically. This collective learning process depends on the perceptual acuteness possessed by each member of the flock, its ability to feel, anticipate, and adjust. Encompassing all the skills and abilities described here, the concept of collective intelligence provides a useful understanding of the phenomenon of purposeful collective interaction. We will refer to this as “*the capacity of human communities to evolve towards higher order complexity and harmony, through such innovation mechanisms as differentiation and integration, competition and collaboration”* (Por, 2008).

Considering human collective intelligence, in the area of HCI for example, interfaces are traditionally designed through a technology centered approach using problem solving methods (Carroll 2000, Dourish 2004). But for almost a decade now, user centered approaches have been thoroughly researched (Dourish 2004, Löwgren & Stolterman 2004) and it is accepted that to develop HCI, collaboration within a multidisciplinary team is crucial. However, in practice, we continue to recognize that HCI specialists, mostly computer scientists and designers, have a different understanding about users’ interests and needs. So design practitioners encounter conflicting situations, meaning, it is difficult for team members to create a shared understanding about the needs and motivations of the end-user.

Needless to say these situations are complex ones. Current mainstream collaborative processes and practices are not always fit to deal with the complexity of our society and the problems it generates because the solutions invoked to solve such problems have themselves been designed *within and from* a much simpler and more controlling view of the world, as Boulding’s nine levels of complexity model suggests (Pondy & Mitroff, 1979)[1]. This absence of complexity-based practice as mainstream collective intelligence empowering conditions draws our attention to the need for change.

Alone, today’s practices, fruit of a modernistic Cartesian reading of reality, are no longer relevant to address the difficult task of finding solutions to problems that no one discipline or expertise can understand on its own (Senge, 1991). Thus, there is a discrepancy between the situations we are facing, and the tools we use to address them. In other words, we can act collectively but it is difficult to be effectively intelligent together.

There is also a discrepancy between the ways actors see the situations: designers deal with 'wicked' problems and ‘messy, problematic situations’. This is as noted by Rittel and Webber (1973), for whom design and planning problems were characterized as wicked problems, contrarily to techniques of science and engineering, which dealt with ‘tame'' problems. Alexander, Simon, and other thinkers also pointed out the distinction between design methodology and science as we can see in the following quotes. Alexander (1964) explained that ”*Scientists try to identify the components of existing structures, designers try to shape the components of new structures*.” Later Simon (1969) described: ”*The natural sciences are concerned with how things are… design on the other hand is concerned with how things ought to be*.” The discrepancy in understanding situations as designers versus other disciplines is highlighted by the concept of the ‘designerly’ way of thinking and communicating, which differs from scientific ways of thinking and communicating (Archer 1979).

Collaborating in complex situations to solve problems in an innovative way often assumes that all the information required for understanding the problems is available and understandable. Schön (1983) challenges this positivist idea which assumes that problems are well-formed and thus possible to solve. He brought about the idea that design has to deal with ‘messy, problematic situations’ and offered a constructivist paradigm instead. He proposed the concept of ‘reflective practice’ which is to search for “*an epistemology of practice implicit in the artistic, intuitive*

---

1 Boulding proposed to read complexity as a 9 levels hierarchy where « all human organizations are level 8 phenomena, but our conceptual models of them (with minor exceptions) are fixated at level 4, and our formal models and data collection efforts are rooted at level 1 and 2 ». (Pondy and Mitroff, 1979, p.7)

processes which some practitioners do bring to situations of uncertainty, instability, uniqueness, and value conflict."

To address the central question of this paper, we therefore propose that by focusing on a constructivist paradigm and interdisciplinary approach, collective intelligence can be generated and complex situations can be addressed. According to Morin (1994), the interdisciplinary approach supports a dialogue and exchange of knowledge, analysis, and methods between two or more disciplines. It also implies interaction and a mutual enrichment between specialists.

Situated in this constructivist paradigm, the task for the research is then to find embodied practices that are collective and lead to intelligence; they should be collaborative, complex, and interdisciplinary. They must also nurture innovation and be innovative in their being, or, that is to say, in the way the process is sketched out in the making and how it unfolds throughout the project. Considering this, there is a need to find inspiration from design approaches focused on contexts rather than steps and procedures.

From design to collaborative design

We have defined several concepts that all contribute to creating collective intelligence situations, where wicked problems are discussed and solved by people from different disciplines who act-learn-innovate together in a creative dynamic. This collaborative design is defined by Kleinsmann et al. (2008) as "the process in which actors from different disciplines share their knowledge about both the design process and the design content. Doing that, they will create a shared understanding of both aspects." This shared understanding leads to collective intelligence, which is needed for dealing with complex situations.

Methodology

To explore the various collaborative design practices with the cases, we will refer to artistic creative processes involving artists and managers as inspiration for developing practices useful for facilitating organizational innovation in the context of sustainable development and corporate social responsibility. We present two parallel cases, the first on organizational innovation with the example of a Cirque du Soleil architectural project held in 2001-2002 (Mahy, 2008), and the second, on collaborative reflective practice within HCI projects (Zahedi et al., 2008) held in 2005-2006 at Princeton University. Two realities of collaboration will be presented: collaboration in a project where the priority was given to innovation and artistic aspects, (Mahy, 2008) and collaboration in a website design project where human-centeredness and development of the project in a timely manner were particularly critical. A comparison between the two projects follows the presentation of their respective practices focused on how collaboration emerges through design.

The Cirque du Soleil Case

The organization and project studied

At the crossroads of arts and management, this Cirque du Soleil architectural project was studied through ethnography (Mahy, 2005, 2008). A group of 25 persons, both artists and managers, worked together for more than a year to design the architecture of a cultural centre, called the 'Complexe Cirque', in Montreal. At the time of the study, while pursuing its principal activity of creating circus shows, the company was seeking to develop new products and services to respond to pressing demands from clients. From these expectations sprang the idea of a laboratory that would serve to imagine and test concepts of a new lifestyle in a place set up in Montreal before being launched elsewhere. The spirit animating the Montreal project was one of an 'innovation lab', where an exploratory prototype of a 'creative life' targeting the creative class would be created.

Any player in the creative industry faces the challenge to innovate in each project, as creativity is the DNA that flows through all business initiatives. Any creative breakthrough will eventually translate into greater business capabilities to fuel future projects, while repeating oneself means diminished power of attraction. How does an organization such as this one deal with the complex task of innovating the outcomes – shows, music, films, television series, private VIP parties or large architectural projects to host theatres, lounges, bars, etc. – as well its work processes – artistic creative content design, business planning, reporting, etc.? What inter-group practices are enacted to foster innovation between artists and managers? The study (Mahy, 2008) revealed that both groups had their own specific creative and managerial practices while some were shared between the two groups.

More specifically, the study led to understanding how the Cirque culture permeated the creative and management practices of two teams working together, the artists and managers. The practices showed how both teams interacted, and what tools they created in order to deal with their innovative challenge by way of collaboration, in an artistic and business environment where both needed to find common ground. Collaboration emerged through the different practices presented below. For the purpose of this paper, following a short overview of the spectrum of practices, one specific practice is underlined: the storytelling process the artists used as a language to sketch out, test, update and communicate their vision. This ongoing prototyping of discourse on -and about- the project acted as a catalyst of their goal and, as such, became a design tool.

The practices

Shedding light on all the practices the artists and the managers adopted, the metaphor of the tribe acts as an anchor point and it reveals fundamental qualities of the culture. For the artists, their team is their family, with all its potential dysfunctions. Falsely egalitarian, this emotional community is propelled by trust and tragedy. Co-optation is the rule and the privileges are numerous. For managers, the tribe translates a peculiar community – they deal with artists in a world where the organization's primary leader is an artist himself. Thus, the artists' culture, rituals, and rules eventually permeate through to the managers, who leverage it and give it the strategic or operational spin they believe it requires to achieve their business goals.

While interdisciplinarity is a shared practice, artists and managers organize their respective work differently. The jam session analogy, with frequent cacophonic sounds, illustrates well the organic organization of artists, while the mountain expedition and a roped party give a good idea of the relatively hierarchic organization of managers.

The rapport between actors reveals itself through an ongoing dynamic, crossbred between the two cultural groups. It translates into openness, as well as silos. Biculturalism becomes an advantage when seeking to cross barriers between groups.

While the tribe of artists and managers try to establish dialogue between the two teams to communicate about their respective work, the artists use storytelling to talk about their goal and the vision they created to convey it. Dialogue about the expectations, requirements and management of the project is made up of encounters and misunderstandings. Through formal and informal meetings artists and managers share their views and misunderstandings are common. Neither do the teams share the same mental models, nor do they speak the same language but artists design their vision by creating evocative narratives. They speak about their creation through storytelling made up of imaginary narratives that give life to various dimensions of their vision. Then, in their work, managers use the artists' stories to sell the vision, along with their economic rationale made of facts and figures. By doing so, they add to the narratives and create their own. A polyphony of stories soon springs out of these ongoing conversations and become available to the different participants to speak about the project.

Storytelling and Narratives

Among the practices presented above, the practice of storytelling and the different narratives are central to illustrating collaboration, interdisciplinarity, and innovation. They act as strong communication tools, vehicles of expression, mobilization, and desire, used by the organizational members in their work for the purpose of creating necessary and affective binds that underlie learning, buy-in, and commitment. Flowing into or disappearing from the organizational collective memory (Halbwachs, 1951), narratives offer concurrent perspectives on the project by tapping into distinct facts, perceptions, and aesthetics, all depending on the storyteller's profile.

As presented above, the study revealed two types of narratives which acted as useful catalysts. The first type was created and used by the artists in the process of organizing the project to give the managers and external partners 'a feeling' of what was being designed by the artists. In this case, stories were told about the architectural project, the Complexe Cirque, which was about to be built. Characters, events, origins, culture, everything was imagined and dramatized to offer an aesthetic, artful, and meaningful story. For their part, once convinced by the artists' narratives, the managers would develop the business side of the same story in order to support it with the rationale of a business plan focused on return on investment, pride of being part of such an innovative, prestigious, and audacious project, etc.

Such an inter-group communication strategy assumes that both understand the others' language and intent. The study showed each group had difficulty thinking outside of their own 'disciplinary' culture, and that they might have experienced more fluid interactions if they had relied more on members who were 'bi-cultural', with interdisciplinary competences, and who were at ease within both cultures. Had there been a reflection on how to improve on these communication flaws corresponding to a collaborative approach to design, the project organization could have helped participants integrate those who were fluent in business, arts culture, and process.

Unable to understand and support each others narratives, members of both groups had to spend time trying to 'translate' the other group's narrative into their own rationality. To do so, both groups held regular meetings and long summits during which they would present to each other the artistic and the business version. The summits would last 1 to 3 days and the executive management team along with the company's founding-president would attend and intervene. The president ultimately refocused, adjusted, commanded, or dismissed ideas and people. This external regulation helped in decision making, but it also ignited rivalries and confrontation. This disconnect between the two rationalities made the project difficult to present to external partners when trying to convince them that it was a coherent, robust, and attractive initiative, both aesthetically and business wise.

The harmonic polyphony of narratives often became a cacophony for many participants in the project and it did create some dissonance among the tribe. Resulting from an artistic creative process, the stories created by the artists carried a dream. The managers ones conveyed the economical interest of becoming a partner. Between the two, stories on how to translate the dream into concrete were missing and the reflexive knowledge on the process did not lead to concluding that another type of narrative was missing and greatly needed. A story on how to work together between the two teams would have helped but it was not observed or heard of in the study.

Nevertheless, a collective narrative evoking the vision was created and had a positive reception. While it was appealing to all participants and partners, the political and economical context of the time played against the project and it was finally stopped before the building phase.

The case of HCI design

The early stages of the design process of a website was studied in order to understand what really happens during collaboration within the assigned team. Project-grounded research (Findeli 2004, 2008) was privileged for this study. This approach allows the designer-researcher to conciliate theory and practice (Findeli 2008, Jonas, 2007). In other words, conducting research and constructing knowledge become part of the design project.

The project was about the redesign of a complex website for Princeton University. The existing website was designed a short time before this intervention, however it had technical flaws which seemed to be the single reason for the client's request to redesign. A careful analysis of the website made it clear that it was designed following the administrative structure of the institution and very elaborated visual elements were used to make the website attractive to users. Although most content was valid for reuse, the site had several shortcomings from a user point of view, including deficiencies for those who had to feed the site and keep it updated. These people were office staff members who had the responsibility of updating the site daily. They were also in direct contact with users of the site and received regular feedback. A functional site was urgently needed to serve both groups but very limited time was available for redesign and development of the website. However, the time constraint in this case was of help; the client accepted to make everyone involved in the project available for the redesign and the development of the site. The availability of these people for a set period of time was the needed condition for applying a new design model, one geared to translate disciplinary collaboration into new knowledge construction, useful for the purpose of the project.

This professional design project became our field of study. Through this research and project, we aimed to find out what conditions were needed for a variety of experts to think outside of their disciplinary boundaries, to enrich the collective knowledge regarding the end-users of the project. The idea was that the enriched knowledge would contribute to a more successful design, and to the development of the project in a timely and more economically efficient manner.

Collaboration within an environment of reflective practice

We introduced a new design model for this project (Zahedi et al., 2008). The model is based on 'interdisciplinary attitude' and 'joint reflective practice'. Its purpose is to facilitate collaboration and knowledge sharing among team members of a complex project, early in the design process, while positioning the user at the centre. The model, 'environment for reflective collaboration', allows for the construction of collective knowledge, which can be achieved by collaborative learning opportunities that combine theoretical and practical aspects.

The concept of interdisciplinary attitude means shared commitment, acceptance of approaches from other disciplines, and looking at the problem from various perspectives (Boyarski, 1998). It allows openness to other perspectives and a willingness to share information. This is to say, the interdisciplinary attitude is the mind-set that encourages an informal teaching and learning dynamic. With shared information in the context of the project, all team members understand divers perspectives and see the relevance of diverging viewpoints. Schön (1983) emphasizes on "complexity, uncertainty, instability, uniqueness, and the value conflicts" of situations of professional practice and explains that these situations are not problems to be solved. They are problematic situations to be understood. Through 'joint reflective practice', we bring together diverse knowledge and skills, allowing the team to notice interconnected problems, construct new knowledge, and to formulate the situation differently. As reflective practice is associated with learning from experience, it allows the team to change its perspective, gain new knowledge, and challenge the concepts and theories by which they make sense of knowledge. By joint reflective practice the team can bridge different understandings and produce new knowledge to deal with uncertainty.

The model is composed of three elements: an intensive workshop to encourage both the interdisciplinary attitude and the joint reflective practice; tools to support knowledge sharing and team performance; and design as a method to facilitate collaboration and understanding between people. The workshop, the tools, and the designer in the role of facilitator, are strongly related. By applying the model, the multidisciplinary team works closely together, focused on user needs and motivations in order to redefine the objectives, the priorities, and the information architecture. Reaching consensus on these factors, coupled with the knowledge produced, was essential for specifying the parameters of the project and realizing it efficiently within our time constraint.

The team was composed of 11 persons, including office staff members, web programmers, content experts, higher management, and a designer. Although, in most activities the workshop functioned with 6 or 7 team members. Based on the previous analysis of the project, its estimated complexity, and the knowledge about the team, the workshop was planned for 6 days. We designed a set of activities to support the workshop and planned to facilitate its progress. Visual representations of design and development process were shared with the team. Also the team developed a web-based system for gathering information about the project which could be accessed when needed. As the main goal of the intensive design workshop was to redefine the information architecture of the site with a user-centered approach, it was clear that a common understanding of users' interests and needs was essential. The team participated in a set of activities such as creating persona and use scenarios. Their discussions and exchange of knowledge contributed to redefining the objectives and priorities of the site, the methods to achieve them, and to retaining a constant focus on the users.

It was clear that we were dealing with a 'messy' situation. In HCI, these situations are complex: they are unique in their context; there is a continuous change of users' needs; development of information technology is fast; and there is a necessity to work within a multidisciplinary team. In working with multidisciplinary teams we had already noticed that team members were mainly concerned with their own expertise, making it very difficult to consider the end-user, and that they had different understandings of users' interests and needs. Being engaged in the activities of the workshop modified the focus and understanding of team members.

The activities of the workshop led to the exchange of knowledge and new ideas. By using the project-grounded research approach, the theory was situated in the project and its implication on practice was directly observable for us, but also for other team members. During the workshop activities, as the team become more familiar with the user-centered approach to design, new questions emerged and modified the viewpoints of all contributors. Their interest in theory and its implications in practice grew. Discussions regarding the concerns of each discipline helped the team to share information and develop a common understanding; it also helped them to realize the complexity of the project. Their attitude toward collaboration and exchange of knowledge was modified. Design as a method for understanding people and knowledge sharing contributed to increased innovative solutions for the project.

Discussion and conclusion

The cases presented here aim to answer the 'how' question introduced at the beginning of this paper: how can design be of help to lead the reflection on collective intelligence and to translate collaboration into pragmatic activities? The two cases showed how complexity and interdisciplinaity are connected. It also showed that design can be used as a means to encourage and motivate construction of new knowledge at a personal and collective level. In both cases, collaborative design brought the team together for social practices. The outcome was that design was very useful as an overall framework for guiding practice. The following is what we have learned.

Design the conditions for meaningful conversations

We saw different social practices and creative ones, both based on one shared assumption: that there is a need to nurture meaningful conversations among the groups and teams who work together on challenging projects. When design helps to bring collective intelligence to a team, it acts as a method to encompass complexity.

A planned-change approach, made of steps and procedures, can be useful in complicated situations where the problems are well defined, not 'wicked', where all the information is available, and when the future can be anticipated. But when a situation is complex, events and situations that could not be anticipated do happen. This characteristic of emergence intrinsic to the concept of complexity (Morin and LeMoigne, 1999) contribute to inviting new approaches, those that do not focus on control but on nurturing and sustaining the process in the making. Consequently, the shared assumption for both cases is the fact that conditions for nurturing meaningful conversations becomes mandatory.

Design attractors to foster culture

Design was also put to work in situations where keeping memory appeared to help projects. In one case, an aesthetic and memory dynamic process was created in order to nurture the creative activities of Cirque du Soleil artists. It was done by offering them a mirror to their work, an alternative perspective on their culture from which they could learn and draw ideas. In the second case, a web-based system was created around which team members could gather and contribute to sharing ideas, understanding, and meaning. This fostering tool nurtured the project culture and its evolution.

Design shared stories

Characters, personas, and scenarios were created in both cases as pieces of a grand narrative about each project. The use of images, metaphors, and stories is a powerful and artistic creative technique able to reach out and touch human senses while acting as an emotional lever. This approach added a rich texture of humanity to daily work and helped team members feel they are part of an inspiring initiative. By contrast, we have seen that the interweaving of different stories can also be delicate when interdisciplinarity is not present. It is a intangible process that implies competencies, and reflexivity from all team members.

Design collaboration

Collaboration is a complex phenomenon, one which fluctuates when context changes and pressures from project environments increase. Because relying only on planning, procedures, and control is irrelevant in a complex situation, collaboration gains from being supported to emerge and maintain itself, thus considering design as a framework for sustaining collaboration is a useful perspective.

Design collective intelligence

As we have seen, different practices in an interdisciplinary setting contribute to leveraging collaboration in innovative projects. Because it is fully social, shared knowledge and the collective learning process reside largely between the team members (Hutchins, 1995), and is enacted through all communication, in all activities. Acting as a favorable condition for collaboration, in an intelligent and positive way, reflexivity presents itself to be a keystone of collective intelligence. The idea of fostering -holding the space for[2] the project to bloom, or in other words, for good ideas to emerge, is a key aspect of this collective intelligence.

Design bridged the gaps

We benefit from the research approaches in design, which helps the team to connect with the complexity of the situation, and integrate the theory and practice within the project. Design, as a vehicle for changing the way team members interact, makes integration of all viewpoints possible.

Conclusion

The previous considerations invite us to propose that collective intelligence is not the sum of all the discourses created in a project and that complex collaboration requires reflexive experience-based rules to shape action. It also implies interpersonal and collective trust, a will to explore, creativity and playfulness, as a recent study on collaborative challenges has shown[3]. In the two cases presented, we saw an ongoing design strategy of sketching out the project vision and its activities through discourse. The successes and flaws lead to proposing that strong reflexive and interpersonal skills are required for this nature of collaboration but because of the very nature of such projects, which implies complexity thus chaos, collaboration needs to be the centre of attention and to achieve this, it needs to be designed. This design does not aim at sketching out complex social interactions through planned procedures but to create the conditions, or in other words the context, for interactions to emerge and to be experienced as positive and nurturing. To support this humanistic view on design, Scharmer (2007) proposes that deep listening skills, reflexive skills, and more than a superficial openness to co-creation are mandatory to create such conditions. Scharmer suggests that these social design skills focusing on how to embody co-sensing, co-presencing and co-creating states of being could be of help to revisit the expected competencies needed to create collective intelligence.

To conclude, we have found that design actually acts as a catalyst when collaboration becomes mandatory for complex projects success. This finding opens further research questions on the appropriate guidelines we could provide project members to help them with organizing their initiatives. Anchored in a complexity paradigm, this question would lead to developing adaptable social change supporting tools and techniques.

Author Biography

Isabelle Mahy

Prior to becoming faculty in the department of social and public communication at the Université du Québec à montréal, Isabelle Mahy worked in various organizations for 25 years, in organizational design, collective learning, knowledge creation and sharing. Her research focuses on transformational change, collective intelligence, organizational communication, participatory action-research and art-based methods. In 2008, her book "*Les coulisses de l'innovation, création et gestion au Cirque du Soleil*" was published at les Presses de l'Université Laval.

Mithra Zahedi

Currently Mithra Zahedi is a visiting assistant professor at the School of Architecture & Design at the Lebanese American University. Prior to this she was a lecturer at the School of Industrial Design at the University of Montreal for eight years. Mithra holds a Masters of Science in Educational Technology, preceded by her study in Industrial design at La Cambre Brussels. Mithra worked as a design consultant for more than 15 years, focusing on human-centered product and communication systems in the IT industry and in educational institutions. In her current research her main interest is in team interaction and support for design activities in a multidisciplinary group. Mithra is currently a Ph.D. candidate.

Perspectives on critical design: a conversation with Ralph Ball and Maxine Naylor

Matthew Malpass, Nottingham Trent University, UK

Abstract

This paper features an edited conversation with designers Ralph Ball and Maxine Naylor. It explores their thinking in relation to critical design.

In the preface to *Form Follows Idea* (Ball & Naylor, 2005) Jeremy Myerson describes Ball and Naylor as being regarded among Britain's most thoughtful furniture designers.

In 1985 Ball formed a design partnership with Maxine Naylor a reputable experimental designer maker. Together they began to challenge the boarders between art, craft and design. They have exhibited work internationally and held teaching positions in colleges in the UK and USA. Over the course of a decade from 1985 Ball taught on Furniture, Jewellery and Industrial design at the Royal College of Art where Naylor taught on Furniture Design, directing the course between 1995 and 1998. Today Ralph Ball is Professor of Design at Central Saint Martins University of the Arts London and Maxine Naylor is Professor of Design and Director of the Design Research Institute University of Brighton.

Through practice and academic tenure they have developed a distinctive approach to practice based research and refined their critical perspectives. They describe themselves as critical designers and use design as a critical, visual discourse to communicate ideas about design culture and society today. Taking experimentation as a research method they subject their ideas to a critical process of refutation. They question the work through a scholarly approach that challenges protocols of design to enhance the design profession.

In this conversation the designer's concepts of 'open-process' and 'design poetics' are discussed. They describe their role acting as critics of design from within design practice. They outline their thoughts on the increasingly un-ideological culture of industrial design. They describe how through playful experiment they question the value of repetition in design and mass production of products. They do this by taking modernist axioms to extremes and 'embedding narrative' into objects as commentary on the state of contemporary design.

Supplementing the conversation the author offers his reflections. Primarily this exposes a form of critical design that differs significantly from popular and often technologically orientated notions of critical design.

Keywords

design practice; industrial design; reflective practices; rhetoric; poetics.

A growing number of designers employ Product Design as a medium for critique and speculation within disciplinary and societal frames. Although they are distinct from each other in their concerns and approaches, what these designers share is not simply a transgressive attitude but a critical perspective on design's self-understanding. Each challenges established discourse, institution or episteme and present alternative roles for design to those characterised by industry and driven by technological and financial concerns. They offer new interpretations of prescribed agendas legitimising and problematizing alternate forms of design work that extend product design's cultural agency.

These alternative approaches are understood under various terms, for example, Moline (2008) describes experimental design. Bruce and Stephanie Tharp (2008) describe discursive design outlining a design approach that leverages functionality to spark contemplation. In a discussion on the origins of critical design and its operation in Sweden Robach (2005) describes koncept design emphasising the link between critical design and conceptual art. More recently a discourse has emerged surrounding speculative design. (Kerridge, Loizeau, Caccavale, Auger, & Soares, 2008)

Arguably, speculative design has developed from of the popular understanding of Critical Design developed by Dunne (1998).

These practices are uniform in that they suggest a move away from commercial design towards a conceptual, discursive, inquisitive and often provocative role. Design as a critical language where the object and medium of design are used as a form of inquiry in societal, technological and disciplinary discourse.

To understand how product is used as a form of critical language in terms that do not exclusively rely on established discourse in other disciplines – for example in Art, Architecture or Sociology– we need to develop a disciplinary understanding of critical designs meaning, potential and explore its contribution to Product Design.

To establish this understanding we need to question in design terms: What are the examples of practice – the designs? In what contexts do these designs operate? By what methods and tactics do they operate? What is the focus of critique or the subject of investigation through design? In addition to analysing individual projects and practitioners we need to consider them in the context of the whole that they form. We need to attend to the subtle differences in the approaches and explore the links between the individual modes of critical practice. Underpinning this we need to consider conditions in mainstream design that have led to the emergence of critical design practice.

In this paper the author begins to address these questions aiming to illustrate one approach to critical design through the perspectives of designers Ralph Ball and Maxine Naylor.

Method

This conversation is one in a series of interviews with critical designers that form part of a PhD project contextualising critical practice in Product Design. The function of the PhD is to analyse approaches in Product Design that have been described as critical in an attempt to conceptualise the field and thematically separate examples of practice (Malpass, 2009). Using literature and interview transcripts as a source of information the author has developed thematic categories through a process of dialogical reasoning and “constrained generalisation” (Butler, 2002). The author aims to structure the field of practice and illustrate through taxonomy: the function of critical design practice; the rationale for critical practice; the contexts where it operates; the projects; the designers; the methods by which it operates.

A hermeneutic is employed (Klein & Myers, 1999; Gadamer, 1998). A nessecery element to satisfy the hermenutic method is to engage with multiple partcipants to elicit multiple interpretations of the field. To staisfy this element interviews were arranged with expert designers. Through interview the ‘critical’ designers were encouraged to reflect on their experience and practice. A conversational approach to interviews is used. (Rubin & Rubin, 2004; Laverty, 2003)

A hermeneutic approach enables the participants to reflect on the meaning of their experiences. Gadamer understood hermeneutics as a process of co-creation between the researcher and participant in which the very production of meaning occurs through a circle of reflective interpretations. This approach supports a dialogue between the researcher and participant. The participant’s contributions are allowed to affect the co-construction of ideas. This principle calls on the researcher to acknowledge and reflect on the construction of the data derived from the interaction. The reflexive discussion supplementing in this paper contributes to this process.

The participants and context

Ball and Naylor are identified amongst a group of expert participants who through writing and practice present an alternative perspective in critical design discourse. Their practice differs from those in critical design that deal with scientific engagement or technological futures – “What if’s” (Dunne & Raby, 2009) or “Design Fictions” (Bleecker & Nova, 2009). Using an experimental approach they design and make furniture. Ball and Naylor’s approach forms part of an academic strategy that they describe as a practice led approach to research. Through object they offer commentary on the impact of design in society. To set the scene the interview was conducted at

Central St Martin's University of Arts London on an afternoon in August 2009 where Ball and Naylor were preparing work for their exhibition 'Chair Poetics: Envisioning Anonymity' part of the London design festival.

On: Critical design

Matthew Malpass: You describe your research activity as critical design practice. It might be good to have some definition of what critical design is. Is this something you can give?

Ralph Ball: I think the first thing it means is that the objects we produce are about making commentary or comment on design practice. That means the objects themselves don't necessarily need to be functional, practical objects but they need to refer to functional, practical objects or to the culture of design in order to make relevant comment. We use objects instead of using text. Those will be visual observations about particular issues associated with design. The issue might be to do with sustainability, excessive obsolescence, it might be to do with obsessive focus on a particular ideology and where that might lead. In some cases, we've explored the axioms associated with modernism and demonstrated how the axioms if taken to an extreme produce absurdities. The ideology finishes up being problematic. It's a way of exposing the fallacy of unreflective ideologies of any kind.

On: Open process

MM: You write about an 'open process' can you explain this?

Maxine Naylor: It's a way in which we work at the moment. We both trained as furniture designers. As a furniture designer you are often working on your own projects – certainly in your educational experience and often as a professional. In a more 'open process' what you're doing is you're working with other designers. It's a much more communal activity and it's where ideas are debated and discussed – they're moved through a conversation. In many ways critical design is a dialogue. It's a visual dialogue about our ideas concerning design thinking. The 'open process' is that process when you are having a discussion and debate while you are working. It's also substantially to do with the idea that you are not working for a client. You are working to a design agenda rather than a client or service agenda.

RB: If you are working as a professional you are invariably doing something relatively preconditioned whether it's a specific design brief or a particular set of required parameters to operate within. In an 'open process' those things are much less constrained and you can allow all sorts of other elements in. We talk about allowing accidents to happen, finding things by accident and the fact that when you are working with the juxtaposition of objects in space something might happen simply by the fact that two things come together. You can be aware of that and use it to lead off. In a conventional design brief you would often have to ignore that newly opened route.

When we talk about 'open process' it doesn't mean there aren't any rules. The rules are determined by the choice of the object or the choice of story that we're trying to tell. When we conceived the 'Archaeology of the Invisible' – the overarching project is called 'Sustaining Desire' – what was interesting is that we were working deliberately and specifically with objects that had already been designed and we were redesigning them.

What that strategy does is that it objectifies the process in a different way because you are starting with a given. For example, that is a generic stacking chair and asking the question, what are we going to do with that? We can both buy into that discussion objectively. It's not about whether I think that this proportion is better than that or I'd detail something in a different way to Maxine. It's about what makes sense in terms of telling the right story about this specific object. The objects impose certain kinds of rules because they are what they are.

Figure 1: Blackstack. Archaeology of the Invisible collection 2003-04

RB: A stacking chair is a stacking chair and not any other kind of chair. It has a certain set of rules about what it does and doesn't do and we have to honour those rules.

Maxine Naylor: There are particular parameters implied by the objects themselves. We try and define and operate with those principles. We almost agree a set of principles before we start working so that we know we can't do that but we can do this. The old design principle of creativity within specific constraints. By limiting the language we actually exploit it better. We get more out of it because we focus on the elements which are appropriate.

This type of designing is a much more open ended activity. When we started the first collection Archaeology of the Invisible it wasn't determined that there would be a collection of chairs. There was a discussion about chairs. The objects are a manifestation of the conversation we were having.

On: Design poetics

MM: You talk about 'design poetics' and the use of rhetoric in your approach. Can you describe the notion of 'design poetics'?

RB: 'Design poetics' is coined and used in the same way as literary poetics and poetry. Something doesn't have to make literal sense it has to make poetic sense. What does that mean? It means that in literary poetry you can put words together that wouldn't necessarily make figurative sense but elicit a different kind of meaning. For example, if I talk about someone having a loud voice that would be a normal literary statement but if I talk about a pale green voice or a dark blue voice that would be a more poetic description – one which engages the faculties of both imagination and interpretation. We can consider 'visual poetics' in the same way. We put together something which creates a contradiction, creates a paradox, or creates some form of visual resonance, which is different to conventional expectation but which throws light on the object that we are dealing with.

MN: Often the work is about engaging people in looking at objects afresh and it doesn't have to be serious and ponderous. It's actually often quite witty and amusing. One of the things we had happen quite a lot when we first showed *Archaeology of the Invisible* was people asked me if it was alright if they laughed at the pieces. I said yes, they're funny, they're funny aren't they? It's about people getting it rather like comedy. Being poetic about something allows people to look at things in a very different way.

MM: Is humour is an important element?

MN: Culturally it is and so it should be in our design work.

RB: Another point about the poetic aspect is that we are making objects that look both familiar and strange. In literature there is a recognisable relationship between ordinary prose and poetic language. Poetic language uses the same words as ordinary prose it just puts words in different orders. When we're working with chairs we're making objects that are familiar but we're remaking them to be simultaneously unfamiliar.

MN: We also look at features, characteristics and differences. Because we're both furniture designers we look at chairs very closely. Chairs have got real personalities and attributes. These characteristics are invisible to most people. By altering them they become generally more readable. We shift and emphasise. We make their personalities stronger and people see them more fundamentally.

Figure 2: Plastic Gold (anonymous and ubiquitous white plastic stacking garden chair) & 24 Star (generic office chair). Archaeology of the Invisible collection 2003-04

RB: The whole point about the *Archaeology of the Invisible* collection is that it's actually 'digging up' awareness, making visible that which, because of it being so common and so ubiquitous, is invisible, culturally buried. The value of stacking, or the economic or structural difference between one chair frame and another goes unappreciated.

MN: Whether an object is 'designed' or not designed, or if it is well conceived or not well conceived is often simply not considered at all.

On: Rhetoric and Embedded Visual Narrative

MM: Other critical designers talk of rhetorical use presenting work that alone you wouldn't have any idea what it is or is for. It needs an external narrative to establish context of use and with that persuasive narrative you can imagine using the design. Is that how you use rhetoric?

RB: No we don't use it like that. We are interested in what we call 'embedded visual narrative'. The idea is that we're trying to use a visual narrative. What we are looking for is to have the object speak for itself or declare its intentions directly. The story ideally is embedded in the object rather than existing as a separate narrative. You don't have to have a piece of text to go with it. That's the difference between what other critical designers may do and what we do. We intend that you are able to directly, visually read what the object is about.

MM: Critical design isn't functional in a traditional sense. Do you ever see this type of design practice feeding into a more traditional idea of the design process or is it something that should remain separate?

RB: I think it can occasionally become conventionally functional as an accidental by-product of the process. In the past some of the things we made prior to *Archaeology of the Invisible* which were developed within a critical or an ideological frame of reference and driven by that particular definition. But we were designing these objects within a product design ethos that meant that we were conceiving and detailing them as if they could be produced. That suggests that if, by accident, they happen to have a commercial viability then it's possible that they could easily migrate over the object boundary and become products. This happened with *Golden Delicious* and *One Day I'll Design the Perfect Paper Light Shade* (Fig 3). They became products but only because they're conceived using the language of industrial design – they therefore already have the latent possibility of being product design. They were originally conceived and presented as one off pieces but within industrial production ideology.

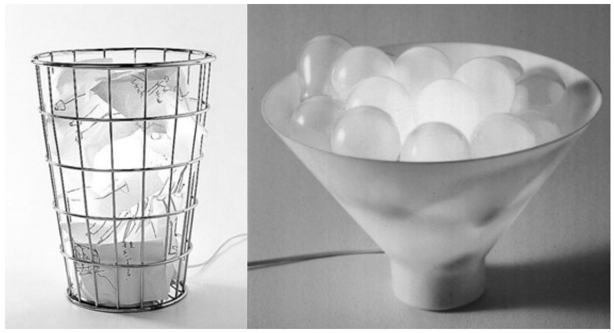

Figure 2: One day I'll design the perfect paper light shade 2000 & Golden delicious 1997-98 for Ligne Roset

MN: By nature because we're designers we try and rationalise as a designer would. We put things together in a rational way using the principles we've grown up with – economy of means and so on and we use materials effectively and appropriately. So in a sense that's what it's also about. It's expressing those traditions. They are now traditions of thinking about how things are manufactured. Even if it is something we've altered it's still reflected in the language of the piece and in the way it was manufactured.

MM: Can you tell me about anything that motivates your practice are there any notable influences, inspirations, education or any theoretical perspectives?

RB: One of the things that initially motivated me was a kind of frustration with what I would call an endless cycle of the same neo-modernist work. Also a frustration with the way that postmodernism and various forms of contemporary design simply seem to be fairly stylistic activities with very little intellectual content. Certainly postmodernism was used to attack modernism as being something, which has nowhere else to go and was caught in a stylistic cul-de-sac. Postmodernism as a replacement can be accused of equally facile activity and limited works. There are exceptions of course; there are exceptions in both camps to that limitation. So yes what we're interested in are the exceptions rather than the rules. In that category we would put people and influences like SITE, the architectural practice, Marcel Duchamp's Rue Larrey Door. There are certain types of objects and certain things that make sense to us in terms of what we are doing now that are historically part of that same lineage. I think initially it's to do with frustration with the design work that was and still is coming out and seems to be more and more of the same. I don't see any value in actually doing something, which is no better than something that Charles Eames did in 1950.

MN: The work extends in terms of education. In many ways the thinking came from – well certainly from me – a frustration with students being unable to look properly at objects. They don't look at things analytically or critically. People don't look at things more than superficially. Students particularly have to cultivate a sustained concentration and the project turned into one where actually I got my students to appreciate objects better. They looked at things for longer. They understood the implications of manufacturing an object. They started understanding that it was built, it was constructed and that many people worked on it. They gained a greater appreciation of artefacts, and this goes back to engaging the sustainable debate.

On: Mature typology

RB: There is another difference in how we work. Because we are furniture designers we are interested in what we call 'mature typologies', types of object which generally have an agreed consensus on basic form. I'm not particularly interested in electronic objects which don't seem to have reached any kind of formal maturity. The other definition we have therefore is that there are 'immature objects' and they haven't reached a final form because, for example with the telephone the function is to communicate with somebody over a distance. That form and method keeps changing doesn't it? With the chair the basic form was established thousands of years ago. We have many variations on the same fundamental form – something that holds your body at a certain height off the ground, to make it comfortable for your legs. With regard to talking to people over a distance that's changed from smoke signals to mobile phones and could continue to morph into something that's almost intangible.

MN: The thing about furniture is it's about ritual, it's about culture, and it's not just about comfort. The electronic world is driven by micro technology, which is fascinating but it's an expansive, shifting and a kind of amorphous entity that in a sense could be almost invisible. In contrast, furniture is always going to have a physical presence.

RB: That goes back to the 'embedded' narrative. We are working with recognisable archetypes. I think the problem with electronic products is that they are less recognisable. That is why some designs need an external narrative to explain what they are. You could have a cube or a minimal shape and you can say this is a something – a radio for example – you declare that's what it is.

MN: Driven by hidden electronics it could be anything. Is this cube a calculator or a smoke alarm?

RB: Then you have the idea of imagining using. As soon as I pick this up and put it to the side of my face it becomes a mobile phone. As soon as I pick this up and behave with it in a certain way it becomes the object associated with that particular behaviour. But it requires a 'theatre of use' to have that happen. With mature objects we already recognise them so therefore we've got a recognisable narrative to start from.

MM: I'd like to talk a little about framing your practice. What makes your objects design objects and not conceptual art?

MN: We have this debate quite a bit. Sometimes out of perverseness, sometimes we want to – if we're labelled as designers – say no we're artists and sometimes when I'm called an artist I say no I'm a designer. But actually in the end I don't know if it's an interesting debate in itself. As soon as you set yourself in that position people look at the work in a particular way. I know they need to set it in a particular context but my thinking is that they look at it how they want to look at it. If they want to see it as conceptual art fine, but if they want to see it as an interesting statement about design that's also fine. I would probably always say fundamentally I'm a designer because I like the problems that designers tackle. I think they have serious implications for the world. If you're going to get deeply philosophical I think designers have an ability to make a huge impact on our environment. Not just in terms of sustainability but to the quality of the environment. We suffer for a lack of quality and integrity and at the moment society still doesn't know what design is. They think it's a styling exercise, they think its packaging, they think its branding, but the core activity fundamentally is coming up with good products.

Figure 4: Chair Archive 2008. Indeterminate Cases exhibition. La Sala Vinçon Barcelona

RB: It follows from that. You might choose to use art as a strategic label because people sometimes take art more seriously intellectually. There is a perception, a position – when you locate something in a gallery it is looked at differently than if placed in a retail store. You can use this perception of the gallery context. It's strategic to use the idea that it is somehow art about design or better, art using design as a point of reference in order to make statements about design.

MN: I think your point earlier, which I would agree with, it's that we honour the process of designing. We don't mean to throw it out of the window and start from first principles. We have a good legacy to work with. What designers haven't done is move design on to where it needs to be. We've corrupted it by doing these copies of things. In general we have a very different idea of what design can be than many designers. I think it is a very, very significant profession that's been much abused and much misunderstood and actually what I find upsetting is I think many other professions understand what we're getting at more than the profession itself, what the value of it is.

MM: Other critical designers focus on issues that can be considered outside of the design discipline – what I describe as ‘With-out’ – using design to address societal and ethical concerns such as bio-ethics and scientific futures. Your work seems to subvert design challenging the discipline by offering critique of a design core – what I describe as ‘With-in’. Is this something you would agree with?

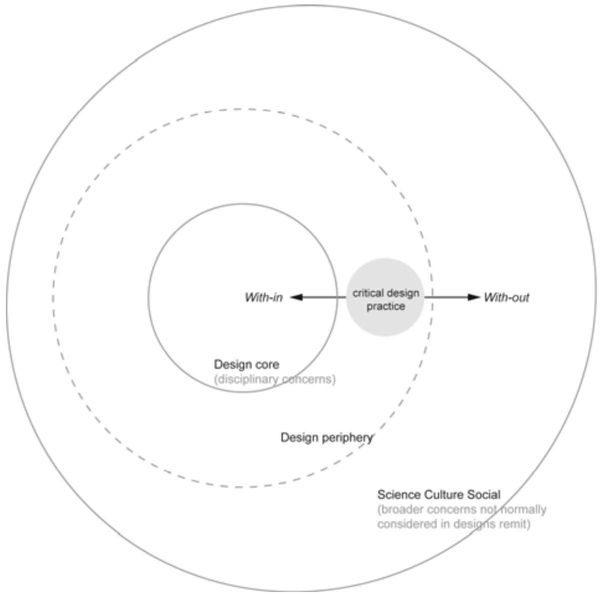

Figure 5: The focus of critique. Illustration used as a discussion prompt.

MN: It’s subversive in a sense of challenging current design thinking and practice, that is, much of design often defaulting to branding exercises. Yes our design actively opposes that. But not subversive fundamentally I believe design can be a powerful tool that doesn’t need to be completely dismantled; it just needs to be paired back to what it’s capable of doing.

RB: I would agree generally with that. However, additionally we are looking at sustainability, in a way I think is different to other people. Sustainability does belong to that larger territory. The umbrella title of the original project was called Sustaining Desire and the idea involved looking inwards to project outwards again to a larger social context. It’s basically proposes that we need to start valuing the good things that we already have rather than making more and more, throwing them away and making more and more again. So Sustaining Desire becomes: let’s focus on both the intellectual and the aesthetic marriage of things which are really good pieces of design. So we have to go inward i.e. to be introspective in terms of looking at what these objects really are and what they do by representing the forgotten and the familiar.

MN: But then also it’s interesting because it depends on the audience. I would say that our audience is primarily a design audience. I see other designers as my audience. I’m trying to inform and motivate that inner core to do something. Yes they are being asked to look outwards but what we are doing is trying to influence design education and in how we deal with, how we think about design as a profession. We’ve got very complacent.

RB: Well it’s not very ideological anymore is it? It’s very commercially orientated.

MN: It’s driven by very specific criteria that are very limited and ultimately terribly disappointing and design isn’t only about that.

RB: I think that’s strange and it’s perhaps why we keep getting attached to art.

MN: Through their work artists are allowed to comment and critique and we’re not. We’re told you’re not really a designer unless you’re providing a ‘service’. I am providing a service it’s just not got a client in a traditional sense. The client is the educational system, it’s design thinking.

Reflections

It is difficult to put in place the critical rhetoric it takes to visualise a need for a revision of the status quo through design. Ball and Naylor aim to do this by reflexively turning design method on design itself. They present a tension of structure and ornament, and point to the contradictions of functionalist design traditions, satirically exaggerating the effects of instrumental approaches to design and superficial replication.

Ball and Naylor describe their approach as research. If critical design is framed as research it must conform to some measure of rigor and validity. In their work Ball and Naylor present a method of visual citation referencing designers and modernist design ideology in the objects they design. In their tactics they draw on literary composition; mechanisms of juxtaposition and satire to create contradiction and visual resonance. They establish an analogous language to that of the written word using object as prose in their concept of 'design poetics' through which they offer both critique and affirmation of design methods.

They aim to challenge design thinking by reassessing contemporary practice and how designers read objects. Their critique is established by grounding critical design in established traditions episteme and discourse consistently referencing design principles; this in turn incites reflection on tradition. They are loyal to a core set of industrial design skills, proportion, production, manufacture, quality and function. These are subverted reinforcing the need for an attention to these principles.

Ball and Naylor recognise their audience as a design audience. Through their 'open process' they enter into a dialogue with the audience. The work is disseminated in the gallery context and through publication. They engage with how the object is shown and read in the gallery context exploiting any association with Art.

Design commentary informed by art sometimes treats design's preoccupations as over-determined and misguided. Ball and Naylor negotiate this suggesting that it doesn't matter if the object is read as Art or Design. Associations with Art and gallery dissemination facilitate the concept behind the object and the commentary through it. Objects of critical design are however, always the result of a design process conceived and developed in the ethos of Product Design.

This identifies a challenge and opportunity to a mainstream design community and raises the question: How do we develop critical practice without relying on discourse in other disciplines –for example Art – and the critical analysis applied in these disciplines and develop a lens with which to view and further understand objects of critical design in our own disciplinary terms?

Author Biography

Matthew Malpass
A PhD Candidate at Nottingham Trent University. Through his PhD he is developing taxonomy of critical practice in Product Design. The aim is to promote a discussion about design as a discipline in transition and contribute to the disciplinary discourse on critical design practice.

Design Research : Towards a History

Victor Margolin, University of Illinois, Chicago

Abstract
Various starting points might be selected for the origin of design research but this paper will begin with the design methods movement in Great Britain. Two of the leading figures in the movement were Bruce Archer and John Chris Jones. The original conference on design methods was held in London in 1962 and Jones published the first edition of *Design Methods: Seeds of Human Futures* in 1970. Archer was involved with the establishment of the Industrial Design Research Unit at the RCA in the early 1960s and was also a founder of the Design Research Society in 1976. The DRS journal *Design Studies* was founded three years later. Design methods in the United States continued to develop through the Design methods Group at the University of California, Berkeley in the late 1960s. Horst Rittel was a central figure in this group. In 1968 Herbert Simon gave the Compton Lectures at the Massachussetts Institute of Technology. These were published shortly thereafter as *The Sciences of the Artificial*, which became a seminal book in the field of design research. Another group on design methods, which included Donald Schön, also developed at MIT. In the fall of 1982, the academic design journal *Design Issues: History, Theory, Criticism* was founded at the University of Illinois, Chicago and the first issue was published in 1984. Among its activities, the editors organized the first conference on doctoral education in design, which was held at Ohio State University in 1968. During the 1990s, the international network of societies and associations involved with design research expanded to include organizations in Europe, Latin America, and Asia. The Design Research Society organized a series of international research conference and an organization that includes a number of research societies in Asia and Europe was formed. While there is much activity today, there is still a problem in connecting the various discourse communities into a more coherent field of activity.

Keywords
design research, design studies, design history

Introduction
Design research is today an international enterprise. Various starting points might be selected to mark its origin but I will begin with the design methods movement in Great Britain, simply because one can identify a trajectory from there to where many researchers are today. However, the field of design research is much broader than most researchers recognize and it encompasses diverse actors, quite a few of whom have little or no knowledge of what others are doing. Actually, the field consists of multiple discourse communities or networks, each of which pursues its interests based on its own criteria for best practice and meaningful results. These communities have diverse aims and are of different types. For some, the research objective is to create new products. For others, it is to gain a deeper understanding of design as a cultural phenomenon. Thus, we need to recognize that the term *design research* has different meanings, depending on who is using it.

I don't want to give the impression, however, that discourse communities have little or no contact with each other. On the contrary, they frequently overlap and sometimes even merge. Researchers often belong to several communities and move back and forth between them. Journals, Internet sites, and conferences may originate within a particular community but often attract researchers from beyond the community's own ranks. In fact, it is through cross-pollination that a research field with multiple communities expands and produces results that transcend the more narrow interests of any given group.

Design methods in Britain

Two of the leading figures in the British design methods movement were Bruce Archer and John Chris Jones, both were engineers who became interested in design. They were among the organizers of the initial conference on design methods, which was held at the Imperial College in London in 1962. In 1970, Jones published the first edition of his seminal book *Design Methods: Seeds of Human Futures*, in which he introduced a number of methods that designers could use, mostly adapted from other fields. Two points about his choice of methods are salient. First, he wanted to enable designers to work at the higher levels of system and community design as well as at the level of products and components. And second, he intended to make the designer's methods transparent, changing the common belief that design arose from a black box of inspiration into an understanding that an articulated methodology could greatly assist the design process. Jones also plays a noteworthy role in the design methods movement for his rejection of it in 1977 when he declared that design methods had become too rigid (Bayazit, 2004). His defection was a major contributor to the demise of what Horst Rittel had earlier called "first generation design methods" (Bayazit, 2004, p. 21).

Bruce Archer was far more flexible than some of his colleagues in characterizing design as a practice that lay somewhere between science and art. In 1960 Tomás Maldonado invited him to join the faculty of the Hochschule für Gestaltung in Ulm, Germany, where he wanted Archer to mediate between several camps of faculty who had firmly set views about the nature of design. In 1962, Archer returned to England to head a research project at the Royal College of Art on the design of hospital equipment.

The establishment of the Industrial Design Research Unit at the RCA in the early 1960s with Archer as its head was a major step forward for design research. When the Design Research Unit became the Department of Design Research, it joined the school's other departments that trained graduate students. In a seminal article of 1981, published in the proceedings of the 1980 conference, *Design: Science: Method*, Archer provided an appendix with a long list of studies that had been carried out by students in the Department of Design Research (Archer, 1981). The range of studies was noteworthy for its emphasis on products for special users rather than on consumer goods as well as for the occasional attempts to deal with values, methodology and related issues. Most of the studies addressed the design of particular products – hospital equipment, products for physically disabled children, or police command and control consoles – but a few were more abstract such as the creation of mathematical modeling systems for use in design. A second appendix to Archer's article is also noteworthy because it lists the studies in related departments that focused on art and design history, design education, and graphic design (Archer, 1981). Though Archer did not go into detail about why he thought cultural studies were a valued component of design research, he nonetheless saw a relation between cultural research and design.

When the Design Research Society (DRS) was founded in 1976, with Archer as one of the original members, design methodology was a central concern as was the question of how to characterize design. Was it a science or something else that made use of scientific methods? What made design knowledge unique and different from other kinds of knowledge? Questions of what constituted design knowledge, how could design be characterized as a discipline, and what exactly were designerly ways of knowing persisted at DRS conferences and were continued in *Design Studies*, the DRS journal that was founded in 1979.

Design methods in the United States

Interest in design methods spread to the United States where a Design Methods Group was established at the University of California, Berkeley, in 1967. Shortly thereafter, the group began to publish the *DMG (Design Methods Group) Newsletter*, which provided news about research and new publications in planning, architecture, and industrial design (Bayazit, 2004). The leading figure in this group was Horst Rittel, a German, who had been at the Hochschule für Gestaltung, Ulm before he was recruited to teach in the College of Environmental Design at the University of California, Berkeley in 1963. Other active members of the Design Methods Group were two professors of architecture, Christopher Alexander and Henry Sanoff,
Alexander remained at Berkeley for the rest of his career but Sanoff had left Berkeley by 1968, the year he co-founded the Environmental Design Research Association, whose aim was to promote research on the relation of individuals to the environment.

Rittel rejected the early design methods as too rigid and simplistic. Instead, he argued that designers frequently dealt with “wicked problems” which he characterized as being “ill-formulated” and “ confusing” (Buchanan, 1992, p. 15). To replace the original methods, he proposed “second-generation design methods,” that would more effectively deal with complex situations (Bayazit, 2004). Alexander took a more extreme position. In 1971, he stated that rationality as the design methods theorists espoused it, “had become a toolkit of rigid methods that obliged designers and planners to act like machines...” (Mitchell, 1993, p. 51). Subsequently, he withdrew from the movement.

In 1968, Herbert Simon, who wrote his doctorate on organizational decision-making but later contributed to many fields including artificial intelligence, and computer-modeling, was invited to give the Karl Taylor Compton Lectures at the Massachusetts Institute of Technology (MIT). As his title, he chose *The Sciences of the Artificial* and the book that ensued, came to denote his broad interest in design and his belief, similar to that of early design methods theorists, that rational analysis was the best method for approaching design problems. Within today’s broad design research community, Simon is not well understood. He is mainly cited to justify the idea that design is not limited to a particular subject matter but can instead be broadly defined as a method of transforming existing situations into preferred ones (Simon, 1996). In fact, Simon, as a professor at Carnegie Mellon University, was involved in many areas of research that lie outside the boundaries of design as most researchers understand it.

In 1982, fourteen years after the Compton Lectures, a group of professors in the MIT School of Architecture and one from the School of Engineering founded the Design, Theory, and Methods Group. They included Louis Bucciarelli and Donald Schön, a philosopher who came to MIT in 1968 and became Ford Professor of Urban Studies and Education in 1972. The group also included Patrick Purcell, who had earlier collaborated with Bruce Archer at the RCA on a mathematical modeling system for design. Both Schön and Bucciarelli had an interest respectively in studying the working processes of architects (Schön) and engineers (Bucciarelli). In fact, Schön’s book *The Reflective Practitioner: How Professionals Think in Action*, published in 1983, became a foundational text for researchers who do phenomenological studies of how designers work.

Design Issues and the Ohio Conference

In the fall of 1982, the academic journal *Design Issues* was founded at the University of Illinois, Chicago and the first issue appeared in 1984. The five founders identified the themes of the journal as history, theory, and criticism, thus staking out a space in the field of design research that was not occupied by any other publication or discourse community at the time. The aim of the journal, as stated in the initial editorial was "to be provocative and raise controversial issues," rather than seek the foundations of a science or theory of design, The editors positioned *Design Issues* as "a journal of ideas that will embrace many forms from scholarship to polemics" (Margolin, 1984, p. 3). Their intent was to explore design as a broad part of culture rather than an enterprise with a particular theory or methodology. The journal's subject matter included both product design and graphic design and has continued to expand to cover new forms of practice such as interaction design and the design of aquariums and organizations. As the editorial policy evolved, the expression of pluralistic views became an explicit aim of *Design Issues*. The journal never sought to define itself as a scientific publication but rather its intent was to accommodate authors from numerous disciplines and practices.

Design education was always a welcome subject for *Design Issues* but the editors had never made a specific commitment to it as a special theme. In 1998, however, they organized a conference on doctoral education in design at Ohio State University. Participants came from almost twenty countries in North America, Europe, Latin America, the Middle East, and Asia. As Dennis Doordan noted in his introduction to the conference proceedings, "The Ohio Conference marked the end of an era of isolated efforts to provide doctoral level design education and the emergence of a vigorous international community of design educators" (Doordan, 1999, n.p.) Similar to the pluralistic editorial strategy of *Design Issues*, the combined papers did not represent a particular objective or point of view. Some reported on doctoral education in specific places; some discussed individual models or curricular content, and others tackled the difficult question of what constituted design knowledge. In his keynote address, Richard Buchanan, one of the *Design Issues* editors, noted that many design researchers were already pursuing multiple lines of investigation. "What is our task," he said, "is to understand the implications of such research, in its breadth, depth, and diversity, for shaping design as a legitimate field of inquiry" (Buchanan, 1999, p. 15). The implication of Buchanan's call was that no single definitional or methodological truth need be sought in design research but rather that useful knowledge would arise from an exposure to competing forms of inquiry and a consideration of their value for understanding and practicing design. Three subsequent conferences on doctoral education were held following the meeting in Ohio but after that discussions on the subject were absorbed into other events. One significant outcome of the conference was that two of the participants, David Durling and Keith Russell, founded the PhD-Design listserv, which has continued to function as a forum for discussion and debate on numerous topics.

Expanding the international network

Despite the burgeoning during the 1990s of societies and associations that addressed specific design activities such as interaction design, or software design, the Design Research Society maintained its identity as an organization whose membership embraced a broad range of interests. In 2002, the society organized *Common Ground*, a conference held near London that sought to involve researchers from some of the discourse communities that previously had little contact with each other. While it did not attract many representatives from the technically oriented design networks nor did many design historians participate, the conference nevertheless created a forum for a diverse group of researchers. The thematic inclusiveness of *Common Ground* became a new conference format for the Design Research Society, which followed it with three subsequent biennial conferences: *Future Ground* in Brisbane (2004), *Wonder Ground* in Lisbon (2006), and *Undisciplined!* in Sheffield (2008) and the format continues with the current conference.

Another group that began to organize research conferences with broad themes was the European Academy of Design, which was founded in 1994. Its stated aim was to promote research collaboration within Europe and to foster the publication and dissemination of design research. Since it's founding the Academy has hosted biennial conferences in different European locations and in 1997 it initiated its own publication, *The Design Journal*. More recent groups of European design researchers are Die Deutsche Gesellschaft für Designtheorie und -forschung (DGTF) (German Society for Design Theory and Research), which has organized five annual conferences since its founding in 2003, the Swiss Design Network, which held its first conference in 2004, and the Nordic Design Research Network, which mounted its own initial conference the following year.

In Brazil, researchers have organized eight biennial international conferences on design research and development in design. Brazilian researchers have been active for many years with special emphases on semiotics, ergonomics, eco-design, and design history. Several research journals are also published in Brazil: *Arcos*, initiated at the Escola Superior de Desenho Industrial (ESDI) as a printed journal but edited now in digital form, *Revista Estudos em Design,* published in Rio de Janeiro by the Associação de Ensino de Design do Brazil (Brazilian Design Education Association), and *Revista Design em Foco*, edited at the Universidade do Estado da Bahia.

In Asia, the first design research organization was the Japanese Society for the Science of Design, which was founded in 1954, followed in 1978 by the Korean Society of Design Science and some years after that by the Chinese Institute of Design. In 2005, these three societies, joined by the Design Research Society and The Design Society, an international group that originated in the Federal Republic of Germany, formed the International Association of Societies of Design Research, which thus far has held two conferences, the first at the National Yunlin University in Taiwan, the year the association was founded, and the second two years later at the Hong Kong Politechnic University. A third was held in October 2009 in Seoul, Korea.

This proliferation of design societies and conferences is markedly different from the aims that motivated the first design methods researchers. Design research, particularly as it is now ensconced within universities, has become an activity that is independent of any preordained purpose. This is valuable in the sense that the potential for a vibrant field exists but the danger lies in the possible absence of a clear sense of what such research is intended to accomplish. While there is no single goal for design researchers nor should there be, the aims of design research in the basic sense are to improve the quality of products and to reflect on the transformation of design practice while at the same time contributing to a greater understanding of design as a social phenomenon.

Conclusion

There is much that I have left out in this paper but to document the history of design research in a more complete way would require a book at least. Discourse communities related to artificial intelligence, design cognition, human/computer interaction, sustainable design, design for development and science, technology & society studies are active and regularly convene conferences and produce volumes of proceedings while research organizations such as Bell Labs, Xerox PARC, Microsoft, Google, and the AgeLab and Media Lab at MIT continue to transform technology into new products.

These new developments are evidence of how much design, design education, and design research have changed since the founding of the Japanese Society for the Science of Design in 1954 and the beginning of the design methods movement at the start of the 1960s. The rapid expansion of doctoral programs in design has created the need for a discourse community or communities that can publish and disseminate a growing volume of research. Thus far, some of this research has contributed to the development of new design practices such as interaction design, sustainable design, medical design, service design, organization design, universal design, and design for development. That is its positive side. It is also true that design research is not always directed towards shared questions or problems and consequently it attracts moderate interest and makes little or no impact on the field..

The problem with the disconnect between discourse communities is that much design that occurs today is highly technical and as it is configured into large systems it has a significant impact on our lives. We need more research to help us understand these systems. New connections need to be made between researchers who study design's meaning in the past, present, and potentially in the future and those who are doing the research that is generating new and unprecedented products.

Bruce Archer was prescient in recognizing the relation between two kinds of research, one directly related to making things and the other concerned with understanding not only things themselves but the milieu in which they are conceived, made, and used. The comprehensive taxonomy of design research that he outlined in his article "A View of the Nature of Design Research," in 1981 may not be the one we would adopt today but the sense of wholeness that it represented is something that we need to recapture. Archer was concerned with the practice (praxiology, modeling, technology, and metrics), understanding (history, taxonomy, axiology, philosophy, and epistemology), and teaching. We would do well to reclaim Archer's broad vision of design research and move it forward with contemporary methods, themes, and purposes.

Representation-phobia and the complexity of embodied interaction

Thomas Markussen, Assistant Professor, PhD, MA
Institute for Design, Aarhus School of Architecture, Denmark

Abstract

In current interaction design research there is a widespread belief that situated action and embodied interaction should replace mental representations in the theoretical account of human cognition. This exclusion of representation is however diagnosed as a sign of representation-phobia by Anderson (2003) who claims that it is misguided. This paper aims to show why and how it can be overcome. Initially, a literature review will show how representation-phobia manifests itself through two different versions in HCI research. On the basis of this I argue that representation-phobia leads to a theoretical dead end. Then, by drawing on semiotics and recent findings from cognitive research, I argue that we cannot understand the rich complexity of embodied interaction unless we furnish our thinking with a dynamic notion of representation.

Keywords: cognition, embodied interaction, representation, experiential knowledge, semiotics

In interaction design research, the two notions of “embodied interaction” and “situated action” are thought to be useful for understanding how to design interactive artifacts or environments that resonate with the rich complexity of our bodily and everyday interaction with the material world (Dourish, 2004; see e.g. Hornecker, 2005; Klemmer, Hartmann, & Takayama, 2006).

Despite their divergent foci of interests, proponents of embodied interaction and situated action generally share the view that cognition is not an internal affair in the head of the user, but something that is shaped and evolves through our actions as we react to real-time requirements from mundane settings. Further, in much recent work, the increased focus on action and bodily experience is coupled with skepticism towards the role of mental representations (Rowlands, 2009, p. 127). In fact, the adjectives “embodied” and “situated” are sometimes used as synonyms for the idea that cognition unfolds in a direct manner without the intervention of mental representations and that HCI would therefore be better off if is simply deleted the concept of representation from its terminological vocabulary. For this reason, embodied interaction and activity theorists often see their frameworks as being diametrically opposed to traditional HCI and classical cognitivism.

However, as Anderson has warned us, the just critique of traditional HCI’s notion of representation should not lead to a “representation-phobia” in interaction design research. Thus, according to Anderson, it is a mistake to exclude representations from frameworks of embodied interaction. What embodied interaction is essentially about is a re-thinking, rather than a rejection of representations (Hutchins, 2005; Rowlands, 2006, 2009; Sinha, 2005; Zlatev, 2005)

Interestingly, a similar warning is echoed in Suchman (2007) who is careful to underline, in the recently republished edition of *Plans and situated action*, that the supplanting of mental representations with action is a theoretical dead end. True, the nature and foundation of mental representations must be re-conceptualized, but embodied and situated cognition relies essentially on a subtle interweaving between action and mental representation.

The aim of this paper is above all to cure interaction design theory of its representation-phobia by showing that, contrary to what is being claimed, mental representations do in fact play a foundational role in user experience – even at the most basic levels of tangible and physical interaction. To set the scene, I begin with a literature review focusing on two different forms of representation-phobia and the common cause of their outbreak. First there is representation-phobia as it comes to the fore in ideas of embodied interaction claiming that our abstract reasoning and making sense of the world is primarily made up from meaning structures the nature of which is physical and spatial, not symbolic and representational. Second, there is representation-phobia as found in activity theory where it is reflected in the belief that mental representations are too static and inflexible for coping with the ever changing and ill-structured nature of everyday situations (for exceptions see Bærentsen & Trettvik, 2002).

Having identified the key characteristics of representation-phobia, I will draw on semiotics and findings from recent cognitive research in order to show why it must be abandoned. More specifically, I will argue that the discovery of canonical neurons show that representations are present at the most basic level of embodied interaction. This presupposes of course a well-defined notion of what a representation is. Therefore, I will provide such a notion together with a stratified model showing how low-level representations grow into more sophisticated symbolic forms. To improve the understandability of my argument, I will provide as many examples as possible throughout the paper.

1. Literature review: Representation-phobia in theories of embodied interaction and situated action

Since its early conception in the 1950s, research into the design of Human-Computer Interaction (HCI) has been a cross-disciplinary scientific enterprise encompassing computer science, cognitive psychology and Artificial Intelligence (AI). Out of this original core of HCI-disciplines various theories of the human mind and cognition have been developed over the years in order to understand how to design human-computer interaction in harmony with principles of human thinking and experience (see e.g. Carroll, 1987, 1991).

As is well known, theories of situated cognition and embodied interaction have been developed because of an increasing dissatisfaction with the once so dominant symbol system approach to cognition. According to this approach, which was originally founded by Newell and Simon (Newell, 1980; Newell & Simon, 1972) cognition basically consists in the algorithmic manipulation of symbol structures. Through the work of Newell and Simon's successors these symbol structures have become known in HCI literature as goal-oriented plans, scripts (1977) frames (1975) and mental models (Norman, 1988; Payne, 2003). Generally speaking, these concepts refer to the idea that we use stereotypical background knowledge as structures for comprehending events and objects reoccurring in everyday life. The basic assumption is that these knowledge representations are built in as part of a prior knowledge base in long-term memory, which we can recruit from for the purpose of planning and executing action relevant in a given situation. For instance, according to Schank & Abelson (1977) we presumably possess a RESTAURANT script representing background knowledge for a sequence of actions relevant to perform when visiting a such a place, namely entering >> get seated >> ordering >> eating >> paying >> exiting.

There are two main objections that have been raised against the notion of such inner symbols. First, it is claimed that symbolic knowledge representations are unable to account for how we handle problems and execute actions in everyday settings. Because representations, under the symbolic view, are algorithmic and presuppose pre-existing and static knowledge structures, while everyday situations, so the argument goes, are unbound and ill structured and therefore not compatible with this format (Winograd & Flores, 1986). Central for the consolidation of this objection was the work of Suchman (1987) who convincingly argued for the role played by the resources of the immediate situation in shaping human action. People are improvisatory and employ ad hoc rules for reasoning instead of abstract algorithmic rules for decision-making and inferences (Kaptelinin & Nardi, 2006, p. 16).

The second objection is that the symbol system approach completely ignores the role of the body for our understanding and making sense of the world. According to Newell and Simon inner symbols are “substrate neutral” in the sense that the nature of our bodies and perceptual apparatus is regarded as irrelevant for the constitution and structuring of their content. This is evidenced by a passage in *Human Problem Solving*, where Newell and Simon overly admit that they have omitted both low-level “sensory and motor skills, and many aspects of perception” from their study of symbols, because they do not consider these factors central for the constitution of symbolic activity (Newell & Simon, 1972, p. 8). However, as the proponents of the embodied mind paradigm have convincingly argued, we cannot understand human thinking and reasoning unless we take structures derived from our perceptual and bodily interaction with the physical world into account (Johnson, 1987; Lakoff, 1987; Lakoff & Johnson, 1999; Varela, Thompson, & Rosch, 1991).

Situated Action and Embodied Interaction are two conceptual frameworks that were introduced in HCI during the late 1980s and 1990s in order to compensate for the theoretical shortcomings of traditional HCI. While situated action is essentially about trying to understand how to design technological systems based on the principles of our online cognitive activity in the world (see e.g. Kaptelinin & Nardi, 2006; Nardi, 1996; Suchman, 1987; Wilson & Clark, 2005; Winograd & Flores, 1986), embodied interaction is a design theory focusing on how to design intuitive, tangible, graspable and direct physical interaction with technology (Dourish, 2004; Ehn & Linde, 2004; Hornecker, 2005; Hurtienne & Israel, 2007; Lund, 2003; Lund & Waterworth, 1998).

What these two approaches have in common, despite their many profound differences and divergent foci of interests, is a widespread distrust of the concept of internal symbols or any sign of mental knowledge representations. In fact, the adjectives of “situated” and “embodied” are often meant to put emphasis on the assumption that cognition unfolds in a *direct and distributed* manner and that human-computer interaction should therefore be conceived of as being non-symbolical.

For instance, AI-researcher and roboticist Rodney Brooks goes as far as to deny internal symbols any existence in his account of embodied cognition, and he claims that this insight is a prerequisite for building human-like intelligence successfully into robotic devices (Brooks, 1999).

In a similar vein, Tangible and Embodied Interaction is promoted as a subfield of interaction design that sees non-symbolic spatial and physical structures derived from sensori-motor experience as predetermining how people understand and make sense of the material world (Hurtienne & Israel, 2007). Under this view, Lund and Waterworth (1998), for instance, define embodied interaction as aiming towards building spatial structures into interfaces rather than seeking to communicate mental models (as suggested by Norman, 1988).

However, some proponents of embodied interaction are not convinced that ascribing primacy to spatial structures over symbolic representations is a tenable strategy. Dourish defines embodied interaction as a design research program that deals with the *relationship* between bodily and physical interaction on the one hand, and a symbolic realm on the other hand. Further, in his insightful field guide to Embodied Cognition (EC), Anderson (2003, p. 100) posits that:

> it is a vice too often indulged by scientists working in EC to make the absence of representations a touchstone of virtue in design, and to therefore suppose, just as do the creatures they devise in the lab, so too must humans display an intelligence without representation. Representation-phobia is a distracting and ultimately inessential rhetorical flourish plastered over a deep and powerful argument. For rather than targeting representation *per se*, the central argument of EC instead strikes at their nature and foundation.

Anderson argues convincingly that the conclusion to be arrived at is not that the symbolic representations of traditional HCI ought to be given up altogether, but rather that we must find ways to systematically relate the symbols and rules of abstract reasoning to the more evolutionary primitive mechanisms which control perception and action. If it can be shown that symbolic representations are at play in the cognitive processing involved in bodily and perceptual experience, then the representation-phobia of embodied interaction must be abandoned.

To expel representation-phobia from situated cognition requires a slightly different therapy. More specifically, it must be shown that representations play a genuine role in online cognitive activity and for the realization of actions. Interestingly, it is worth noticing that in the recently republished edition of *Plans and Situated Actions*, Suchman (2007) actually asserts that viewing her situated cognition framework as non-representational would be a gross misinterpretation of her original argument. In her book, she did not wish to deny the existence of plans conceived of as mentally projected representations of courses of future action. Rather, in 1987, when the book was originally published, Suchman wanted to point towards the critical and, at that time, largely overlooked role played by the immediate context as actions are realized, that is, how real-time requirements and unexpected changes in the context usually call for a continuous revision and modification of the mentally projected plans. Thus, Suchman sums up that her emphasize “is *both* on the utility of projecting future actions *and* the reliance of those projections on a further horizon of activity that they do not exhaustively specify” (Suchman, 2007, p. 19). And further on:

> My position then and now has been that plans are conceptual and rhetorical devices […] that are deeply consequential for the lived activities of those of us who organize our actions in their terms. Just how plans are consequential for the actions they project defined, at least potentially, a territory of mutual interest for the social and cognitive sciences. (Suchman, 2007, p. 20)

Try to compare Suchman’s theoretical afterthoughts with the following description taken from a special issue of the journal *Cognitive Science*, where Vera and Simon (1993, p. 10) defend the symbol system approach against the claim that it is incapable of relating inner symbols to actions in everyday settings:

> Symbol systems can be (and sometimes are) used to store in memory representations of external stimuli. They can manipulate these representations as one way of planning actions, and can then execute these actions to change the external situation. Of course, the internal representation of a real scene will be highly incomplete and may be inaccurate, with the result that the actions may or may not have their desired consequences.

Ignoring the fact that the term “system” would undoubtedly be foreign to Suchman’s vocabulary, we might say that for Suchman as well as for Vera and Simon, the projection of plans and the execution of actions constitute an open-ended feedback loop between a context, a conceptual system and a sensori-motor system. Hence, the situated action approach should not, as Suchman is careful to underline, be seen as antithetical to the symbolic approach. On the contrary, the two approaches would ideally be able to complement each other in productive ways.

Admittedly, as almost everybody else, Suchman has reservations concerning the narrow algorithmic definition of plans defended by Simon (Newell & Simon, 1972; Simon, 1969). But if the notions of plans and mental representation, as found in the symbolic approach, are broadened so as to include a more dynamic, flexible and situated understanding of the interplay between mental representations and real-time interaction, then a representational view of online cognition might even enrich the SA account of this interplay. This however would require a re-conceptualization of fundamental ideas and concepts belonging to the symbolic approach. The question is of course whether such a re-conceptualization exists? If it can be shown that it does, then the representation-phobia haunting much current work in situated action would seem unjustified.

2. Levels of mental representation

In this section I aim to show that mental representations permeate our perceptual and bodily interaction with physical objects. This presupposes of course that one has a more elaborate notion of what a representation is.

Taken in its most basic sense, a representation involves a sign that stands for something else in a real or imaginary world to the individual. Note that a representation thus consists of a relationship between three elements: world, sign and an agent. Smoke rising in the air stands for fire, but not in itself. It relies on the interpretive work of the perceiver. Just as traces in the forest standing for the feet of an animal or lines and figures on a picture plane standing for the naked body of the model.

Theories of representation in design research have often been criticized for naively believing that representations acquire their meaning from the things or events in reality that they refer to (cf. Krippendorff, 1992). But this criticism seems to have confused “reference” with “representation”. In semiotics, the term ‘reference’ is generally used to designate the relationship between a sign and its referent, while representation is seen as the activity of knowledge-making which the use of signs allows humans to carry out (Nöth, 2000, pp. 148-9). Representations are not mere copies or faded reflections of reality; they involve an active and deliberate use of signs motivated by the individual’s egocentric purposes and cognitive abilities. This is a key insight in the semiotics of Charles S. Peirce (Peirce, 1932). What makes Peirce’s semiotic project seem highly relevant even today is that he anticipates the idea in cognitive science that representation is the most central explanatory device for human cognition (Apel, 1981; Innis, 1994).

When applying the notion of representation to human cognition, we are postulating that mental states somehow act as representations. In cognitive science, it is common, as Cummins (1989) has shown, to distinguish between four different forms of mental representation. Mental representation may thus refer to (1) neuro-physiological states, (2) perceptual content, (3) mental concepts; and (4) more complex symbolic structures, which can take the form of mental models, frames or scripts.

The revolt against representations in embodied interaction hinges upon the idea that human thinking emerges primarily from sensori-motor interaction between an organism and its environment and that representation play no role at all at this level (Johnson & Lakoff, 2002, pp. 249-50). But what if neuro-physiological states in the sensori-motor brain actually show signs of representation themselves? Indeed, the recent discovery of canonical neurons asks us to consider this possibility.

2.1 Sensori-Motor Representations

Canonical neurons are neurons in the pre-motor area of the monkey brain (F5) that are activated when monkeys engage in action execution. In an experiment conducted by Murata et al. (1997), it was shown that canonical neurons that become activated when monkeys physically grasp an object also become active upon the mere observation of the object. Later studies have indicated that similar mechanisms exist in the human brain. This has been taken as evidence for the idea that canonical neurons are crucial for our ability to recognize object affordances: “when a three-dimensional object is seen, the F5 motor neurons for the actions it affords are activated“ (Sahin & Erdogan, 2009).

What is interesting about this study is that it points toward the centrality of representations in the sensori-motor system. If canonical neurons fire upon the mere sight of an object, then it means that, on a neuro-physiological level, they inform the organism about a possible future action that can be performed with this object. They do not refer to the object as such, but help to select one functional value of the object that might be relevant for the organism-environment interaction. In this sense, canonical neurons seem to be a good candidate for a neuro-physiological state that acts as a representation as shown in Fig. 1:

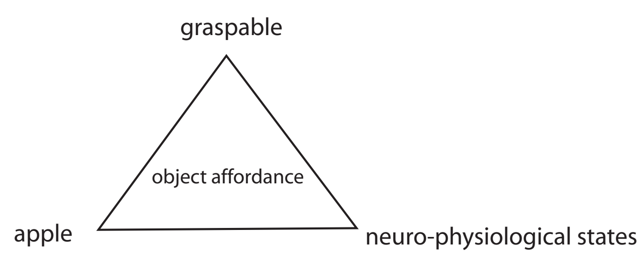

Fig. 1 The representational structure of object affordances

This is in line with Jeannerod (1994) who argues that these neurons are rough motor representations encoded into our semantic knowledge about the object. These motor representations contain initial plans for generating low-level kinesthetic operations presupposed by the execution of an action, for instance grasping, holding, throwing, and so forth. It is important to note that the motor neurons represent a *type* of action and not the bodily operations themselves. This means that if we see a red apple, we may recognize immediately – thanks to the neurons – that it is graspable. But these motor representations evoked from this perception say nothing about whether we should use our left or right hand for carrying out this action.

2.2. Affordances as representation

The discovery of canonical neurons seems to run counter against the concept of affordance, as it was originally introduced in Gibson’s ecological theory of perception

(Gibson, 1977). According to Gibson, affordances are possibilities for action that we simply pick up at a pre-reflective level of awareness. As such affordances are thought to be perceived directly without the interference of mental representations or higher-order cognitive operations of any kind. However, Rowlands (2006) has argued that we need to take a refreshing new look at this assumption, because it rests upon a too narrow view of the forms representations may take.

According to Rowlands, there are three kinds of actions that we need to be able to distinguish from each other: *actions, deeds and doings*. An action is inextricably bound up with our intentions such as our volitions, motives or belief-desire couplings. Deeds are defined as pre-intentional acts that depend on the online, feedback-modulated adjustments we perform during the course of interacting with the environment; and doings are sub-intentional acts that are not performed for any reason. Let me try to explain this in more detail.

Actions are performed for some reason in order to accomplish a goal or realize a state of affair that will satisfy our intentions. In philosophy, there is a strict concept of action that holds that the status and identity of an action can only be defined in terms of an antecedent intention (Rowlands, 2006, pp. 96-7). For instance, I may whistle a melody while, at the same time, tap my foot on the floor. Are there one or two actions involved here? According to the strict concept of action this can be determined by asking what intentional states I am the subject of. If I am the subject of a single intentional state then there is only one action. Thus, if my intention is to tap my foot while whistling (for instance as a way to keep the beat), then the corresponding action is one rather than two. If, on the other hand, I am trying to tap my foot and trying to whistle, which just happens to be synchronous, then according to this view I would be performing two actions instead of one (cf. Rowlands, 2006, p. 96).

By reaching out for a goal or state of affair in the near future an intention clearly bears the mark of a representation as it has traditionally been defined. More specifically, an intention can be seen as a plan that is projected imaginatively (however short-lived) and that contains motor representations for how this plan could be fulfilled .

It is important not to confuse these motor representations with the motor representations that have been discovered to be at work at the level of canonical neurons. Compared to intentional states, canonical neurons are intimately bound up with their connection to the physical environment and the perceptual acts we perform in order to cope with our surroundings. Their firing depends utterly on the directness and presence of objects and information available from the environment. Suppose my sister gets angry with me and wants to throw an object at me. She may quickly scan the room visually for objects with the functional value of being *throwable*. In this scanning process canonical neurons may fire upon the sight of an apple, a tennis ball, or a pencil, but not on her viewing the teak dining table in the corner or the car parked outside the window. This means that the canonical neurons are activated because of an action potential evoked from my sisters perceiving of the first three items. Since throwable is indicated from her perception of very different phenomena, it cannot be reduced to some physical properties. Rather it is dependent on the relationship between the surface of the object and the visuo-motor operations of the perceiver. In this sense throwable counts as an affordance. However, since throwable can also be applied to various different phenomena, it must have a certain type-like quality about it. Hence, it also qualifies as a representation.

According to Rowlands many of the acts we perform in order to exploit and manipulate object affordances are not anticipated by any intentional states in the strict sense. Suppose I have noticed the intention of my sister and I therefore start running to escape her attack. In a second or so, she must pick up a throwable object, before I run out of the door. She immediately grasps the pencil and throws it at me. Less than a second is not sufficient to form the intention of whether she should pick up the pencil by grapping it with her whole hand or if grasping it between her thumb and index finger gives a better hold. “In such situations we simply find ourselves acting” (Rowlands, 2006, p. 104). Since these acts cannot be determined with reference to an antecedent intentional state, they are not actions taken in the strict sense. Rather they are what Rowlands calls “deeds”. Deeds are pre-intentional, meaning that even though they are performed in order to fulfill a goal, they cannot be accounted for in terms of intentions. However, they are not reducible either to mere bodily movements, since we do perform them for a reason.

This is what distinguishes deeds from doings. Doings are sub-intentional acts we perform without any reason. If you start attending to your bodily limbs and organs you’ll notice that almost every part of you are in motion: your tongue, toes, eyes, and so forth. We simply cannot help performing these micro-sensational acts or doings to use the term suggested by Rowlands.

By using Rowlands’ three categories, it has been possible to differentiate between representations at the level of actions and representations at the level of deeds, that is the online feedback-modulated adjustments we perform in order to handle everyday situations. These representations are to a very large extent detected by canonical neurons in the flow of our interaction with the physical environment. However, while canonical neurons may inform us about the type-like actions potentials of visible objects – for instance that an apple is graspable – another question that seems relevant to ask is whether we also know from the canonical neurons that the apple is tasty and juicy inside? (cf. Eco, 2000) This seems highly unlikely. The background knowledge we use for inferring such gustative qualities from the apple depends rather on knowledge acquired through our previous experiences of objects of the same kind. If you have never eaten an apple before, you wouldn’t now what to expect. This implies that we draw on prototypical conceptual representations of objects stored in our memory in order to project plans for more complex embodied interactions with the objects at hand. These representations are involved in the forming of intentional states and in the next sections I will briefly account for these representations in terms of concepts, perceptual judgments and mental frames.

2.3 Mental Concepts

It is generally assumed in cognitive science that we use mental constructs of the kind that is usually referred to as ‘mental concepts’. Thus we have concepts for almost everything in this world: apples, stones, the sun, God, shopping malls, and so on. When we encounter things and events, we not only use mental concepts for determining the nature of objects. We also employ them for making what is known as *perceptual judgments and for performing more abstract forms of reasoning*. According to Eco (2000, p. 63) a perceptual judgment is a hypothetical inference based on object affordances and other perceptual inputs that we set up in working memory for purposes of local understanding. Some examples of perceptual judgments would be: “This X is an apple” or “Apples are juicy inside”. Or “This X in front of me is a stone”, “It is struck by sun light”, and “it is hot” . We may even construct more complex propositional representations out of these perceptual judgments, for instance, if we manage to reach the conclusion that “The sun heats the stone”. In this instance we subsume a particular relationship between two entities in the world under the general law of C*ause-Effect*.

Interestingly, Johnson (1987, pp. 37-40) has argued that such logical inference patterns like Cause-Effect, the Law of the Excluded Middle and the Law of

Transitivity, which we normally see as part of abstract symbolic reasoning, have their intuitive basis in our daily experiences with physical objects and orientation in space. The idea then is that symbolic reasoning is constrained and, to some extent, made up from structures derived from sensori-motor interaction between the organism and its environment (this idea is accurately captured in the so-called Spatialization of Form Hypothesis, see Lakoff 1987, p. 283). While Johnson who is an esteemed philosopher argues convincingly for this idea, the truth of his claims has in fact not only been anticipated, but also demonstrated by the experimental phenomenologist Albert Michotte. Through a series of empirical experiments Michotte found that our immediate sensory experience consists not only of objects or entities, but also their causal relations (see e.g. Michotte, 1963). For example, in one of his studies Michotte proved that the duration of contacts between two colliding objects is crucial for how we understand their causal relation. This study is nicely summarized by Heft (2003, p. 167):

> If an object "makes contact" with another, and then ceases moving just as the second object begins to move along the same prior trajectory, observers report that the first object "launched" the second. However, when the first object even after contact continues to move along the trajectory with the now-moving second object, observers report a pushing or a chasing ("entraining") rather than a launching effect.

Michotte's study shows that spatio-temporal relations among objects that we experience might lead to our perception of different types of causal effects. A result like this challenges the influencing assumption that was introduced by Hume, namely that entities in sensory experience are disjoint and that the order and lawfulness, they appear to have, are the result of reflective operations on the part of the subject that subsume sensory tokens under *a priori* logical principles of the intellect (an idea that reached its culmination in Kant's *Critique of Pure Reason*). What Michotte's experiments reveal is that some causal effects are not the result of reflective intellectual judgments, but of pre-reflective perceptual judgments.

However, in order to provide an adequate account of human cognition, we need to move beyond the level of perceptual judgment toward inferences and mental representations of an increasing complexity. There is clearly a difference between perceiving one ball as having a launching effect on a second ball and the causal relations that may be involved, for instance, in the planning of a trip to Montreal. Eco (2000) has suggested that we conceived of inferences as semiotic processes that work their way up from the level of sensory experience to higher-order mental representations as a kind of scaffolding process. Like a cognitive spiral where low-level meaning structures develop into ever more complex mental representations. For instance, according to this model object affordances are integrated as part of the perceptual image of 3-dimensional objects; this perceptual content can then integrated as part of perceptual judgments or be subsumed under mental concepts, when, for instance, we identify this X as a species belonging to this category. Further, mental concepts can be integrated as part of more advanced symbolic forms such as mental models, frames and scripts. If we take an apple as our example this scaffolding process can be diagramed as in Fig. 2:

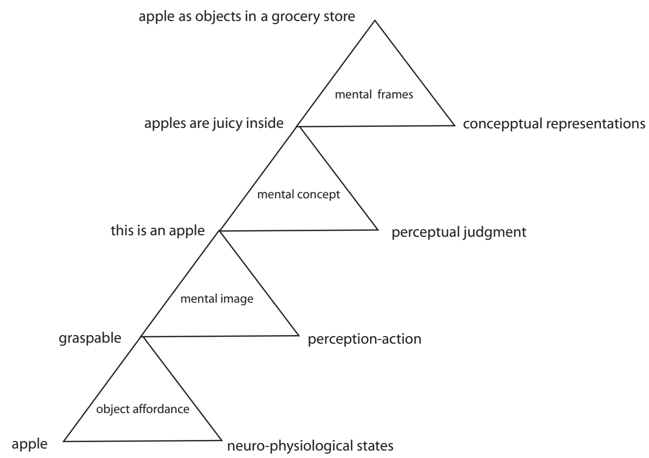

Fig. 2 Diagram of how higher-order cognition relates to the mechanism controlling perception and action.

The interconnected triangular structure of Fig. 2 illustrates how representations from low-level cognition grow into more complex knowledge representations. The next two sections will explain the nature of these representations.

2.4 Mental Frames

Apart from perceptual judgments, mental concepts are also important for building up even more complex networks of conceptual representations. Among such networks we find mental frames. Basically, a frame is conceived as referring to an organized system of concepts representing stereotypical background knowledge that people unconsciously draw upon when using language and thinking and acting in the world (Kövecses, 2006, p. 69). Consider Fillmore's (1982) so-called BUY frame (see Fig. 3). The idea is that we would not be able to understand the meaning of the verb "buy", unless we automatically activate a mental frame that allows us to make default assumptions about the situation that the verb can be used to describe. For example, "buy" presuppose a *buyer* owing an amount of *money*, a *seller* that offers some *goods* that the buyer wants to have, and so forth (cf. Ungerer & Schmid, 2006). Since the frame thus represents intentional roles they are important for forming goal-oriented plans.

Fig. 3 Fillmore's Buy Frame (adapted from Fillmore, 1977)

In Artificial Intelligence Minsky (1975) found the notion of frame valuable for explaining people's default knowledge about objects or events involved in routine tasks and reoccurring situations in work places. In cognitive psychology and cognitive linguistics it has also been shown that we use frames in our perception, planning and memory for events (Coulson, 2001; see also Barsalou, 1992). In so doing, we become able to create expectations and make predictions about the consequences of actions in a given context.

For example, I may have some friends coming over for dinner. To surprise them I want to make a juicy apple pie. But I realize that I don't have any apples at home, so I go to the grocery store to get some. To fulfil this intention I must draw upon a rich array of conceptual representations and knowledge structures. For instance, I need to be able to distinguish certain sort of apples from others, so that I'll get the right ones for my pie. At the point where I have to pay for the apples, it might be assumed that I draw unconsciously on a BUY frame in order act appropriately in this economic transaction. Obviously, the structure and content of such a frame will be sensitive to people's socio-cultural learning and background. For instance, in the Southern parts of Europe it is custom to bargain over the prize, while in the Scandinavian countries it is not. Hence, the precise nature of the BUY frame must be assumed to vary slightly from one cultural context to another.

However, while this is relatively uncontroversial, one of the main critiques of the notion of frames is that it is unable to account for how people manage to cope with changes in practices, unforeseen occurrences or novel situations that violate their expectations. Being products of long-term memory, frames offer pre-existing and default mental templates for thinking, not dynamic and flexible models adjustable to the immediate context as actions are realized. This is one of the central objections made by proponents of situated action and distributed cognition.

To many situated activity theorists, our everyday life seems most of all to resemble river rafting. In river rafting it is impossible for the canoeist to act according to abstract mental plans, because the violent stream, turbulence and protrusions, force him constantly to improvise and act according to *ad hoc* rules in order to control and keep the canoe in balance.

Everyday situations have their own turbulences and protrusions. Ethnographic field studies of people's shopping behaviour have been taken as evidence for this. When people are going to put the items they have bought into a shopping bag, there are typically a whole series of factors that might distract them from the purpose of their actions. Items come down the line in the shopping mall in a random order, so it is a challenge to us to decide what items should go in the bottom and which ones at the top. Then, while we are in the midst of packing our bag, our mobile phone may start ringing, or the cashier may interrupt the course of actions telling us that we haven't given him the exact amount of money. In such instances, it is unlikely that we rely on an abstract representation or algorithm in the head telling us what to do. Or put more accurately: perhaps there is such an algorithm but it is of no use, since unforeseen occurrences and events constantly force us to deviate from such idealized mental models. To explain how we nevertheless succeed most often in getting home without finding splashed eggs in our shopping bag, it has been suggested that we use the items themselves as external vehicles for informing us about weight and size and whether they should be placed in the bottom and at the top. By externalizing cognitive resources into the environment we are able to adjust to real-time requirements (see e.g. Hutchins, 1995; Kirsh, 1995).

However, even though I agree that such situations undoubted question the universal validity of abstract mental representations such as frames, they should not be taken as a model for all forms of cognition (Rowlands 2006). Just as well-structured intentional acts such as following a recipe or going to the grocery store should not be taken as a model either. Moreover, even stressful situations do not prove that the role traditionally assigned to representations can be completely taken over by actions without representations. Spontaneous acts and improvisation that we may perform during our shopping do not unfold beyond the representational. If so, they would be reducible to mere doings, bodily movements that are performed without any reason.

This is clearly not the case. We perform those acts spontaneously in order to accomplish goals or satisfy our will. Hence, they are deeds that – as we have seen – rely to a large extent on representations, however not of the kind that intentions are made up from. Deeds stand halfway between doings and actions. They involve our real-time coping with representations at the level of canonical neurons and direct perception.

3. Conclusion

To sum up, in this paper I have argued that representations permeate our entire existence from its most basic manifestation at a neuro-physiological level to conceptual representations in people's memory motivated by social-cultural learning and practices. We must of course recognize that representations come in various forms defined by increasing complexity (cf. Fig. 2).

If this idea is taken seriously, then we must reject the idea that the absence of representation should be made a touchstone of virtue in design. Many representation-phobic researchers either from the design or HCI community seem to believe that embodied interaction is a design strategy for working primarily with physical structures at the sensori-motor level. However, from a representational point of view, physical structures can only be properly understood if they are seen as one element in a triadic relationship between object, sign, and organism.

Taking my point of departure from Anderson (2003) and Suchman (2007) I initially claimed that the central argument of embodied cognition and situated action consists in a re-conceptualization rather than a rejection of representation. More specifically, this re-conceptualization relies on one being able systematically to relate the symbols and rules of abstract reasoning to more evolutionary primitive mechanisms, which control perception and action (Anderson, 2003). In order to carry out this task I first drew upon Rowlands' (2006) distinction between actions, deeds and doings, which allowed me to isolate representations at the level of intentions from representations at the level of our pre-intentional perceptual interaction with the physical world, that is deeds. The latter are adjustable to dynamic changes in the context. In this sense, it seems as if deeds could have the potential of bridging a situated action perspective with a representational perspective. This however needs to be studied more carefully in a future work.

Furthermore, I have attempted to show how the ability to infer generality in terms of laws and relations between objects in perception (such as Cause-Effect), which we normally associate with abstract reasoning, in fact emerge from primitive mechanisms in perception itself.

In order to provide the reader with a clearer view of the rich interplay that are at stake from neuro-physiological states to abstract thinking, I have laid out a diagram in Fig. 2. Much of what has been said about the upper levels in this diagram is standard knowledge in cognitive science. However, the idea of including these levels in the diagram is of course that embodied interaction encompasses the whole continuum of representations from canonical neurons to mental frames. It is this continuum that accounts for the full complexity of embodied interaction.

Abstract

In the last ten years, findings in medical science reveal that light plays important roles in maintaining optimum regulation of biological rhythms and hormones on a daily basis. Despite the decades of research, it was only in 2002 that David Berson discovered the connection between light and a third type of photoreceptor in the retina and this was the missing link in the description of the mechanism of biological effects controlled by the light and dark cycle. This discovery revolutionized the research on the spectrum, the intensity, the duration and the type of light that affects biological responses. This work addresses this issue of non-visual impacts of human exposure to light, in an attempt to relate the quality of lighting design to health, comfort, and well-being of female retail store employees. The sample for the cross-sectional study was randomly established with 30 female volunteers in street retail stores (possibility of outside visual contact) and shopping mall retail stores (no outside visual contact). Assessment of lighting considered the occurrence of glare, color appearance of light, flexibility, and possibility of lighting control by employees. The tools to assess well-being and health were psychometric scales internationally validated by the psychiatric field to measure depression, anxiety, and stress symptoms. Assessment of sleep conditions and analysis of the activity/rest rhythm was carried by a wrist monitor with attached luximeter and the analysis of the body temperature rhythm was made by a temperature sensor, to which each participant was submitted for five consecutive days. The lighting pattern's influence on the circadian system was verified by measuring saliva melatonin and cortisol levels. The degree of satisfaction of employees and their preferences regarding work environment lighting were surveyed by applying questionnaires. Data were analyzed using Pearson correlations, ANOVA, and stepwise regression.

Keywords

lighting design; health; circadian rhythm; cortisol; melatonin; retail stores;

The role of design has become increasingly more complex in daily life, increasing the need for understanding users' desires, needs and priorities and the way they interact with new products and technologies, which include, among others, new lighting design technologies. Studies (Campbell et al., 2007; Margolin, 1997) have systematically pointed out the relevance of incorporating the information provided by the user into the design in order to develop innovative products, spaces and, especially, sales outlets. In the specific case of lighting in retail stores, the previous work by the author (Martau, 2009) shows that there is a significant conflict between a lighting design oriented to product sales and a design oriented to the health and well-being of store employees, which can influence their productivity. In view of these complex challenges, a user-based research approach is an alternative for qualifying answers provided by the design. The Human-Centered Design approach aims at the better understanding of human needs in order to monitor, assess and propose innovations in the field of design having social and financial viability in mind. Desmet and Hekkert (2007) describe the potential of this research approach which encompasses from behavior studies to the affective experience resulting from the interaction between humans and products to define design attributes and parameters (Wellings, Williams & Pitt, 2008). The study of the interaction process between user and retail store lighting system has this goal, since in placing human beings once again as the central object of lighting design new strategies need to be established so as not to fail to address the primary objective of a retail space, namely, advertising a product or brand while at the same time allowing users/workers to be in good health and well-being conditions.

Background

The architectural typology adopted in shopping mall buildings in Brazil and the type of service provided generate many environments without outside contact and work shifts that advance into the night, both potential factors for the alteration of biological rhythms. A major challenge in the past years in the illumination field has been to define how light affects health, not only in aspects related to vision, but also related to metabolic processes (studies of circadian rhythms and tumor development, for instance). A population of special interest for the study of the relationship between light and health conditions is that comprising shopping mall employees, who are subject to artificial lighting in environments without windows during the day and often work until late at night. These individuals seem to be potentially more susceptible to diseases related both to excess lighting and to insufficient lighting. Although literature presents several studies on offices (Galasiu & Veitch, 2006) there are very few works relating commercial space employees to lighting (Heschong Mahone Group, 2003), both in the area of architecture and marketing or behavior, in which only Bitner's work (1992) stands out for including the employee and not only the consumer. Consequently, many shopping mall buildings have uncomfortable conditions for occupants, who, out of necessity, end up adapting themselves to the environment (Martau e Duro, 2005; Martau, 2009).

The knowledge about the relationship between lighting, man and Architecture can be summarized through several approaches to this topic. Regarding human performance, there are three main routes of analysis: through the visual, perceptive and circadian systems. The two former have some consolidated knowledge demonstrating how to illuminate in order to obtain visual comfort and stimulate perception. However, the knowledge of the relationship between lighting and the so-called human circadian system (24-hour daily rhythms) is still incipient. Exposure to light may have both positive and negative impacts on human health. These impacts may become evident shortly after exposure or only after many years. Understanding how light influences the human body helps describe the impact of lighting on building occupants.

The circadian rhythms can be regulated by a variety of external indicators, but light (light/dark cycle) is the primary and most important variable in the synchronization (or desynchronization) of humans with day or night rhythms (Gronfier, Wright, Kronauer, & Czeisler, 2008). he activity-rest rhythm, the body temperature rhythm and the hormone levels (melatonin and cortisol, see figure 1) are examples of light-regulated biological rhythms in the body that can be measured. When an individual is in a healthy state, all of his/her rhythms have a natural relationship, we say that said individual's phase is normal (Kaplan, Sadock, & Grebb, 1997). When the system is disturbed (by staying up at night, for instance), some biological rhythms become disarrayed (e.g., cortisol or melatonin rhythms) and are considered to be out of phase. The fact that the biological rhythms are out of phase contributes to the harmful effects experienced by the individuals. Some disorders have phase disturbances among their symptoms.

Melatonin is a very important hormone in the investigation of human biological rhythms regulated by the light/dark cycle (Kaplan,Sadock, & Grebb, 1997). The relationship between melatonin inhibition and light is direct, and melatonin responds to lighting only. Its rhythm is considered an excellent phase marker for the endogenous biological clock (Arendt, 2005), and it may also be a great indicator for the quality of lighting in relation to employees' health.

Cortisol is another hormone that takes part in the so-called adrenal axis. Cortisol shows a clear circadian rhythm, with its peak around the time the individual wakes up (Kudielka & Kirschbaum, 2003). Cortisol plasma concentrations are higher in the early morning (around 6 a.m.) and their values are lower in the afternoon and evening. As cortisol is controlled by the biological clock in the suprachiasmatic nucleous (SCN), cortisol rhythm and concentration are expected to be influenced by light.

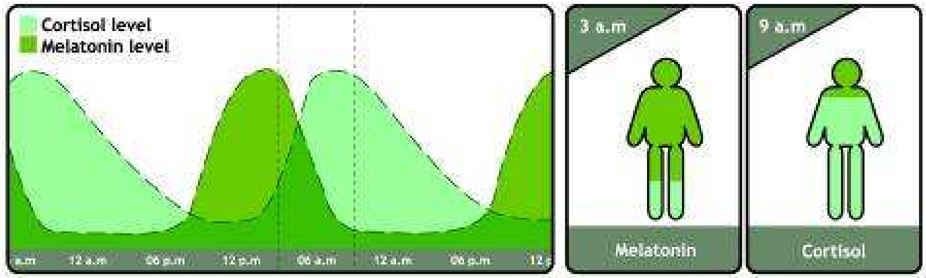

Figure 1: Relationship between melatonin and cortisol rhythms

The body also has an endogenous temperature rhythm called body temperature rhythm, which is considered to be the most stable body rhythm in relation to external variations (Noguera, Riu, Hortensi, & Cucurella, 2007). The hormones cortisol (stress hormone) and melatonin (sleep hormone) play an important role in the sleep/wake regulation, and there are some rhythm relationships between cortisol, melatonin and body temperature. In order to maintain one's health, it is important that these rhythms remain steady. Biologically, the time and duration in which light (or darkness) is received play a crucial role in establishing body temperature (Boyce, 1997).

Studies have shown that stress is also associated with lighting conditions. Stress changes rhythmically with diurnal regulation, as well as with cardiac regulation and neuroendocrine responses, which seem to be responsible for the higher rates of cardiovascular disease found in chronically stressed individuals (Monk, 1983).

Research goals and Methodology

The general goal of this study was to evaluate how lighting conditions interfere with the health and well-being of street retail store and shopping mall retail store employees in Porto Alegre, a city located in south Brazil. For this purpose, specific goals were also defined: to characterize the relationship between lighting conditions and emotional variables such as depression, anxiety and stress; determine if differentiated lighting conditions interfere with the biological rhythm (sleeping conditions, activity/rest rhythm, and body temperature rhythm); determine the levels of the hormones melatonin and cortisol in female employees' saliva in relation to different lighting conditions in stores; and verify female employees' satisfaction and preferences in relation to lighting systems at the workplace. The research was characterized as an exploratory study, with empirical investigation of phenomena in their actual context, with multiple evidence sources (variables).The study sought to assess and relate visual, biological and emotional aspects of lighting in the stores analyzed from the perspective of the individuals who worked therein (figure 2).

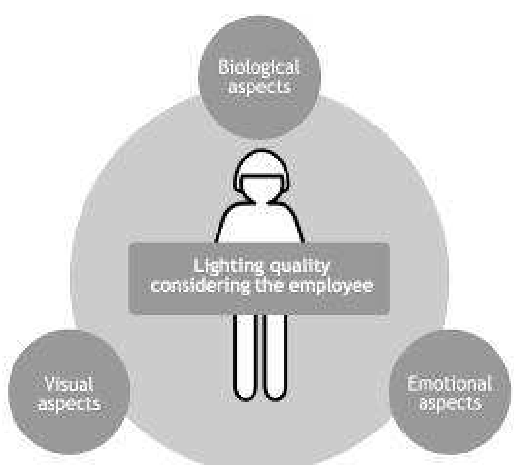

Figure 2: Lighting quality: visual, emotional and biological aspects should be considered

Subjects

Women aged between 18 and 65 years, who lived in the city of Porto Alegre, were selected. All subjects were employees in commercial spaces and must have been working for at least one year at the place and shift under study and could not be working double time. Despite minor variations in entry, lunch, break and exit times, female employees who worked for five to eleven hours on a daily basis were included. All of them volunteered for the study. They were divided in three groups:

- Group A: Ten street retail store employees with presence of daylighting and daytime work (8 a.m. to 6 p.m.).
- Group B: Ten shopping mall retail store employees, without presence of daylighting, and daytime working hours (10 a.m. to 6 p.m.).
- Group C: Ten shopping mall retail store employees, without presence of daylighting, and afternoon and evening working hours (2 p.m. to 10 p.m.).

Procedures and equipment

Evaluation of lighting conditions

Lighting conditions were evaluated by taking photos of the luminous environment and by completing a survey form in which the main aspects of the physical environment and lighting system were recorded: ground plan of the spaces under study, containing the shape and basic dimensions, description of materials and colors, list of light bulbs and luminaries. Items such as color appearance of light bulbs were obtained from the manufacturer's technical specification catalogue. The entrances were marked (if any) and the distance between the employees and the entrance was measured. The general illuminance of the space was measured at four points (to average general illuminance) and at work planes with a portable lux meter. The spaces with day lighting were measured at noon, within the climatic period referred to as spring/summer, on days without rain and at times without direct insulation into the space. All the spaces analyzed had an artificial lighting system activated throughout daytime or at least most of daytime, day lighting in these spaces being, therefore, only quantitatively complementary. The visibility of visual tasks was checked by using the Snelling Chart, which is a standard test to assess visual acuity at preset distances. Undesired reflections were evaluated by moving around the space and placing a reflective surface at different positions to check the presence of it. See synthesis of procedures in figure 3.

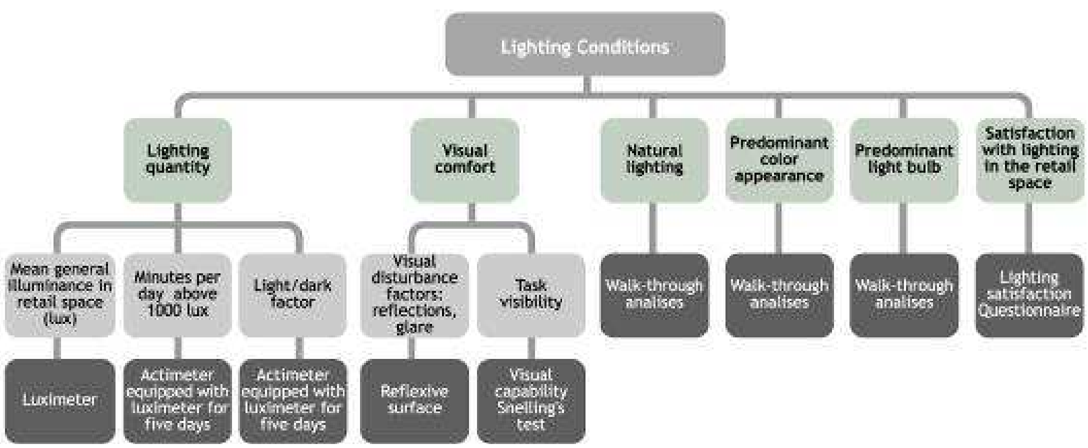

Figure 3: Synthesis of procedures for evaluating lighting conditions

Evaluation of satisfaction with workplace lighting

To evaluate employees' satisfaction with the store lighting, a questionnaire was applied which was developed from other lighting quality evaluation tools (Bean & Bell, 1992; Boyce & Eklund, 1995; Veitch & Newsham,1995; Veitch, 2001), as well as adaptations of part of the guide proposed by the Commission Internationale de l'Éclairage (Commission Internationale de l´Éclairage, 1986 &1972) to evaluate lighting in office environments, with adjustments to the type of existing visual tasks in commercial spaces.

Evaluation of emotional aspects: possibility of mental disorder, depression, anxiety and stress

To evaluate emotional aspects, the so-called psychometric scales were used, validated for Brazilian Portuguese. These are: Self Reporting Questionnaire -SRQ-20 (psychiatric disorder) (Mari & Williams, 1986), Montgomery-Asberg Depression Rating Scale (Dractu, Ribeiro,& Cal,1987), Beck Depression Inventory – BDI (Gorenstein, Andrade, Vieira Filho, & Tung, 1999), Hamilton Depression Scale (Hamilton,1967), State-Trait Anxiety Inventory –STAI (anxiety) (Spielberger,1983) and Lipp's Adult Stress Symptom Inventory (LSSI) (Lipp & Guevara) for stress assessment.

Assessment of sleep conditions

The Pittsburgh Sleep Quality Index questionnaire – PSQI (Buysse, Reynolds, MONK, BERMAN, & KRUPFER, 1999) and the Epworth Sleepiness Scale (Johns,1991) were used to evaluate quality and daytime sleepiness.

Assessment of the timing system: body temperature rhythm and activity/rest rhythm

Body temperature was measured continuously, for five days, by means of a thermistor (Ibutton, 2008) used together with an actigraph (Mini Mitter, 2007) to check if there were changes in the body temperature rhythm between the groups. It was fixed with an adhesive on the internal region of the forearm (figure 5 and 6). The Activity/Rest rhythm was measured by an actigraph with a coupled lux meter (figure 4), for a period of five consecutive days, always including the weekend. The use of an actigraph allowed the illuminance patterns to be analyzed for 24 h in each employee.

Figure 4: Actimeter placement on the wrist of the non-dominant hand.

Figure 5: Thermistor placement on the internal area of the wrist of the non-dominant hand.

Figure 6: Fixation of a thermistor on the internal region of the wrist of the non-dominant hand with skin-colored tape.

Melatonin and cortisol

The melatonin and cortisol levels were analyzed in the saliva, collected by the employee herself (participants were asked to rinse their mouth with water before collecting saliva) directly by expectorating into a collecting tube (12a.m,18 p.m.,12 p.m). After the collections, the saliva was frozen. For melatonin levels, a commercial ELISA kit from APCO Diagnostics® (ELISA kits, Buhlmann Laboratories, AG Swiss) was used. For cortisol levels, a Roche chemiluminescence kit was used. All the procedures for evaluating health and well-being conditions are synthesized in figure 7.

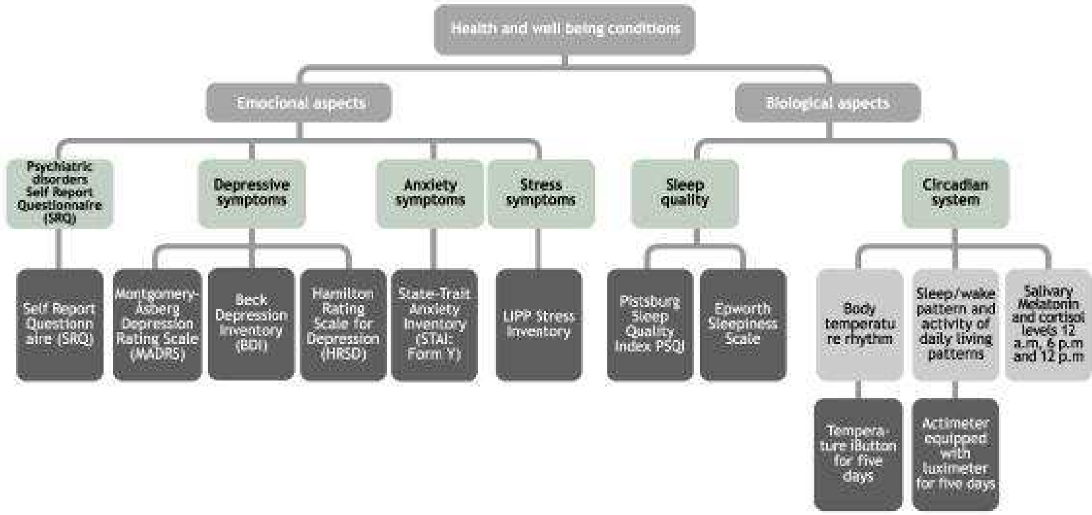

Figure 7: Synthesis of procedures for evaluating health and well-being conditions

Data processing and statistical analysis

Data were organized in a databank using the Excel software (Microsoft). The statistical analysis was carried out with the Statistical Package for Social Science (SPSS) program for Windows, version 13.0. A consistency analysis of the results was performed after the tools were applied by means of the Cronbach's alpha. The distribution of variables was described as mean and standard-deviation or frequency and proportion, when suitable. Stepwise multiple regression analyses were performed. Correlations between variables were analyzed using Pearson's Correlation Coefficient and variance analysis (ANOVA). The potentially confounding variables controlled in the statistical analysis were age, working hours and working shift

Results and Discussion

The results point to a greater dissatisfaction with the workplace lighting in the category shopping malls (groups B and C) than in street stores (group A). This dissatisfaction is highlighted in some aspects assessed, such as possibility of contact with the outside, lighting for the employee to feel relaxed, happy and motivated to work, in which the scores are far lower than in the street store group. The stores of groups B and C, where dissatisfaction with lighting in general is 20% higher than in group A, were the ones in which the employees reported greater dissatisfaction with the absence of visual contact with the outside, which was found to be inversely correlated with depression (Beck) in group C, specifically. The study in the stores demonstrated that the individuals who were more satisfied with the lighting system (independent of the type of lighting to which they are subject) are the ones having a greater light/dark factor and greater satisfaction with the possibility of visual contact with the outside, and these were in group A. In this group, the greater the satisfaction with the possibility of visual contact with the outside was, the lower the depression scores were (Montgomery-Asberg).

The most consist finding, which has a greater impact on the current lighting practice in shopping malls is the inverse correlation found between the average general illuminance of a store and the satisfaction with lighting, as well as the positive correlation of this variable with scores showing a possibility of mental disorder and depression, in group B, and with biological indicators (24-h temperature and melatonin acrophase) in group C. The shopping mall retail store groups presented greater average illuminance in the store (340 lux, group A, 478 group B and 666 lux group C), with predominance of words chosen by the employees describing illuminance as "bright and glaring", who showed a greater need for modifying the amount of lighting in the store, and the main change desired was a reduction in lighting during daytime. These results point to excess lighting for the employee, which may be related to greater stress, anxiety and tendency to cortisol rhythm loss in group B, and, in group C, higher scores indicating a possibility of mental disorder, depression and worse sleep quality, as well as changes in the 12-h melatonin level, with likely phase delay in the production of this hormone.

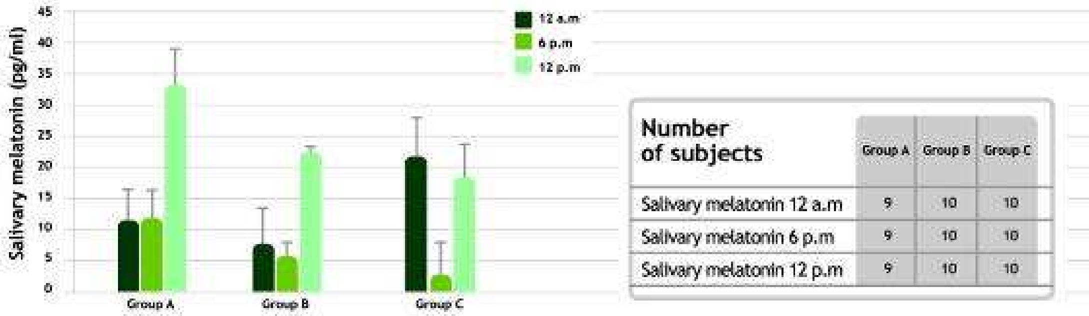

Figure 8: Salivary melatonin levels at 12 a.m, 6 p.m and 12 p.m by groups

The results shown in figure 8 suggest that individuals of group C suffer an alteration in melatonin rhythm, with probable phase delay (its peak is supposed to occur between 3 a.m and 4 a.m and decline significantly between 8a.m -9a.m, since, based on the level found at 12a.m and the relationship with the skin temperature rhythm, the peak must take place later than in the other groups. The observation of the melatonin production behavior in this group reflects directly the influence of the working environment lighting pattern of the store. These data, associated to the dissatisfaction with the average general illuminance of the store, in which the employees indicate a need for reducing daytime lighting, supports the hypothesis that the luminous environment is not suitable to meet the health and well-being requirements of the employees in these stores.

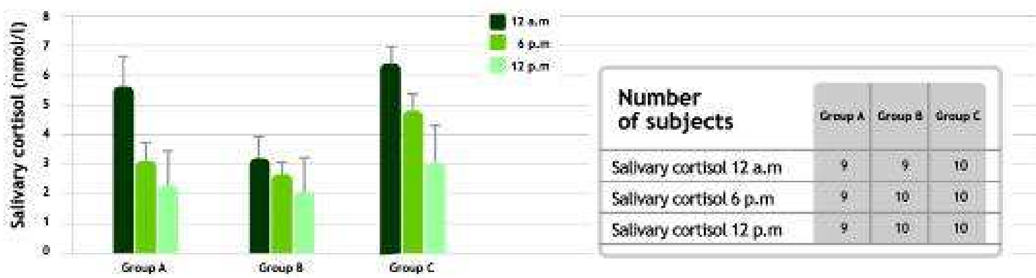

Figure 9: Salivary cortisol levels at 12 a.m, 6 p.m and 12 p.m by groups

Considering the situation of street stores (group A) as the optimal situation among the three groups, especially due to the presence of natural light and visual contact with the outside, groups B and C showed cortisol levels and variation between times different from the optimal ones (figure 9). The results found in the saliva cortisol levels (12 a.m, 6 p.m, 12 p.m) indicate a rhythm change (tendency to loss) in group B, in which a small variation between levels at three different times is observed, when a clear circadian rhythm is almost not perceived, with a peak around the time the individual wakes up (Kudielka & Kirschbaum, 2003). This may be explained by the absence of contact with more intense and natural light during daytime, because they are in a closed environment both in the morning and in the afternoon. Literature indicates that the exposure to intense light (preferably natural) in the morning is responsible for activating cortisol, more than at other times (Leproult, Colecchia, L'Hermite-Baleriaux, & Van Cauter, 2001). The group C employees spend the morning period outside the workplace, which enhances the possibilities of being exposed to higher and different illuminances (natural light). This may be associated to a better performance in relation to cortisol than the group that works in the morning and in the afternoon. Considering that other factors can change the cortisol rhythm, such as stress (Leproult et al., 2005), it is difficult to find a direct relationship between the tendency to cortisol rhythm loss in group B and lighting. Taking into account that in the groups without windows more than half of the employees are found to be stressed and that this percentage is higher in group B (60% stressed), it is necessary to evaluate more thoroughly the relationship between lighting, stress and cortisol rhythm loss detected here. There is a hypothesis that the need to adapt oneself to unsatisfactory lighting may lead to greater stress in this group and, consequently, to an alteration in the cortisol rhythm. The associations (positive correlations) of the cortisol level found with the SRQ, Hamilton and Epworth scores, in group B, support the hypothesis of a loss of cortisol production ability in these individuals due to stress, and the scale scores associate with the average general illuminance of the store positively (SRQ, Beck and Montgomery). As stress and depression are often part of the same disease situation, the hypothesis that the store illuminance is influencing health is suggested by the results found. Nevertheless, the results indicate that the luminous environment of the workplace, despite being influential, must not be studied separately, since workplace illuminance alone cannot explain variations in the circadian phase. The lighting in the workplace certainly influences the circadian effects, but it has to be interpreted in the context of the individual's full 24-h luminous pattern.

In all psychometric scales applied, the results pointed to higher mean scores for symptoms indicating a possibility of psychiatric disorder, depression and anxiety in groups B and C in relation to group A (figure 10). The higher absolute values in all variables analyzed showed that the more severe symptoms indicating a possibility of health alterations were also found in groups B and C, and that the environmental factor, including lighting, may be contributing to these results, which calls for a deeper analysis of these relationships.

	Group A	Group B	Group C
psychiatric disorder	**SRQ** lower No disturbance	No Disturbance	**SRQ** higher Disturbance found
depression	**Hamilton** lower 40% disturbance **Montgomery** lower **Beck** lower	**Hamilton** 50% disturbance **Beck** higher	**Hamilton** higher 40% disturbance **Montgomery** higher
anxiety	Lower	Higher	
stress	Lower 40% stressed	higher 60% stressed	50% stressed

Figure 10: Synthesis of psychometric scales

Since circadian rhythm regulation depends on the time and duration of exposure to light, the workers in group C seem to be more influenced by the light in the workplace, perhaps because they are exposed to high illuminances until a later time than the other groups. Group C was the one that differed from the others in the light/dark factor (lighting pattern), activity rhythm, mesor of skin temperature rhythm and acrophase behavior of activity and body temperature rhythm. The latter aspect is directly related with melatonin mechanism, which seemed to be altered in this group. These data, associated to the dissatisfaction with the average general illuminance in the store, through which the employees indicate a need for reducing lighting during daytime, support the hypothesis that the luminous environment is unsuited to meet workers' health and well-being requirements in those places.

The pattern of exposure to light provided by the actigraph lux meter did not find any difference in the amount of time of exposure to lighting between the groups, since the mean exposure time in minutes per day above a 1000-lux illuminance was similar between them, ranging from 62 to 68 min/day. A difference was found in the light/dark factor, which was lower in group C, which also differed from the others in the activity rhythm. This can be explained because, even though the times of exposure to certain illuminance is quantitatively similar, the type of light received is different (as regards spectrum, color temperature, visual access to the outside), which is quite important to people's health, as also shown in literature (Figueiro, Rea & Bullough, 2006; Farley & Veitch, 2001).This is an issue that needs to be discussed, because the regulations pertaining to lighting standards regulate the amount of light only, and not the quality or type.

The issues of uncomfortable noises and heat produced by light sources appeared in different correlations with the psychometric scales (anxiety in groups B and C), demonstrating that the non-visual aspects of lighting also have an influence on employees' well-being. In group A this correlation is not observed to appear, although their lighting systems have a worse quality than in shopping malls. This may be explained by the greater external noise found in street stores, masking the noise from light sources, which may make it more harmful. Similarly, the dissatisfaction with the heat produced by the light sources seems to be correlated with emotional variables in shopping mall groups B and C, in which the greater illuminances account for the greater discomfort with this aspect.

Conclusions

The study demonstrated that the female employees in the retail stores responded differently to lighting conditions in the three groups analyzed. There is a high degree of dissatisfaction with the lighting system in the three groups and satisfaction with lighting design was demonstrated to be associated to emotional and biological factors. By demonstrating this relationship, one can encourage entrepreneurs to invest in female employees' satisfaction with lighting and, indirectly, in their productivity.

The employees in street retail stores (A), where we found lower illuminances (up to 300 lux), showed higher drowsiness during the day and higher dissatisfaction with issues related to task visibility. Probably, it would be necessary to increase general illuminance in the category street stores, since dissatisfaction with lighting and daytime drowsiness may be indirectly associated to low illuminances (likely little circadian stimulation). The presence of windows and visual contact with the outside was an important factor for this group to present better conditions in the assessment of depression and stress, as well as the normal behavior of cortisol and melatonin levels.

The female employees of shopping mall stores working in the morning and afternoon shifts (group B) showed the worst conditions in the assessment of anxiety and stress among the three groups because they had no contact with natural light during the day as a result of their work time. The altered cortisol levels may be related to the high stress in this group and the lack of contact with natural light to stimulate it. Allowing them to have visual contact with the outside and access to natural light, whenever possible, is a precondition for health and well-being, since the results indicate direct and indirect correlations between this factor and higher depression and anxiety scores. This means that the project must prioritize the presence of windows, employing technical resources currently available to deal with issues of potential color fading caused by light, such as placing filters and special films on window panes.

The female employees of shopping mall stores working in the afternoon and night shifts (group C), where the highest average general illuminances were found (up to 700 lux) and the time to which they are subjected is later than the other shifts, showed physiological alterations in melatonin production and worse conditions in the assessment of depression. It is necessary to reduce general illuminance, since the alteration of the hormones melatonin and cortisol and the dissatisfaction in the shopping mall groups are directly and indirectly associated to high illuminances in the workplace. It also seems to be advisable to avoid using only one type of light bulb (same spectrum), reducing, thus, the risk of the existence of only one type of wavelength in the environment that may be harmful to the circadian system, until we learn what kind of spectrum is the most suitable and how these spectra interact with one another in a real environment. We must be careful so as not to use sources that are more suppressive of melatonin at night time and pay attention to new technologies, such as LED sources, until their influence on people is confirmed.

The results for the amount of light in stores indicate a need for adopting lighting techniques that incorporate intense light spotlighting the merchandise – which is the key to the process of attracting customers to buy – and milder general lighting for employees, light sources with reflected or indirect light being the most suitable for this, which is important for their health and well-being. It is crucial to review the international legislation that dictates high general illuminance for this type of stores.

The shopping mall typology must be reviewed since the lack of visual contact of employees with the outside is related to higher depression scores in these groups. In stores without visual contact with the outside, the variation and control of artificial lighting systems by employees or the use of a programmed system should be enabled, varying the amount of light and color appearance, since great dissatisfaction was found with the lack of variability in the luminous environment of stores without openings.

An important question raised by this study was that of the methodology used, which tested the variables to assess the quality of lighting focusing on human needs (visually, biologically and emotionally), as well as the tools brought from the fields of Psychology and Medicine. The methodology was deemed to be appropriate, since countless associations (correlations) were found between the variables under study, and the results were convergent and coherent between the different tools used. However, the methodology was found to be too complex and long for the employees, which resulted in a high number of drop-outs (12 people) after the start of the evaluation.

Lighting design needs to be regarded as a multidisciplinary field of knowledge aiming at developing and applying information on human behavior and physiology to environment lighting. The conceptual-theoretical base that is being established in the field of lighting design allows us to point out that, as human requirements become understood, a new paradigm is needed for contemporary lighting design. The technological solutions of lighting systems will remain of key importance, but it will be necessary to learn how to reorganize design guidelines in order to render them user-centered.

Author Biography

Betina Tschiedel Martau

Architect and Urbanist (1992), MSc in Architecture from Universidade Federal do Rio Grande do Sul (1998), with a PhD in Civil Engineering (2009) from Campinas State University in Campinas, São Paulo, Brazil. She has been a teacher in Design School at the University of Vale do Rio dos Sinos (Unisinos) in Porto Alegre, She is a researcher and advisor in the Master's Degree Program of Graduates Studies in Design from the School of Design at Unisinos. She has also worked as a guest researcher since 2007 in the group of Chronobiology at Hospital de Clínicas in Porto Alegre, Her studies are focused on the influence of lighting design on the health of the building occupants with a focus mostly on the study of circadian rhythms. She has also run her own architecture office since 1993.

Paulo Sergio Scarazzato

Architect (1979), Master (1988) and PhD in Architecture and Urbanism (1995) University of São Paulo. Professor at the University of São Paulo and Campinas State University, and Professor at the Catholic University of Campinas. Exercising functions in academic teaching and research in natural and artificial lighting design applied to buildings and urban spaces, and teaching functions in thermal comfort, acoustics and architectural design freedom. It is affiliated to the IES (Illuminating Engineering Society of North America) and member of CIE Brazil (representing the International Commission on Illumination in Brazil)

Maria Paz Loayza Hidalgo

Graduate at Medicina from Universidade Federal do Rio Grande do Sul (1991), master's at Clinical Medicine from Universidade Federal do Rio Grande do Sul (1997) and PhD at Clinical Medicine from Universidade Federal do Rio Grande do Sul (2001). Has experience in Medicine, focusing on Psychiatry, acting on the following subjects: circadian rhythms', hysterectomy abdominal total, morfina, clonidina, cronotypos.

Iraci Torres

Graduated in Pharmacy and Biochemistry from the Catholic University of Pelotas (1985), MA (1999) and Ph.D. (2004) in Biological Sciences-Biochemistry, Federal University of Rio Grande do Sul and associate professor of the Department of Pharmacology, Federal University Rio Grande do Sul Coordinator of Research Groups-CNPq/UFRGS- Pharmacology of Pain and Inflammation and Experimental chronopharmacology. Has experience in pharmacology, with emphasis on neuropharmacology of pain in neonates and experimental chronobiology.

Clarice Luz

Graduated in Biological Sciences from the Catholic University of Rio Grande do Sul (1984), MSc from the Catholic University of Rio Grande do Sul (1982), Ph.D. in Biomedical Gerontology with emphasis on Psychoendoneuroimmunology from the Catholic University of Rio Grande do Sul (2006). She is currently a technician - Vitrus Laboratory Analysis and Clinical Research. Specialist in Clinical Analysis, Immunology and Biophysics.

Interactive Tools and Online Communities that support Media Literacy

Discussions about online media often neglect the engagement and interpretation of these technologies. The Internet has become a primary resource for learning, but schools are often not prepared to train students to understand online content. Outside of the classroom teenagers are active online. Conversely, many schools rely solely on analog tools to teach this already digital generation. This disconnect may result in teenagers who are not prepared to be critical digital citizens.

According to research by the Massachusetts Institute of Technology and Stanford University, teenagers tend to rely on the look of online information to determine credibility. As design software and image manipulation tools have become more available, average users can create content that looks professional and therefore trustworthy. Online content facilitates public discourse, but positions amateurs and experts at the same level. This flattening of source credibility is problematic for teenagers with limited cognitive abilities and life experiences to make judgements.

As online participation in inevitable we must determine ways for students to practice communication and collaboration in activities that are facilitated by an educational framework. We cannot simply ignore participatory communities and reject interactive tools as learning strategies. Educators have an opportunity to encourage new media literacy by leveraging existing social participation into teachable moments.

Based on literature, field interviews, persona development and research, we have identified five main challenges that merit pedagogical shifts to address media literacy. We propose two speculative case studies to address these five challenges.

What is Media Literacy?

Media Literacy has become a buzzword, much like design thinking, resulting in a need to clearly articulate our interpretation. We follow Marshall McLuhan's definition of media as any extension of our selves through technology. (McLuhan, 19) Media or (Mediums) include, but are not limited to, television, newspapers, books, articles, blogs, web sites, portable devices, games, computers, cell phones, digital videos, photographs, illustrations, text messages, e-mail and the printed word.

Literacy refers to the ability to read and write and the thinking that goes into that work. It is a social, cultural and historical activity. (Finders, 8) School literacy is associated with the reading and writing in education, determined by a set curriculum, with specific outcomes and objectives. (Kelly, 8) Activities related to literacy evolve and are altered by media. We see media literacy as addressing the need to educate teens and adults about the interpretation and understanding of media they confront everyday.

As participatory communities like Facebook, Flickr, and YouTube have grown in popularity more attention has been given to media literacy. In a white paper authored under The John D. and Catherine T. MacArthur Foundation, "Confronting the Challenges of Participatory Culture: Media Education in the 21st Century;" the concept of new media literacies was explored:

> *"We call the new media literacies: a set of cultural competencies and social skills that young people need in the new media landscape. Participatory culture shifts the focus of literacy from one of individual expression to community involvement. The new literacies almost all involve social skills developed through collaboration and networking. These skills build on the foundation of traditional literacy, research skills, technical skills, and critical analysis skills taught in the classroom"* (Jenkins, 4).

These new media skills include play, performance, simulation, appropriation, multitasking, distributed cognition, collective intelligence, judgment, transmedia navigation, networking, negotiation. (Jenkins, 4)

Digital Natives

Urs Gasser and John Palfrey, authors of *Born Digital: Understanding the First Generation of Digital Natives,* explain that this unique generation has had lifelong exposure to online technologies, which has lead them to view digital information as malleable. Teens do not view technology simply as a tool or a means to an end, they sometimes view the technology as the end in itself. As technology, tools, and online spaces are embedded in a teens day to day life, educators must assess if they are comprehending and critically engaging with media.

Many young people are members of online communities and their participation is increasing. Social networking sites like MySpace and Facebook are "virtual malls," where today's tweens and teens can commune together, without the annoyance of observing teachers and parents. A study conducted in 2006 by The Pew Internet & American Life project found 55% of online teens (ranging in age from 12 to 17) had profiles on social networking sites. (Boyd 119 –121) Not only are teens participating, they are immersed in media engagement.

Accessing these communities has become increasingly fluid with the introduction of smart phones and other portable digital devices. "Without question, this generation truly is the media generation, devoting more than a quarter of each day to media. As media devices become increasingly portable, and as they spread even further through young people's environments — from their schools, to their cars, to their pockets — media messages will become an even more ubiquitous presence in an already media-saturated world" (Roberts 60). A Kaiser Family Foundation study released just this January showed dramatic growth in young people's use of media.

> *"Over the past five years, young people have increased the amount of time they spend consuming media by an hour and seventeen minutes daily, from 6:21 to 7:38—almost the amount of time most adults spend at work each day, except that young people use media seven days a week instead of five.*
>
> *Moreover, given the amount of time they spend using more than one medium at a time, today's youth pack a total of 10 hours and 45 minutes worth of media content into those daily 7½ hours—an increase of almost 2¼ hours of media exposure per day over the past five years" (Rodgers, 2).*

Teenagers today are not digital observers, but are full participants of the digital landscape growing up in what Lawrence Lessig calls a "read-write culture." Unlike previous generations that existed during the 20th century, they not only consume media, they author it. (Lessig, TED 2007 Conference) "Some 57% of online teens create content for the internet. That amounts to half of all teens ages 12-17, or about 12 million youth. These content creators report having done one or more of the following activities: create a blog; create or work on a personal webpage; create or work on a webpage for school, a friend, or an organization; share original content such as artwork, photos, stories, or videos online; or remix content found online into a new creation" (Lenhardt & Madden).

As more teens become online media authors and participants in their social lives, we must ask how these activities can, and should, be employed within the classroom? Educational instruction that incorporates online resources may provide teens a broader spectrum of information on a subject. Textbooks go out of date quickly and provide one point of view, that of an author, editor or publishing company. Educators now have a challenging opportunity to teach subjects such as history from current, multi-faceted points of view.

As new media is integrated into classrooms, textbooks and other old media do not disappear. The most successful technological integration in classrooms support a convergence of old and new media. For example, in Ken Ellis's video, *Media Smarts: Kids Learn How to Navigate the Multimedia World*, teachers use a variety of old and new media resources, including textbooks, newspapers, posters, film and online tools to teach about media literacy.

This media convergence helps students make a bridge between real-world problems and those created in the classroom. In addition to brick and mortar schools, what if teaching about media could take place in the very environment in which teens encounter new media?

Online environments offer teens a space to converse with their peers without being scrutinized by adults. Despite the lack of direct supervision by teachers, there is no doubt that these spaces can result in learning. Independently, teens transform social spaces and interactions into learning situations. A recent article in *The New York Times* interviewed several teens and found that many preferred reading and researching online because they "crave the ability to quickly find different points of view on a subject and converse with others online" (Rich). According to a study done in 2005 by the US Department of Education, roughly 94% of instructional classrooms have internet access compared to only 3% connected in 1994. (US Department of Education) Online access is not only used for instructional support. 71% of online teens used the Internet as the primary source for major school projects or reports. (Lenhart, 44) This rapid growth in usage results in great shifts in our social and cultural behaviors. It is important to address how online resources are used and understood by students.

Online Challenges

Teens and adults face many challenges online and teens are particularly at risk. We see five main challenges that merit pedagogical shifts to address media literacy. First, teens engage with media on their own, often without the involvement of their parents or teachers. When teens use technology in the privacy of their own bedrooms, parents lose the ability to supervise activities. Wireless handheld devices bring the challenges of independence to the forefront. In 2007, 84% of teens owned at least one mobile device; a laptop, cell phone or PDA (personal digital assistant). (Lenhart, 30)

Second, online environments offer multiple perspectives and diverse narratives, but not all content goes through an editorial process. The web has changed the terms by which we judge sources. With print media, a source may be viewed as single and authoritative, such as an editor or author, and is often spotlighted. Online content often has multiple sources and the original sources are often buried under trails of hyperlinks and commentary. Contextual relationships between things such as hyperlinks and supporting articles become important online due to users' reliance on more than one source. This lack of editorial vetting and clarity of source is a challenge for teens when they are trying to determine who and what to trust online.

Third, technology allows amateurs to create content that looks and feels as trustworthy as content created by experts. A traditional diagram of the message cycle places the audience only in the perception and consumption phases (figure 1). Historically and sometimes currently, design is limited to the creation and reproduction phases. Digital media, online access and current trends invite participatory audiences to operate in every step of the message cycle. Free online tools are readily available, for instance Picnik.com allows users to create and share visual information that may look very professional and therefore credible to teens.

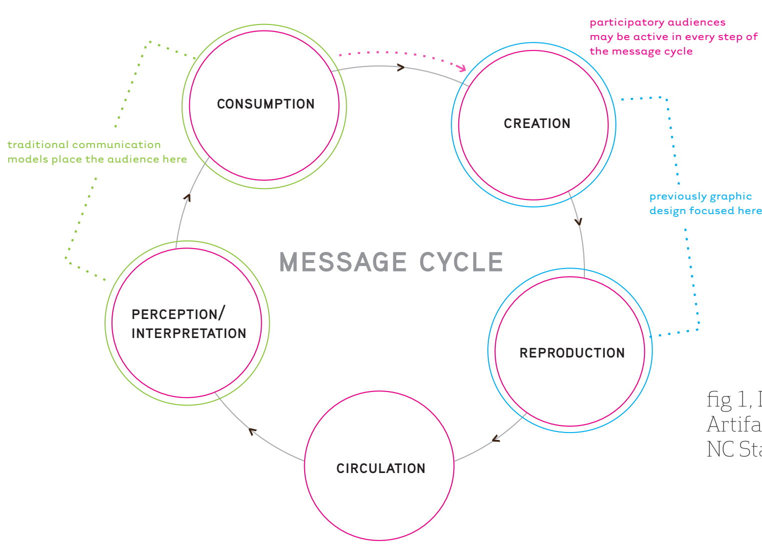

fig 1, Design as a Cognitive Artifact,Meredith Davis, NC State

Fourth, teens tend to rely on the look and feel of information to determine credibility. Researcher B.J. Fogg at Stanford University cites four types of credibility assessment that relate to human computer interaction: reputed, presumed, experienced and surface. While the internet gives us the ability to find multiple perspectives, it also requires more care when determining credibility. S. Shyam Sundar states that credibility assessment tools that leverage teens' desire to judge content by the look and feel may be more successful than tools that try to steer them away from these surface characteristics. (Sundar, 76)

Reputed credibility is "the extent to which a person believes someone or something because of what third parties — people, media, or institutions — have reported" (Fogg, 135). This type of assessment is common in online environments, and can be based on links from one website to another, user commentary and expert endorsements.

Presumed credibility is "the extent to which a person believes someone or something because of general assumptions in the person's mind" (Fogg, 132). Media based assumptions are common and some users trust online information without much thought. "Defaulting to a medium-based judgment is perhaps cognitively less demanding than other strategies … Assessments at the level of medium are crude, and while they may be appropriate for government or industry related content such as that offered through television and newspapers, they may not be appropriate for online content that is freely offered, altered by anyone with technological access and skill, and subjected to no or very little governmental regulation" (Eastin, 39). Audiences often assume that what they are able to see is true and find photography and video to be mirrors of the truth rather than glimpses of perceived realities. Culturally based assumptions also influence presumed credibility assessment. New technology is often associated with credibility because users assume that the creator has a high level of skill.

Experienced credibility is based on user experience over time and is perhaps the strongest type of assessment as it depends on the development of a user's experience with one source. Experiences vary among audiences, but being aware of a person's individual experience can play a role in personal assessment.

Surface assessment refers to initial reactions to the look and feel of information and is the fastest and most common type of assessment. The study, "How Do Users Evaluate the Credibility of Web Sites? A study with over 2,500 participants" found that 74% of participants relied primarily on the design of the website to determine credibility. (Fogg, Soohoo, Danielson, Marable, Stanford, Tauber, 5) The participants stated that credibility was signaled by cues such as a "balanced composition of information" and "soothing color palettes."

Finally, there is a risk of information overload. How do teens cope with all of this digital information? Print media offers a beginning and an end, a front and back cover to mark the experience. The internet is infinite, but there are limits to what teens can absorb and comprehend. Most research on information anxiety focuses on adults, whereas affects on teens are just now beginning to be explored. Researchers have found that "One of the primary reasons to be concerned about too much information being accessible to young people is the possibility of negative effects on decision-making" (Gasser and Palfrey, 192). Balance needs to be struck between getting enough contextual information to make judgements and getting too much information that can overwhelm and paralyze a teen's ability to think critically.

Teens face more challenges online than adults because they are basing decisions and judgments on limited life experiences. Adults have the experience to make comparisons and informed decisions about who and what to trust online. Teens are often left to sort through the complex landscape without a guiding compass. As online environments become more complex, the cognitive challenges increase. Matthew Eastin, from The University of Texas at Austin, states that "Lacking a reference base can create confusion and lead to inaccurate interpretations"

(Eastin, 30). Teens lack the skills to manage and organize complex information that they confront online, as an average Google search returns millions of results, the challenge is knowing what information is credible, authentic and useful.

Evolving View of Media Literacy and Education

"Media change is affecting every aspect of our contemporary experience, and as a consequence, every school discipline needs to take responsibility for helping students to master the skills and knowledge they need to function in a hypermediated environment" (Jenkins, 57). Often, if media literacy is taught at all, it is by librarians in isolated environments. A cross-curricular approach may provide a richer experience for students.

In schools, students are not taught how to be critical when engaging with visual language in the same way that they are taught to evaluate verbal and written language. The arts tend to focus on creativity while English-based classes focus primarily on the written word, rather than on text and imagery, motion or sound. As more and more people become visual communicators, new media literacies are required to analyze visual communication.

Participatory communities can act as "affinity spaces;" as they have the potential to motivate peer-to-peer teaching and learning. (Jenkins, 9) Affinity spaces are communities focused around a common endeavor, masters and amateurs share a common space, content organization shifts according to interaction among the users and participants, knowledge gathering and dissemination is encouraged and there are multiple facets to participation. (Gee, 85 – 87) Affinity spaces are successful as they actively engage participants through shared tasks, goals, objectives and ultimately successes.

These spaces allow experimentation, and open ended answers. The activity is only limited by the participants own motivation to use the system. In schools, teachers are required to keep a tight rein on student activity. Teachers are bound by school calendars, schedules, learning assessments, and government enforced testing, as we have seen with No Child Left Behind. The addition of digital tools and spaces would allow a traditional classroom to blossom, as the environment would expand, and be flexible to an individuals learning preferences.

While the research regarding young people and new media is flourishing, there are few models on how to successfully move forward and apply research findings. We propose two case studies that aid in critical media engagement and assessment, inspire participation, and prepare young audiences to become critical digital citizens.

Case Studies #1: Video Book.

Video Book is a component-based, web application to be used by multiple users. A web application exists online and allows users to complete tasks together. Unlike traditional software applications, web applications usually do not require users to pay for access. They are open source, and do not require a site license to run. Examples include Yahoo Mail or Google Docs. The *Video Book* interface supports direct correspondence between students and educators. Student groups work together and share their findings as they complete class projects. All participants can save, share, and delete their work. Each study focuses on specific curriculum goals, as referenced in *The Content Knowledge; A Compendium of Standards and Benchmarks for K-12 Education, for Language Arts Level III, Grades 6-8*. This source served as a means to ground the design in practical, real-world educational objectives.

Video Book supports peer-to-peer learning as the space encourages collective intelligence and the transfer of ideas. Design studies were used to form a system of tools that together create a participatory community focused on objects and interactions in time. The community is named *Video Book*, as it integrates various types of media content into a digital video format. At the center of the interface is the time line and the stage. These are the previewing and performance spaces for content and student activity (see figure 2, next page.)

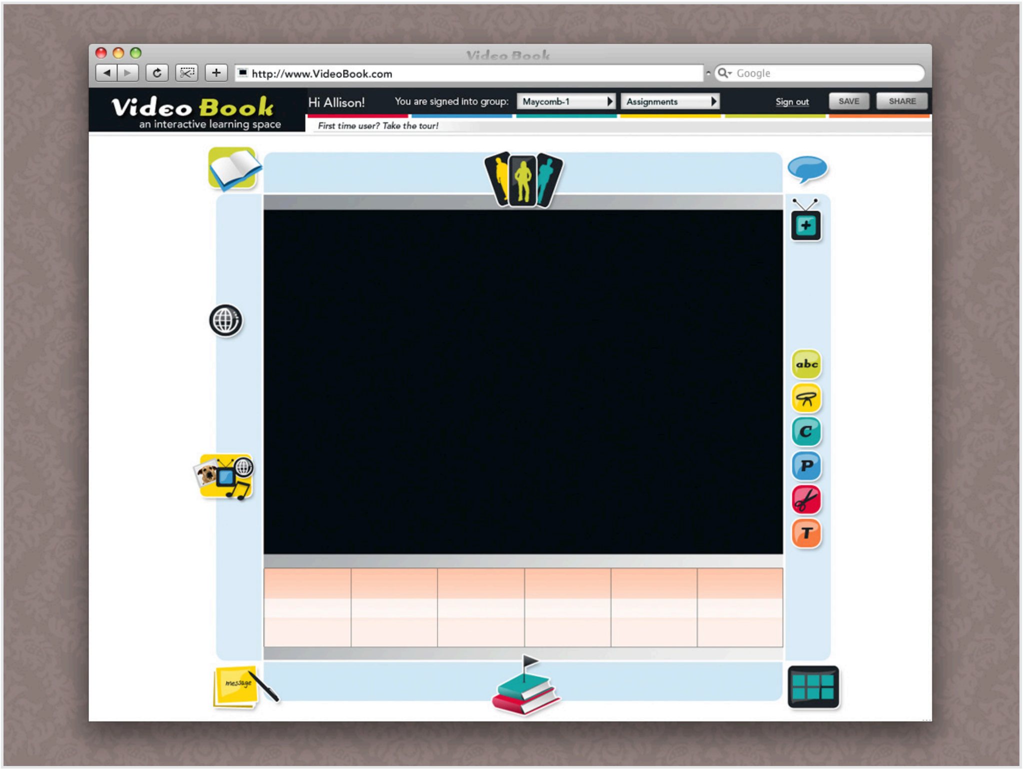

fig 2, the Video Book interface

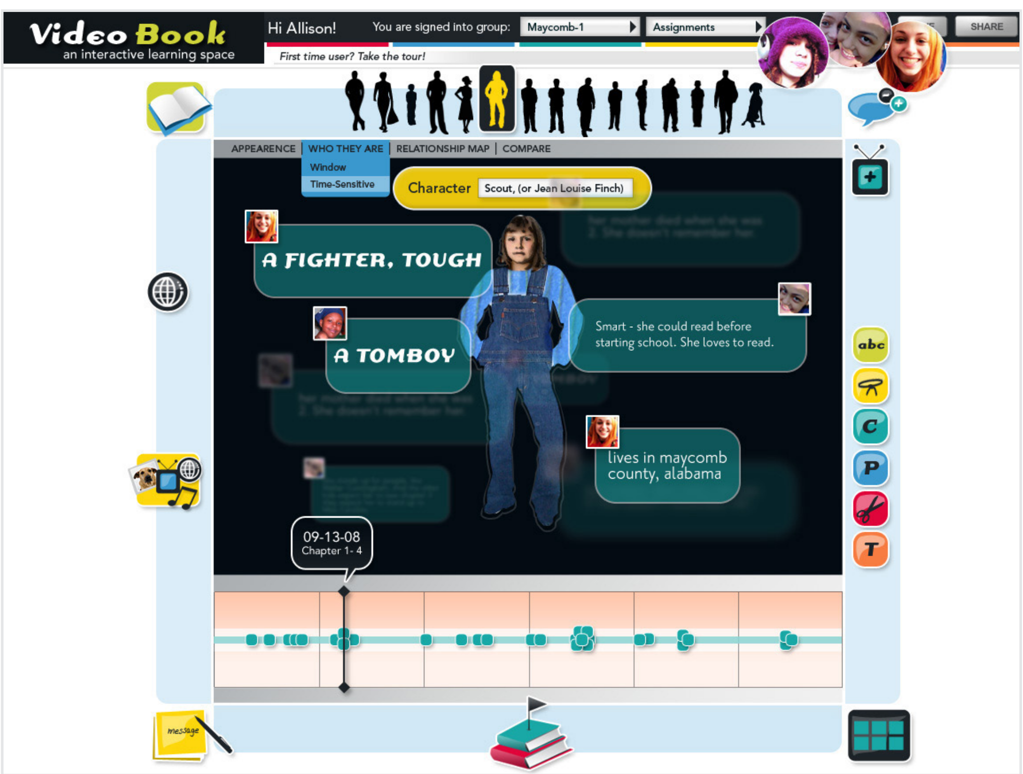

fig3, character building in a time based format

The *Video Book* prototype is demonstrated through four scenarios that represent students working through distinct clusters of components. Each component enables a set of interactions. Students can complete a diverse set of tasks and create various digital learning objects that take shape as digital avatars, storyboards, research collections and movies. Students may use *Video Book* in a remote setting, working from a home computer with Internet access, a mobile device or on a computer at school. Teens are clustered into groups of three or four students, and their work is primarily collaborative. These scenarios follow Allison, a seventh grader, as she works with her group in *Video Book* to complete school assignments.

In scenario one, (figure 3, previous page) Allison builds a character from the book *To Kill a Mockingbird, by Harper Lee*. Allison begins by building the appearance of Scout, the main character in the novel. She selects her facial appearance and her clothing. This function allows the student to visualize the physical character. The interface responds to the Allison's movements. As she wands over the character with her mouse it invites her to select a face from a given set of actors. This virtual character is a concrete representation, which the student can save into the class database. This capability allows the students to practice collective intelligence as the students can each contribute notes and ideas about a character to the whole group. Each student has access to the character database as they build storyboards and make movies. The character analysis changes over time, and is recorded by the system. The emphasis is on the relationships between characters and the story structure.

Allison finishes by posting her comment, and viewing the comments of her group members. A few weeks in the future, when the class is several chapters ahead, Allison may look back in the time line and sees how Scout's character description has evolved throughout the book. The system documents participation, archiving the class activity for later retrieval.

In scenario two, Allison works with her group to build a storyboard illustrating chapter ten from *To Kill a Mockingbird*. (figure 4) The students gather actors from the character bank and compose them to visualize the key moments in the chapter. The interactions taking place in scenario two emphasize meaningful play.

fig 4, storyboarding and captioning of a key moment in a novel

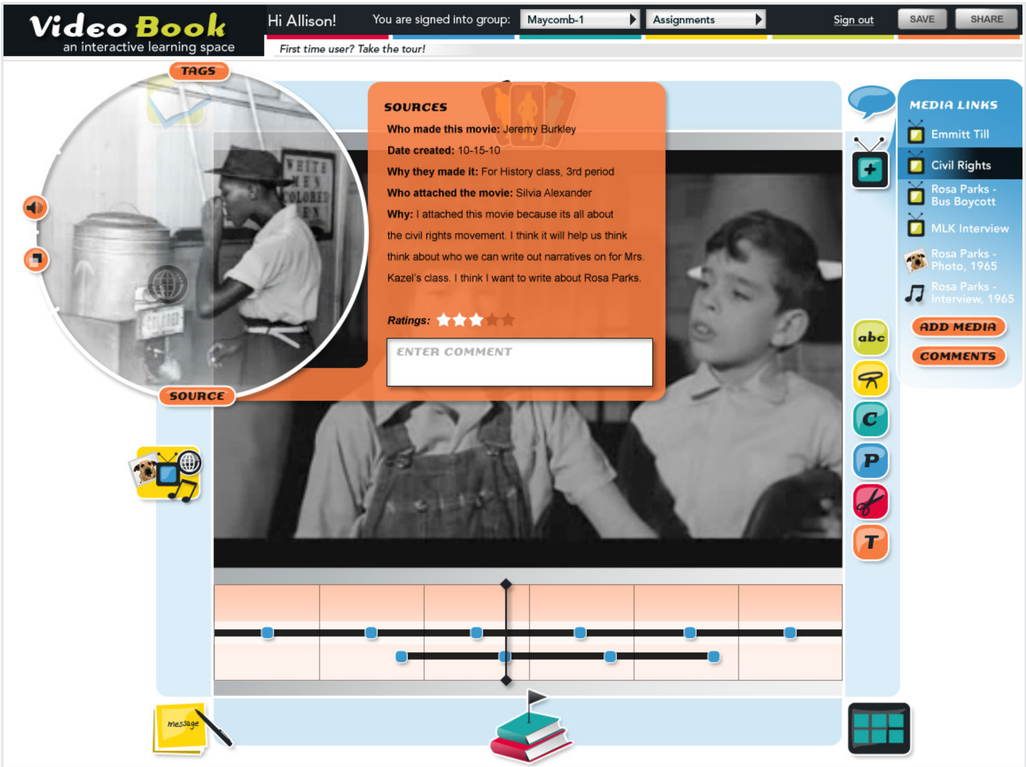

fig 5, conducting research, using and contributing to the media links

fig 6, movie making tools being employed on the stage

Students reveal to each other the intricacies of the plot as they collaborate. Teachers may view individual participation and quickly assess if students comprehend the novel and its literary themes. Storyboarding allows students to view the narrative in a concrete, chronological format. Students understand the story visually as they share their mental pictures with one another.

In scenario three Allison and her group work to compile research for an informational report. In history class the students are studying the Civil Rights movement, in addition to reading *To Kill a Mockingbird*. This scenario reflects their progress as they work through ideation and brainstorming. (figure 5, previous page) Using the attachment tool the students connect media content from the Internet and their collective gallery. They make connections between related media objects. They may also edit out what they find to be inappropriate, making judgments and negotiating what is relevant to their topic. The tools allow the students to compile information quickly, and to see assigned tags, and the facts behind the media; where it was created, who authored it and when, as well as comments attached to the file. The tools act as educational framing devices.

Scenario four shows Video Book functioning as both an individual work space and as a community. (figure 6, previous page) Allison works independently, developing an informational video report incorporating video, photography, graphics, audio and text-based information. Allison imports her own recordings. Her amateur movie demonstrates not only what she has learned about Rosa Parks, but also reveals her creative and expressive talents. It allows her to perform by sharing her movies with her group members, her teachers, and her class. This exercise encourages Allison to become an author, building her confidence, as she shares work within a safe learning space. By allowing students to share work through an online learning space, critique and assessment will be focused on the learning object, not on the physical presence of the student.

Case Studies #2: Trust It?

Our second case study, *Trust It?* explores how online interfaces can encourage students to analyze, interpret and judge the credibility of visual language. *Trust It?* is a plug-in that approaches credibility assessment from different angles, is a bridge between controlled and independent experiences and would be available on aggregated websites such as Flickr, You-Tube and Google Images. *Trust It?*, is a movable tool set (figure 7 , 8, 9) that is managed by an area called Home Base. Students may choose where to put the tool, how large or small it is and when is visible. Putting credibility assessment tools in the hands of students encourages independent judgment. *Trust It?* presents three scenarios in which Alex, a 15 year old, uses the system to do research for assignments related to her Language Arts Class.

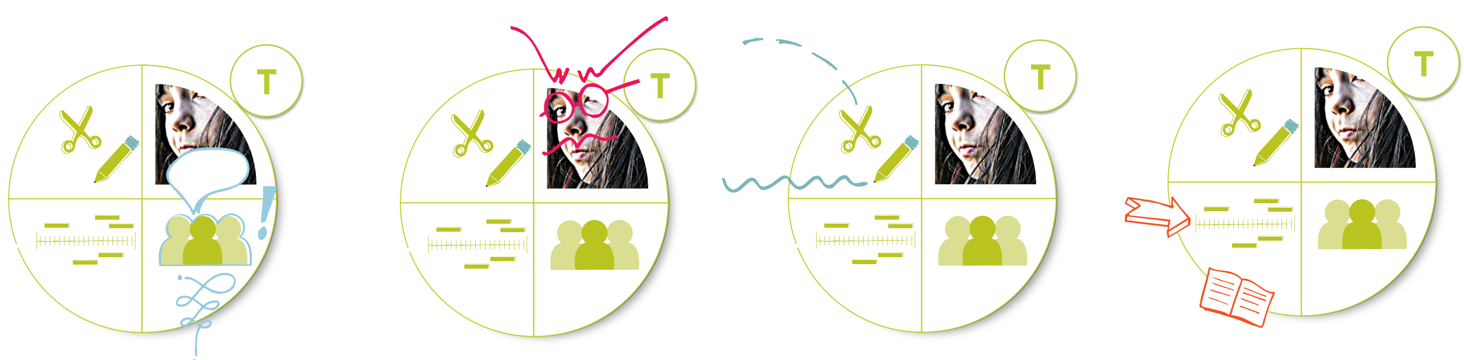

fig 7, three states and the Home Base of the movable tool set

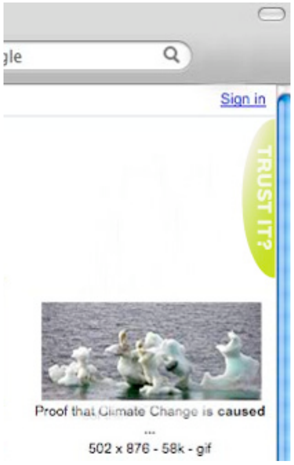

fig 8, plug-in in static state

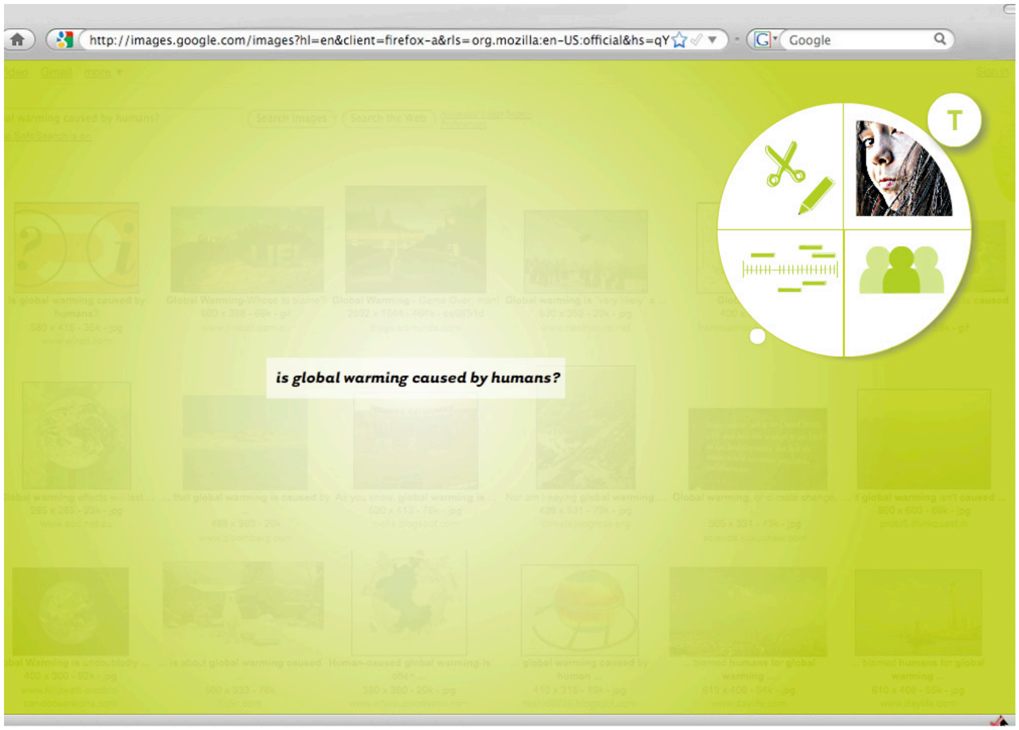

fig 9, tool in active state

In scenario one Alex explores aspects of visual language and originating sources that inform and educate her to the credibility of information. Because teens rely on look and feel to determine credibility, *Trust It?* explores how specific visual cues can infer credibility. Alex is searching for information regarding the causes of global warming. *Trust It?* search results are categorized by genres such as journals, blogs, news media and academic libraries. (figure 10) These categories include contextual information that is often lost in web searches that yield millions of results. No categories are considered entirely credible, so Alex is encouraged to make credibility assessments in all genres. The dynamic nature of the images hints at the level of credibility assigned by a team of experts: teachers, professionals and mentors who support the Home Base.

fig 10, categorization

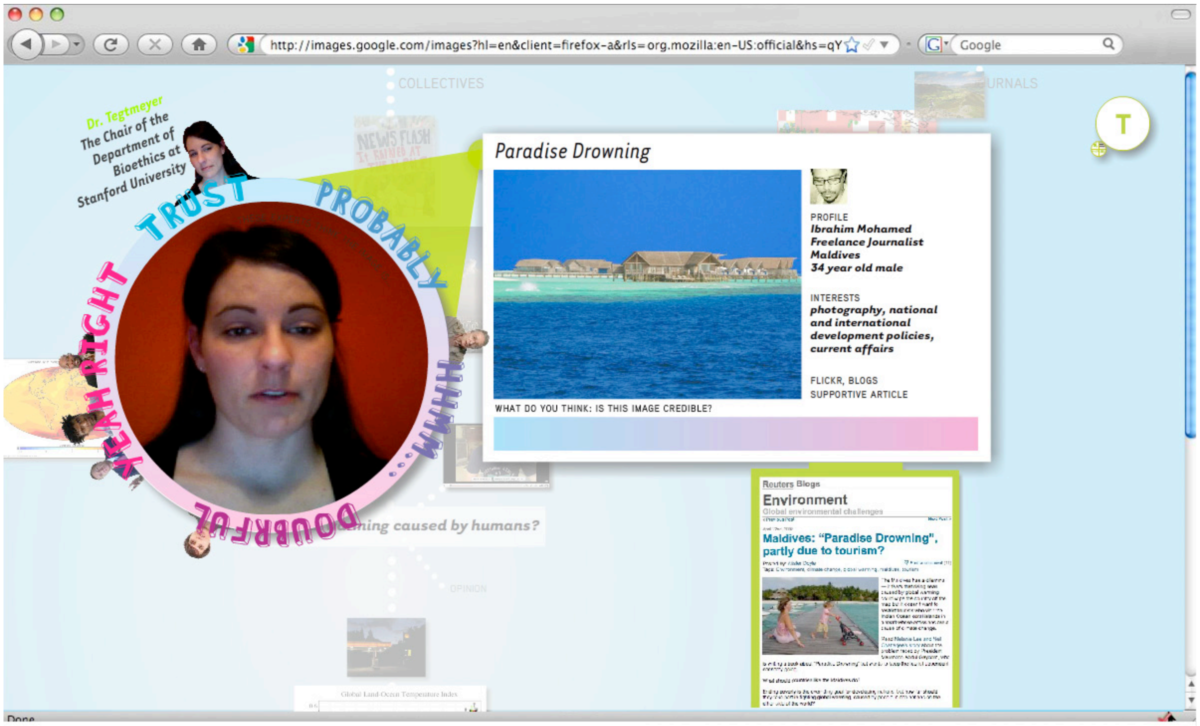

fig 11, detailed source information, supportive content and expert testimonials

With participatory sites many authors use nicknames, further complicating source assessment. Using *Trust It?* Alex may view detailed source information as well as supportive content without leaving the space. (figures 11) Participatory assessment in *Trust It?* relies on contributions from teens and experts rather than on a system or single authoritative voice, allowing students to understand that people perceive images differently. Alex is shown what several experts think about a photo. (figure 11) Credibility is determined by the group and by giving teens tools they become a part of the process.

Scenario two addresses what online activities encourage students to critically analyze the visual language they view, create or alter on informal learning environments. Alex searches for images related to three subjects for her class research assignments: global warming, domestic violence and US presidents. *Trust It?* functions as a prompt for interaction and learning. When Alex chooses to roll over different parts of the tool set or an image, open-ended questions are revealed that hint at larger educational goals. (figure 12, next page)

Visual language is constructed, just like written language. Formal choices in photography — whether made in the moment of capture or later when editing — affect the understanding of the message. Little research has been done on how teens understand the concept that visual language is constructed, however, tools are widely available for teens to alter images. A simple cloning tool allows a teen to change the background of an image. This type of alteration affects the meaning of the image and the message. While searching about global warming, Alex is confronted with an image and when she rolls over the image, the cloned snow appears; when she rolls off the image, the snow goes away. Making a connection between time-based comparisons and Alex's explorations, is meant to inspire further investigation into what the message means. A chat area in the same space as the images allows discussion among teens. In surface level exchanges, social interaction may be limited to conversational chatting. However, in more specialized knowledge areas, such as researching global warming, more in-depth dialogue may occur. The 'thoughts' area in the toolbar gives Alex a space to construct an argument about the poster advertising the documentary film "An Inconvenient Truth." Alex is questioning the appropriateness of a manipulated image to promote a documentary film. (figure 13, next page)

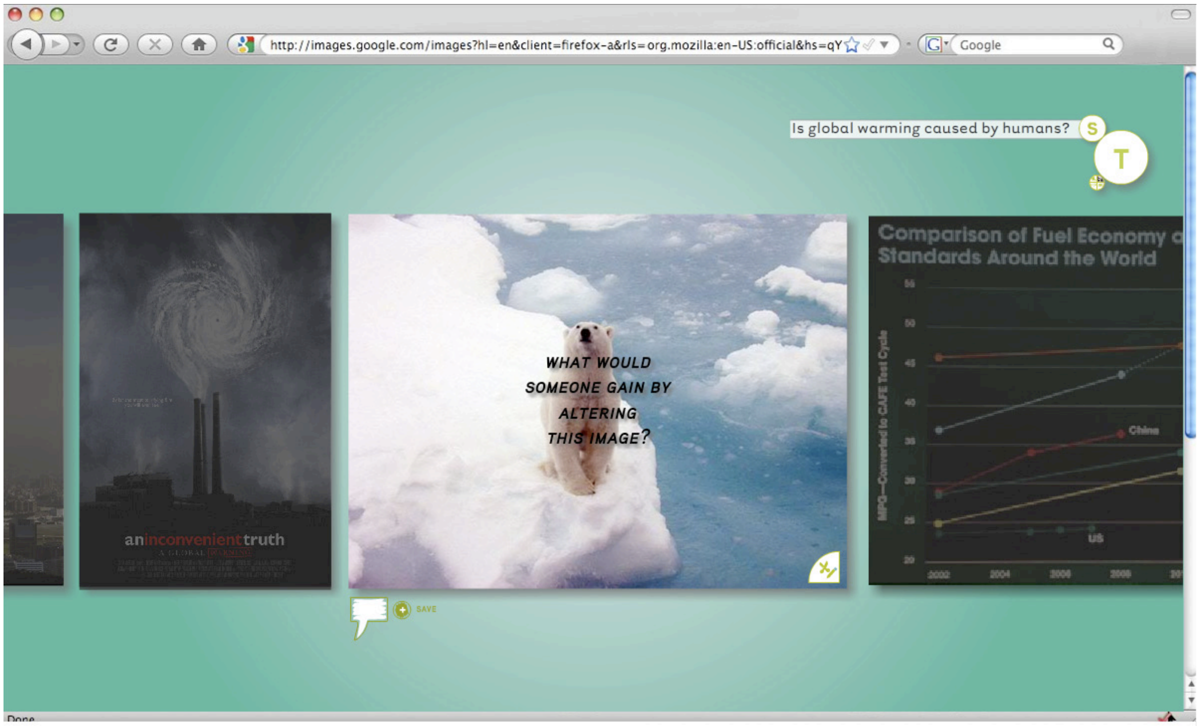

fig 12, prompt for interaction and learning

fig 13, in-depth writing space for teens to construct arguments and add content from their library

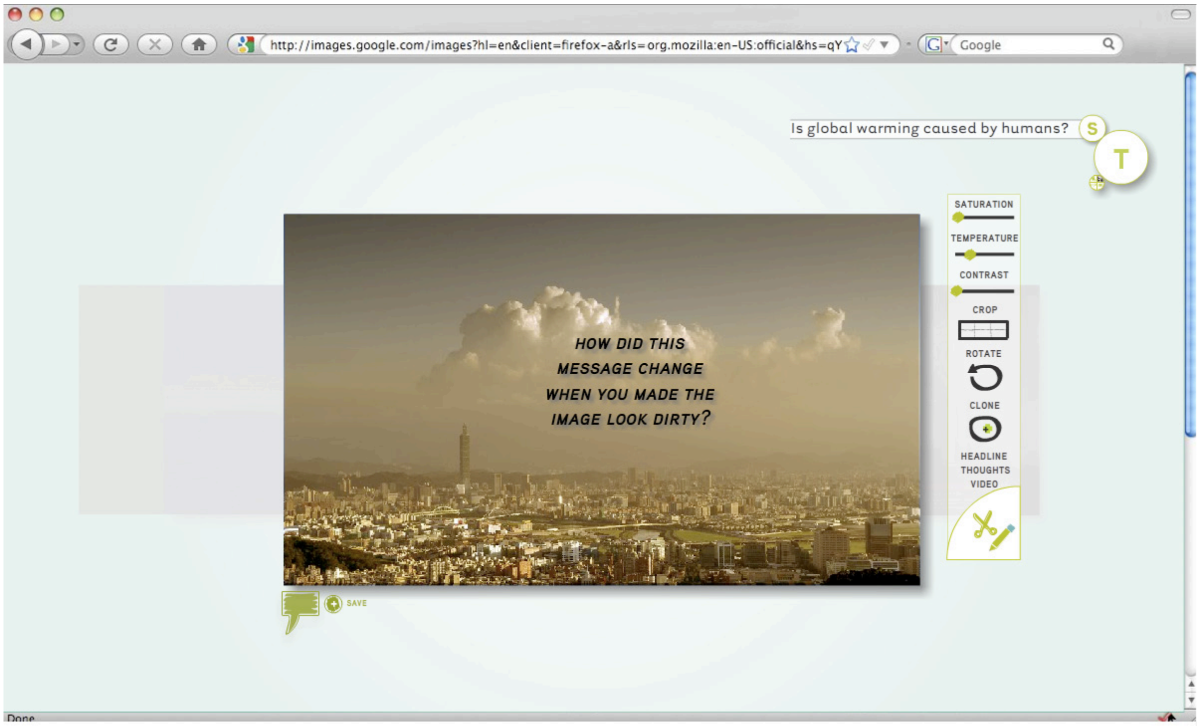

fig 14, questions regarding editing

As Alex continues to scroll through images in her global warming search, she comes to an image of a cityscape. As she rolls over the manipulation tools, a question appears: "How would this message change if you made the image look dirty?". She chooses to adjust the temperature of the image, which makes the scene look polluted. The system then prompts her with another question, "How did this message change when you made the image look dirty?". (figure 14) The goal of active editing is to reveal that images are constructed and easily manipulated.

Alex now chooses to search "domestic violence" and "rihanna." She stops at an image of Rihanna and Chris Brown that she has seen a lot in the news. As Alex hovers over the 'headlines' tool, she is prompted by the question, "How do these headline treatments affect your perception of this photo?" The headline, "Teenage girls stand by their man" from the attached *New York Times* article is presented on top of the image. She has the ability to play with typefaces, positions, angles and colors. Textbooks lack the ability to address such recent cultural occurrences as the Rihanna case that could be teachable moments for teens.

Alex continues and finds a video from the Video Music Awards in which Chris Brown and Rihanna perform a duet. The visual language of this spectacle is seductive, so the system narrows the focus. Alex can explore five formal properties: light, pose, special effects, cropping and props. With a prompt to focus on lighting, Alex continues to watch the video as other images of the couple appear over time. (figure 15, next page) The juxtaposed images are accompanied by textual analysis. The goal is to bring attention to the role that lighting and juxtaposition play.

Alex now searches for information about US presidents. Framing is used in advertising, pop culture and news media. Like most public figures, presidents have teams working for them to ensure that they are posed in a desirable way and surrounded by the necessary props to reinforce their image. Perhaps most importantly, undesirables are excluded from the frame. In her search, the middle image is from a speech given by President Bush at Mt. Rushmore. Upon rollover, she is confronted with user annotations that show alternative framing options, resulting in varied messages.

In scenario three, we address the history and context of images. Two types of history are relevant to this scenario: the way that an image has been used over time; and the context within which an image was created. Continuing

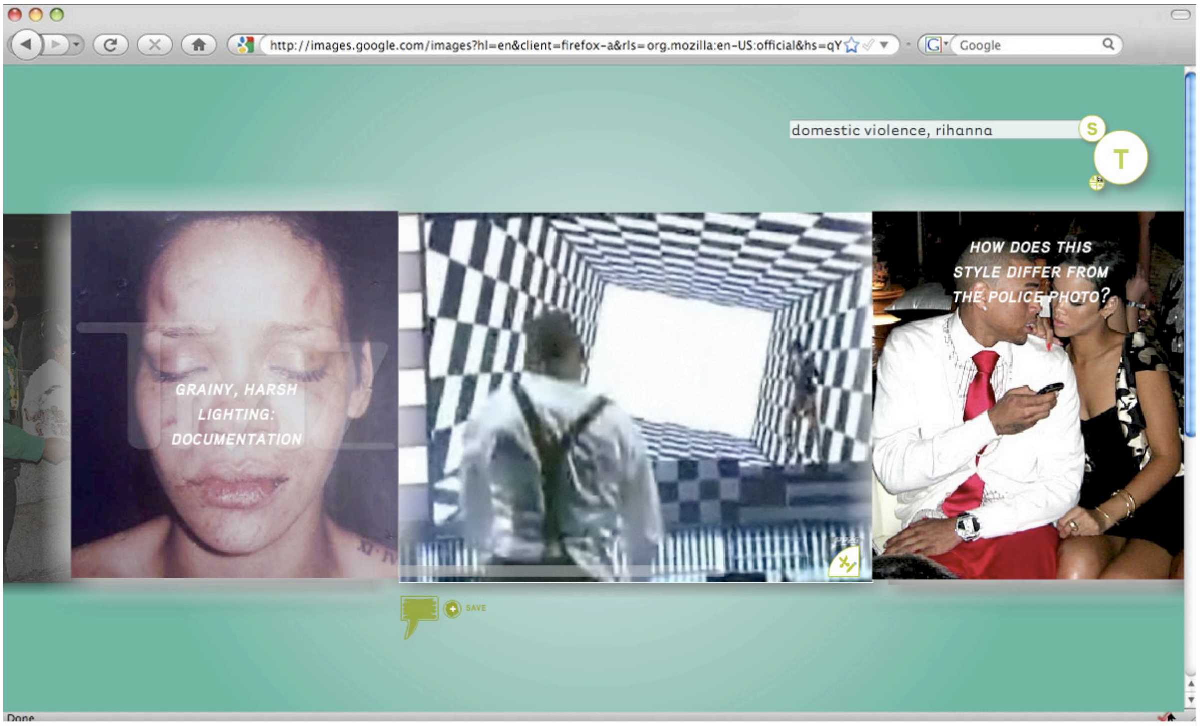

fig 15, textual analysis and questions regarding juxtaposition and lighting

fig 16, framing choices and use in media with her presidential search, *Trust It?* provides Alex with a collection of iconic images, subject matter, locations and dates. (figure 16, previous page) The goal is to reveal the original context by providing a variety of images. Building on the framing tools from scenario two, she may now see how the images were used in newspapers three days later. Alex can zoom out to find a large timeline expanding to the current day, or zoom in to access more information. When she is in the full-timeline view, the system points out significant moments in time regarding the image as well as questions, such as: "Do you know that this image has been used as satire?", "How has this image been used to convey a positive myth?" Through interaction with the images, Alex may gain an understanding of the entire event and see how an image has been used overtime for various ends.

Final Thoughts

As technology becomes less expensive and increasingly more available, graphic design has a great deal to offer the educational landscape. Perspectives are often shaped not by what students read in textbooks, but from what they see and read in the media, even by content their peers create. Designers have a means to create tools, interfaces, and systems that allow the convergence of media content and alternative educational strategies that afford the student endless learning experiences.

We are moving forward with these case studies, developing functional prototypes in order to conduct user testing, classroom trials and in depth analysis.

The ASD Friendly Classroom – Design Complexity, Challenge and Characteristics.

Keith McAllister, Queen's University Belfast, United Kingdom

Abstract

As architects and designers we have a responsibility to provide an inclusive built environment. For the Autistic Spectrum Disorder (ASD) sufferer however, the built environment can be a frightening and confusing place, difficult to negotiate and tolerate. The challenge of integrating more fully into society is denied by an alienating built environment. For ASD pupils in a poorly designed classroom, their environment can distance them from learning. Instead, if more at ease in their surroundings, in an ASD friendly environment, the ASD pupil stands a greater chance of doing better.

This paper sets out the triad of challenges faced by designers when considering the ASD friendly environment and then examines lessons to be learnt from 9 studied ASD friendly classrooms in a Northern Ireland context. The objective is straightforward. By increasing the awareness of the ASD friendly classroom it will hopefully facilitate greater inclusion of the ASD pupil into mainstream education and society at large.

Keywords

Architecture; Autism; Children; Design; School Environment

Autism Spectrum Disorder (ASD) is a term that covers the many sub groups within the spectrum of autism. Autism can be termed as a lifelong complex developmental disorder. It is characterised by a triad of qualitative impairments in social communication, social interaction and social imagination. (Wing & Gould, 1979) In addition to these problems, sufferers often struggle with sensory sensitivity to visual, auditory, tactile, proprioceptive, gustatory and olfactory stimuli. (Hinder 2004) The range of the spectrum is such, that while some sufferers may be able to live relatively independently, others will require lifelong continuous support.

Accordingly, one of the very difficulties for the ASD sufferer can be to simply fee lat ease in their own environment. For such people, the built environment can become difficult, confusing and even threatening. (Grandin, 1995; Harker & King, 2002; Williams 1998)

For architects and designers, this is indeed a stark reality. The architectural profession has long been entrusted with the duty, responsibility and privilege to provide a built environment that will promote well-being, be inclusive and enrich life. By contrast, the disorientation and fear experienced by many ASD sufferers is very far removed from this ideal and greatly distances them from the possibility of feeling the "pleasure and protection when the body discovers its resonance in space." (Pallasmaa, 1996, p.67)

To add to this concern is the fact that recent statistics suggest that the incidence of ASD is on the increase and even growing at alarming levels. The UK National Autistic Society has put the current incidence of ASD at around 1% of the population. In Northern Ireland recent figures match this. In an interview with Martin Clarke, the Principal Educational Psychologist of the Belfast Education and Library Board (personal communication, April 14, 2009), he gave the following statistics. At that time he stated, there were 283,803 pupils between the age of 5 and 16 in Northern Ireland. Of these, 1.2 % had a diagnosis of ASD. 63% were educated in mainstream schools, 16% in special schools and 21% in special language, learning disorder and autism support units.

Despite this, ASD has so far, been largely ignored by the architectural profession. In the UK there are no specific guidelines when considering ASD. Those guidelines that do make mention of ASD, tend to do so in general terms only and in less detail than other learning difficulties and special needs. With regard to the school environment, the 2005 publication *Evaluating Provision for Autistic Spectrum Disorders in Schools,* co-authored by the Department of Education in Northern Ireland and the equivalent An Roinn Oideachais in the Republic of Ireland outlines three-performance indicators for consideration. These are that,

1 The learning environment is supportive of the child with autism: lighting, sound and colouring are sufficient to encourage the child to relax and settle to work.

2 There is sufficient personal space for the child with autism to find comfort and to distress when necessary.

3 The learning environment contains areas of high interest to reflect the particular interests of the child with autism.

Similarly the recently 2009 published UK government Building Bulletin 102 (BB102) *Designing for disabled children and children with special educational needs,* lists the design issues for children with ASD as;

> Simple layout: calm, ordered, low stimulus spaces, no confusing large spaces; indirect lighting, no glare, subdued colours; good acoustics, avoiding sudden / background noise; robust materials, tamper-proof elements and concealed services; possibly H&S risk assessments; safe indoor and outdoor places for withdrawal and to calm down. (DfEE, 2009, p.199)

The widespread exclusion from, or when included, the general nature of the design considerations listed in the current guidelines is in no doubt due to the difficulties and challenges presented when dealing with a spectrum of disorders. (Khare & Mullick, 2008; Mostafa, 2008; Young, 2004). Not only may sufferers exhibit different sensitivities and personal difficulties, the severity of these too can vary. In effect, the design parameters are fluid and variable. There is of course the danger when dealing with autism, that prescriptive design guidelines or single rules will not take into account variations among sufferers and their different levels of ability. Therefore, the challenge is both complex and difficult. But the need to confront these difficulties is huge. This, it could be argued, is especially true in a school setting. Feeling ill at ease in the classroom environment can hamper learning, thereby further alienating the ASD sufferer in society.

Design Complexity and Challenge

With regard to the classroom (environment), the ASD suffer and writer Donna Williams outlined her ideal environment as;

> ..one where the room has very little echo or reflective light, where the lighting was soft and glowing and upward projecting rather than downward projecting lighting. It would be one where the physical arrangements of things in the room was cognitively ordered and didn't alter and where everything in the room remained within routine defined areas. It would be an environment where only what was necessary to learning was on display and there were no unnecessary decorations or potential distractions. It would be one where nobody unexpected would enter without everyone getting a cue and processing time to expect the change. (Williams, 1996, p.284)

This description helps illustrate the many concerns the writer had when at school. She makes the case for constancy, structure, with neither the unexpected nor superfluous. In many ways, Donna Williams is advocating a potential solution for classroom design for the ASD pupil. If designing for the 'worst case scenario' then all children would be catered for on the autistic spectrum. Why not have a classroom environment that is totally calm, quiet, without distraction and enclosed from external influences. Would that not constitute an inclusive design solution?

However if we consider inclusive design as ***better design*** this is not the case. The classroom is a learning environment for life, a place of preparation for the challenges and negotiations we all face in our everyday life. Cocooning the ASD pupil from all external factors will not necessarily help them reach their full potential in life. Maximising a pupil's ability to cope with change and external factors is an important and vital consideration for teachers in the ASD classroom.

Therein lies the most difficult challenge for the designer when dealing with the ASD pupil in the classroom – that of trying to provide an environment where change can be introduced, where the ASD pupil can be challenged, encouraged and supported to maximise their potential. Dominic Cullinan, makes this point stating;

> A recent seminar for teachers at the Institute of Education, looking at the relationship between buildings and behaviour, explored the idea of designing spaces specifically for children with autism. Underlying the discussion was the belief that certain criteria could hold true; setting a desk facing a blank white wall, for example, might give the child the visual calm they need for concentration. However, it was also argued that such spaces do not help the child learn to live in the world at large. This refinement neither helps the child to cope, nor those who support them. (Cullinan, 2009, p.51)

So in effect, just as the ASD sufferer has a triad of impairments to contend with, so too do we as designers, have a ***triad of challenges*** to overcome. Not only are there the challenges firstly of the differing severity of the autism inherent within the spectrum and secondly the varying and differing range of sensory difficulties of individual ASD sufferers to contend with, there is the third difficulty in the classroom setting to consider – how best to promote and bring change and subsequent independence for the ASD pupil in that environment. Overcoming the triad of challenges for designers will hopefully then allow, in a school setting, the design of the best possible and most appropriate learning environment that will aid in pupil performance. With increased pupil performance and corresponding ability to cope with the challenges of their environment, the ASD pupil is more likely to manage to integrate more fully into mainstream education and society in general.

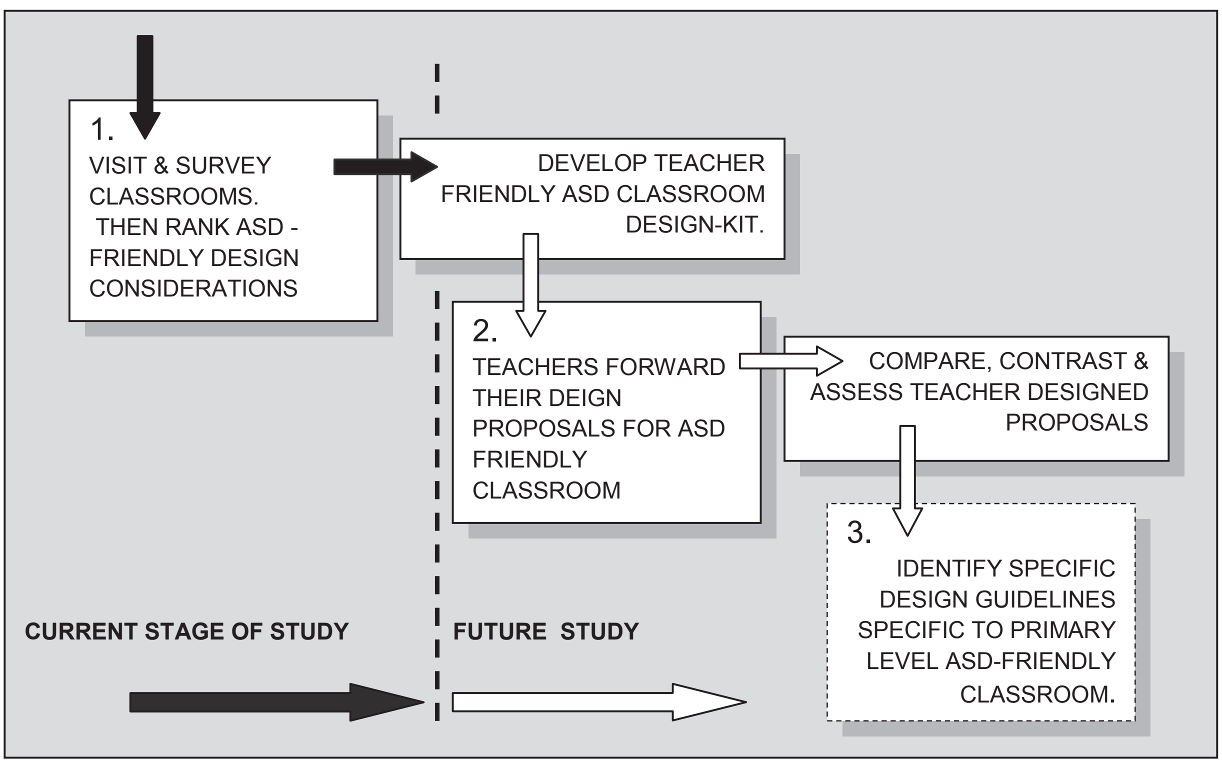
The Study

There is widespread consensus that an appropriate classroom environment will aid the performance of the ASD pupil. (Khare & Mullick, 2008; Whitehurst, 2006a) Therefore, this study seeks to identify what environmental factors and considerations contribute most to the ASD friendly classroom. It will be carried out in two stages. In this the first stage, 9 ASD friendly classrooms were visited, surveyed and the teaching staff asked to rank and give consideration to a number of autism friendly design criteria for the classroom. It is these results that are represented in this paper.

This, the first stage of the study, will then be followed by a future second stage where the teaching staff will be asked to design their ideal ASD friendly classroom environment. This will be in an attempt to further evaluate the environmental and built design considerations in an ASD friendly learning environment.

Ultimately it is hoped that this will then facilitate a third stage when ASD-friendly guidelines and design considerations specific to the primary level classroom will be developed.

Table 1 – Proposed Study Stages



In 2005, as a response to the report *Evaluating Provision for Autistic Spectrum Disorders in Schools*, (DoE(NI) 2005), the Northern Ireland Southern Education and Library Board (SELB) implemented as scheme where existing school accommodation in ten different schools would be converted and refurbished into ten ASD friendly classrooms. The SELB is currently one of 5 Education and Library Boards covering Northern Ireland. It spans 1,450 square miles and is responsible for providing education for 75,000 pupils in an overall population of 322,000 residents in its area. Refurbishment and conversion of the classrooms took place in 2005 and 2006.

This means that after three or four years working experience in the classrooms, the teaching staff have had time to formulate their opinions and evaluate the effectiveness of the interventions. All ten of the class refurbishments were carried out in mainstream schools, nine at the Key Stage 1 level (age 5 – 8) and one at Key Stage 3 level (age 12-16). Moreover because the conversions to ASD friendly classrooms were taking place in existing accommodation and were not new build solutions, it afforded the opportunity to better understand what worked and what did not work since, by their very nature, the refurbishments and conversions were in some ways constrained by existing the structure and fabric of the former accommodation. Also, because 8 of the 10 conversions were done in previously used mainstream classrooms, it might facilitate with the consideration of transfer of ASD friendly criteria into the mainstream classroom. If this was the case, it might aid in ASD pupil integration or transfer into the mainstream classroom.

To compose a set of criteria for the ASD friendly classroom teachers to rank, existing available literature was appraised (Harker & King 2002, Humphreys 2005, Whitehurst 2006, Mostafa 2008, Vogel 2008,) 16 design criteria for ranking were then compiled These consisted of combining the 8 considerations detailed by Vogel (2008) in *Classroom Design for Living and Learning with Autism,* with 8 of the less classroom specific criteria suggested for consideration by Humphreys in *Autism & Architecture* (2005). For purposes of comparison and understanding afterwards, the 16 chosen criteria were broken down into four category bands – control and safety, classroom character, classroom usage and classroom physical factors. These are listed below in Table 2. To allow further analysis, a checklist of factors was also developed, based largely on Tufvesson & Tufvesson (2007) and used to gain a greater understanding of each classroom environment visited. This is shown in Table 3.

It was decided at an early stage not to interview the children, but instead the teachers. This was done for three reasons:

1. As commonly noted (Khare & Mullick, 2008;Tufvesson & Tufvesson, 2007, Woodcock, Georgiou, Jackson & Woolner, n.d.), because of their disability, ASD-suffers can find it hard to communicate freely.
2. The age of the majority of the children, 5 to 8 years old, would render objectivity extremely difficult, and
3. As noted by Whitehurst (2006b) – environments designed for the ASD sufferer not only impact upon the sufferer but also for the teacher / carer. An environment where staff too can feel at ease is extremely important. That too can have a profound effect on the ASD

sufferer. As highlighted by Plimley (2004), autism friendliness is a combination of both a human component and the built environment.

Staff were asked to score each of the chosen sixteen classroom criteria in terms of importance from 1 (low) to 5 (high). All classrooms were visited at the end of the day when the children had left for home. On each occasion, when asking the teachers to score the classroom criteria, the order of the criteria for consideration was randomly selected.

Table 2 – Design Criteria for ASD friendly classroom. (H -after Humpreys, V after Vogel)

		Classroom Criteria	**Brief Description**
CONTROL & SAFETY	H	CONTAINMENT	Secure boundaries to stop the child running off or getting lost.
	H	GOOD OBSERVATION	To put staff and helpers at rest without infringing upon pupil's space.
	V	SAFE	Both in terms of physical and emotional safety. ADS-children commonly have little concept of danger.
	V	NON-THREATENING	A restful and secure setting to help foster encounters and relationships.
CLASSROOM CHARACTER	H	SENSE OF CALM + ORDER	Complexity can cause stress. For the ASD sufferer, this can be especially upsetting and confusing.
	H	GOOD PROPORTION	Might the sensory sensitive ASD sufferer find well proportioned space inherently more comfortable.
	V	NON-DISTRACTING	To decrease the chance of sensory overload for the ASD pupil.
	H	PROXEMICS (PERSONAL SPACE)	Many ASD sufferers need more 'personal space' around them or they can feel threatened.
CLASS USAGE	V	FLEXIBLE + ADAPTABLE	An ability to adjust the classroom to suit the ASD pupil's needs
	V	CONTROLLABLE (FOR PUPIL)	A degree of choice for the child to help promote independence
	V	PREDICTABLE	Clearly legible for the ASD pupil who is often reliant upon visual cues.
	V	NON-INSTITUTIONAL	Not sterile but welcoming and comfortable. A place where the ASD pupil can relax.
PHYSICAL FACTORS	V	SENSORY-MOTOR ATTUNED	Providing a range of sensory experiences in the classroom
	H	GOOD QUALITY ACCOUSTICS	Many ASD sufferers can be sensitive to noise and find it difficult to differentiate between different sounds.
	H	NATURAL LIGHT	The use of natural daylight in preference to artificial lighting.
	H	REDUCTION IN DETAIL	Both in terms of reduction in detail and palette of materials. ASD sufferers can get absorbed in minutia.

Table 3 – Survey Checklist for Classroom Visit

CLASSROOM		**PHYSICAL FACTORS**		**INTERIOR**	
	LENGTH	**VIEW**	BACKGROUND		PLANTS
	WIDTH		BUILDINGS		AQUARIUM
	SHAPE		GREENERY		QUIET SPACE
	HEIGHT		SKY		SENSORY SPACE
	No. of DOORS		PLAYGROUND		COMPUTER(S)
	No. of WINDOWS		NO VIEW		WALL DECORATION
	% OF GLAZING				SHELF STORAGE
	ORIENTATION	**NOISE**	INFILTRATION		BOX STORAGE
			EXTERNAL		CUPBOARDS
FINISHES	FLOORING		BACKGROUND		COLOUR
	HEATING	**LIGHT**	SUNLIGHT	**EXTERNAL**	
	CEILING		DAYLIGHT		
	LIGHTING		ARTIFICIAL LIGHT		ACCESS ARRANGEMENTS
		SENSES	SMELL		PLAYGROUND
WINDOWS	CURTAINS		TEXTURES		DINING
	BLINDS		PATTERNS		GARDEN
PLUS	NUMBER OF STAFFIN CLASSROOM – TEACHERS & CLASSROOM ASSISTANTS				
	NUMBER AND AGES OF CHILDREN IN CLASS				
	TEACHING METHODS EMPLOYED – ONE TO ONE; GROUP; BOTH				
	POSITION OF CLASSROOM IN RELATION TO REST OF SCHOOL				
	WC PROVISION FOR CHILDREN				
	PREVIOUS USE OF ASD FRIENDLY CLASSROOM				
	ANY SHARED CLASSES WITH THE REST OF SCHOOL				

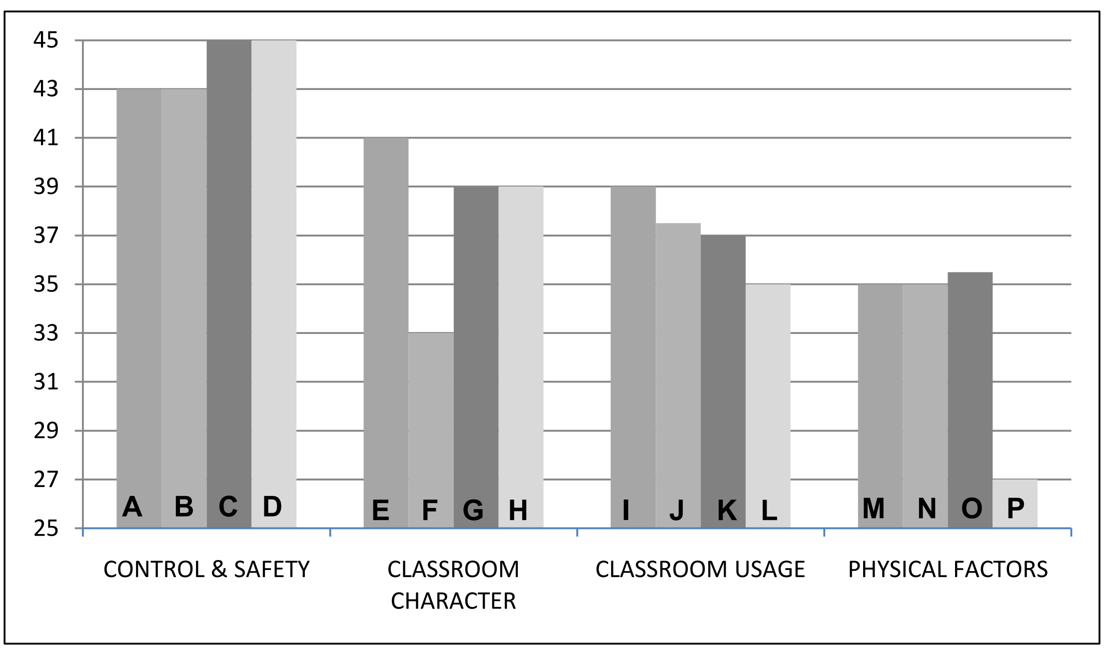
The Study Results

Between November 2009 and January 2010, nine of the ten ASD friendly classrooms in the SELB region were visited and their staff interviewed. Interview results were recorded and then combined together under the headings of the sixteen ASD friendly classroom criteria. The results are shown below in Tables 04 and 05. The results will now be further expanded in turn under the four category headings of control and safety, classroom character, classroom usage and physical factors.

Table 4 – Ranking Scores for ASD Friendly Classroom Criteria.

	Classroom Criteria	Score (out of a possible 45)
Control & Safety	**A.** CONTAINMENT	43
	B. GOOD OBSERVATION	43
	C. SAFE	45
	D. NON-THREATENING	45
Classroom Character	**E.** SENSE OF CALM + ORDER	41
	F. GOOD PROPORTION	33
	G. NON-DISTRACTING	39
	H. PROXEMICS	39
Classroom Usage	**I.** FLEXIBLE + ADAPTABLE	39
	J. CONTROLABLE	37.5
	K. PREDICATABLE	37
	L. NON-INSTITUTIONAL	35
Physical Factors	**M.** SENSORY-MOTOR ATTUNED	35
	N. GOOD QUALITY ACCOUSTICS	35
	O. NATURAL LIGHT	35.5
	P. REDUCTION IN DETAIL	27

Table 5– Bar Chart of Ranking Scores for ASD Friendly Classroom Criteria.



Factors of Control and Safety

Perhaps unsurprisingly, it was the criteria concerned with pupil safety and teacher control that scored most heavily in terms of importance overall. Regarding pupil safety, it was stressed that sharp edges and angles should if at all possible be avoided in the classroom. Climbing opportunities should be limited - bookcases, shelving and radiators are all likely candidates for climbing opportunities. The bookcases and units favoured by staff to sub-divide the classroom into different zones are potentially troublesome in this regard.

To aid with containment, most doors in and out of the classrooms were fitted with double handles, one at normal height and one at high level out of the reach of the children. Both had to be turned for the door to open. Of the 9 classrooms surveyed, 7 had direct access to adjoining WC facilities. For the 2 that did not, it meant staff had to leave the classroom to accompany the pupil to the WC. This was seen as a major disadvantage. A clear benefit liked by the staff where in operation, was direct access to a secure external play area. This could be used as a reward, as an incentive, for external teaching or for pupils unwilling to join larger numbers in the school playgrounds. It was also stressed that accessing playgrounds was best done over a small distance and that at all times the playground must be secure.

The importance of pupil observation was stressed. This was not only to help evaluation of the child in the classroom but also to prevent any pupil 'meltdowns' if the pupil was growing agitated or distressed. To this end, 2 of the classrooms visited had their quiet withdrawal space actually in the classroom, separated from the teaching and play spaces by fixed 1450mm high partitions behind which the children could withdraw into tents or fabric tunnels. Separate quiet areas accessed directly off the classroom commonly had glazed vision panels into them.

To aid with a non-threatening environment, easy access for the pupils to their visual timetables was stressed as essential. To facilitate with this it was preferred if possible that a separate cloakroom area outside the classroom or in the classroom if space allowed, be provided. Having the cloakroom area in a main corridor outside the classroom was not felt to helpful – ASD pupils benefit from 'transitional space.' This is very true for the transition from the hustle and bustle of the school circulation space into the classroom itself. In this regard, a well considered cloakroom area for coat and shoe storage can help.

Factors of Classroom Character

Regarding the character of the classroom, having an environment of calm, order and simplicity was ranked highest. (see Table 3) This was felt by staff to be most critical around the children's individual workstations when demands upon concentration would be highest. There, pupils have screened, separate cubicle-like workstations with minimal possible visual distraction. When able to cope in that environment, pupils would then be encouraged to work alone at a desk and if able to cope with that over time, would be encouraged to work at a group desk or table. To aid in this, a clear structure within the classroom is important.

The importance of having a non-distracting environment varied dependent upon what areas of the class were being considered. In the pupils' workstations, it was considered vital, less so in other areas. What was consistent however were the similar comments regarding what was most difficult for staff to combat in terms of visual distraction in the classroom. The necessary flexibility of being able to move or screen off the visually distracting computer(s) in each room was not possible with the fixed surface mounted radiators and pipes occurring in 8/9 of the classrooms. Even worse was the one instance where the classroom was fitted with recessed blow heaters. These proved to be both noisy and uncomfortable to be near. Furthermore, the grills provide an opportunity for the pupils to play with them.

The distractions of views-out were best dealt by having blinds or curtains in the classroom. Two of the classrooms kept the blinds closed at all time being described by one teacher as ‘the only way.’ Others closed the blinds when necessary. What was clear was that if low level curtains or blinds were closed, staff in classrooms with high-level clerestory glazing really appreciated having a visual connection to the exterior and the natural daylight that brought. However, orientation of windows was also a factor as direct sunlight entering the classroom was problematic.

The need for the pupils to have extra personal space in comparison to other pupils was recognised. To this end the maximum number of ASD pupils in each classroom was eight. One teacher and two classroom assistants accompanied this.

Less important to the staff was the concept of proportion. This is due in part to its very qualitative and subjective nature. Interestingly, the teachers whose ASD classroom had previously been diagnostic and learning disorder accommodation and therefore consisted of a collections of rooms of differing sizes rather than one primary classroom, reported that the children’s behaviour was different in different room volumes – the children tended to be calmer in smaller rooms. This is an observation shared by Myler, Fantacone & Merritt. (2003) Similarly in the one classroom of differing ceiling heights where the ASD classroom was a combination of former 2350mm high flat ceiling circulation space and a mono-pitched sloped classroom rising from 2670 mm to 4930 mm, the teacher reported that the pupils felt more comfortable in the lower ceiling area (whereas for the staff the opposite is true!)

Factors of Classroom Usage

Concerning the usage of the classroom, the two most common topics of concern for staff were storage and flexibility of classroom layout. The classrooms that were visited were sub-divided into different teaching zones such as work, group, play, computer, reading and story-telling areas. This was commonly done by using screens or shelving and storage units. Having a number of these on lockable castors was of great benefit in quickly changing the classroom layout to suit different needs and also bring change into the classroom. The one major variant from this came from the staff of the one converted Key Stage 03 classroom. Here when dealing with older children and especially boys between the ages of 12 and 16 rather than the 5 to 8 year olds of the other classes, the staff were adamant that furniture needed to be fixed and secured to the floor to prevent the possibility of it being thrown by an upset, physically stronger pupil.

In every classroom, the staff stated that they did not have enough storage. This might well be a complaint from most teachers but in the ASD friendly classroom it can be very significant. Firstly there is the huge range of non-standard equipment used by the pupils. This can include bulky equipment used in occupational therapy sessions or in individual lesson plans. Secondly, clutter can of course be potentially distracting and tempting to the pupil to access it when not appropriate. It is much better for the staff to have adequate storage so that they can decide what to bring out and when to put on display, again responding to the pupils' needs. This then overlaps with giving the pupils a degree of control in the classroom, important when trying to encourage pupil independence. Having some open shelves or accessible drawers and cupboards can help foster this, if considered appropriate by the staff.

Factors of Classroom Physical Factors

Physical Attributes within the classroom were thought by the staff to be the elements that the pupils could with help and time, come to terms with. Accordingly, they were ranked as the least important design considerations in the classroom. Having good levels of natural daylight in the classroom was popular. However what was raised by staff as a more important issue was the quality and type of artificial light in use. This was especially important if the blinds or curtains were closed. In 8/9 classrooms, the lighting was supplied via fluorescent strip lighting with diffusers to minimise flicker while the other class (in the most recently built school) was fitted with spotlights. In all cases, staff favoured variable lighting rather than the constancy achieved by the lighting systems currently in use. Dimmable lighting, separate lighting circuits and a range of task lighting as alternatives were all suggested by staff. In fact, in some of the classrooms, the staff themselves were using personally supplied free standing task and mood lighting to add contrast to the classroom.

Regarding acoustics, it was noted by all staff that background and infiltrating noise could be distracting for the pupils. However it was also explained that different types of noise could have different levels of impact. For instance, distant passing traffic (especially the sirens of emergency vehicles) could grab a pupil's attention for a short time, as would grass cutting or hedge trimming. However, this was part of everyday life. More problematic was sound infiltration from nearly music classrooms, playgrounds, sports halls or nearby corridors where noise might not only be prolonged but could also vary suddenly in volume. In this regard, the positioning of the ASD friendly classroom within a mainstream school can be an important initial consideration.

Considering sensory-attuned features, the main factor that all staff stressed was the need to have an immediately accessible quiet withdrawal space for the pupils to use if getting distressed or needing to 'recharge their batteries'. These ranged from converted small stores off the classroom, space under an adjoining staircase to the partitioned areas in the class. The two classrooms who did not have these reported it as a major negative. In one case this was because the school had converted their quiet room into a sensory room, something they now in retrospect wish they had not done. This is because a distressed pupil might be agitated and run the risk of hurting themselves on some of the installed lighting and sensory equipment. In the second example, the quiet area was not accessed directly off the classroom, instead via an adjoining link corridor. Therefore the pupil had to be accompanied to the quiet area out of the classroom. All staff expressed the view that they felt the quiet area was more important than the sensory area – the latter was more of a luxury whereas the quiet area was absolutely essential. If needed, staff suggested, if finances allow portable sensory equipment could be set up in a play tent or part of the classroom if required.

Of all the factors considered, it was the minimal detailing in the classroom that was ranked as the least important by the staff. In all the classrooms, the floor covering was a mixture of carpet and slip-resistant vinyl. These tended to be single colours. Geometrical patterns, because of their distracting qualities, always avoided. Walls were painted in 8/9 classrooms, usually muted colours and then used as a backdrop for pupil's work and occasional notice-boards. Having the children's work on view was thought to be very important by the staff as the pupils derived great pleasure from seeing their work exhibited. In the one remaining classroom the internal walls were not painted plaster but instead (as was the case in the majority of classrooms throughout the school) exposed brickwork, this was problematic. The teacher felt the brickwork would be better painted because the multi coloured natured of the brickwork was a distraction for the pupils. Finally, with regard the ceilings in the classrooms that did not seem to be an issue, these either smooth-finish painted plaster or suspended ceiling tiles. The latter were sometimes popular with staff because it allowed them to hang occasional displays easily from the ceiling.

In all cases, staff felt it important that the detailing and finishes in the ASD friendly classroom be as much like the mainstream classroom as possible in order to facilitate into it by the ASD pupil. In short, because the mainstream class had painted walls, work and notice-boards on show, with specific floor and ceiling finishes, as far as possible, so too should the ASD friendly classroom.

Conclusion

It should be stressed in concluding that it is important that not only architects and designers make the decisions for ASD friendly environments, but instead listen to teachers, educational psychologists, therapists, parents and if possible the ASD sufferers themselves. The built environment needs to be more inclusive, particularly when considering the needs of the ASD sufferer. Similarly, the ASD classroom is only one component of promoting integration of the ASD pupil into the mainstream school. The relationship of the ASD classroom within the school is one that needs consideration. The importance of not building something in isolation but 'also repairing the world around it' in order to make the whole more coherent is eloquently made by Alexander (1977, p. xiii)

Both the human and built environment interactions with the ASD pupil can make a meaningful difference. The classroom is an important environment. As the place where learning takes place, it needs to be considered very carefully. It is the environment where progression from more sheltered and protective surroundings can be, with help, peeled away gradually introducing the ASD pupil to greater challenges. This process can be further enhanced by using the school at large, where the ASD pupil can mix with their mainstream colleagues in shared playgrounds, sports, dining and class activities.

But it needs to start with the classroom itself. There, pupil safety and teacher control cannot be compromised. The class needs to be flexible whilst having a sense of calm and order. It is important to recognise the need for additional area in space allocations, both for storage and pupil personal space. Directly off the classroom, WC's and a quiet withdrawal space should be provided. There are benefits to be derived from direct access to an external secure play area. If the classroom is structured into different zones, different qualities of lighting should reflect this. (Beaver, 2006) High level clerestorey glazing is advantageous when curtains and blinds often need to be closed. Under-floor heating would do away with the need for surface mounted heating. Giving careful consideration to the position of the ASD classroom within the overall school could help nullify the effects of auditory distractions from music, external play and sports.

Conflicts are inevitable, but the potential rewards of initiating genuine change for the better are huge. Well considered and designed ASD classroom spaces can be creative and genuine 'environments for learning.' (Scott, 2009; Vogel, 2008). Recognising the design complexity and challenges involved when considering the ASD friendly classroom is the important first step to towards providing a better learning environment for the ASD pupil.

Author Biography

Keith McAllister BSc(Hons) BArch (Dist) RIBA FHEA.

Keith McAllister is a Chartered Architect and Lecturer in Architecture at Queen's University Belfast. As the Stage 02 Co-ordinator, he has a deep interest in promoting the design process, an understanding of context and exploration of spatial progression for students in the design studio. His current research projects include Architecture and Autism, Architecture and Special Needs and the promotion of Architecture in the School Classroom. He has practiced architecture in Russia, Italy and the UK and is the extremely proud father of an autistic son.

Collaborative Design Pedagogy: An Examination of the Four Levels of Collaboration

K. Thomas McPeek, Ph.D., Assistant Professor, School of Architecture, Southern Illinois University at Carbondale, Carbondale, IL, USA

Laura Morthland, NCIDQ, Assistant Professor, School of Architecture, Southern Illinois University at Carbondale, Carbondale, IL, USA

Abstract

This paper reexamines research conducted with more than a dozen authorities in architectural education on collaborative methodologies over a three year period. The focus of initial study, a doctoral dissertation entitled: Collaborative Design Pedagogy: A Naturalistic Inquiry of Architectural Education (McPeek, 2009), examined the apparent disparity existent between the practicing profession of architecture and the academic preparation of its future members. In this paper, a condensed examination of specific findings from the previous data set point to four key levels of pedagogical collaboration (community, institution, faculty, and student) that are critical components to the implementation of collaborative architectural curriculum. These levels contain both inhibiting and facilitating elements that appear in all types of higher educational institutions (public, private, liberal arts schools, land grant universities, etc) and in varied curriculum settings. Thus, while the authors' main emphasis lies in enhancing the pedagogical scope of architectural education, this data may also be pivotal in facilitating and/or inhibiting collaborative endeavors in any major field of study, particularly those which incorporate collaborative methods in the context of situated learning.

Architecture; Collaboration; Pedagogy; Cross-disciplinary; Trans-disciplinary; Multidisciplinary; Interdisciplinarity; Intradisciplinary

Background & Purpose

The research presented in this paper is based on original work conducted by McPeek from 2003 to 2009 which resulted in the completion of a dissertation entitled; Collaborative Design Pedagogy: A Naturalistic Inquiry of Architectural Education (McPeek, 2009). The focus of the initial study was to examine the apparent disparity existent between the practicing profession of architecture and the academic preparation of its future members.

> Historically, the education of an architect has been a highly individualized pursuit, focused on the development of an individual skill-set (Boyer and Mitgang, 1996) that seldom required collaboration beyond that of student and professor. While this individualized, hands on approach to education has been highly revered by many (Cossentino, 2002; Shaffer, 2003; Kuhn, 2001) it often falls short of its potential and fails to recognize that the greatest design accomplishments of humankind have been the undertaking of collaborative enterprise (Bennis and Biederman, 1997). Furthermore, architecture students are being prepared in a manner that is contrary to the highly collaborative nature of the architectural practice they will enter (Crosbie, 1995) (McPeek, 2009, pg 3).

This paper examines, in specific, the portion of research which highlights critical factors (inhibiting and facilitating) which can impact the implementation of collaborative teaching within American schools of architecture by focusing on four key levels of collaboration (community, institution, faculty, and student) that exist in American universities, both public and private. The purpose of this condensed examination is to provide a platform for discussion and ideation regarding the implementation (and support) of collaborative pedagogy. While the authors' main emphasis lies in enhancing the pedagogical scope of architectural education, it is important to understand the role that the four levels of collaboration (community, institution, faculty, and student) play in facilitating and/or inhibiting collaborative endeavor.

Methodology

The research analyzed within this paper is based on a series of interviews conducted by McPeek over a three year period with several leading architectural educators. Participants were selected based on published academic literature as well as personal referrals. Interviewee's included past and present deans, department heads, and professors of all rank. Although a variety of institutions (public, private, liberal arts schools, land grant universities, etc) are represented within the data, interviews were limited to participants employed by schools of architecture with full member status in the Association of Collegiate Schools of Architecture [ACSA]. The only exception to this standard was the inclusion of interview responses from a limited number of associated research professionals employed outside of ACSA member institutions.

The data collected and cataloged was based on qualitative research via naturalistic inquiry techniques. These techniques were based on a variant of Rubin's (2004) outlined methods and followed the format known as "Ethnographic Interpretation." This method was particularly well suited for the one-on-one interaction and dialogue desired for study. Although the data was derived from independent and unique conversations, each discussion followed a standardized interview guide which sought to identify key norms, rules, values, and traditions commonly associated with collaborative teaching and learning in architectural education (McPeek, 2009). It is important to note that in order to ensure confidentiality and enhance candid dialog, all of the quoted participants have been given pseudonyms to protect personal and institutional identity.

Overview of Findings

The findings of the original research were categorized into five general themes: Levels of Collaboration, The Role of Collaborative Pedagogy, The Collaborative Skill Set, Implementation of Collaborative Methodologies and Collaboration in the Design Studio (McPeek, 2009). Collectively, these themes provided a basis for outlining impacts to collaborative design pedagogy in architectural education. However, throughout the course of interviews, respondents engaged in consistent discussion centered around four key groups: community, institution, faculty, & student. Each of these groups (while at times inherently interrelated) brought forth a variety of distinct factors impacting the success, or failure, of collaborative architectural education.

The community

Service to the community is a central focus for many schools of architecture across the United States and there are numerous examples of architectural programs actively engaged with their communities. Some higher profile examples include The Studio at Large (Palleroni and Merkelbach, 2004) out of the University of Washington and The Rural Studio (Oppenheimer-Dean and Hursley, 1998, 2002) at Auburn University. Collaborative community based projects tend to focus primarily on working with groups who often lack funding for, or access to, architectural services. Groups such as Habitat for Humanity, Native American tribal communities, the local farmers market, and outreach programs for disadvantaged youth were all cited by respondents in the initial research as examples of collaborative partners at the community level. Respondents overwhelming emphasized the importance of community involvement in the collaborative educational process. In particular, respondents felt that student interaction within the community yielded a greater awareness regarding the importance of shared ideas. "I think another important dimension to this is the discovery that others pull, insights and wisdom and other points of view, that we don't hold as individuals" (Thompson, 2005 as cited in McPeek, 2009, pg. 91). Respondents also concluded that creating a foundational attitude and basic skill set of community collaboration during formative academic years was critical to future professional attitudes. "As future professionals, they're involvement with the community, it starts here. Because if it doesn't start here, it doesn't happen…" (Connors, 2005 as cited in McPeek, 2009, pg 90).

However, a critical factor involved in collaboration at the level of community is that of preconceptions (or even simply, personal perceptions). Even the most well intentioned collaborative efforts can be stymied if the participants involved are not alert to the potential motivators (culture, economic, religious, political, linguistic, etc) that impact participants from all sides.

> …we decided by working with the Singapore, we thought that we would kind of erase these kinds of cultural differences that would exist…And Singapore having this kind of large Chinese population, and Hong Kong, again, being Chinese, we thought that we would have some kind of cultural thinking so to speak, and that they would be in tune…actually, what we have discovered is there are huge cultural differences, and all sorts of misunderstandings that took place during that semester (Jones, 2005 as cited in McPeek, 2009, pg 117).

Unlike the traditionally fictitious, individually competed architectural academic projects, community collaboration often involves real life scenarios with real life participants. Thus, while educationally vital and foundational, such projects must be executed with extreme care due to the high potential for causing misunderstanding and genuine harm.

The institution

At the level of institution, respondents spoke of interaction between their respective academic units (University, College, School, and Department) and the internal intellectual community in which they served. Shared experiences associated with collaboration between units on a campus highlighted the role that institutional and departmental structures play in either facilitating or inhibiting the collaborative educational process. In particular, financial pressures and course structure were often cited as critical factors. "We are a much more integrated, interdisciplinary in research than we are in instruction, and that's largely because of the centers and the fact that there still are powerful incentives for people to collaborate which basically is money." (Connors, 2005 as cited in McPeek, 2009, pg 96). As institutions face growing demands to increase revenue streams beyond state appropriations or the individual donor level the focus shifts to financial gains found through research grants. However, the fiscal emphasis on collaborative interdisciplinary research often fails to include teaching. This is because interdisciplinary teaching is often viewed as a potential expense and/or resource drain, rather than a strong source of financial expansion. "…whenever an administrator speaks to unifying and collaborating and going across to institutes across campus or whatever the complexity begins, who should use the resources…" (Smith, 2004 as cited in McPeek, 2009, pg 97). This struggle over division of resources is particularly acute when examined in terms of distributing academic credits.

> You're work in the university, so you know that if you were to teach a class with a colleague from another department, the immediate question that you will get from the department heads will be, okay, how do we divide the credit units…So in other words, is it going to be 50 percent committed to architecture and 50 percent attributed to whatever, either mechanical engineering and so on? So there are these kinds of institutional barriers that have to do with the funding of the various educational activities. (Jones, 2005 as cited in McPeek, 2009, pg 121).

Respondents noted that collaborative skills are a fundamental requirement amongst architectural practitioners and a skill that should be learned in the classroom. Several respondents noted that the ability to work well with others and lead teams in professional practice were amongst some of the most important skills that the architect has in professional practice and the earlier they can be developed the better. However, many comments reflected a frustration with departmental structures, particularly regarding the congestion of accredited curriculum, which can significantly hinder collaborative efforts. This is due in large measure to current course structures that are simply too overloaded to allow for any additional courses or the development of dual degree programs with other majors on campus.

> … What would architecture and public policy be up there, if you came in as a hybrid degree? But we've created our curriculum in such a way that you cannot take anything like that…You can't take dual degrees of architecture in most of the schools in the country. You can barely play hockey once a week… (Wilson, 2005 as cited in McPeek, 2009, pg 109).

Another inhibiting factor discussed by many respondents focused on the structure, duration, and curricular emphasis placed on design studio courses. The average architectural studio course in American institutions of higher education runs in three to four hour blocks of time, three to four times weekly. This amounts to upwards of 12 hours of class time per week (every semester for four or more years) dedicated to predominantly solitary project work.

> I think also we need to become more flexible about this idea that we are giving studio anywhere from a third to a half of your load and two thirds of your life, has got some potential to be reconsidered…the backbone of this mythology about this simultaneous presence of design every semester and that its ever-present nature is a place to pursue, synthesize the other learning that is done in the curriculum. I don't think of it as a kind of theological truth…(Thompson, 2005 as cited in McPeek, 2009, pgs 110 - 111).

In discussing ways to overcome and/or manage collaborative issues at the institutional level many respondents noted the need for faculty, administrators, and departments to be both opportunistic as well as holistic. "It raises questions about how should we be teaching; how pertinent that is that we maintain these divisions within the university if they are starting to radically blur out in the field…" (Phelps, 2005 as cited in McPeek, 2009, pg 126). Some respondents found opportunity in bridging the financial gap through expansion of their publication efforts into alternative professional groups. "One of the interesting things is we're finding, I think if we applied to any conference in the country - nursing conferences, neonatal care conferences - we are the anomaly. 'You're a designer? Oh, we'd love to!'" (Wilson, 2005 as cited in McPeek, 2009, pg 127). By generating connections with other disciplines outside of the realm of "institution" many educators are finding not simply receptive audiences, but potential partners for both research and pedagogical collaboration. Bridging the gap, it appears, may be better accomplished from an outside-in approach. Other responses exposed that it can be much easier to facilitate collaboration between units in the same college than between units of different colleges. "…we wanted to collaborate with engineering and we have tried of course, but we've been more successful collaborating between the two disciplines inside the college, which is architecture [and] landscape architecture…" (Phelps, 2005 as cited in McPeek, 2009, pg 100). This seems to be due, in large measure, to the existence of common pedagogical goals and administrative policies which can be much easier to navigate at the department level than at the college or university level. Additionally, overlapping job site interaction, which takes place in later professional practice, is viewed as a strong incentive for interdepartmental teaching strategies between units.

Respondents also point to the vital importance of collaborative educational 'buy in' from higher levels within the institution. Communication is critical and many departmental chairs and college deans are beginning to understand that, for true cross disciplinary collaboration to occur at the course level, they must initiate the dialog. "Right before the holidays the dean of our liberal arts college and I got all of her school chairs and all of our directors together for a half day talking about collaboration. What are you doing of interest to one another?" (Connors, 2005 as cited in McPeek, 2009, pg 99). Additionally, the thread of inter (and cross) disciplinary collaboration must be holistically embraced at the curricular level. "The University of Oregon, there's a lot of collaborative work. They built it into their culture in every course, so it's not just collaborate, 'Oh, we'll do a little bit of collaboration here,'…It's pervasive. It's a given" (Wilson, 2005 as cited in McPeek, 2009, pg 132).

The faculty

When considering collaborative interaction between individual faculty members, respondents pointed to a number of critical issues which directly impacted collaborative endeavors including: teaching load, the tenure process, time commitment, grades, and faculty personality. A central concern on the part of faculty and administrators is co-teaching. "…co-teaching does it count as a full course? Is it part of the full load or is only part of the course, you get into teaching or work load issues with faculty which is also a kind of can of worms" (Phelps, 2005 as cited in McPeek, 2009, pg 122). When there are shared teaching responsibilities how does the department evaluate course loading of co-teachers relative to those that do not have shared teaching responsibilities? The perception among those not engaged in co-teaching course work might be that their colleagues are potentially skirting full time responsibility. However, respondents often disputed this notion. "…if you talk to faculty they tell you know that co-teaching can be just as hard as teaching. Even though you might be only teaching half the courses, you were still putting in all the work of a full time class" (Phelps, 2005 as cited in McPeek, 2009, pg 125). But the dilemma extends beyond personal or departmental perceptions and can have implications regarding the process of tenure and promotion. Some of the respondents felt that this was simply a convenient excuse for not doing collaborative work that is readily accepted by many. However, most agreed that collaborative work is difficult for many institutions to assess due to a lack of clear 'ownership' over course material, outcomes, etc.

> Because most schools it's very difficult to do, from not tenuring the people who are in multiple disciplines to not valuing the courses that do that…we still do things where you have to have ownership and who did it and why did you do it, it has to be attributable to an individual (Wilson, 2005 as cited in McPeek, 2009, pg 121).

As the instigator of collaboration, faculty members are charged with creating an environment conducive for collaborative work, fostering collaborative relationships between the students, and assessing the collaborative work produced by the students. It can often be a laborious process, particularly when beginning such work for the first time. "Just as an observer, interdisciplinary instruction is not easy. It's very, very difficult, and you have to have the patience, you have to have the time, and you have to invest in the infrastructure…" (Connors, 2005 as cited in McPeek, 2009, pg 121). Additionally, there is a very real challenge to establishing clear methods of assessing group work. Many faculty find this portion of the collaborative equation to be particularly difficult to overcome. "Collaboration also creates certain kinds of tensions because it seems invariably in every team there are some students who work more than others you know and so you just have to make sure you not penalizing the hard workers by kind of giving shelter to ones that aren't working as hard" (Phelps, 2005 as cited in McPeek, 2009, pg 130). This sentiment is further underscored by broader institutional pressures, "We are always struggling with the demand of the university that we give individual grades to individual students…" (Phelps, 2005 as cited in McPeek, 2009, pg 129).

Although the pressure to produce individual work based on individual effort exists for faculty in both their own academic careers as well as with student project work, many respondents expressed a belief that these factors need not be the last word in collaborative pedagogy. In the case of student grades one respondent explained,

> …the idea that grades come, let's say at the end, and they are anointed by a divine perspective is part of the problem….more important than the grade I think, ultimately, is the feedback and if you cultivate feedback not as something only you award but something that exists among peers then collaboration is a lot more present…(Thompson, 2005 as cited in McPeek, 2009, pg 127).

Respondents also expressed the need to be actively engaged in student group dymanics.

> I keep close track of who's doing what. I employ intelligence gathering techniques… I would actually interview - informally interview students asking them who's doing what. Asking them if they have complaints about the group; Pointing out to students that are not doing work that they should do work and contribute…(Jackson, 2005 as cited in McPeek, 2009, pg 128).

Beyond the rigors of tenure, course load, and grading dilemmas, many respondents also cited faculty personality as a pivotal factor in collaborative efforts. In some instances this was attributed to longstanding departmental routine and "…older faculty who have been doing things a certain way for a long time…" (Smith, 2004 as cited in McPeek, 2009, pg 120) who were not always willing to undertake group projects. There was also a sense among some interviewee's that perhaps inherent in the aspect of 'teacher' was a notion of individuality. "Often people who go into academia go into academia because they're mavericks, and so you want team players, you've got to go to industry" (Wilson, 2005 as cited in McPeek, 2009, pg 103). But, as one respondent pointed out, sometimes these inhibitors can be avoided through common observation. "I have learned in tons of settings that were collaborative over the years that it still simplistically comes down to individual chemistry and my best collaborations have always been when I really wanted to work with somebody…" (Smith, 2004 as cited in Author, 2009, pg 103).

The student

Each of the preceding levels of collaboration serves to enable, or hinder as the case may be, collaboration at the level of the student. By insuring that the preceding levels of collaboration are in place the likelihood of successful collaboration in the classroom is greatly enhanced allowing the instructor to prepare the students for the rigors of collaborative learning. An important consideration when pursuing collaborative learning in the design studio is to understand how design students differ from students in other disciplines and how these differences affect collaborative endeavors. When discussing collaboration at the level of the student the respondents frequently noted the “nature” or “type” of students that pursue an architectural education. A great many of students entering into schools of architecture have a “maverick” personality and as a result are not intrinsically predisposed to the social nature of collaborative efforts.

> I think that the students who are attracted are the same students that were attracted 20, 50, 70, 80 years ago, and they’re makers, but they may not be social mavens…When we have students who are great public speakers, or very involved with student council, they often are not our strongest students in architecture, and we run them off…it’s very interesting (Wilson, 2005 as cited in McPeek, 2009, pg 106).

In discussing facilitating factors for collaboration at the student level, respondents cited the impact of observational learning. Because many students lack social or collaborative expertise, the need for “learning” such behavior is paramount. Effective co-teaching was noted as a primary, and mutually beneficial, means of observational learning regarding the collaborative process. Observation of community based collaboration within organizations (i.e. Habitat for Humanity) also provides excellent opportunities for exposure. Observation can then be followed by emulation, where the students mimic behaviors previously observed followed by increasingly complex collaborative challenges.

Another primary focus in teaching students to be good collaborators is to help them develop a common dialogue. This common dialogue is the primary tool, in a collaborative skill set, needed for sustained collaboration. The ability to establish and maintain an ongoing dialogue is mandatory for successful collaboration and this requires the establishment of a common language. It has also been determined that the process of establishing a common language is one that can be taught or coached in the classroom environment. It is this common dialogue that serves as the foundation for a collaborative social construct.

One respondent in the study described this in the following way.

> Collaboration is functional. …part of that is getting over your own vocabulary and beginning to understand and have empathy for the vocabulary of the collaborator. These perceptions that students from management bring, or engineering bring, or our own architecture students bring, it has to be overcome before we can get meaningful collaboration and partnering and the joint exercise of problem solving, alternative generation and so forth. (Connors, 2005 as cited in McPeek, pg 114).

Yet another respondent noted

> There’s also the greater danger of them just finding having no common language. … [For example] the generalist can’t even speak with the specialist anymore. Peterson, 2005 as cited in McPeek, pg 114).

It was determined that like design ability, the development of a common dialogue, requires practice and repetition. This is a skill that on the surface may appear to run counter to the "maverick" tendencies of the typical design student actually complements and enables the natural abilities and tendencies of the design student.

Conclusions

This paper offered a compressed overview of research from an original data set, focusing on four key levels of collaboration that exist in American educational institutions: the community, the institution, the faculty, and the student. Based on research conducted to this point, it appears critical that, in order to facilitate successful collaborative exercises in the classroom, these key collaborative levels must be working in concert. In particular, if the levels of community, institution, and faculty have not been addressed, then achieving a positive outcome at the level of student becomes an even greater struggle. Successful collaborative engagement is dependent upon the interplay of these four levels and, with the proper facilitation (McPeek, 2009), can greatly enhance the educational experience, for architectural education as well as many other increasingly collaborative fields of study.

The Construction of Complexity in Design and Public Policy Contexts

Chris Urbina Meierling, Arizona State University

Abstract

This paper explores the nature of complexity and how it is manifest in the practice of design research and public policy given their unique contexts. This comparison is made by examining the tools and approaches that are used in understanding problems and creating outcomes in each field. This paper is based on a recently conducted action research study at a state legislature in the United States and is supported by foundational literature on modern problem theory, decision making, methods, and process in the two fields.

Complexity emerges from the many stakeholders that surround and define our issues, the enigmatic nature of our ill-structured problems, and the multiplicity of variables that confound progress towards one solution. An interdisciplinary opportunity is presented; the study suggests tools are a function of the complexity in any given context and provides examples of varying modes of managing complexity in design and policy environments. By juxtaposing the similarities and differences in how design practice and policy development construe and manage complexity, this paper frames the overlap between the two areas of practice and builds a mutual space for learning and collaboration.

Keywords

Design practice, participatory approaches, politics, policy, human / user-centered design, methods, complexity, decision making, design thinking

Complexity is very familiar to designers and policy makers. It is present as we struggle to generate acceptable solutions for as many people as possible, as we ceaselessly reevaluate the goals of our outcomes and when we carefully seek the sources of the problems our outcomes attempt to address. We look towards broad strategies, ranging from implicit to explicit, like collaboration, interdisciplinarity, data analysis, or brainstorming as a means to apply our thinking in order to acquire a better understanding of our complex environments. Yet, these strategies have emerged out of the distinct cultures and work contexts of design and policy. An assessment of the complexity management strategies from each discipline creates a mutual space for learning and is telling of how our end products are shaped by our approaches and the way they steer complexity.

This paper suggests that the complexity faced in the design process and the policy making process is not merely shaped by an existing complex natural state but also by our modes of management. Complexity emerges from the many stakeholders that surround and define our issues, the enigmatic nature of our ill-structured problems, and the multiplicity of variables that confound progress towards one solution. This paper, based on a survey of literature and an action research study at a state legislature in the United States, actively examines these characteristics in design and policy by investigating policy tools and exploring how design tools might be incorporated in the policy context. The transferability of design methods, and approaches, to the policy making realm has recently achieved great acclaim (DFFN, 2003; Owen, 2007; RED, 2006), yet there is a paucity of research that has explored this topic in its real-life context. This examination of complexity becomes particularly valuable in the search for better public decisions and decision making.

Research Approach

This study explores complexity as a boundary spanning phenomenon by asserting that the tools employed in design and policy are a function of their respective decision-making contexts and that these tools might be able to be applied across boundary. It weaves together a recently conducted action research study that explored how design methods might be used in state-level policy making with relevant literature on problem theory, decision making, methods and process in the two fields. This mixed approach appropriately poises this research to ask how issues are constructed and what instrumental roles methods play in the definition and resolution of the inherently complex problems across contexts (Meierling, 2009).

The primary research used a state legislature as a case study as per Yin (1994) and directly engaged key stakeholders in the policy process through observation, interviews, and collaborative modeling of political processes. The research strategy for this study combined evaluative and applied methodologies in a qualitative approach. The evaluative study assessed information from a literature review and initial interviews with lobbyists, community members and legislators to analyze the intersections between design methods, legislative methods and citizen issues. The applied study introduced nine representative design tools to eight state legislators in order to explore the relationship to legislative methods. The nine design tools are as follows:

- **Personas** are rich narratives that describe a person's unique experiences.
- **Storyboards** are visualizations that represent a sequence of events and their imbedded relationships.
- **Mind mapping** is a type of diagramming where a person intuitively places related and potentially related ideas around a central concern in order to classify concepts and to generate new ideas.
- **Systems diagramming** helps understand how complex systems work by visualizing networks of interrelated issues, their lifecycles, and how they interact with other inputs
- **Prototyping and evaluation** involves testing an idea before full-scale implementation. This can lead to greater success in the full-scale project.
- **Research frameworks** segment collected information into relevant, pre-established categories; this aids in seeing relationships among many issues and ensures all aspects of a research target have been accounted for.
- **Co-creation workshops** gather a group of people to create their own solutions to problems side by side with expert moderators who keep real-life constraints under consideration.
- **Make kits** allow an individual to show their own experience using words and images without the imposition of another person. After completion, they are returned to the research team for analysis.
- **Visual representation**, as opposed to verbal, facilitates a different understanding of a problem through diagramming and explanation, and is adept at clearly showing relationships.

This phase was also accompanied by in-depth interviews with advocates, interest groups and policy organizations and a number of observations of legislative processes. A dialogue was created that collaboratively explored the potential currency of design tools in the policy context and a path towards design-policy integration.

This paper builds upon established discourse in problem theory and planning. Design and policy making are both planning activities; they are locked into the transition from 'what-is' to 'what ought to be' (Buchanan, 1992; Schön, 1994; Simon, 1969). It is within this discourse that complexity and politics are found to be similarly intrinsic to design and policy (Rittel & Webber, 1969; Dubberly & Rith, 2007). Yet, two different institutions prevail: the design process and the political process, each corresponding to their own unique methods, or set of tools, and unique issue contexts. Robert et al. 's (2002) systems framework suggests that disparate systems can share a common dialectic between the constitution, outcomes, *processes*, actions, and *tools* of each system. By framing design and policy contexts as separate systems, it is possible to compare the manifestation of complexity in design and policy development through an examination of tools.

Problem Complexity as Common Ground

Though little literature explores any sort of collaboration between the design fields and the policy development world, they are frequently paralleled in terms of problems and their solutions. Both areas of practice are involved in the development of knowledge surrounding social interactions, are significantly influenced by the social sciences, and are equally entrenched by the same root issues (Birkland, 2005; Schön, 1994; Owen, 2007). These root issues are best characterized by the ill-defined, wicked problems faced in planning activities (Rittel & Webber, 1969). Different from tractable problems involving measurement and direct relationships, many of the problems that designers and policy makers face are fraught with complexities outside our comprehension, leaving us only with tools, ranging from intuitive approaches to explicit strategies, as vehicles to apply our thinking to complex problems. For both designers and policy makers, complexity is a result of a confluence of multiple variables, the interplay between problem and solution, and diverse, irreconcilable stakeholders (Buchanan, 1992; Schön, 1994).

A Multiplicity of Variables

A multiplicity of variables is central to complexity for designers and policy makers. Subsequently, complexity arises from the level of facility we have in evaluating these variables and our ability to generate solutions sympathetic to those variables. In this case, complexity is often a question of how variables interrelate, coalesce and compound as part of a larger system (Weaver, 1948; Sarewitz, 2000). In fact, the development of systems theory is an indelible result of the identification and recognition of complexity as a phenomenon in our world. Warren Weaver, a founding thinker in complexity science, characterizes it as the predictability of outcomes of the variables within a system (Weaver, 1948). He juxtaposes disorganized complexity, with measurable properties and predictable outcomes, with organized complexity, "dealing simultaneously with a *sizable number of factors which are interrelated into an organic whole*" inherent to physiological, economic and political pursuits (Weaver, 1948). This same juxtaposition comes later from the more familiar language of Simon and Rittel in their conception of the ill-defined, wicked problems faced in planning activities. Different from the “tame” problems involving measurement, this type of problem is marked by unmanageable variables, conflicting stakeholder perspectives, interdependencies with other problems, and ultimate unsolvability.

The Interplay Between Problem and Solution

A second aspect of complexity comes from our inability to identify root causes and definite solutions to problems and the exchange between problem and solution. Many designers and policy makers might find that “the information needed to understand the problem depends on one’s idea for solving it” (Rittel & Webber, 1969, p. 225). That is, the process of identifying a problem yields a solution. Additionally, every wicked problem is an indicator of another wicked problem and solutions are coupled with other solutions (Rittel, 1970; Keeney, 1982). Given the difficulty of 'taming' these wicked problems and the plurality of problems and solutions, a problem has many unknown sources and a solution reveals other issues. This problem-solution quagmire and the aforementioned multiplicity of variables brings us to the limits of our cognition or our 'bounded rationality' leaving us only tools and strategies to cope (Farnham, 1990; Simon, 1969; Weiss, 1982).

Irreconcilable Stakeholders

While the multivariate, wicked nature of complexity indeed plagues much of decision making, additional difficulty arises out of the diversity of stakeholders that these decisions intend to represent. In this vein, complexity can quickly be traced to the social interactions between stakeholder groups surrounding an issue. Value trade-offs, multiple objectives and the absence of an overall expert among stakeholders are all characteristics of complex contexts (Keeney, 1982). When weighing the benefits of one decision over another and identifying what might be the most desirable outcome, the diverse, heterogeneous groups around issues can entrench our decision making contexts with competing values. Designers and policy makers diligently seek a "transcendent solution because…it is the only strategy which serves all of the values involved in a decision no matter whether they are assessed in terms of their intrinsic worth or in terms of the importance of interests behind them" (Farnham, 1990, p. 100). Therefore, complexity is inherently a social phenomenon and a result of the different perspectives and goals of actors in the decision landscape.

Policy makers are aware of these unclear solutions and understand them through the interconnectivity of the many symptoms of wicked problems (Connors, 1996; Easton, 1965; Lloyd, 1978; Stone, 1988; Susser, 1992; Verduijn, & Brugge, 2001). The uncertainty that is described in policy development is also manifest in the design process through the designer’s inability to determine one definite, successful solution to a problem (Buchanan, 1992; Margolin, 1996; Owen, 2007; RED, 2006). Policy makers and designers share the same wickedness and deep uncertainty of their problems yet different approaches to cope with them have risen out of each area of practice. Similarly, both fields address these problems with a continuum of temporary solutions that only tame issues without resolving root problems. The insolvability of these root problems emerges as a point of departure for comparing complexity in design and policy development via the tools in each discipline.

Design and Policy Tools as Complexity Management Strategies

Design and Policy Tools

The problems and work context in design and policy do indeed share similar complexities; yet, we take different *approaches* to managing variables and use different *tools* to navigate our complex environments. These approaches and tools are agents of impending decisions that help us better understand the landscape of our problems. A tool has multiple uses and takes on different meanings depending on its operator, the intended task, and the work environment.

However, tools also represent the thinking and intent behind actions in each discipline and are actively used in an instrumental fashion. This research draws from the tool sets of designers and policy makers and compares how complexity is framed and managed in each.

The nine identified tools described earlier can be expanded to cover many other methods and approaches and represent the core values of design tools such as user-centeredness, the development of alternatives, a strong capacity for visual thinking, and an orientation towards collaboration. The primary operating paradigm for designers has its roots in the much discussed dichotomy of the designer as an "analyzer" and as a "creator," to use Heiko Sacher's (2002) terms; this contextualizes the types of tools that are used in design and can describe how designers engage in practice (Frascara, 2002; Owen, 2007; Sacher, 2002) using tools for analysis and tools for creation. Thus, design tools are used in a flexible, interpretive fashion, strikingly dissimilar from traditional representations of the design process characterized by step-by-step, discrete occurrences that arrive at an outcome (Dubberly, 2005). This mode of structuring design tools refrains from implying any temporality and allows decisions, and therefore the tools implemented, to be made in an intuitive and non-linear way. This research broadly discusses design tools and acknowledges that variations of each tool exist across the design silos and other related disciplines. The toolset was a vehicle to express the approaches of designers, the values and intents of the design process, and the apparent methods that are strategically used by designers.

Based on observation of the legislature and initial interviews with stakeholders in the policy cycle, nine tools were identified to represent the larger policy tool set used by state legislators in understanding issues:

- **Expert consultation** brings in a specialist perspective on a particular issue whose advice is considered reliable.
- **Evaluation of current law** in respect to a proposed bill can be vital. The elected official upholds and interprets current statutes and regulations.
- **Analysis of other policies** and case studies from other states offer insight into the potential success of newly introduced legislation.
- **Stakeholder meetings** provide a forum to voice concern or support on an issue. These focused meetings are intended to address the specific concerns of affected stakeholders and bring clarity to conflicts.
- **Town hall meetings** are public gatherings where community members voice group concerns, gather grassroots support, or receive feedback from public figures.
- **Debate** and deliberation amongst individuals representing multiple perspectives is useful to understanding the facets of an issue.
- **Committee meetings** gather advisory committees to consider bills of similar subject matter prior to being passed. Testimony from experts and the lay are invited to these public meetings.
- **Constituency outreach** can shed light on the varying viewpoints surrounding an issue. It can involve communication with the media, being a part of the local fabric, or attending community meetings.
- **Staff research** is useful to gain a complete understanding of a proposed bill, its history, and any related bills.

The underlying political philosophy supports these findings and characterizes the policy context and the approaches therein as adversarial, competitive, agenda-driven, participatory, and discursive. Not to be confused with 'policy tools' or 'policy instruments' which are "method[s] through which government seeks a policy objective" (Salamon & Lund, 1989, p. 29) such as a public education program or a new water use program, each of these tools embodied steps taken by a legislator during policy development that shape the way issues take form. Some of the tools are procedural requirements that are a part of the policy cycle such as committee meetings, others take place on an as-needed basis such as town hall meetings, and still others are a part of a legislator's daily activities such as expert consultation. While, these tools are employed at varying points through issue development at the legislature, the implementation of the tools is closely tied into the formal ebb and flow dictated by the policy process from issue recognition to the formalization of a policy in the state's revised statutes.

Using Tools to Frame Complexity

> Actors in the policy drama design policy much as architects or engineers design material artifacts. They compete and cooperate to set policy problems, and they invent policy solutions that evolve as a result of the actors' transactions with the policy situation. When policy objects are put out into the larger environment, they tend to take on meanings unanticipated by their designers, as other actors see and respond to them in the light of their own frames and, often, in a changing policy context (Schön, 1994, p. xix).

The way in which tools frame complexities, namely the variables, problems, solutions, and stakeholders of each professional context is revealing of manifestations of complexity. This paper suggests that the tools are used to manage and organize the aforementioned aspects of complexity and that they effectively become complexity management strategies that have emerged from the differing cultures in the two fields. An analysis of these tools reveal four key areas that are of central importance to design and policy practice yet differ in how complexity was framed in each field: context, problem definition, value orientation, and participation. The following accounts describe these areas with specific examples from the aforementioned primary research as well as secondary sources.

Context

Perhaps at the heart of the differing approaches to complexity are the underlying structures and contexts in which designers and policy makers work. Private and public sectors impose different constraints on actors and lead to different motivations and actions in practice. A key observation of the legislature was that it cultivates a short-term mindset even when policies have long lasting implications. While legislators recognize the value of longitudinal thinking, they want a quick return on their investment in terms of pushing bills successfully in as little amount of time as possible. This incremental pattern of policy creation might be prompted by motivations of being re-elected the following election cycle, the need to see the results of their work for continued support from their constituency, and the imbedded disposition of a part-time legislature (they are not salaried enough to live without a secondary income). Issues with long-term consequences are more difficult to understand and support. It is possible to conclude that this disposition for the short-term is transferred to stakeholders, thus propagating a cycle of incremental policy development.

The most generative design tools such as brainstorming might be perceived as counter productive to developing policies and misconstrued as creating unnecessary risk. The generation of ideas complicates the approaches taken to gather support from opposition and other stakeholders and works against the grain of policy development. The context presented in design is that of selfless dialogue for the sake of generating better ideas, while the context presented in policy development is that of incremental adjustments that accommodate stakeholders, yet, both result in collaboratively created outcomes.

An example of these differing contexts can be seen in the way prototyping takes place in design and policy contexts. When presented with this tool, legislators closely associated it with the use of pilot studies that are initiated by legislators as a means to test a policy idea. Prototyping or piloting a policy is valued as a way to bring unforeseen issues to light prior to full adoption of a bill and as a way test the efficacy of a potential bill. In design, the value of prototyping comes from quick feedback loops, iteration, and refinement. There are a number of impediments in the policy process that cause the use of this tool to take a different course: When pilot studies are introduced to the legislature they need bill approval. In this situation, one legislator would need to successfully introduce a bill for a pilot study and then reintroduce the bill as a full-scale policy the following legislative session or after the study period is complete. This process is too slow when legislators' concerns lie within one singular session. A pilot can lose support if: another issue takes prominence; if the sponsor leaves; if money dwindles; or if an idea does not fit well with the current legislatures concerns. Moreover, long-term projects are difficult to sponsor when legislators are motivated by quick results that contribute to their reelection. This example shows that the differing operating paradigms of design and policy are tied to the same need for testing out an idea and incorporating feedback into a future iteration, yet two distinct ways have emerged from different manifestations of complexity.

Problem Definition

Just as our professional contexts shape the landscape of complexity, so do they dispose the problems that we face to the constraints, opportunities, and affectations of each field. That is, problems are identified and defined uniquely to the contexts in which they arise. Problems in the client-based, business-driven professional model of the design world are shaped somewhere in between the client, customer and designer. In contrast, the body of individuals who actively appeal to policy makers characterizes the public context of the policy world: they compete for a voice in the policy process and for representation in the policy outcome. Problems are effectively shaped by the voices represented and heard in this process. The significance of how problems are defined is evident in the manifestations of complexity, the management strategies of our tools and the outcomes that result.

Problem definition is widely recognized as a contributor to the successes and failures in policy formulation and carries a long-standing tradition in policy discourse. In part, this discussion revolved around the notion that issues and problems are shaped by the way people individually or socially define them and result in policies that are inherently linked to the original problem construction. For example, homelessness can be considered the result of a shortage of housing, the result of economic strife, or the product of the deinstitutionalization of mental hospitals (Rochefort & Cobb, 1992). However, more salient in terms of how complexity manifests itself is the concept of problem ownership. Rochefort and Cobb (1994) conclude that some problem definitions may be under complete control of one body of authority. For example, the judiciary defines the severity of a certain crime through its enactment of retribution and therefore owns a problem. Another example can be seen when a community organization represents the many voices of the gay, lesbian, bisexual, transgendered community to the legislature, effectively owning and taking responsibility over an issue, and as a result omits outlying needs and leaves them unrepresented. Schattschneider (1960), well-cited for his work in political analysis, concludes that those who own a problem at the point of definition and through deliberation will successfully define the solution to it.

Equally important are the means in which issues come to the attention of legislators. Observation in the research revealed four types of transactions that provide starting points for problems in the policy context:

- **Special interest lobbying** includes the presence of any type of lobbying effort; it can be ongoing or issue specific.
- **Personal experience** refers to any event, either casual or organized that a legislator personally experiences. These experiences tend to build empathy and can be catalysts for bill sponsorship or the recognition of an issue by the legislature.
- **Proactive citizens** can band together or act individually to voice their needs and opinions on a particular issue. This may be referred to as citizen lobbying.
- **Policy analysis** is undergone by research staff, policy organizations, think tanks, public interest groups, and other private organizations and serves as a measurement of efficacy of previously created legislation; policy analysis directly sways which issues will be heard and which will not.

While paying clients usually represent the origin of problems for designers, the design team must champion the needs of a user group to encourage a client to take a certain course of action. However, in the policy context there are numerous ‘clients’ with differing agendas and there is proactive representation that results in uneven depiction of a population's needs. The divergence of actors and roles of stakeholders delineates how problems are defined and how our tools shape and are shaped by complexity.

Value Orientation

Different value systems have also emerged out of the contexts of design and policy. The competitive, adversarial nature of the policy world bears a two-value dynamic that permeates the underlying political structure and the policies produced by these regimes. The design context puts great weight on people's stories and interactions around a given circumstance and is implicitly open to the subtleties of people's experiences with design products. Designers create a multifaceted depiction of potential outcomes through the use of drawings, stories, and words. This is evidenced by the systems bent of many design tools such storyboards, mind maps and brainstorming and emphasis towards understanding the interdependence of variables and inclusiveness within a user group.

The two valued orientation in politics can be traced to the literature in a variety of ways, however, it is well-articulated by the preeminent linguist Hayakawa; he writes, "This penchant to divide the world into two-opposing forces-- "right" versus "wrong," "good" versus "evil" -- and to ignore or deny the existence of any middle ground, may be termed the *two-valued orientation*." (Hayakawa, 1990, p.113). Originally coined by philosopher Alfred Kozybski, this value orientation is endemic to our two-party political system and can be seen in the political positions that each party maintains and in debate, a cornerstone of politics. Take for example the emergence of 'pro-life' and 'pro-choice' as the two predominant positions on abortion. The two-valued system is also tied to policy makers expectation of rational decision-making, attempting to remove emotion from decisions, and the legacy structures of the political system that attempt to whittle problems down to a single interest, chosen from two. However life is not this simple, nor are we rational actors; we have aspirations, emotions, and needs and react to our world with scales of judgment, not with "right" and "wrong." It is in this convergent policy process that a reactive political culture is bred and the tools of debate and discourse manage and temper complexity.

This fundamental difference is exemplified by exploring the use of mind mapping, a design tool, in the policy context. Mind mapping or webbing, as several legislators knew it, was a familiar concept to interviewees at the legislature and was interpreted as a method of structured brainstorming. However, mind mapping would ultimately not be able to be utilized as a tool to generate policy ideas for two reasons. First, legislators simply do not feel they spend their time creating new, original legislation; they manage bills. Second, in the context of argumentation and adversarial relationships, the generation of ideas, a key aspect of the design process, complicates the approach of garnering support on an issue from opposition. The generation of alternatives as it is construed in design happens in a more dispersed, ambiguous fashion in policy making, somewhere between legislators' agenda and the interests of those represented in the policy process.

Participation

In exploring how complexity is framed in design and policy, it is important to understand how we engage people, the end-users (and sources of inspiration) of the products that we work towards. Design tools typically come from a grounded perspective, treat problem areas as unique, and are inclusive by involving stakeholders at the stage of their own experiences. Quite different, the organization of legislatures include salient issues, stakeholders, and variables that are represented proactively while quieter voices fall by the way-side. For example, interest groups and lobbying efforts often represent specific issues or larger ideologies in place of direct citizen involvement (Kingdon, 1989). Complexity in policy manifests itself through the proactive voices of lobbyists, interest groups and citizens incited by the structure of representative democracy. In the design context, complexity is proactively sought by designers through inclusive tools in an attempt to preserve ambiguity of variables until constraints require convergence on an outcome.

The paradigm in policy development is that of representative democracy where a legislator represents a group of people, their needs, and their expectations for the legislative outcome. Legislators are primarily reactive in their actions and handle issues as they present themselves. In the same vein, legislators have limited opportunity to engage in proactive policy making. While design practitioners must be reactive when responding to client expectations, they remain proactive in the process of understanding the needs of end users and stakeholders. As the designer is situated between the expectations of consumers and the expectations of a client, they act as an intermediary and communicator between both sets of actors. Therefore, the operating paradigm in managing complexity in design is the designer as expert interlocutor who proactively reaches out to stakeholders and incorporates their needs and expectations into the design outcome.

Design practice heavily relies on the experiences of individual people during the design process to achieve desirable outcomes (Arnold, 2005). In contrast, the research made it clear that citizen viewpoints and opinions were often solicited late in the policy development process, after issues had been formed and agendas were set. Evidence of this is also seen by legislators interpreting personas as a tool to understand other legislators (as opposed to members of the public) given that representatives and senators represent a defined segment of the state's population. This coincides closely with the verbiage consistently used by legislators that embodies a tone of appeasing and even placating stakeholders. For example, one representative endorsed town hall meetings because they make "people feel like you're listening." Another representative suggested that stakeholder meetings are "more of a PR move," that they "make sure people don't complain." The everyday citizen holds a unique place at the legislature where "they are typically reached after the damage has already been done."

Conclusion

This paper tracks issues of complexity in design and public policy contexts and proposes that differences in context, problem definition, value orientation, and participation are at the root of the differing constructions of the same types of complexity. The research found that the aforementioned variance in values is brought on by different management approaches of stakeholders, styles of defining problems, and methods of accounting for variables. This leads to different representations of complexity and ultimately different types of outcomes. It is clear that the different cultures have produced different systems to handle complexity and vary in the way they approach problems. Strategies such as collaboration, the development of alternatives, iteration and participation assume different forms depending on the context in which they are present. Tools also result in different outcomes, whether they are used in a competitive, representative and reactive environment or an inclusive, participatory, and proactive environment. Now more than ever, designers and policy makers are becoming familiar with the complexities brought by our ill-structured, wicked problems. This research serves as a foundational discussion by shaping a common language between design and policy practice and is a starting point to begin sharing best practices and exploring interdisciplinary collaboration.

Sustainable Alternatives to Industrial Printing Practices: A Case Study Analysis of *Esquire* Magazine and Electronic Paper Display

Christopher Moore, Concordia University, Montreal, christopher.moore@concordia.ca

Abstract

In October 2008, *Esquire* magazine became the first commercial publisher to utilize electronic paper display technology (EPD) for mass production and distribution of printed ephemera. Initially developed at the MIT Media Lab in 1997, E Ink displays have been integrated into a variety of hardware devices, including the Amazon Kindle and Sony Reader. However, the *Esquire* cover represents a milestone achievement in the evolution of a more sustainable, paperless print solution due to the medium's flexible nature, low power consumption, and limited circuitry requirements. 100,000 copies were sold on newsstands for the regular cover price of $5.99 USD, proving both the economic viability and flexible application of the technology, which is impervious to ambient lighting conditions and adaptable to multiple modalities. This paper outlines the key features and benefits of E Ink, as well as the critical challenges impeding widespread adoption of EPD.

Keywords

Sustainable design (primary keyword); design and society; eco-design; communication and information; case study/studies

In response to political and consumer pressures, traditional print industries have increasingly adapted production methods to utilize more ecologically conscientious practices. Transitions to vegetable dyes, post-consumer fibres and dissolved air flotation de-inking processes have contributed to reduced environmental consequences from the paper and printing industries, but the overall output of ephemera has remained largely unchanged. The secondary carbon offset resulting from energy consumption and chemical disposal in the recycling and transportation of printed matter needs to be reconciled with advancements made in material technologies, and our cultural desire for tangible media. Clearly, a new paradigm for mass dissemination of content is required to bridge the gap between consumer demand and industrial production practices.

Challenging the Archetype: Sustainable Print

Environmental Impact and Transitional Phases

Pulp-based printing presents a number of environmental concerns, relating mostly to material pollution and energy consumption—issues that have been troubling environmental activists and earth-conscious consumers for decades. In recent years, many proactive solutions have been developed and implemented to lower the impact of mass printing. Toxic inks can now be effectively substituted with water-based pigments and vegetable dyes, with minimal investment or retrofitting of existing equipment. Virgin paper is also falling out of favour with designers and clients, steadily being replaced by post-consumer hybrids or 100% recycled paper products. Even within the recycling process, traditional bleach-based de-inking employs the use of toxic solvents and detergents. However, as the emergent technology of dissolved air flotation becomes a more economically viable proposition, it is expected that this practice will become an industry-regulated standard. The devastating effects of clear-cutting have been partially ameliorated through public acceptance of post-consumer products, as well as through remote forestry and replanting activities. Paper processing and pulping is an unmistakably significant contributor to negative environmental consequences, as is the transportation of the paper product from the manufacturer to the consumer—both unavoidable aspects of paper production.

With an increase in recycled paper production, certain perceptual shifts have occurred in paper and printed matter consumption. The negative connotations and cut-rate image of recycled products have diminished, as the technologies for reconstituting pulp continue to improve the quality of goods. Product lifecycle is more commonly taken into account when selecting papers for specific print applications; for example, paper with degraded quality is often used for printed ephemera expected to have a shorter cultural currency. Consumers have also naturally adopted multi-modal reading practices, given the abundance and accessibility of news and other texts on the Internet. Although the advent of digital technology was thought to have lead to reduced literacy rates, it seems that greater numbers of individuals are reading online, thus demonstrating increased reading rates due to the convenience and availability of reading materials.

Adoption of Digital and Paperless Print

A logical next step in the evolution of print is a transition to digital and paperless print displays. It would be naïve to suggest that traditional printing process will be completely eschewed in favour of digital modes of dissemination, but the balance is beginning to shift.

E Ink and electronic paper display technologies have been heralded as sustainable solutions to the proliferation of printed artifacts. Their key environmental benefits include the modest power usage, the reduction of printed material, the general inertia of the chemical substances used, the volume of storage available and the flexibility of application, being embedded or standalone. However, numerous economic, technical, and marketing challenges must be addressed before this technology presents a viable alternative to traditional publication. Chief among these concerns is the perceptual shift required among user-communities, who must adapt lifelong reading habits to accommodate new hardware devices and modes of content purchase or acquisition.

Case Study: E Ink Corporation

Overview and Features

E Ink was established in Cambridge, MA in 1997 as a commercialization of research incubated at the MIT Media Lab. It was, and still is, considered a proprietary technology and not an industry standard. The primary innovation of the E Ink material is that it is able to produce a digital image without the use of a constant power supply or a backlit display. The technology, as described by the E Ink corporation website, is as such (see figure 1):

> The principal components of electronic ink are millions of tiny microcapsules, about the diameter of a human hair. In one incarnation, each microcapsule contains positively charged white particles and negatively charged black particles suspended in a clear fluid. When a negative electric field is applied, the white particles move to the top of the microcapsule where they become visible to the user. This makes the surface appear white at that spot. At the same time, an opposite electric field pulls the black particles to the bottom of the microcapsules where they are hidden. By reversing this process, the black particles appear at the top of the capsule, which now makes the surface appear dark at that spot. (E Ink Corporation, *How it Works*, n.d.).

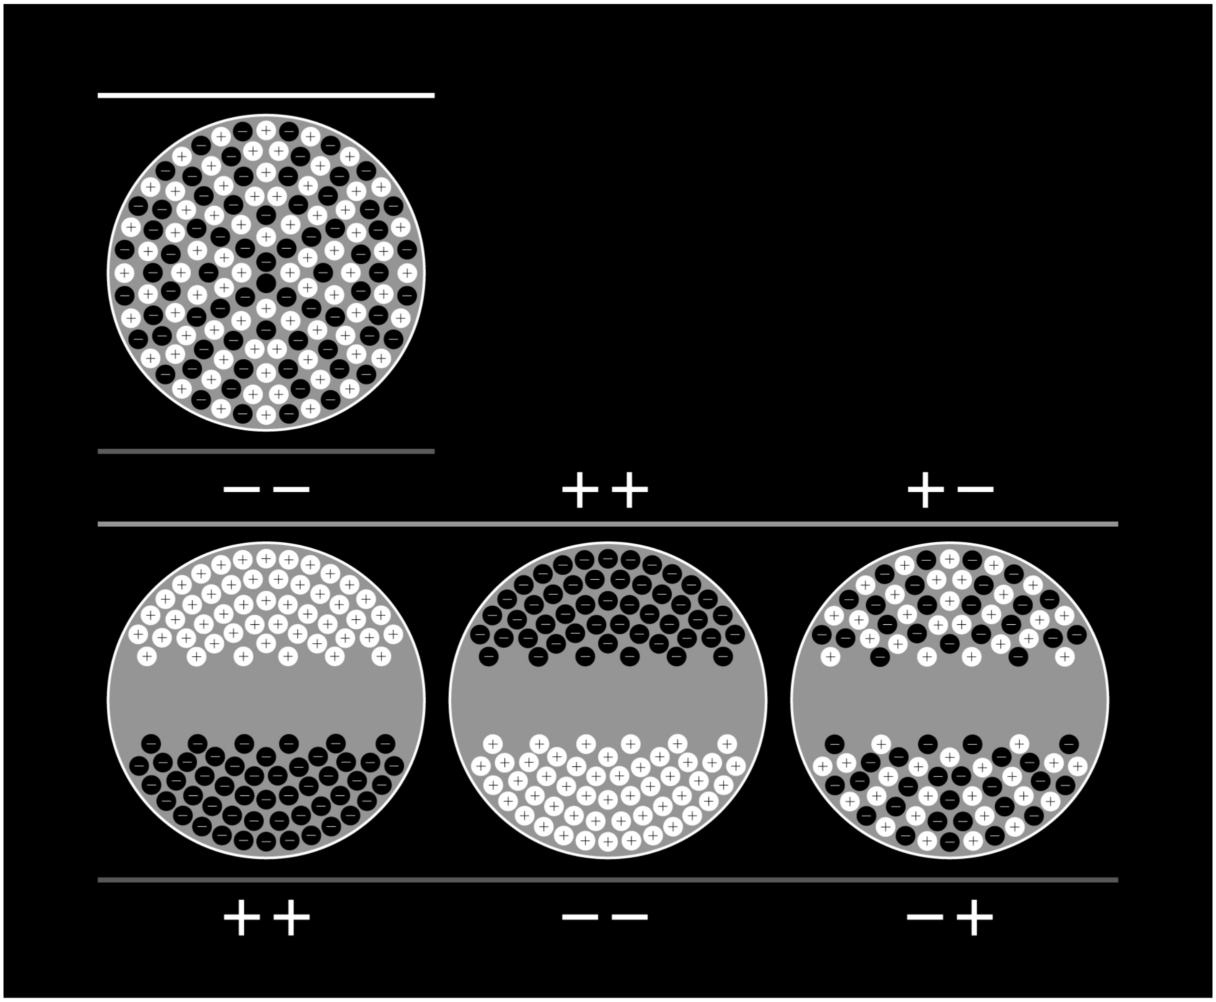

Figure 1. Charged Microcapsules, adapted by author from E Ink Corporation (*How it Works*, n.d.).

The scientific term used to describe the process making E Ink possible is electrophoresis. This refers to the separation of electrically charged substances in a solution under the influence of an electric field. It is based on the difference between the rates of migration of pigmented particles, typically Rutile, Anatase, Barium Sulfate, Kaolin, or Zinc Oxide (Albert & Gates, 2008). The microcapsules function as de-facto binary pixels, turned on or off by transmitting surges of power through embedded circuitry (see figure 2). The output is controlled by a display driver, which is activated only when the image display needs to be refreshed. Suspended in a liquid "carrier medium," the capsules may be screen printed onto a variety of surfaces, thus freeing the electronic image from bulky hardware devices. The flexible nature of the E Ink material permits virtually any substrate to function as a display, including glass, plastic, or paper (E Ink Corporation, *How it Works*, n.d.).

Figure 2. Booken Cybook Gen3 Display Magnified 6x (Genuth, 2008)

Quality and Readability

Few reliable studies have been conducted on the legibility and long-term physiological impacts incurred from sustained use of E Ink displays. Despite dissenting research and opinions, it is widely believed that there is a reduction of eyestrain, as no backlighting is employed by the system. At the consumer level, E Ink is currently available only in black and white, although Samsung is developing colour prototypes (Unidym, 2008). In terms of output quality, the current technology can support a 3- or 4-bit greyscale display, and simulates a resolution of 150-200 DPI, depending on the display size (E Ink Corporation, *Visplex Imaging Film*, n.d.). It is said to demonstrate qualities of paper, exhibiting high contrast and reflectivity, and is not subject to legibility impairments as a result of ambient lighting conditions, unlike liquid crystal displays (Comiskey, Albert, Yoshizawa, & Jacobson, 1998).

eBook Readers: The Amazon Kindle

Market Dominance and Sales Figures

eBook readers persist as the principle commercial application of E Ink technology. Amazon Kindle is currently the leading device in this product category, although there are others—its prime competitors being the Sony Reader, the iRex iLiad, and the Plastic Logic eReader. It is estimated that around 380,000 Kindles were sold in 2007 during their first year on the market (Jackson 2008), and estimated revenues of $1.2 billion USD are expected for Amazon, as of 2010 (Galante, 2009). These figures clearly indicate that sales have crossed the threshold of early adopters, gaining more widespread acceptance among the general consumer market.

Available exclusively in the United States during its introductory years, the Kindle was recently launched internationally in over 100 countries, offering upwards of 400,000 titles, as well as applications for personal handheld devices (Amazon.com, n.d.). In the first 14 months after Kindle's 1997 release, 10% of Amazon's sales were eBook titles, although Amazon has not been forthcoming with exact figures regarding sales of its proprietary device.

From a marketing perspective, convincing a skeptical public to invest in an underdeveloped technological platform with little seeded content, and the potential to be rendered obsolete, presents significant challenges. Elevated price-point, limited content availability, usability issues, and mixed user testimonials have primarily hindered the widespread adoption of eBook readers. Such issues are not unique to this product class, but are further amplified as the consumer's financial investment increases. One need only examine the history of photographic cameras and other durables to detect similar promotional encumbrances.

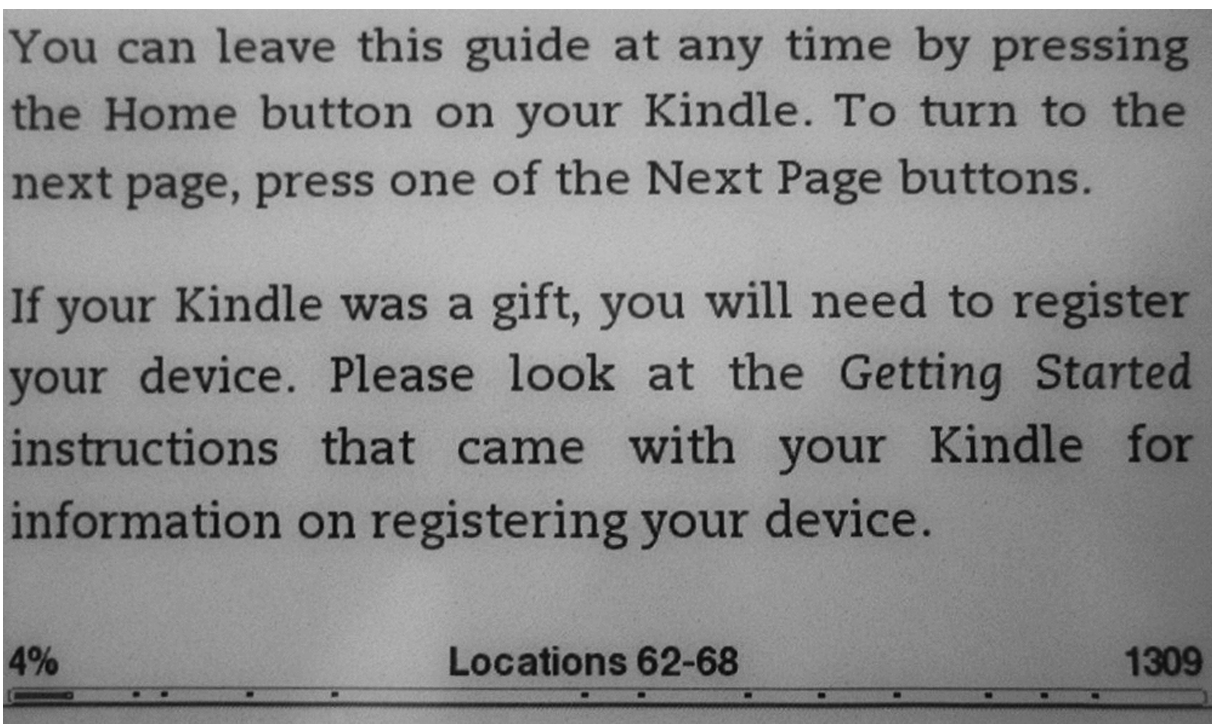

Figure 3. Kindle 2 Display (Evans, 2009)

Device-Based Applications of E Ink

As with most emergent technologies, immediate concerns regarding the viability and longevity of such a technology present major marketing problems. E Ink reinvents the paradigm of reading, and requires a pricey initial investment, both challenges on the road to public acceptance. Many readers have reported experiencing eyestrain and fatigue from reading eBooks, as it is more taxing on the eyes than scanning a traditional printed page (see figure 3). However, this comparison does not take into account netbooks, laptops, or other self-illuminating digital displays, which incite similar criticisms. The output quality is simply not as clear as the printed counterpart, principally due primarily low resolution and reduced screen contrast.

In terms of physical design, it has been difficult to miniaturize the technology to a weight and size conducive to convenient transportability. Combined with questions of durability, the designed obsolescence of the technology has forestalled many potential consumer audiences. Inevitably, the eBook reader will need to be upgraded or replaced as new functionalities and content formats evolve. Other challenges to address include limited availability of content, as well as legislation of digital copyright and licensing, which preclude copying or lending. The latter point negates the ethos of reader culture, which predicates itself on knowledge sharing and a discursive exchange.

Usability and Accessibility Issues

The major content limitations associated with eBook readers are largely attributable to digital incompatibility and copyright issues. There has been extreme market segmentation caused by multiple proprietary file formats and limited interoperability between devices. Digital rights management software also imposes another layer of restrictions on content (Clark, Goodwin, Samuelson, & Coker, 2008), setting limits on copying, lending and reselling of eBook purchases.

There are also some issues with the look, feel and interface of the device itself, which present practicality issues for the consumer. Users have reported experiencing wrist pain caused by holding the Kindle device for prolonged periods of time, claiming it is too narrow to hold comfortably with both hands (Clark, Goodwin, Samuelson, & Coker, 2008). Other general concerns with the physical device are that the buttons are placed awkwardly, neutral space is lacking, the scroll wheel is overly sensitive and the touch screen lacks functionality. The interface is also problematic, including the inability to change the font and style of the text, the poor display resolution, and the reduced contrast caused by a middle-grey background. Practical concerns include the reportedly flimsy case, its insecure closure and the inconvenience caused by flight travel restrictions disallowing use of electronic devices during taxi, takeoff and landing (Clark, Goodwin, Samuelson, & Coker, 2008).

In Kindle’s defense, it is said that use on exercise machines is more effective than books, as it lays flat more easily than a paperback. That being said, it does not provide the full immersion experience that books do, attributable to its slow response time, accidentally pressed buttons and other technical difficulties (Clark, Goodwin, Samuelson, & Coker, 2008).

Commercial Print Applications: *Esquire* and E Ink

Background and Overview

E Ink technology was employed in the production of a cover and overleaf feature for the October 2008 issue of *Esquire* magazine—a 75th Anniversary special issue that was published in an edition of 100,000 copies. Integrating a black and white E Ink display and coloured plastic overlay into a heavyweight cover, a series of words flashed on and off in a linear sequence (see figures 4-5).

Figure 4. *Esquire* Magazine Cover, October 2008 Issue (Image by author)

Figure 5. Detail of *Esquire* Magazine Cover, October 2008 Issue (Image by author)

Figure 6. Detail of *Esquire* Magazine Internal Electronics, October 2008 Issue (Metzger, 2008)

Prototype for Commercialization of E Ink Technology

The October 2008 *Esquire* magazine cover presents a model case study alternative to embedded device-based applications of E Ink technology. Utilizing a self-powered, standalone display panel and programmed microchip, the *Esquire* cover demonstrates the possibility of implementing electronic paper display without the requirement of specialized, external hardware. As a prototype for mass dissemination of electronic content, this application signifies a shift in design approach. By divorcing the rigid structure of a device from the flexible presentation of media, the language of traditional printed matter becomes highlighted, while the technological aspects are diminished. The relationship between reader and artifact becomes reinforced, while the disintermediation of the electronics is sublimated into the tangible, material qualities of the interaction.

The paradox of the *Esquire* proposition is that it presents a pragmatic application of E Ink as a sustainable solution, but its manufacturing process results in devastating environmental consequences. With research and development sponsored by the Ford Flex SUV/mini-van, *Esquire* hired a Chinese engineer to develop a battery small enough to slip into the cover, involving a six-figure investment. The custom-designed battery carries a limited charge to power the display for a mere 90 days (Paul, 2008), and cannot be replaced, rendering the display dormant and the electronics obsolete (Carnoy, 2008) (see figure 6). Due to the fragile nature of the battery and components, each volume was hand-assembled and subsequently shipped in refrigerated vehicles throughout all stages of the product's lifespan. From the parts manufacturing in China, to Texas and on to assembly in Mexico, then to the distribution centre in Kentucky and finally, to display and consumption on the newsstand, it is estimated that the total carbon output topped 150 tons of CO_2. This amount is roughly equivalent to the output of fifteen Hummers or twenty Americans per year (Kamenetz, 2008), and does not account for the CO_2 emissions produced during the manufacturing of the devices. Given that the batteries are single-use, they will no doubt end up in a landfill, as they are nearly impossible to recycle.

Comparison and Conclusions: Disposable Versus Device

Challenges and Promises

There are benefits and disadvantages to both embedded (*Esquire*) and device-based (Kindle) applications of E Ink technology. Currently, eBook readers present a more viable, efficacious model than standalone uses, and are simply more functional. They feature rechargeable, rather than single-use batteries. They perform more complex functions, such as mobile Internet access and document editing capabilities, as well as a boasting a larger storage capacity. The *Esquire* cover benefits from having a flexible form, but the lightweight Plastic Logic eReader from Barnes & Noble will challenge traditional eBook models when it is released to the general public in 2010.

Some current consumer challenges facing content and device providers include the high price of eBook readers and their duplication of services already available on other more widespread devices. The emergence of Apple's iPad and powerful portable netbooks that have the added functions of eBook accessibility have made it difficult to sell the eBook readers as a monofunctional technology. The unfamiliar interface does not replicate the familiar look and feel of paper, bringing consumers far out of their comfort zone when it comes to reading habits. The resolution requires enhancement and the screen contrast is too low. In fact, the device cannot be read in dark or even dim lighting conditions, due to the lack of a self-illuminated display. The breadth of content selection is quickly improving, but distributors will need to address licensing and copyright issues that inhibit lending or sharing, as one would with a traditional book. Furthermore, there are fragility and durability concerns, as with any electronic handheld device. All of these factors only add to consumer skepticism regarding perceived design obsolescence—a concern similar to the iPod paradigm of rapid and successive product releases. To broaden the consumer market from early adopters to a general public, manufacturers will need to establish product confidence while responding to accumulated usability data. Positioned at a luxury goods price-point, consumers demand reassurance that their purchase is robust, and will not be superseded by a revised model in an unduly rapid product launch cycle.

Conclusion

Consumer and Sustainable Benefits Analysis

In summary, there are many promising consumer and sustainable benefits involved with the evolution and adoption of paperless print and electronic paper display. For one, the reduction of paper-based ephemera would be a significant environmental benefit if the technology were to become widespread enough to lessen traditional printing. This would result in a reduction of CO_2 emissions from the pulp and paper industry and recycling plants, as well as a reduction in solvent contamination from the de-inking process necessary in recycling. eBooks consume less power than laptops, and if one were to replace some of the functions of the laptop with an eBook reader, additional power would be conserved. Furthermore, the text size can be adjusted on an individual basis to suit readers' needs, which is especially useful for visually impaired consumers, and would eliminate the need for large print book editions. There would also be a long-term cost reduction for students, educators and other voracious readers, providing them with easier access to library collections. Ergonomic benefits include the storage of multiple titles on a single device, doing away with transportation of weighty books that can lead to back strain and related injuries. Future applications will also undoubtedly exploit E Ink's flexible options for display formats and signage, as it can be printed on any surface.

While the *Esquire* design methodology is fundamentally flawed, as a case study analysis, it provides concrete evidence and material data to assess the possibilities of an alternative to existing green printing practices.

Author Biography

Christopher Moore

A designer and educator whose cross-disciplinary practice ranges from commercial publication design to media-based installations. Moore's creative and scholarly research currently focuses on appropriated digital content, and the emergence of new genres of folk culture facilitated by social media applications.

Designing Design Learning: A Case Study

Gale Moore, KMDI & Department of Sociology, University of Toronto

Danielle Lottridge, KMDI & Department of Mechanical & Industrial Engineering, University of Toronto

Karen Smith, KMDI & Faculty of Information, University of Toronto

Abstract

As 'designerly' ways of thinking and knowing are increasingly understood to be relevant in fields outside the traditional design disciplines, there is need to conceive of and design appropriate pedagogy. The challenge is to successfully negotiate disciplinary crossings in ways that simultaneously respect the discipline of design and provide a space for exploration and innovation, while at the same time produce results that satisfy individual disciplinary standards as well as the institutional standards of the university. The paper presents a case study of a novel graduate course in design research in the University of Toronto's Knowledge Media Design Institute (KMDI) – a multidisciplinary community in which the design has been largely grounded in models from human- computer interaction (HCI). The model of pedagogy that emerged out of this experience and reflection is then situated in terms of prior work on interdisciplinary pedagogy. We propose that our model of pedagogy grounded in what we call *disciplined transdisciplinarity* has the potential to generalise to other settings.

Keywords

Pedagogy, interdisciplinarity, multi-disciplinarity, transdisciplinarity innovation, human-centred design

The complex and interconnected nature of many contemporary problems is increasingly recognised, and the need for more systemic approaches for addressing them increasingly understood. This understanding will resonate with designers and design scholars as this framing respects the now half century of scholarship on design research and design thinking. 'Designerly ways of knowing' (Cross, 1982) are increasingly part of the public conscience and being taken up by business schools, and in various ways by scholars in other fields.

In principle there is much to recommend increasing the knowledge flows across disciplines, and the value of disciplinary crossings has been recognised by bodies such as the National Academies of Science (*Facilitating interdisciplinary research,* 2005) and the US Council of Graduate Schools (2007). This is not, however, easy to do either intellectually or institutionally, and there is an ongoing debate on what constitutes interdisciplinarity; the term used to describe both disciplinary crossings in general and a specific form of practice (Moore, 2009). As well, the myriad challenges of engaging faculty and students from different disciplines in the traditional university have not yet been resolved (Moore, 2003). The Report of the US Council points specifically to the need for an increase in interdisciplinary training stating that: "interdisciplinary research preparation and education are central to future competitiveness, because knowledge creation and innovation frequently occur at the interface of disciplines" (2007, p.18).

This brings to the fore the importance of pedagogy, the need for experimentation and the development of innovative new approaches that foster the kind of productive collaborative outcomes that interdisciplinary engagement is argued to generate. Our paper is motivated by these concerns.

We set out to explore this complex set of relationships through reflection on the origins and development of a graduate course in design research. The process whereby the course emerged was highly informal, but on reflection and through the subsequent design of new course materials and the writing of research papers that came out of this engagement, we began to understand the potential of this case to inform a model of pedagogy for graduate education grounded in what we call *disciplined transdisciplinary.* Reviewing the literature with this framing in mind, we found others who have taken up the challenge around the design and delivery of 21st century graduate education to support interdisciplinarity.

The paper begins by situating our case study in its institutional context, and in the context of the intellectual ideas that informed the development of the institute. We next present the case and the model. Lastly, we situate the development of the model in the context of literature on interdisciplinary pedagogy.

2.0 The Institutional and Intellectual Context

The University of Toronto's Knowledge Media Design Institute (KMDI) was established in 1995, to foster tri-campus[1], cross-divisional research and teaching in the emerging field of knowledge media[2] design (Moore & Baecker, 2003). Faculty and graduate students from 25 academic departments and faculties today engage in the scientific study of the ways in which media shape and are shaped by human activities and values; the design, development and evaluation of media applications and systems, and critical reflection on the implications of these developments in the broader social and cultural context.

This bold agenda challenged traditional university structures and existing practices as it required a broad base of collaboration across the disciplines. The University of Toronto, founded in 1827, is one of Canada's largest and most prestigious universities. It has a traditional organisation structure in which disciplinary and departmental boundaries tend to coincide, and departments and faculties are the site of scholarly legitimation, evaluation and reward for faculty and students. The ability to work across disciplinary boundaries is not readily accommodated, and it is especially difficult for untenured faculty and graduate students to engage in these practices. Second, knowledge media design is an emergent field and the potentially transformative nature of the internet and the associated cluster of technologies and applications emerging, was generally not appreciated in the mid 1990s. With limited funds, the institute was established as a virtual institute, a novel networked organisational form. Thus, despite the fact that interdisciplinary practices are not new, and had become re-invigorated in the 1960s (Klein, 1990,1996), the institutionalisation of these practices in universities can continue to be a challenge.

---

[1] The University of Toronto is comprised of three campus; the St. George campus in the City of Toronto and two satellite campuses located 25 km to the east and west.
[2] KMDI defines knowledge media (KM) as a specific class of media and media technologies designed to enhance human thinking, creativity, learning, communication, and collaboration.

In 2002, KMDI's Collaborative Masters and Doctoral Program in Knowledge Media Design proposal was approved by the Ontario Council on Graduate Studies thereby providing a specialisation for graduate students from a variety of academic backgrounds to engage in this emerging field. The Collaborative Program model[3] administered by the School of Graduate Studies at the University of Toronto was one institutional process that supported the ambitions of KMDI to offer graduate education in which students from more than one discipline could participate. Today there are ten academic units[4] participating in the program, and 57 masters' students and 30 doctoral students have been enrolled. Four specialised courses have been offered in addition to two core courses that provide the fundamentals of knowledge media design. On average two courses are offered per term. The potential for disciplinary mixing of students, already the norm for faculty participating in the institute, was thereby established.

2.1 The Role of Design in KMDI

Questions about how to engage with design and design practice have been a central concern in KMDI from the outset. The focus was a specific form of design; one that came primarily from the field of human computer interaction (HCI). This orientation reflected the origins of the institute in research on collaboration technologies as well as the physical location of a number of the faculty and the institute administrator in the department of computer science – also the home department of the first Director. KMDI's orientation to human-centred design (Moore &Timmerman, 1996), however, differentiated it from other North American computer science departments, in which the notion of user-centred design proposed by Norman & Draper (1983) was the norm at that time. As well, a number of the faculty founding KMDI had been associated with the Ontario Telepresence Project and worked with researchers from Xerox PARC and EuroPARC on media space. Many had been active in the field of CSCW: Computer Supported Cooperative Work, and associated with the Scandinavian model of participatory design (PD) since the 1990s. Thus, from the outset, a wide range of theoretical and methodological approaches informed the research carried out in the Institute. A diverse array of epistemological foundations do not necessarily co-exist comfortably and part of the research of the institute has been to explore this issue (Moore, 2003; Lottridge and Moore, 2009), and to develop strategies to negotiate these differences in ways that are both productive and creative.

Collectively, the faculty were less aware of the research in design that came from the design disciplines; architecture, industrial design, graphic design. However, with the emergence of the field of interaction design in the late 1990s with roots in both communities, this began to change (*Being Human*, 2008; Fallman, 2003; Leblanc, 2009). The question that began to emerge for us was how, and in what ways, might this scholarship inform our design practice? Would viewing knowledge media design through the lens of scholarship on design research be a source of new insights?

---

[3] The University of Toronto through its graduate departments, centres, and institutes offers unique, non-degree granting, collaborative programs. These emerge from cooperation between two or more graduate units, providing students with a broader base from which to explore a novel interdisciplinary area or a special development in a particular discipline, to complement their degree studies. Source: http://www.gradschool.utoronto.ca/programs/collaborative.htm

[4] These include Computer Science, Sociology, Information Studies, Mechanical and Industrial Engineering, Architecture & Landscape Architecture, Medical Science, Urban Design, Visual Studies and two departments in the Ontario Institute for Studies in Education, Curriculum Studies and Teacher Development and History and Philosophy of Education.

Following Cross, we understand design "as a coherent discipline of study in its own right, based on the view that design has its own things to know and its own ways of knowing them" (2007, p. 4-5). It was our goal to explore how this way of knowing with its focus on 'making' as well as thinking, on the elaboration of the relationship between practice and research, and on the need for collaboration and integrative thinking could help advance design research in the emergent field of knowledge media design. Buchanan has written: "Some see no need for design research, and some see in the problems of design the need for research that is modeled on the natural sciences or the behavioural and social sciences as we have known them in the past ... others see in the problems of design the need for new kinds of research for which there may not be entirely useful models in the past – the possibility of a new kind of knowledge, design knowledge, for which we have no immediate precedents" (2001, p. 6-7). To achieve the objectives to which KMDI aspires, a deeper understanding of design research and the epistemic communities involved in the production of design knowledge appeared to offer promise.

We were also aware that not all aspects of design research theory, methodology and practice would be relevant to the evolution of knowledge media design. We asked: how does one explore an unfamiliar field with a group of people from different disciplines, none of whom are experts in the field? How should we learn, and how might what is learned be mobilised going forward? And finally, how does one actually do the work of exploring the relevance of a field of scholarship to an emerging area such as KMD from several perspectives while simultaneously accommodating the formal requirements of students for academic credit?

Our approach was pragmatic and initially informal. We simply started to meet and a process began to evolve. Methodologically, this approach is closest to Schon's idea of 'reflection in action' which is in a complex relationship with 'knowing in practice'. As Schon notes: "A practitioners' reflection can serve as a corrective to over-learning. Through reflection, he can surface and criticize the tacit understandings that have grown up around the repetitive experiences of specialized practice, and can make new sense of the situations of uncertainty or uniqueness which he may allow himself to experience" (Schon, 1983, p. 61). Reflecting on the outcomes months later we began to formalise this as a model of pedagogy; a model to which we will return after describing the case.

3.0 The Case Study

3.1 From reading group to reading course

In the fall of 2007 an informal reading group was organised to explore the literature on design research. This began a process that would unfold over the next four months in a 'designerly' way – open, engaged, and iterative. The inspiration for the reading group can be traced to growing awareness of the potential that traditional design theories and practices might offer. A visit to a studio in landscape architecture was part of a KMDI core course, and a seminar on *Research design: Design research,* in the other core course led a number of doctoral students to take up the instructor's invitation to engage in further explorations of the field of design research. In the summer of 2007, the faculty member sent out a brief prospectus that included an excerpt from an earlier design project which she had led, and a number of questions that might be explored. Students were asked to contribute their expectations in terms of content and focus and to commit to attending a reading group in the fall if interested.

The challenges were two-fold. First, to look deeply into the scholarly literature on design research to consider what of this corpus might be relevant to a graduate research program in knowledge media design, and second, to consider how this might be taken up in the context of the institute and the university. The four doctoral students who participated were members of the KMDI Collaborative Program, and enrolled in faculties of engineering, education research and information, and had backgrounds in computer science, engineering, and media and communications. The faculty member was a sociologist.

The group shared common ground in that all were familiar to some degree with the design literature in the fields of HCI and human factors. Each was interested in reading more broadly to explore how, and in what ways, other disciplines contributed to the literature of design research. The group met regularly, more or less biweekly, and agreed upon a set of readings co-identified by the group members. At times these seemed random and almost disconnected, but in the process of sorting, sharing and reflecting, certain patterns began to emerge. We looked across the fields of engineering, architecture and industrial design, and saw how these fields mapped to the dominant intellectual history of each period. Not surprisingly, points of tension and transition generally aligned – for example, the challenge to the rationalist perspective and the impulse to participatory practices. Yet, despite similarities in periodisation there appeared to be little cross-fertilization across the fields with the exception of the classics such as Simon's *The Sciences of the Artificial* (1970). The field of interaction design[5] that began to emerge over a decade ago is now one bridge linking traditional design disciplines and HCI.

With the richness of the material uncovered and the quality of the conversations, the group decided to continue into the second term. However, the instructor felt these efforts should be formally acknowledged. The only formal university course structure that could accommodate this style of work was a reading course. Traditionally, reading courses involve a single professor and a student, and there is no procedure for a group to work in this way. The solution was that each student had a separate reading course, a specific research paper they negotiated with the faculty member, and they continued to meet as a group.[6] (See Figure 1.)

The group met more or less weekly through the 2008 winter term, and, a seminar series was developed to complement the course. (See Figure 2.)

---

[5] While there is still "no commonly agreed definition of interaction design, its core can be found in an orientation toward shaping digital artifacts – products, services, and spaces – with particular attention paid to the qualities of the user experience" (Fallman, 2003, p. 4).

[6] This constraint is a barrier to collaborative practice, as is the fact that reading courses don't 'count' toward faculty course load requirements.

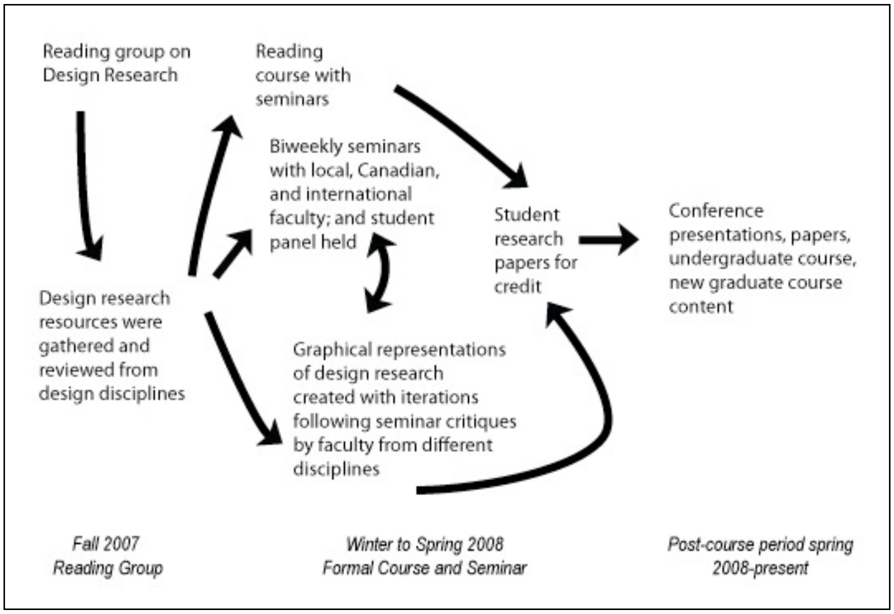

Figure 1 Design Research Reading Group, Course and Outcomes

The first seminars were given by local faculty from different departments teaching design, followed by Canadian experts with design expertise not available at the university. The students presented their research in one session and the series closed with two international scholars who participated in the seminar series and in addition gave a public lecture. These lectures were widely advertised in the university community and webcast. Overall, the series brought together design researchers from industrial design, information visualization, architecture, biomimetics, and critical design, and explored theories ranging from actor-network theory to critical design, and practices that included sketching and the use of design probes.

Figure 2 Design Research Series Poster[7]

[7] This poster includes an image from flickr.com under Creative Commons license by viagallery.com

To foster discussion regarding epistemology and Cross' concept of 'designerly ways of knowing', a number of steps were taken. First, each of the presenters was asked to provide a reading or two that was illustrative of their research perspective. This was distributed to the local community one week in advance as part of the seminar promotion with the request that anyone attending the seminar have read it. Second, the seminar series was not advertised outside the KMDI community, nor with the exception of the final public lectures were they webcast as is customary. The goal was to keep the seminars small enough for active engagement. Third, each presenter was asked to engage and reflect upon a graphical representation of design research that was being created in the course, and iteratively modified in response to the seminar discussions. The graphical representations became a set of shared artifacts around which the attendees, course participants, and presenters could orient, allowing us to consider what aspects of their epistemology, methods and practice might be relevant to the field of knowledge media design. These creative activities were one way in which our growing understanding and appreciation of design thinking could be put into practice.

3.2 Outcomes

The outcomes of the Design Research seminar surpassed expectation.

The curriculum and readings were co-constructed by the students and faculty. Each student worked throughout the term on a paper inspired by the course readings, bringing literature from their home discipline into the discussion as part of an exploration of disciplinary assumptions and perspectives. This led to deep enquiry that was reflected in the writing. Two term papers were expanded; one was published in a high-ranked peer-reviewed journal (Lottridge & Moore, 2009) and the other was presented at peer-reviewed technical conference (Smith, 2009). The ideas are being taken up in doctoral theses, and mobilising awareness of design research in the students' home departments.

The director of an undergraduate program in new media approached one of the doctoral students from engineering to develop a design-oriented course. In collaboration with a social science doctoral candidate they revised and updated an undergraduate course that drew on their experiences in the reading course. This course has been run twice and is being considered for addition to the core requirements for the undergraduate program. The students in the course have also brought this material into other undergraduate and graduate courses in which they participate. For example, in 2009, the course project in the core KMDI course *Fundamentals of KMD* was changed from a traditionally HCI three-step process of user-centred design (user requirements, prototyping, evaluation) to a four-step process that introduced the concept of ideation and included a sketching requirement.

Another significant outcome was the adoption of this approach for the newly established KMDI annual pro-seminar. Two doctoral students, inspired by their participation in the Design Research Seminar Series and the level of engagement and interaction, proposed a course and complementary seminar on the topic of Visual Thinking to the Collaborative Program director. This was taken up as the pro-seminar, and a faculty member who had contributed to the design research seminar agreed to serve as the course instructor. The students and faculty met to create a curriculum and to design a seminar series. While this course was inspired by the earlier model, the approach was modified to fit the specific needs and constraints of the group and the subject. For example, the major assignment was more visual and focused on the creation of an artifact, while continuing to integrate literature from the students' disciplinary backgrounds. This course and series was a success, and KMDI is now encouraging another group of students to articulate their choice for an emerging topic for the next pro-seminar. In the summer of 2009 the authors approached the 2009 course leaders to present a poster on the model and its evolution for the KMDI@13 Research Showcase (Lessard et al, 2009).

4.0 The Emergence of a Model of Pedagogy

A key observation from the case was that students were learning to think across disciplinary boundaries and to understand the ways in which epistemology, methodologies and values shape disciplinary knowledge and knowing. As well they were developing ways to negotiate cultures constructively even where epistemological differences were irreconcilable. This went beyond the disciplinary crossings normative in KMDI's research and collaborative program that have been primarily multi-disciplinary. The generative nature of these interactions is characteristic of transdisciplinarity.

Interdisciplinarity as a field of scholarly enquiry has long been part of KMDI's agenda (Moore & Timmerman, 1996; Moore, 2003, 2009). In transdisciplinarity the primary focus is not on the discipline per se but on the transformative potential of the interaction of individuals from different disciplines working together in a context of application. The process is dynamic, flexible, and generative. Figure 3 illustrates the various forms. It is the transdisciplinary form that we feel holds the greatest promise for addressing complex problems.

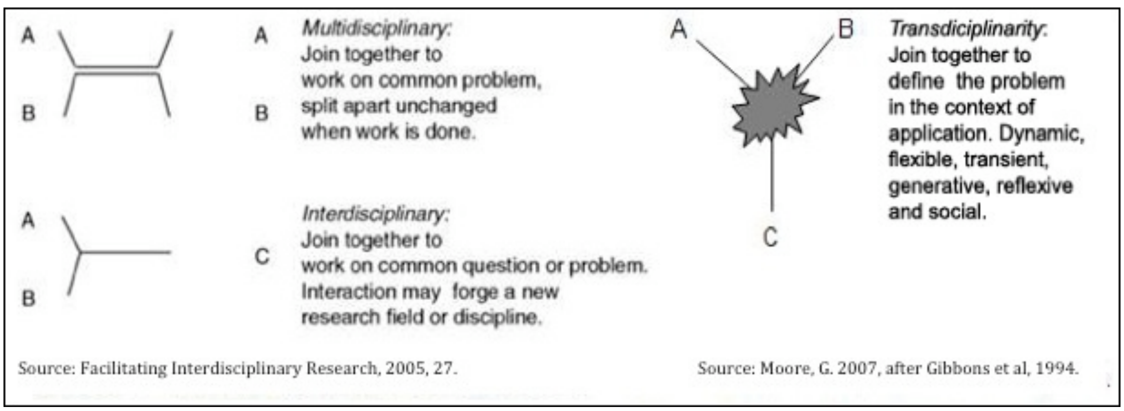

Figure 3 Inter-, Multi- and Trans-disciplinarity

Our model is summarized in Figure 4 below. Reflecting on the success of our case, we discuss three contributions beyond the activities that took place: the 'designerly' progression; the disciplined transdisciplinary nature of the engagement; and knowledge mobilisation. The model is then reviewed in terms of the literature on innovations in interdisciplinary pedagogy.

First, we position the visual model of design research by Sanders and Stappers (2008) at the base of our model to indicate the 'designerly' way the process unfolded. This references the transition from the 'messy' and informal practices at the origin to the more refined and formal outcomes at the end.

Second, by initially moving outside the boundaries of formal course requirements, we experienced the generative potential of the interaction of individuals from different disciplines working together in the context of a specific application, or what Michael

Gibbons (1994) refers to as transdisciplinarity. However, we continue to value the expertise gained through disciplinary training, and success in our case was in enabling a specific form of transdisciplinarity that we call *disciplined transdisciplinarity.* The notion is that by making disciplinary assumptions and values explicit, it is possible to co-create the bridges required to negotiate disciplinary divides and to appreciate the different epistemologies and perspectives revealed. KMDI students are frequently engaged in the design of digital media projects and have their own experiences to draw upon. The introduction of design thinking and ideas from the design disciplines engages them intellectually with how this is similar and different from design coming from a computer science or human factors perspective, The understanding and knowledge that results from this process can then be taken back to the disciplinary home unit.

Knowledge mobilisation is the third element in the model. Over the period of the course there was movement across what we are calling the *continuum of access* as the ideas moved outward from the students in the course, to the open seminar, and to their home departments and faculties. Finally these are disseminated in the university through public lectures, and via webcasting and publications, to the world.

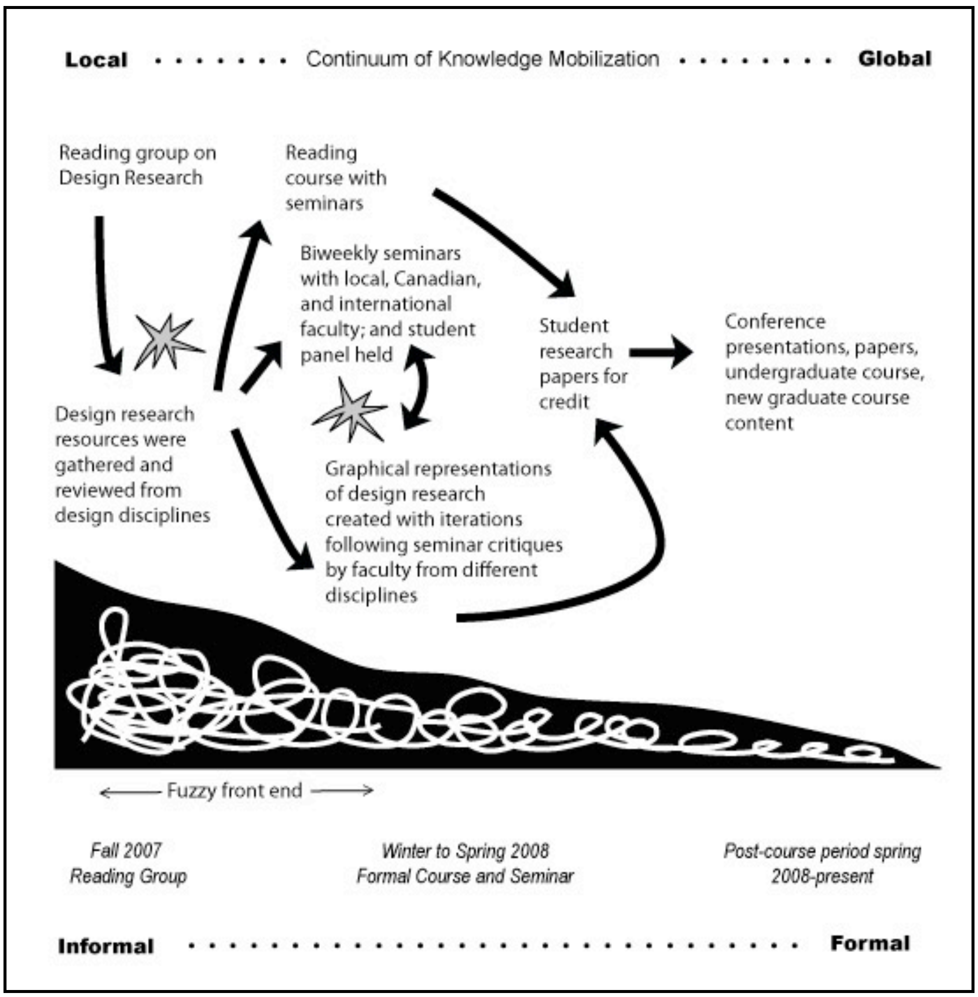

Figure 4 Pedagogical Model

5.0 Discussion and related work

A review of the literature illustrates the timeliness of this topic as educators from many disciplines consider how to prepare students for the challenges and complexity of the 21st century. In situating our work in relation to this corpus we focus specifically on pedagogy for interdisciplinary graduate education. We draw in particular on the work of Gerhard Fischer (2008) and Simon Penny (2009). Fischer's focus is on education for IT; and Penny's is on interdisciplinary education in the emergent field of media-arts and digital cultural practices, both highly relevant to knowledge media design. As one of our goals in reviewing the literature of design research was to identify the ways in which this field could be taken up and become part of graduate education in our field, we were encouraged to find scholars engaged in questions of pedagogy.

Fischer, a member of the Center for LifeLong Learning & Design, the Institute of Cognitive Science and the Dept. of Computer Science at the University of Colorado, Boulder, argues that there is a need to develop transdisciplinarity competencies which "refer to knowledge and skills required to identify, frame and address important scientific and practical problems that cut across disciplinary boundaries" (2008, p.3). The conceptual framework required to deliver these competencies, he suggests are derived from the learning sciences, Human-Computer Interaction (HCI) and Computer Support for Collaborative Learning (CSCL). Fischer's framing of transdisciplinarity is similar to ours in that it recognises the innovative and creative potential inherent in this form while also recognising the possibility of failure if there is an inability to find common ground (2008, p. 8).

The educational model of 'courses-as-seeds' (dePaula, Fischer, Ostwald, 2001) "explores meta-design and social creativity in the context of fundamentally changing the nature of courses taught in universities. Its goal is to create a culture of informed participation" (cited in Fischer, 2008, p. 5). Instructors provide the initial seed, rather than a final product and students actively co-create the course. While unaware of this research during the course, it describes our process well. However, while Fischer's approach to transdisciplinary education highlights the advantages of diversity and is awareness of the complexity of achieving it, we suggest that an important aspect of transdisciplinarity – discipline – remains masked. We argue that it is critical to foreground discipline and the significance of disciplinary differences in norms, values and ways of knowing in order to fully release the innovative and creative potential of transdisciplinary interaction. For this reason we prefer the term *disciplined transdisciplinarity*.

Penny addresses the question of the development of effective interdisciplinary pedagogy for the ACE project at University of California, Irvine; a project in the emergent field of media-arts and digital cultural practices. "The key components of such a project are: deep technical training and understanding; deep training in artmaking and cultural practice; deep theoretical and historical contextualization, and an open and rigorous interdisciplinary context which maximally facilitates the negotiation of these often divergent ways of thinking and making." (2009, p. 31). The disciplinary crossings are generally broader than in knowledge media design as ACE includes the experimental and conceptual plastic arts. While our goal is disciplined transdisciplinarity, Penny is reaching for interdisciplinarity and the creation of a new discipline. The goal of ACE is the "formation of practitioners who are neither artists nor engineers, or who are equal parts both" (2009, p. 31). And, he suggests that "there is a fair argument that, as of around 2005, the descriptor 'new media' has become an anachronism, and the 'field' has moved into a post-interdisciplinary transition phase; it is actively undergoing the transition to disciplinary status…" (2009, p. 37). Both agendas require extensive work in negotiating disciplinary or epistemic cultures, and the awareness that the exploration of the epistemological foundations of individual disciplines may prove uncomfortable (Lottridge & Moore, 2009). The ACE project, however, goes further as their slogan – "danger of permanent damage to axiomatic assumptions" (2009, p. 37) makes explicit.

While ACE and KMDI differ in their goals in terms of the desired outcomes of disciplinary border crossings, there are interests in common and two of these are questions asked in the discipline of design. First, what is the relationship between theory and practice and second, what is the relationship between problem setting and problem solving? The work of Rittel & Webber (1973) on problem setting is framed by Penny as "asking the right question" (2009, p. 46). He contrasts this with the analytical intelligence required for problem solving, and we are sympathetic to this view. We also agree with Penny's observation that "such broad integrative inquiry often demands the negotiation of world views and epistemologies that may appear quite immiscible" (2009, p. 46). However, from the perspective of knowledge media design it is important to continue to problematise the theory/practice space, as efforts toward developing a model that represents this field continue to benefit from exploring this tension. For Penny, "the reconciliation of theory and practice is a central dimension of the interdisciplinarity of ACE" (2009, p. 34). From our perspective, transdisciplinarity rather than interdisciplinarity, continues to be preferred for reasons that are critical. It keeps the future open, and does not risk falling into the trap of disciplinary rigidity and institutionalisation, precisely what a project of interdisciplinarity risks if it succeeds. Furthermore, there is value in disciplinary depth; a goal with which our notion of disciplined transdisciplinary is not incompatible. The challenge is to find those disciplinary experts willing to engage in intellectual conversations of this nature. We concur with Penny that this requires humility, courage and intellectual rigour (2009, p. 39-40).

6.0 Conclusion

"Interdisciplinary thinking is becoming an integral feature of research as a result of four powerful 'drivers': the inherent complexity of nature and society, the desire to explore problems and questions that are not confined to a single discipline, the need to solve societal problems, and the power of new technologies" (*Facilitating interdisciplinary research*, 2005,p.40). Support for this kind of thinking requires innovative approaches to education and training, and nowhere is this more important than in our universities where future researchers and scholars are trained. We will continue to require the specialised knowledge and expertise that disciplinary training produces. But while this is still necessary, it is no longer sufficient. To succeed in the 21st century graduates will need to have learned how to be self-directed learners, how to negotiate across cultures, including disciplinary ones, and how to work collaboratively in environments from the material to the virtual. Innovations in pedagogy and in our universities are required, and much we have argued can be learned from the discipline of design. This paper represents our first steps in an ongoing process of exploration to understand how best to prepare students to take a human-centred approach to the design of knowledge media as well as to be able to engage in constructive criticism of these media, technologies and related policies. A model of pedagogy grounded in disciplined transdisciplinarity we propose is one approach to preparing students for the uncertainties of a complex world.

Acknowledgements
We thank Kate Sellen and Joan Touzet who participated in the reading group and the course and Peter Coppin and Lysanne Lessard who participated in the biweekly seminar and took this model forward and participated in its evolution.

Author Biography

Gale Moore

A member of the Graduate Faculty, Dept. of Sociology; former director of KMDI, University of Toronto and adjunct faculty member in OCAD's SF&I graduate program. Gale's primary interests for the past 20 years have been the social impacts of ICTs in everyday life, and on bringing an understanding of peoples' experience and interaction with technology into the design of technical artefacts. She has a longstanding interest in institutional innovation and the ways various forms of interdisciplinary practice can enhance creativity and foster innovation. kmdi.utoronto.ca/people/bios/GaleMoore.aspx

Danielle Lottridge

A PhD candidate in Human Factors, Mechanical and Industrial Engineering, and collaborative program student in Knowledge Media Design at the University of Toronto. Danielle's thesis looks at the design and evaluation of tools that collect continuous reports of emotion/feelings. Her dissertation aims to deepen our understanding of how emotions change as an interaction experience unfolds, how to assess such emotions, and what patterns exist. www.imedia.mie.utoronto.ca/~danielle

Karen Louise Smith

A PhD candidate in the Faculty of Information and collaborative program student in Knowledge Media Design at the University of Toronto. Karen's dissertation research explores internet and social media based infrastructures for public participation in policy-making. In previous work, Karen explored the design and use of technology in the health sector. Karen blogs at www.karenlouisesmith.net

Set in Concrete? Crafting Innovation

Ruth Morrow, Professor of Architecture, Queen's University Belfast, Northern Ireland
Trish Belford, Senior Research Fellow, University of Ulster, Belfast, Northern Ireland.

Abstract
This paper draws on the experience of practice-led research based in academia, which investigates the possibility of making hard surfaces soft.

So far the project, in its fifth year of development, has led to three patents being filed on technology allowing manufacturers to embed textile technologies onto the surface of precast concrete surfaces resulting in hybrid but integral finishes.

The work was initially understood as decorative but as the project has moved into testing and analysis phases a better understanding of the resultant altered characteristics of precast concrete surfaces has emerged – ie the resultant hybrid concrete surfaces overcome some of the negative characteristics of concrete to become colourful, warm, acoustically soft, thermally less variable and people friendly. In short, this design-led research process has extended the characteristics and hence potential of a global material.

Following on from a brief outline of the project and evidence of its innovation, the paper will be structured around two central sections examining some of the strategies that have evolved in this hybrid process and examining potential tactics that have led to innovative outcomes. The first section will examine how conceptual and theoretical thinking, generated out of a user-centred critique of the built environment and an understanding of the relationship between architecture and textiles, can demonstrably lead to pragmatic, innovative and marketable solutions. The second section will look at the interrelationships between creativity, innovation and collaboration and address some potentials and challenges.

The paper represents an early attempt to make sense of this design–led project. It aims to capture and contextualize some possible transferable tactics that might lead to more conscious and explicit processes for crafting innovation.

Keywords:
architecture; textiles; concrete; collaboration; design-led research; research-led design; craft; innovation

1.0 Introduction
This paper is based on an ongoing collaborative project called 'Tactility Factory' between a textile designer and an architect. Other than the first few years of the project, the primary author of the paper (the architect) had been principally involved in design pedagogy, helping to establish new design studios and undergraduate architecture courses in the UK. Much of that pedagogy was informed by an interest in what at times felt like two diametrically opposed areas ie how to teach design to first year students;

and, how to address critical theories that surround architectural education and practice, namely, inclusive and feminist theories. Between these two areas sits a seldom-voiced and rather rudimentary question; do design practices that seek people-sensitive outcomes result in *ugly* outcomes? (An Architektur and Heyden, 2010)
The project offered a place to explore this tension and an opportunity to practice and test what the architect had previously taught. It has therefore become a place to theorize socio-politically whilst making innovative and aesthetic products, and reflecting on the efficacy of previous pedagogical practices.

The project however was not initiated within the format of a traditional research project ie to test a research question. Rather it began with the design intentions of *making hard things soft,* in order *to mainstream tactility in the built environment.* The means by which this was to be achieved was through the application of textile approaches and techniques to the design and manufacture of built environment materials (see section 3.1.1 for the theoretical justification of this 'methodology'). The results of this design-led approach are regarded as highly innovative and much external attention has fallen on the project (see section 2.0 for indicators of innovation).

Within the context of this research paper, we will examine and question: *what tactics within the project led to an innovative outcome*? The hope is that by doing so we might identify transferable practices to other situations, leading to a conscious and explicit process for crafting innovation.

The possible tactics that craft innovation will be examined under the following areas:

- Cultivating a Distinct Context
- Creativity, Innovation and Collaboration

The paper will examine each of these in turn, acknowledging the overlaps and challenges. Firstly, there is a necessity to scope out the nature of the project and its outcomes in the following section, allowing the reader to get a sense of the nature of the project.

2.0 Project Outline

The Tactility Factory project combines the hard properties of concrete with the softness of textiles by designing innovative processes that deliver beautiful and sensorial engaging surfaces. The approach of applying 'textile thinking' to hard materials used in the built environment, is one that is not necessarily concrete-specific and could, we believe, be eventually applied across a range of materials. However for the moment we have focused on combining concrete and textiles.

It has taken four years of testing and development to identify the appropriate materials and resolve the technologies that can be used to combine textile and concrete manufacturing processes to create pre-cast concrete surfaces with an integrated and permanent textile surface. The textiles are designed and manufactured to incorporate voids, meaning that surface patterning is created as much by the concrete as by the textiles. The resultant surfaces convey an antique feel, despite being principally created using the latest digital technologies and processes. The end result is described conceptually as the 'fossilisation of textiles'.
Three technologies have been perfected to date

1. ‘linen concrete’: Varieties of linen weights and colours are used. Voids are created through which seeps the concrete, leaving an integrated and robust surface of concrete and linen. Linen is chosen since it survives in alkaline environments
2. ‘stitched concrete’: A variety of technologies is used to allow the stitched surfaces to remain on the surface. Yarns in a range of colours, weights etc can be used to create endless variations in pattern and design.
3. ‘flocked concrete’: short flocking fibres are integrated onto the surface of the concrete resulting a highly tactile and ‘stroke-able’ finish.

Fig1: ‘linen concrete’- linen textile allows concrete mix to flow through to surface creating visual and tactile patterns

Fig2: ‘stitched concrete’- textile, digitally stitched and imbedded into concrete surface gives an appearance of an embroidered surfaces

Fig3: ‘linen concrete’ panels used in private commission

The level of innovation residing in the processes and products is indicated by the external interest the project has drawn. This includes a number of awards for innovation, invitations to exhibit nationally and internationally and features in international design journals and magazines. The work is also cited in publications on trend forecasting and innovative products and forms of practice (see www.tactilityfactory.com/publicity.html) Recently Tactility Factory has been successful in winning two major competitions related to the next ‘Big Idea’ and the project is now in the early stages of forming a spin-out company.

So the question is what has caused these innovative outcomes to emerge. The next section will consider some of the possible conditions or tactics to craft innovation.

3.0 Possible Tactics that Craft innovation

3.1. Cultivating a Distinct Approach

The question: *why do this*? has echoed throughout the lifetime of the project. More particularly, *why place delicate, beautiful fabrics into harsh alkaline environments?* The most direct answer is – *why not?*. But more profoundly, because the project is a response to observations and critiques that have occurred throughout the careers of the collaborators and increasingly throughout the progress of the project. The process therefore is far from the usual process of product development that addresses an identified customer need or a specific gap in the market. Instead the Tactility Factory process begins from a conceptual range of critiques and seeks to exemplify, through a product development, an approach, indeed an ethos, that addresses wider critiques.

These critiques act as sources of motivation or investigation and are:

3.1.1 A sensory approach to technology (textile context)
The textile designer's skill in creating rich tactile surfaces through the application of appropriate technologies has led to an examination of how effectively this is achieved within the discipline of architecture.

Tactility is certainly referenced in wider critiques (Levin, 1993 and Pallasmaa, 1996) of modernism in architecture that challenge the dominance of the visual and call for the corporal and psychological experience of space to be better understood and elevated in significance. In addition, many phenomenologists that influence and practice architecture (Maurice Merleau-Ponty, Christian Norberg-Schulz, Steen Eiler Rasmussen, Juhani Pallasmaa, Steven Holl, Peter Zumthor) also position tactility and sense of touch within their wider concerns for the 'experience of architecture' and its material manifestations.

Juhani Pallasmaa whose own relationship to the senses and architecture are well documented across a range of publications (Pallasmaa,1994 and 2005), states in his most recent publication: *The Thinking Hand*, that:

> The boundary line between the self and the world is identified by our senses. Our contact with the world takes place through the skin of the self by mean of specialized art of our enveloping membrane. All the sense, including vision, are extensions of the tactile sense; the senses are specialisations of skin tissue, and all sensory experiences are modes of touching and thus related to tactility'
> (Pallasmaa, 2009 p….)

Pallasmaa understands the centrality of touch within the body's sense of itself and the world around it, but also accepts that architecture falls short of delivering a full response; *"Our architecture may entice and amuse the eye, but it does not provide a domicile for the touch of our bodies, memories and dreams'*

He does cite some examples where architectural detail offers tactile sensations. However such work represents only the elite output of the profession and in general whilst architects may want and believe architecture to deliver a full mind/body/ soul experience, in the practice of everyday architecture, it all too rarely does.

On the other hand, technology does occupy a central position in architectural practice. Many conceptual and stylistic shifts in architecture have been interdependent on technological advancements. There exists a long tradition and strong culture of architecture that pushes the development and celebrates the use of technology. However, whilst such architecture often has strong visual impact, the experience of occupying, using or passing through such spaces can be cold and alienating. As Perez Gomez fears "Technology substitutes a 'picture' for the world of our primary experience." (Perez Gomez, 1994, p5)

In contrast, interacting with a textile is personal and unique; a *cosy*, *cuddly*, *slippy*, *scratchy*, *warm* encounter. Simultaneously, one experiences an intimate physical and aesthetic reaction. Behind this emotive experience of textiles lies as much technical expertise as is required in the making of space. It is therefore the remarkable achievement of textile designers to use 'hard-core', chemical and mechanical processes (abrasive/ corrosive technologies) to transform and combine yarns into an artifact that evokes strong emotional responses. In other words, technology may be core at the textile designer's process but it is rarely present in the user's interface with the product.

The Tactility Factory project draws on such reflections and seeks to apply a textile approach to the technological development of building products in ways that respond to these concerns. In addition, the project seeks to echo Peter Rice's ethos of *Trace de la Maine, to*, "..make real the presence of the material in use in the building, so that people warm to them, want to touch them, feel a sense of the material itself and of the people who made and designed it." (Rice, 1994)

3.1.2 politics of inclusion. (Inclusive context)
The architect in Tactility Factory has been involved in inclusive design (evolving from disability studies) over a longer time span. As such, concerns for a people centred design approach are also reflected in the processes and products of Tactility Factory.

Products and components used in constructing the Built Environment are designed, almost exclusively, to meet technical specifications only. It requires the skill of the architect to use these building products in such ways as to create environments suitable for people. Tactility Factory brings a 'human' specification to the development of its surfaces, considering it to have equal importance as the technical performance. Indeed the profoundest challenges do not lie with meeting technical specifications (since much of that work has been done by technologists before us), but rather to apply technological understanding in such a way as to make artifacts and surfaces that people wish to interact with. In the shadow of this apparently pragmatic statement sits a real concern for multi-sensory experience, design quality and beauty.

The process of Tactility Factory is built on a belief in transparency and sharing. This frequently challenges the cultures of intellectual property protection and in-house academic politics, however we understand it as an instinctive and core politic to the work processes of Tactility Factory and feel compelled, as pedagogues and members of wider design professions, to demystify processes and products through active dissemination. We use traditional and electronic media (blogs/ websites) to make links, reveal our inspirations and chart tactics. Naturally, dissemination invites response and Tactility Factory has benefited by the links, suggestions and collaborative relationships that have evolved because of these disclosures.

3.1.3 A context of historical and contemporary precedents and theory
As we work practically on the project we are at the same time party to wider academic discourses. Defining and researching contexts for the work helps contextualize Tactility Factory within a range of theoretical contexts and architectural legacies.

In particular, we have become interested in the enduring and ever-evolving relationship between architecture and textiles and adjacent relationships such as fashion and surface. Starting with Gottfrield Semper's (1803-1879) theories on the interconnection between textiles and the origins of architecture itself and his development of the

'Principle of Dressing' in relation to architecture, through to the work of architects such as Hoffman and Van de Velde's who simultaneously designed clothing and architecture at the end of the 19th Century. Followed by modernism's rejection of all things decorative, influenced by Loos's 1913 text 'Ornament is Crime' (Kinney, 1999) and onward to those architects whose work has engaged creatively with surface, for example Rudolf's seminal surface treatments in the Art and Architecture Building at Yale (Rohan, 2000) and the work of the Spanish architect Miguel Fisac in 1970's and 1980's [i]. More recently the developments in nano and smart textiles covered in the work 'Architextiles' by Mark Garcia (2006) also informs the work of Tactility Factory.

We have found through this process of contextualization and analysis, examples of architecture where textiles are used either literally or conceptually. When used literally, textiles are typically used within framed and strictly regulated structures; taut, stretched and controlled; they are the 'smart' petrochemical constituents of space-age lightweight structures, seen but not touched. Where there are used conceptually, it is their characteristics of *'lightness, surface, complexity and movement'* that mirrors *'architecture's shifts towards a more fluid state'* (Garcia, 2006). Overall the result is architecture that may **look like** and indeed may even appropriate textile technologies, but rarely **feels like** textiles. (Authors, 2008). (There are of course some interesting exceptions to this rule that serve as guide points for the project.)

An awareness of existing precedents has helped Tactility Factory advance through a critically aware process. By creating a clear and distinct line of theoretical intent, which alongside logistics helps to define and order the pragmatic investigation, Tactility Factory hopes that this reduces the changes of replication and builds what Yair, Tomes, and Press (1999) call 'immunity to imitation'.

There are in the end many ways to tackle any problem, but we endeavor to choose a route forward through an informed 'creative opportunism' (Cross, 2007) rather than a random one. Our aims therefore remain focused on **mainstreaming tactility in the built environment** and whilst that may be perceived as utopian it helps guide and formulate the project, even within the scope of a business plan or the text of a patent.

Interestingly while we argue that the development of the hybrid surfaces is not a direct consequence of responding to a market need, the utopian goal closely reflects what Kim and Mauborgne (1999) in the *Harvard Business Review on Breakthrough Thinking* identify as one of the strategies of 'value innovation' ie 'the ability to pursue a quantum leap in value'. It could be argued that *value innovation* naturally arises because at the centre of Tactility Factory is the *value-laden* methodology of design.

3.2. Creativity, Innovation and Collaboration

In its early stages, Tactility Factory was driven by a singular collaboration between a textile designer and an architect. This remains at the core of its development but as it has progressed the project has drawn on and been tangibly informed by collaborations with pre-cast concrete specialists, mould makers, digital textile designers, weavers, embroiderers, graphic designers, marketing consultants, business advisors and patent attorneys.

Whilst many of those who contribute to the project do not come from a creative profession per sec they all contribute to *the application of creative ideas*; and since this is regarded as one definition of innovation (McKeown 2008), we acknowledge the contribution of all those involved in driving forward innovation in Tactility Factory.

Within Tactility Factory therefore we work hard to recognise and give space to the personal motivations of all involved. Motivations range from wishing to experiment with a familiar technology, to holding true to a certain ethic or work process. The importance and relevance of these motivations are discussed and where possible time is set aside for them to occur. However we also recognise that what motivates most creative practitioners is time for play, creative experimentation or risk-taking. Whilst this can be personally fulfilling and result in highly creative outcomes (a Tactility Factory strap line is "creativity is our currency") it can sometimes cause us to avoid the obvious, more direct routes and choose instead to explore new territories at the cost of moving the programme forward in an efficient and effective manner. This applies not only to the material manipulation of the surfaces but also the strategic direction of the project as a whole.

It is also important within such a context to value the strengths that each person brings to the process. So for example it's understood that the textile designer brings a wealth of knowledge and experience from the textile design industry. She therefore offers

- Profound technical skills, a natural curiosity and a confidence to experiment within new and unfamiliar technologies.
- An acute sensibility in creating rich tactile surfaces through the application of appropriate technologies.
- A fastidiousness about *the fabrication of the aesthetic*; trialing, testing and ultimately crafting and controlling each technical move to ensure quality outcomes.
- A pragmatic approach to product development and a track record in delivering.
- An ability to lead in trend sensitive markets

By comparison, the architect / academic brings

- A strategic clarity to the process
- A strong belief in the 'concept' / design intention mapping to the detailed level
- A confidence that large problems can be broken down into logical steps and managed.
- Skills in communicating across 'languages' and cultures ie from visual to verbal, from conceptual to operational, from creative to pragmatic

The intensity of learning around collaboration has been due in no small part to the hybrid nature of the project. Bringing concrete and textile cultures together in one project has been a challenge. Of course much has been written about the strength of working collaboratively across cultures or professional disciplines (Paulus and Arian, 2003), less is said about how to cope where cultures appear to be antithetical to one another, such as concrete and textiles.

"Where attempts are made to create diversity, the effort is often incomplete because people with varied backgrounds and thinking styles tend to have difficulty understanding one another. In practice, their differing viewpoints tend to lead to personal disputes and the creative process breaks down."

Karlyn Adams, 2005

Given that this is a multi-layered project, the chance of experimentation across the material technology of concrete moulds, concrete mix, multiple textile techniques and also across a strategic direction means that the potential for diversion, confusion and ultimately error is multiplied many times over. Communication and documentation is therefore key. We aim where possible to build diaries, schedules of materials and recipes, tables of trials and critiques collectively and over time we have renamed processes and products in a third language, specific to Tactility Factory and non-discipline centred. The creation of this 'third' nomenclature is a symptom of collaboration across a wide stretch of cultures and is a necessary outcome of a hybrid collaborative practice.
Naming is also part of the categorization and critique of design trials. We aim for bi-weekly round-table discussion about the artifacts produced. All collaborators in Tactility factory regardless of their background or role take part in these sessions, and it is at these moments that we witness what Cross describes as the 'co-evolution of problem and solution', where 'Designing appears to be an 'appositional' search for a matching problem-solution pair, rather than a propositional argument form problem to solution'. Given that this project has not sought to address a defined need in the market place but rather to respond to a conceptual gap, this act of 'crafting' the problem, categorizing and re-categorizing the potential solutions relates not just to making a product but also defining an as-yet unrealized market-scape. As we categorize and name we also ask: why would anyone need this product? what purposes could it serve? what other problems does it relate to? The design process therefore appears to be in flux, almost uncertain of its own rationale. To some extent this also echoes Lawson's study of the architectural design process where, after observing the processes of many architects, he argues that the only thing one can be certain of is that ".. designers have to gather information about a problem, study it, devise a solution and draw it, though not necessarily in that order." (Lawson, 2006). The one chief difference here is that architects traditionally accept that however convoluted the design process, the solution to the problem will ultimately be a building. For Tactility Factory, however, there is no foregone conclusion.

4.0 Conclusion

The Tactility Factory project has opened up many lines of enquiry. The work of making sense of its processes and outcomes is ongoing and this paper is an initial attempt to capture and contextualize some of the tactics used during its development that seem to have resulted in, or crafted, innovative outcomes.
In terms of Cultivating a Distinct Approach, there is little doubt that the project has benefited from having a clear intellectual context to respond to (3.1.3 historical and contemporary precedents and theory); a justifiable and defined methodology (3.1.1 a sensory approach to technology); and perhaps less obviously, an alignment to a set of values that help to sustain and focus ongoing development (3.1.2 politics of inclusion)

Even before the technology to produce the surfaces had been fully resolved this Distinct Approach had given the project a unique identity and had drawn sympathetic collaborators and interested parties to it. It would seem therefore that innovation can be supported not only through a crafting of the process but also a crafting of the intention, approach and context.

In terms of Creativity, Innovation and Collaboration it is clear that understanding the different approaches and modes of creativity that each contributor brings to the process is crucial. Tactility Factory's regular round table discussions are convened in front of the surfaces produced. The very tactility of the surfaces causes the meetings to take on a less conventional format and contributors interact directly with the surfaces and each other; humanity in combination with creativity, are part of the discussion. This interaction is further underpinned by the ongoing development of a hybrid language used in the naming, categorizing and re-categorizing of design and surface outcomes. This third nomenclature becomes another form of representation, opening up new perspectives on processes, possible markets and new relationships. It helps define actions, present and future.

Finally, understanding the context, the extant skills and motivations of the team, the nature of materials, process of fabrication and the extent of resources; combined with a critical confidence in the design process, may not only allow for the evolution of new products but also unexpected results.

Sketching in Hardware and Building Interaction Design: tools, toolkits and an attitude for Interaction Designers

Camille Moussette, Umeå Institute of Design, Umeå University, Sweden, camille.moussette@dh.umu.se

Fabricio Dore, IDEO, Munich, Germany, fdore@ideo.com

Abstract

In this paper, we present a *Sketching in Hardware* perspective to Interaction Design (IxD) education and practice. We start our discussion by highlighting the differences between *Prototypes* and *Sketches*, and explaining why we believe the term *Sketching in Hardware* is suitable and appropriate to the IxD practice. We introduce a short history of the term and its origins before relating it to Experience Prototyping activities and other related design processes/methodologies.

Our main discourse consists of observations and a critical analysis of academic activities and professional work suggesting that *Sketching in Hardware* remains quite challenging despite the recent progress in the development of new tools and toolkits. The low barrier to entry and the explosion of tools and toolkits are very welcome, but this democratization can also be misleading. The learning curve is still steep in many ways. The current sketching tools seem to have leapfrogged our design skills and our ability to deal with that avalanche of technical capabilities. Designers regularly loose a critical perspective on their sketching and prototyping activities. We noted that students and designers alike spend a lot of time mastering intricate tools and debugging technical issues when they should be developing, evolving and fine-tuning interesting experiences or sketches informing their design process.

We close our discussion with a review of various toolkits and building blocks currently available to interaction designers for designing new technology and future concepts. We ultimately suggest five guiding principles to be taken into account in the design of new toolkits or upgrading of existing ones. These same principles and qualities not only can, but should also radiate in the experiential qualities, well beyond the built material artifacts. *Sketching in Hardware* is not just playing with electronics; it has serious implications and repercussions in the way we design stuff.

Keywords

Interaction Design, Prototypes, Prototyping, Sketches, Sketching in Hardware, Toolkits, Experience, Design Tools.

Prototyping is a core aspect of design activities. As a loose definition, prototypes are manifestations of a design made before the final artefacts exist. Many authors have written about the various forms and variations of prototyping activities (Buchenau & Suri, 2000; Buxton, 2007; Houde & Hill, 1997; Lim, Stolterman & Tenenberg, 2008; Shön, 1982). They often diverge in the specifics but globally, they describe the same design activities used to filter a design-space and build corresponding representations. In the field of Interaction Design (IxD), such design activities are often encompassed in terms like Experience Prototyping, Hardware

Prototyping and Physical Computing. Our main objective with this paper is to present a new perspective on sketching in Interaction Design and describe our view of how students and designers go about it.

Sketches are not Prototypes

A few authors like McCullough (1996) and Buxton (2007) point out the importance of the mediums and that prototypes are different from sketches. Sketches, in any mediums, have different qualities and purposes. Without simplifying too much, sketches are generally used and valued earlier in the design process, while prototypes are more beneficial towards the later stages of the process. These two representations have their own specific role, intent, qualities and purposes in a designer's toolbox. Buxton (2007) proposes this comparison or continuum (Fig. 1). In our view, while this polarization can be useful to discuss and understand the differences, most design manifestations sit somewhere in the middle, depending on the context and situation they originated from.

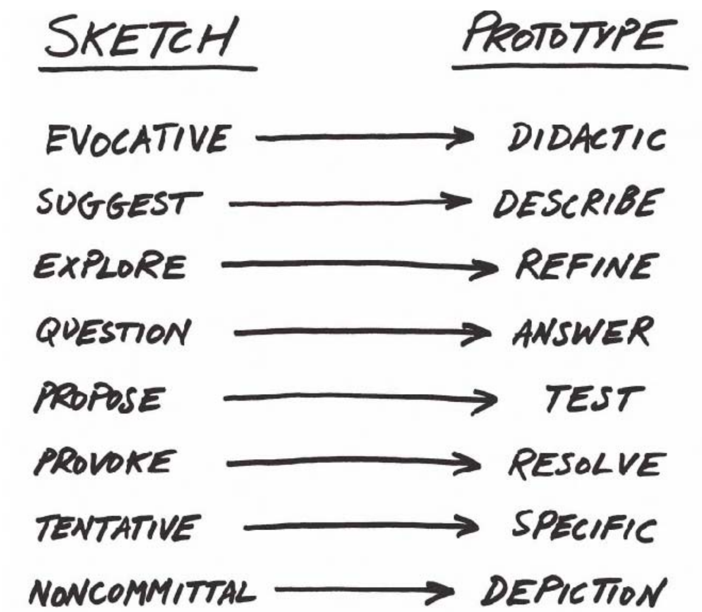

Figure 1. The Sketch to Prototype Continuum (Buxton 2007)

Prototyping is a term widely used in many domains outside design. In software development, a prototype is generally understood as a working proof of concept, a partial instantiation of the final application where some aspects are usable for testing or internal reviews with client, users and contractors (Floyd, 1984; Wikipedia, 2010). The focus is clearly towards showcasing solutions, evaluating options and agreeing on specifications, all of which are situated in the later stages of development. Although newer approaches and methods are breaking this tradition (agile method), prototyping in software development involves very little ideation and explorative and noncommittal activities.

In Industrial Design and Product Engineering, a prototype corresponds often to the latest instantiation before going to final production (Feirer, 2002). All problems are solved at this stage and the prototype is (ideally) an one-off copy of the upcoming production item. What comes before the prototype adopts a variety of names depending on the use and purpose: exploration models, volumetric or form study models, visual models, functional models, proof-of-principle models, engineering models, throwaway prototypes, concept prototypes, etc. Sketches are also well understood and highly valued in Industrial Design. They are fast, explorative and tentative representations to exteriorize and communicate ideas. Additionally, the self-reflective qualities of sketching are often more important than the resulting sketches themselves (Hanks & Belliston, 1990). Numerous authors have highlighted the crucial underlying processes of sketching that support creative thinking (Schön & Wiggins, 1992).

From our perspective, we believe ‘*sketching*’ is an important term that designers and design students should be using more when referring to design activities that relate to evolving and building interaction ideas creatively. Although not perfect, the term ‘*Sketching in Hardware*’ reflects well the action of sketching in any mediums (with or without computing capabilities) well beyond pen and paper. Compared to ‘*prototyping*’, ‘*sketching*’ feels definitely more appropriate for evolving ideas and developing design concepts. To our knowledge of educational curriculums and today’s practice in design consultancies, very few designers work in the later phases of the design process: close to mass manufacturing and production, where ‘real’ prototypes are commonly found. These activities tend to be very technical and are naturally best handled by competent engineers and professional builders.

History of Sketching in Hardware

The term *Sketching in Hardware* is not exactly new. Researchers like Holmquist (2006) have introduced the term some years ago, and it is somewhat present in today’s IxD teaching curriculum and professional practice.

It is important to note that although the term is relatively new, the activities and motivations have been around for decades. Companies, design consultancies and research groups have been developing interactive physical products or projects with a strong focus on early electronic sketches or half-faked interactive demos (Fitzmaurice, 1993). Almost a decade ago, Greenberg & Fitchett (2001) introduced Phidgets as a toolkit to support, build and test physical interfaces quickly. During the following years, the ideas and tools evolved rapidly, left the research labs and gained widespread adoption in design school and consultancies. The term ‘*Experience Prototyping*’ is well recognized today in the design community and has strong roots with the user-centered design movement (Buchenau & Suri, 2000). We agree that both *Experience Prototyping* and *Sketching in Hardware* have a lot in common and are almost interchangeable. Our intention with this paper is not to argue over exact definitions, but more trying to describe, understand and enhance the design activities taking place. Let us just finish by mentioning that both terms complement each other very well, *Sketching in Hardware,* due to it’s strong sketchy, almost messy and more designerly connotations, has the benefit of emphasizing the material and experimental qualities, whereas Experience Prototyping highlights that the goal is to design and support the experience and not the prototype (or the built artefact).

Sketching and building Interaction Design differently

Technical know-how can be a blessing or a curse

From our teaching and tutoring experience (as well as being students ourselves), we observed that students are often mesmerized by the new technological and technical possibilities. Discovering new technology and being able to appropriate it to build something that works (partially at least) is usually very satisfying and gratifying. It is somewhat natural to be in that 'wow phase'.

But designers have to move on and make good and meaningful use of those tools. As good craftsmen, designers should avoid pursuing a project (or prototyping) relentlessly to a point where it becomes self-conscious demonstration and point-less perfectionism (Sennett, 2008). Great and seductive demos and prototypes surely have their value in the design process, "but they are only one part of a means to an end, and certainly not the end in itself" (Buxton, 2007, p. 412)

However, the skills and knowledge required to build hardware sketches are difficult to outline, mostly because the nature of the work spans many disciplines and domains. Technical know-how in electronics, mechanical systems, programming, sensors and the like are absolutely helpful, but so is knowledge in improvisation, performance arts, storytelling, communication, movie making and psychology. In our opinion, it is not necessarily the sketch you make that counts, it is how you use it to inform your design activity.

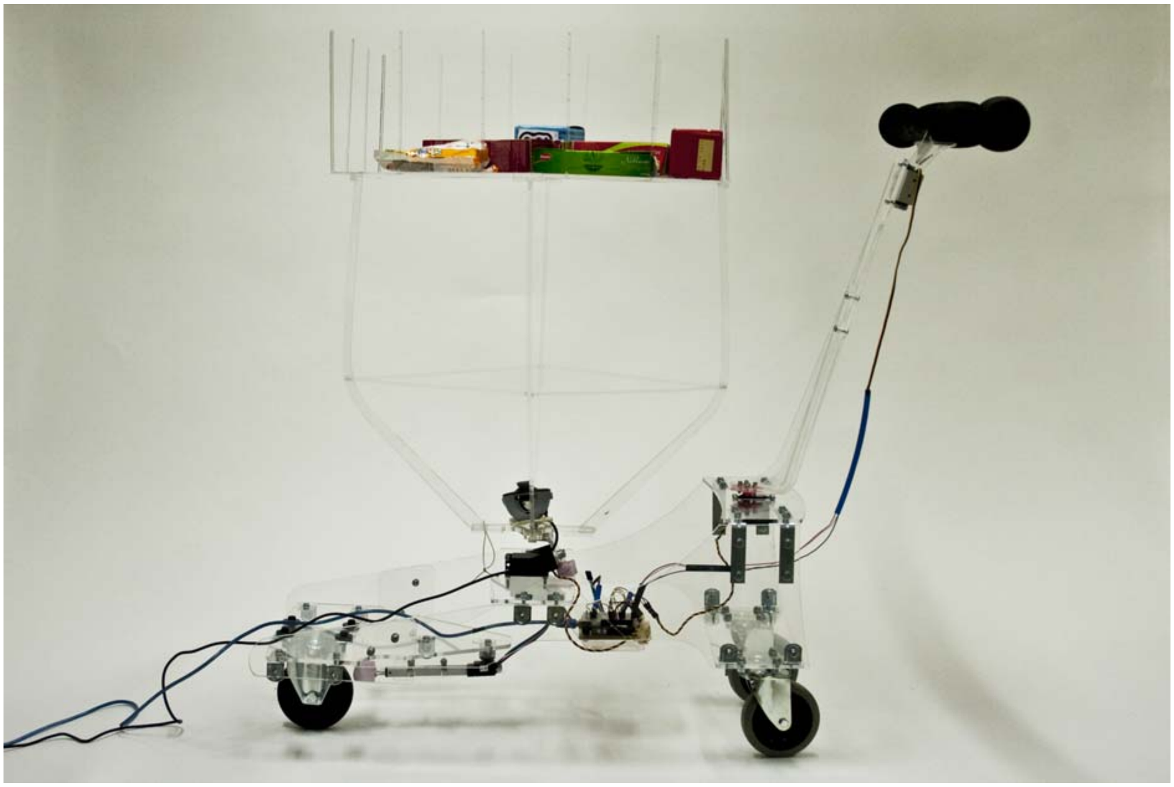

Figure 2 Shopping Cart prototype, an example of over-prototyping (image credit: George Paravantes and Amid Moradganjeh)

Throughout the courses we teach in Experience Prototyping and Sketching in Hardware, we repeatedly have technically-inclined students who have difficulties balancing technical prowess and the actual design outcomes they get from building hardware sketches. They build technically impressive stuff "because they can". Despite clear learning benefits, we feel these projects are missing core characteristics of *Sketching in Hardware*, namely the noncommittal, rapid and disposal aspects. Whatever comes out of these sketches has usually very little to do with the actual design project they are associated with. Impressive: sometimes; informative to the design project: often no. Figure 2 shows an example of an ‘over-prototyped’ project realized by two interaction students at the Umeå Institute of Design. The realization of the hardware sketch of a shopping cart represents a substantial amount of work. It never worked properly and was never presented to users or other participants. The remaining of their project was terribly well executed and coherent. In short, it didn’t help or support their design project significantly. We can see in it a perfect example of a prototype realized just for the sake of prototyping.

At the other end of the spectrum, designers and students with no programming or electronics knowledge have also their share of challenges. Although quite approachable, most tools or toolkits still require some understanding of programming, code and electronics. Without these skills, it is very difficult to evolve beyond ready-made examples and pre-caned configurations. Students often feel frustrated when they cannot get anything interactive working on their own. We understand their frustration but encourage them to try different routes or attack smaller and more manageable problems. What these students are generally very good at is finding alternatives and detours around problems, to eventually reach their intended goal (or a different one).

We see this ‘problem-solving with detours’ as a highly valuable skill in Sketching in Hardware because it is humanely impossible to know everything. Everyone has his/her limits. How one manages to keep moving forward despite these hurdles and constraints is in our opinion admirable. We could call this cleverness or pragmatic sketching.

In an ideal world, students and designers should have the perfect mix of technical skills and creative approaches to evolved complex but useful and informative hardware sketches. There are no magic recipes or prescriptive notions that dictate how one should go about building hardware sketches and using them in a particular project. It is a life-long (or career-long) learning experience.

Bringing back the Experience

Prioritizing design outcomes over technical know-how

The current prototyping toolkits use technology about 10 to 20 years old, if not more. Compared to what can be found in the latest electronic devices today, they are dinosaurs. From an engineering perspective they are almost laughable. Therefore, having something that works using those toolkits might be personally gratifying, but from a technical standpoint it is not exactly groundbreaking. The real value for designers and other collaborators in toolkits comes from leveraging their simplicity, mixing and remixing technology with creative processes, and most importantly aiming on the experiential outcomes and not so much on the process of ‘making it work’.

We have seen that in other disciplines like Industrial Design (ID), doodles or volumetric models fulfill different functions during the design process. The vocabulary in ID is not extremely sharp, but decades of activities have laid considerable foundations to describe processes and methodologies that are commonly agreed upon. The Interaction Design discipline is in its infancy. Our current shared vocabulary, mostly adopted from other disciplines, often falls short to properly describe the dynamic nature of our sketches and interactive prototypes. We usually try to minimize this gap the best we can by using a variety of mediums and interactive depictions (like hardware sketches). Without a clear vocabulary and understanding that intuitively connects intent and outcomes, designers can sometimes find themselves focusing on building something that works and not explicitly identifying why they are sketching for.

In our view it is important to consider that hardware sketches can also work as tangible and intellectual springboards towards other disciplines. They help the designer play in other disciplines' sandboxes, and learn how to better communicate their design ideas in different technical jargons. Finally, hardware sketches and experience prototypes are key components in establishing shared reference points with colleagues, users and other collaborators. They naturally invite others to relate and build on something (half) real, tangible and concrete.

Toolkits: technology building blocks for Interaction Designers

A toolkit has to be useful and helpful to its users: that is easier said than done. What is useful to reach these *sketching in hardware* objectives? The big answer is: it depends! As we highlighted above, each project is unique and the designer's skills and understanding of hardware sketches are constantly changing. Toolkits need to balance flexibility and simplicity. What is useful for a first-time user can be very different for an advanced user. An advanced user might enjoy very basic features if pressed by time or under certain condition/mindset. So it is never black or white. It's all grey!

In our quest towards a better education curriculum and a more enjoyable IxD practice, we decided to reflect on what would be, in our view, the ideal toolkit for interaction designers. We quickly came to the conclusion that it is futile to think that such unique magic-bullet toolkit exists. If we look back at history, we notice that a multiplicity of tools and toolkits will always prevail, some very highly specialized ones, others more multipurpose and aimed for general use.

Despite this failed intellectual attempt, we believe that current toolkits are not always well suited for Sketching in Hardware activities. In regards to the current status of the design practice, we think there is definitely room for improvement in many areas. Students and designers are often struggling on the same issues over and over again. We think new or improved tools and toolkits could be developed to better match today's needs in sketching in hardware activities. These beliefs come from our experience in teaching and using such tools ourselves, but they are also inline with similar discourses from numerous researchers and teachers in the field of Interaction Design (Buxton, 2007; Moussette 2007; Saffer, 2009)

We identified five high level characteristics or qualities that should be supported or at least considered when developing new toolkits for interaction designers. They are presented in no particular order of importance. We try to support each point with concrete propositions, examples or critique found in today's toolset.

Openness and level of visibility/accessibility

Just like Nature, complex and elaborate systems are made of simple underlying parts or processes. Accessing and peeking at how things work or are composed can be very beneficial to develop a good understanding.

The goal is not to expose and decompose all processes, but allow for different levels of visibility/accessibility. Complex processes can be encapsulated in simple representations/actions to ease introduction and support high-level perspective/work. The inner working processes should be accessible if one is interested to dig in. Some complexity can be exposed to invite or tease the user to explore more. The level of details cannot be infinite, but documentation should be as good as possible. Knowing that one can further explore references, sources, libraries and other internal details is very reassuring, even though very few are actually doing it. Open-source software and hardware like Processing and Arduino exist and are successful because of the all-embracing commitment to this openness principle.

On a more graphical level, applications like LabVIEW, VVVV, MaxMSP and Pure Data offer simplified graphical dataflow programming environments where encapsulation is obvious. Advanced and curious users can access the functional code behind each individual graphical node. Expert users can often build new functionalities into the tool if the underlying processes are exposed properly.

Each design problem can be said to be unique. Manufacturers and toolmakers cannot realistically envision every possible use or situation for their tools. With open tools, designers and users can fully embrace the system, and effectively help the producers to refine or enhance their offerings. Note that simplicity or reduction in complexity doesn't translate to simple or trivial work. Some level of abstraction is necessary for humans to cope with complex task or endeavors.

Hackability

By hackability, we mean that parts, modules, or the whole toolkit should be open for unintended and unplanned uses. While manufacturers cannot obviously support these activities, the design or functions should not thwart those who feel adventurous. For example, parts from one toolkit should be usable with other toolkits without major difficulties.

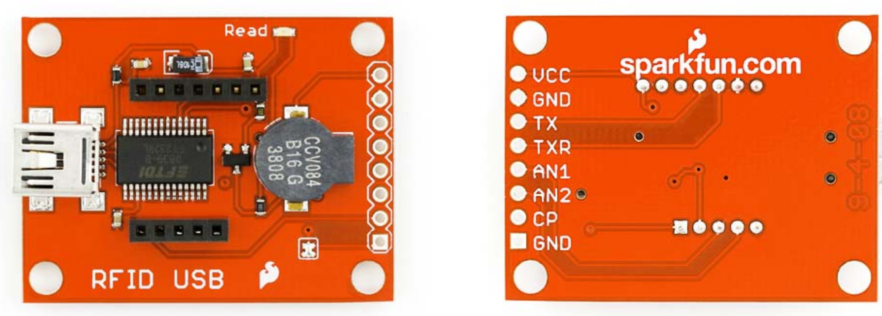

Figure 3 Sparkfun's RFID module, with numerous exposed connectors. Ready for repurposing or hacking (image credit: Sparkfun.com)

Sparfun's model (Fig 3) provides breakout pins for wiring extra parts or using the module with other than the default USB port. By exposing the already-available functions, one can repurpose it more easily. The module from Sparkfun uses a very ubiquitous technology (RS232 serial communication) to transmit its data. The design is intentionally simple. This simplicity has a cost. The module is quite dumb and only send data values. Once attached to a computer, it cannot announce its functionalities and share other secondary status or auto-configuration data.

Figure 4 Phidgets RFID module. Friendly but a closed platform, on the hardware side at least. (image credit: Phidgets.com)

The Phidgets module (Fig. 4) works with a special set of hardware and software combination and offers advanced software functionalities (notification when the RFID tag is removed). This tighter integration can be a double edge sword: it is simple and works very well as long as you work within the limits offered by the manufacturer. Outside this area, it is very difficult if not impossible to reuse the module and combine it in your own ways. For example, it is impossible to use with a dedicated microcontroller due to the USB connectivity. By design, it has to be plug into a computer to work, despite the low computation power required to send and receive RFID tag values.

Added value when time is limited

The ability to get going quickly and get results fast, within minutes if often crucial in the design practice. In educational settings the time constraints are not so present and crucial. Nevertheless, the focus or the work should be elaborating on variations of the experiences, not on debugging technical issues.

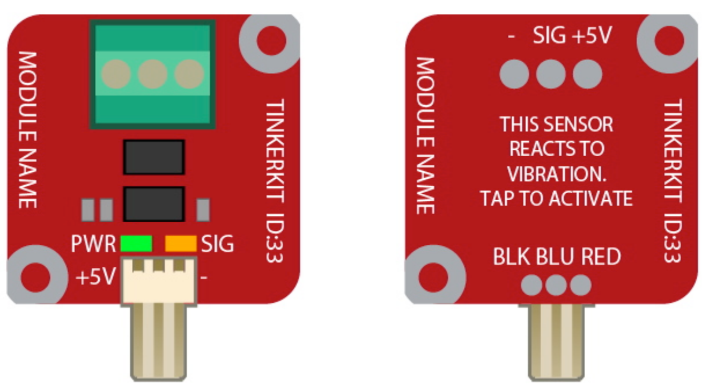

Figure 5 A proposal for new TinkerKit modules, with emphasis on labels and at glance information.

Labels, diagrams, numbering and details on the device are crucial for novice users, or users under stress or pressure. These details usually incur no additional hardware costs, but they do require extra care and attention by the people who develop the tools. What can be evident to an electronic engineer (designer/builder of such modules) might not be obvious to an interaction designer. Having to download and look up a PDF document just to find how much voltage is needed to power a device is frustrating and not efficient.

At IDEO and presumably in many other design consultancies, the most challenging sketching/prototyping issues lay beyond the technical skills of its designers. The difficulties reside in how to balance *build-to-learn* – from the medium or experimentation – and *build-to-gather* rich user feedback within a constrained timeframe. Projects last on average 12 to 16 weeks. The team needs to define the problem, come up with innovative concepts and provide deliverables that have the potential to outlive inside the clients' organizations and ultimately impact their product portfolio and business.

Spending anything more than a few days building something is a luxury and need to be well justified even within a company with a strong culture of prototyping like IDEO (Buchenau & Suri, 2000). Prioritization is key and there isn't much time available for experimentation. Low-fidelity prototypes are still useful to gather initial feedback but once we move towards designing the user experience, the fidelity needs to be tuned up immediately for two reasons. First, because the user experience usually means 'behaviors, transitions or gestures' that might have never been done before; second, because users are increasingly technology and user-experience savvy. Obtaining a 'suspension of disbelief' when presenting pen and paper concepts for electronics devices is becoming harder and harder.

From our experience in practice, only a few (2-3) serious prototypes/hardware sketches are realized for a particular project. Their aim is to have the most impact in the overall design, or present extreme concepts that occupy opposite places on a scale (e.g. knobs and levers vs touch screen and voice commands) and that can be used to align the designers' intents with real user expectations.

No matter how diverse the project challenge is, three points or needs consistently show up when developing hardware sketches under stringent time constraints. For us, the ideal tools or toolkits would:

- allow the designers to experiment different versions of the 'experience',
- build something convincing to be presented in user feedback sessions and
- allow for improvements and modifications at a later point in time.

Versatility or 5 ways of doing the same thing

Design is all about exploring options and possibilities. The toolkits shouldn't force the users into a monolithic approach and impose an unique way to solve a particular problem.

We find value in approaching a problem from many angles and perspectives. Building or sketching interaction can take so many forms. The continuum from a highly specialized tool to a totally generic device is vast.

If we take the case of Phidgets, designers have a large choice of programming languages and platforms to develop and build their ideas. An expert user can use C++ to configure and interact with the devices, while a novice designer might use Actionscript or Java instead. The manufacturer of the system supports both equally.

On the hardware side, electronics modules can "speak" many protocols and adapt to various host systems. For example, a particular distance sensor can work in analog mode for simplicity and out-of-the-box use without reading much documentation. The same sensor can also be connected using a serial protocol in order to reconfigure it or send more complex commands/queries. This versatility comes with some drawbacks (the device in inherently more complex), but does offer flexibility and some form adaptability.

Generally, exploring options and possibilities will involve more than one system or toolkit. Mixing and matching different components in new and creative ways help designers the space of possibilities. We appreciate tools and systems where designers can come in and apply knowledge they already acquired previously. Each tool has its limitation and requirements, but often a knowledgeable user will be able to quickly get up to speed if the tool follows best practices and general conventions. Having to learn new ways of working can be frustrating and time consuming.

Human friendly

Technology should speaks for itself, ‘transpires’ its status or ways of working. Power lights, communication status, functions broadcast, non-symmetrical connections are small details that make the life of designers so much more enjoyable (or less painful).

One recent example that our students have been struggling with is the new ActionScript 3.0 language from Adobe. When writing code in the Flash application, one has to include and specify various libraries to add functionalities to the interactive application. The application requires you to “include” and type the exact name of the libraries you want and need to use. For an experienced programmer, this might be standard or obvious procedure, but for a designer this is quite tricky. How one should know which libraries to include and what is the exact name for it, even if it was never encountered before? No default choice, pre-made lists or options are offered to the user. You have to look deep down in the documentation to find that information, and manually type the information in your document. It is not very straightforward and satisfying indeed. You inevitably learn the most common ones quickly.

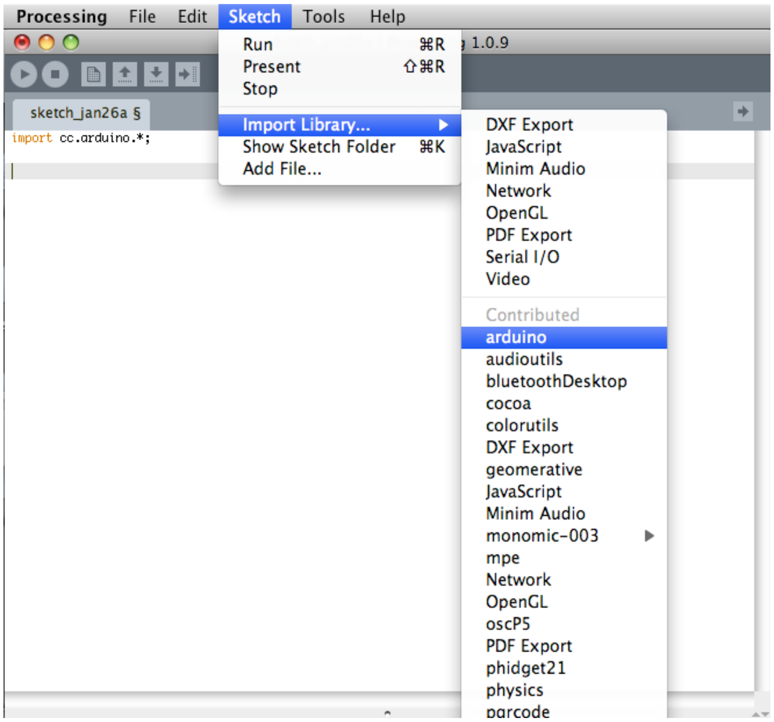

Figure 6 Processing application and the available libraries selection.

If we compare this experience to developing software sketches in the Processing application, the task is almost the same, but the application in this case provides various cues and selections to choose from. First the application has default libraries covering the core functionalities, so you do not have to write anything for the standard libraries. Second, if you need to use a specialized library or set of functions, a menu entry lists all the installed and available additional libraries. In one or two clicks, one can choose, include and readily use new functionalities in your sketch (Fig 6). We find this procedure definitely more humane, at least for novice and casual programmers like us.

On the hardware side, we strongly encourage the widespread use of status lights to communicate power status and activity right at the hardware layer. It is much easier to track down problems with blinking LED (or absence of it) instead of writing custom debugging code in software. A quick glance at a power status light will let you know if the device is properly powered. Physical affordance can definitely help too. Non-symmetrical connectors enforce the right polarity when connecting devices and cables. They often incur no or ridiculously low additional costs (fraction of a cent) in parts. Small details like this make huge difference in the long run. All humans make errors, even the highly trained ones.

Discussion

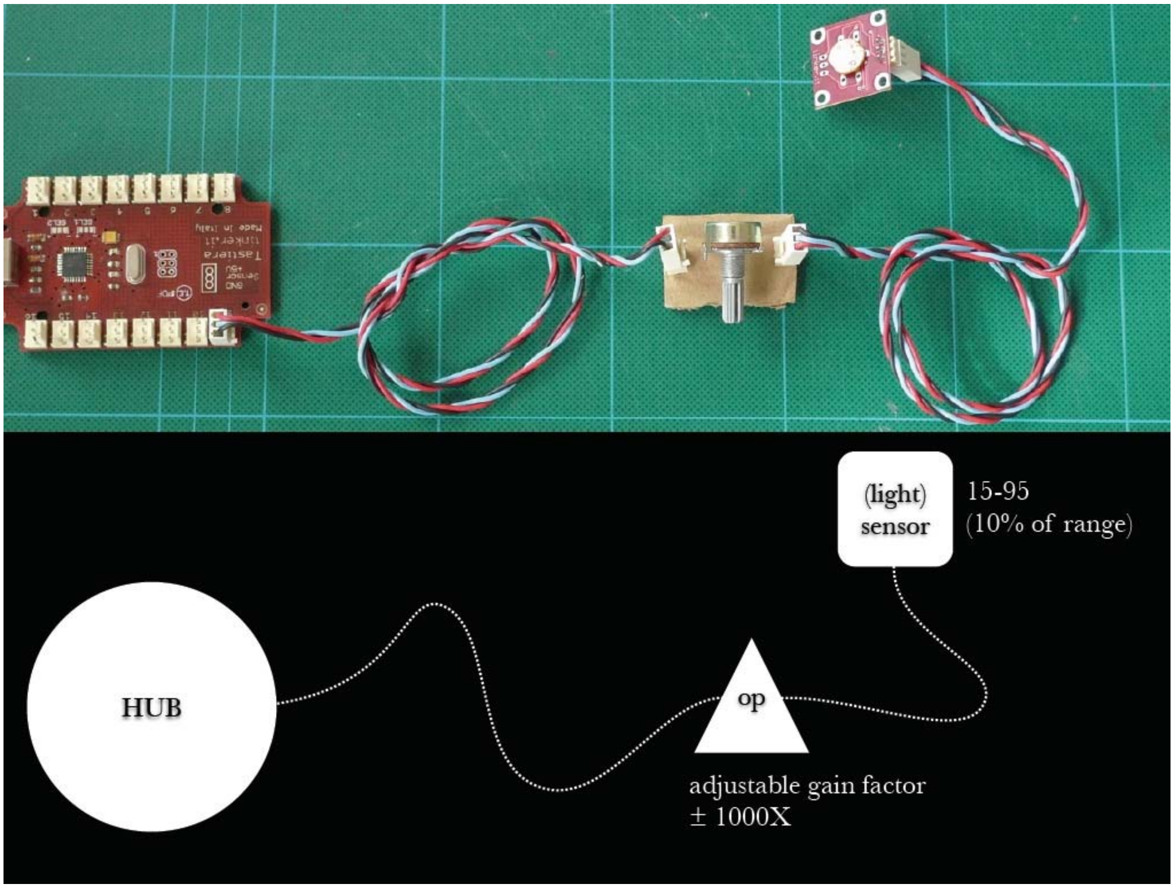

Figure 7 A non-working depiction of inline operator module.

Our work is currently ongoing but we are actively developing instances of tools where these values or qualities are put forward. We are building on previous tools and toolkits, leveraging previous successes and de facto best practices and standards. Figure 7 shows an early sketch of inline operators that provide a tangible control over sensors and various modules. The operator allows one to explore and adapt to a much wider spectrum of values, without changing code or sensor module. It supports expanded design explorations in a simple tangible way.

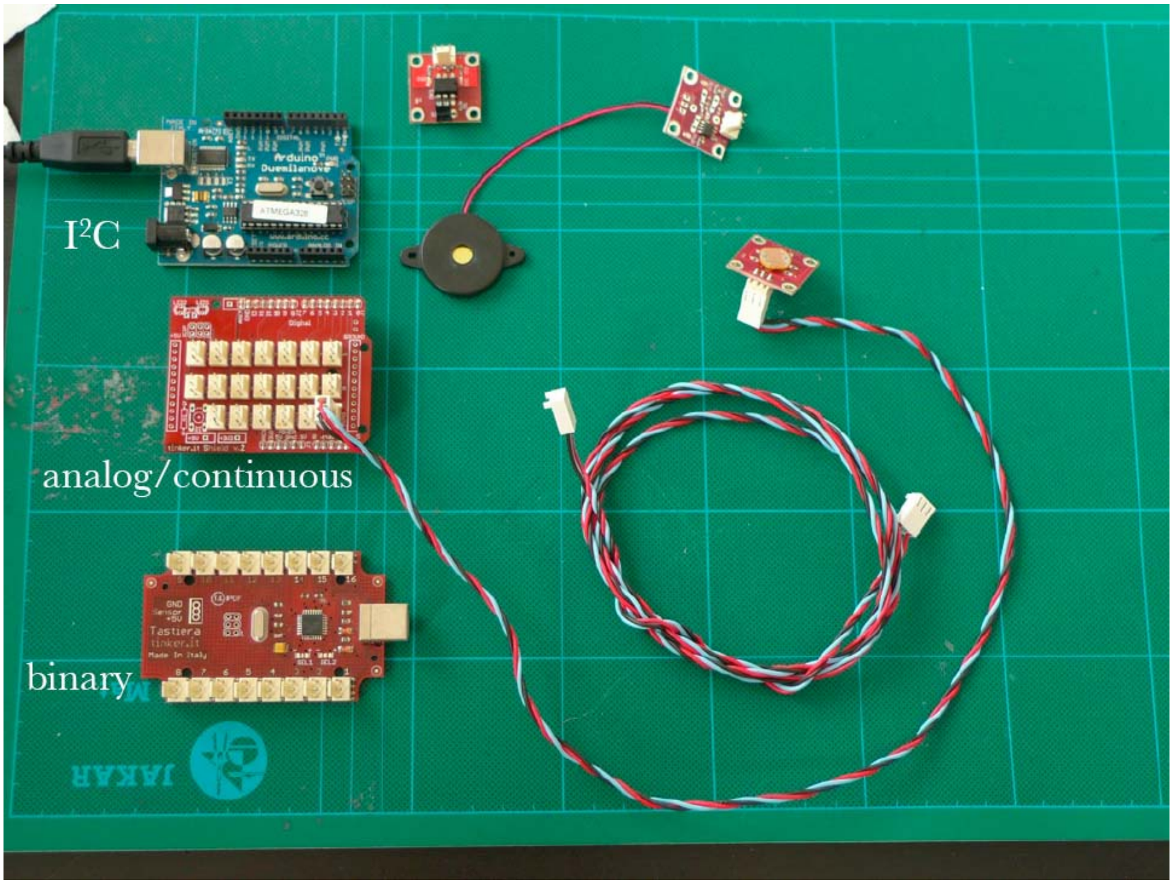

Figure 8 Smart sensors/modules can be used with different host systems

The availability of faster and more powerful microcontrollers means we can build “smart” toolkits and sensors more easily. When connected, modules broadcast their functionalities and requirements, and then establish the most desirable protocol of connection or communication. Simple analog parts can be mixed and combined with fancier or more complex ones. Older parts and items can be used without worrying about compatibility and interoperability. Designers can focus more on the outcomes of their sketching, and less on the technical side of things. Figure 8 shows how a particular smart light sensor would work depending on the capability of the host system. It would transmit configuration and status data only if the host module can receive and understand it. Otherwise, the smart light sensor would revert to a simpler analog mode, or even to a binary mode (on/off) if necessary.

This is work in very early stages. We hope to refine our ideas and sketches further, and evaluate them with design students and practicing professionals in design consultancies.

Conclusion

With this paper, our main objective was to present the *Sketching in Hardware* perspective in the field of Interaction Design, and explain our view and experience around those somehow new ways of building or sketching ideas. We observed and noted numerous challenges, but also very rich and stimulating design activities. Despite our criticisms, we strongly believe in this new perspective and its potential for establishing a strong understanding of interaction concepts, solidifying prototyping knowledge and taking sketching activities to a new level. Designers have to know their limits and when it is advisable to ask other professionals. *Sketching in Hardware* is not just playing with electronics; it has serious implications and repercussions.

Ultimately there is an open discussion that pervades the professional practice of (interaction) design about whether designers should focus on being excellent craftsmen of human-to-human and human-to-device interactions, or should designers excel as good design generalists ready to take on challenges a few levels up in abstraction (the big picture). It is our belief that one cannot live without the other. Some designers will go deep into the technical side and into the art of crafting intricate interactions, while others will focus on high-level themes and global agendas. We hope those sketchers and visionary designers can together build a better and more enjoyable world.

Designing for Cultural Diversity: Participatory Design, Immigrant Women and Shared Creativity

Naureen Mumtaz, University of Alberta, e-mail: naureen@ualberta.ca

Abstract

Immigration and multiculturalism are realities of the globalized world that has given rise to subcultures, which possess specialized knowledge and language that is not shared by the main culture. This increasing interaction among people from diverse cultures has produced a complex ethno-cultural mosaic that presents formidable challenges for visual communication designers' as well to other designers. Complexity has always been part of human environments that comprises of mutually dependent social relations. Cultural diversity of designers and audience of messages in a design scenario brings complexity in the design research process.

This research study explores an effective visual communication language, through the medium of the poster, for culturally diverse audience of immigrant women in Edmonton, Canada. The decision, to investigate the effectiveness of a visual message through the medium of the poster was informed by triangulated results from a pre-workshop survey, interviews with the staff and discussions with the immigrant women who are either interested or in need of services of the centre, *Changing Together*. While designing messages for a culturally diverse audience, participatory design exploration approach assisted in developing a framework for research methodology. A participatory design workshop was planned, for the Centre for Immigrant Women in Edmonton, to investigate possible visual vocabulary for an ethnically diverse group. The workshop results were synthesized in the form of three poster prototypes, which represented the needs and realities of those immigrant women. Prototype poster designs were tested to examine the results of the mutually identified visual concepts. Based on the observations and synthesis of research findings, it is concluded that user-centered participatory approaches of design can work effectively for developing a visual vocabulary for an audience of culturally diverse women.

The research direction of this project is based on the concept of shared creativity of ethnically diverse immigrant women, through collaborative design exploration workshops. The concept of shared creativity is also harmonious with the spirit of multicultural pluralism, which forms the basis of the Canadian culture. This role of a designer to identify problem-oriented activity, and to develop participatory strategies to address those real issues provided a chance to contribute to the social process concerning cultural diversity in a constructive and sustainable manner.

Key Words

Participatory design approaches, Collaboration, Design process, Rhetoric, Interdisciplinary, Design and society, Human / user-centered design, Learning, Social and cultural studies,

Cultural Diversity

The United Nations World Commission on Culture and Development Report titled 'Our Creative Diversity' defines "culture" as the whole complex of distinctive spiritual, material, intellectual and emotional features that characterize a society or a group. It includes creative expressions, community practices and material or built forms

Multicultural ethnic diversity in first world cities has created subcultures. Micro-communities fed by these sub-cultures possess specialized knowledge and language that is not shared by the main culture. World development organizations around the globe are developing culturally sensitive approaches to strengthen community projects' planning and programming effectiveness and create conditions for ownership and sustainability. United Nation Population Fund's (UNFPA) 'Cultural Lens' is an example of one such promoted approach, which recognizes the importance of the socio-cultural capital of various micro-communities and emphasizes community participation and people centered approaches in community project design and development. This approach recognizes that acknowledging, appreciating and working with the social capital in these communities can create conditions of ownership and sustainability, which can lead to strength the main culture.

Immigration and Immigrant Women in Edmonton, Alberta, Canada

> People of different religions and cultures live side by side in almost every part of the world, and most of us have overlapping identities, which unite us with very different groups.
>
> — *Kofi Annan, Former Secretary-General of the United Nations*

According to the Oxford Dictionary, Encarta and Wikipedia, immigration in general, refers to the movement of people among countries, or it is the act of entering a country with the intention of remaining there permanently.

The Report of Auditor General of Canada (Fall 2009), states that immigration plays an important role in the economic, social and cultural development of Canada. Statistics Canada indicates that immigration accounted for two thirds of Canada population in 2006. Alberta reports the highest percentage of immigrants/visible minorities of the three Prairie Provinces.

The 2006 Census enumerated 527,030 immigrants in Alberta representing 16.3% of the total population. Between 2001 and 2006, Alberta's immigrant population increased by 20.2%. This was more than two times higher than the non-immigrant population, which grew by 8.7% during the same period.

There were slightly more females than males in the immigrant population of Alberta. In 2006, out of 100 immigrants residing in the province, 52 were women. About 31,930 immigrants in Alberta were children under age 15. This represented 6.1% of the immigrant population.

As of 2006, 143,335 immigrants call Edmonton home and 52% of these immigrants are women. In late 1990's Statistics Canada reported that nearly 20% of women living in Canada were newcomers to the country and on average these immigrant women were more highly educated as compared to their Canadian counterparts but they usually survive on low income. This is due to various reasons, the discussion of which is beyond the scope of this paper, but it clearly suggest there are barriers that prevent the successful participation of immigrant women in the mainstream culture.

It has repeatedly been declared in a variety of Government of Canada's Statistical reports that diversity is one of the defining characteristics of Canadian society. Over the last two centuries, the linguistic, cultural and religious make-up of the country has significantly changed in the wake of various waves of immigrants, first, mostly from Europe; and more recently from a wider range of societies including many non-European countries.

The diversity that marks Canadian society has had a positive effect on the country as new skills and ways of looking at the world have been adapted from succeeding waves of newcomers. The diverse nature of the country, however, can also introduce tensions into the social fabric as different groups struggle to adjust to their new social milieu while at the same time trying to maintain their cultural identity in a rapidly changing environment.

In 2006 UNFPA-IOM (United Nations Fund for Population and International Organization of Migration) jointly organized an expert group meeting to formulate a set of recommendations for action by governments, international organizations and civil society, as a contribution to the high-level dialogue on international migration and development to mainstream female migrants' needs and rights into the agenda. All participants agreed that women's migration or immigration had received too little attention rather it stated:

> Insufficient attention to female migration in its different aspects violates the human rights of the people concerned, holds back development and reduces the possibilities for achieving the Millennium Development Goals.
> — UNFPA-IOM (2006)

Visual Communication Design for Social Change

Victor Papaneck (1974) in the opening remarks of his book *Design for the real world* states that design is basic to all human activity. Niesuma (2004) argues for alternative design scholarship, which offers designers an opportunity to think about how their work might be directed at social change and well being of marginalized social groups. Sifting through the discourse about design, Fuad-Luke (2009) admittedly says design plays a comprehensive role in suggesting or setting new values and inculcating a societal change. Communication design research is defined by it's interdisciplinary complexity as the problem content always comes from another disciplines as emphasized by Strickler & Neafsey (2002), Frascara (2002) and Fuad-Luke (2009). Poggenpohl (2002) goes further by saying that 'Design envisions the future' by taking a felt need or problem or for what is often an abstract idea and making it tangible so that the various stake holders in the idea can imagine together, socially, creatively and interactively to give the abstract some shape.

Frascara (2002) argues that social relations are complex and the introduction of people in a design equation introduces further complexity. According to Patton & Woodhouse (2004) the inherent nature of design as a human activity is that it is generally, deeply socially oriented. It encourages human participation at various stages of design process from contextualization of problem, ideation, and conceptualization, making, use and reuse. Participation in design, as mentioned by Stairs (2005) meets the human ideal of mutual support or altruism. Which is agreement with Buchanan (2001) when he says that the implications of the idea that design is grounded in human dignity and human rights are enormous and they deserve careful exploration.

Centered on the Users

As in today's globalised world there is a highlighted trend toward specialized audiences, McCoy(1995) pointed earlier, that focused messages and eccentric design languages tailored to each audiences unique characteristics and culture, need to develop. Buchanan (2001) adds that the quality of communications, artifacts and interactions and environments within which all of these occur is the vivid expression of the cultural values.

While addressing cultural plurality and related issues by the development of visual vocabulary for a diverse cultural audience for communication of a social message has diminished the focus on homogenized audiences that used to be the focus of the designers in the recent past. Elizabeth Sanders (2001) very rightly predicted about the evolution and emergence of new design spaces in response to user's needs for everyday creativity, which requires the designer to understand the experience domains of people. Sanders predicted that in future as designers involve the everyday user in the design process, tools, rules and methods for research and design would begin to blur. This will result in research becoming more creative; and design becoming more rigorous and complex.

> Participatory design is a high-level feature of design methods that can be implemented in a myriad of ways. It is not a single and integral design method. I consider the following dimensions: domains of human activity, roles of stakeholders in a design; types of shared design representations, the scope and duration of participatory interactions and the relationship of users to the design activity with respect to changes in heir knowledge and skill. I believe these dimensions have important implications for some of the fundamental issues that have been raised regarding the effectiveness of participatory design methods. (Carroll 2006, p 3)

Effective communication can contribute in strengthening the communicational power of the messages being developed for the female immigrants globally and specifically in Edmonton for the proposed research project. According to Bonnie Sadler Takach (2003), effective communication results from meaningful interpretation of well-designed artifacts and that context, purpose, and individual experiences affect that interpretation. She maintains that to produce effective results, we must work continually with members of the public to assess and calibrate our actions. And as established by Fuad-Luke (2009, p 347) one of the fundamental premise of co-design is that it offers an opportunity for multi-stakeholders and actors to collectively define the context and problem and in doing so improve the chances of a design outcome being effective.

Designing Posters for Immigrant Women

A publication by Statistics Canada about 'Women in Canada: A Gender Based Statistical Report published in March 2009, states that these immigrant women may also have to overcome many of the gender-related inequalities, which women in Canada have traditionally experienced. In this scenario, it is very likely that foreign-born women face a particularly more complex set of hurdles in their attempt to adapt to Canadian society. On the one hand, they have to cope with all the problems associated with adjusting to, what for many, may be a completely new lifestyle. Language has been identified as one of the main barriers for many immigrant women, by various surveys conducted by the Alberta Government and Non-Governmental Organizations that are offering services to immigrant women. Lack of ability to speak any of the two official languages i.e. English or French; compounds the social navigational problems of these women.

A year ago while volunteering for Community Service Learning at University of Alberta, I was introduced to “Changing Together – A Centre for Immigrant Women”, which is the only organization in Edmonton that focuses exclusively on the needs of immigrant women of all ethnic backgrounds. The Centre has grown significantly in the last 23 years and is ready to expand its outreach by employing culturally appropriate mediums and messages to serve the community of immigrant women in Edmonton.
The decision, to investigate the cultural sensitivity of a visual message through the medium of the poster, was informed by a short survey form filled by the staff and some of the immigrant women clients of the centre. Thus starting the cooperative design or participatory design journey of user inclusion within the development team, as J.M Carroll discussed in his paper *Dimensions of Participation in Simons Design.*

> In an age of transmission and computerized technology, it is surprising that the poster continues to flourish as a significant form and primary means of communication (Timmers, 2003).

Timmers articulates that an effective poster is a dynamic force of change, in the social context. She continues by stressing that the means by which a poster’s messages are conveyed are crucial to its effectiveness, as they are intended for varied segments of the society. The accessibility and adaptability of the poster communication through its graphic vocabulary makes it a popular medium for social messages. She makes a strong argument for the poster, as a communication medium, which can by changing its tone and vocabulary, reflect shifting cultural values and codes of behavior.

Interviews with the professionals of the Centre for Immigrant women also supported the idea that the initial communicational material of the facility should be supplemented with a poster to get a better outreach response from the culturally diverse audience of immigrant women. From the initial seminal research a number of questions emerged, for example; is there a real need for clear visual communication message for this culturally diverse audience? Why does this need exist and who identifies this need? How can the issue of uniformity within diversity be addressed in the design of these visual communication messages for the medium of a poster? Some of these questions helped in refining the following final research question of this exploratory research project, which sets the direction for future design explorations for this important community of immigrants in Edmonton, Canada.

How to Explore an Effective Visual Communication Vocabulary for a Culturally Diverse Audience of Immigrant Women?

Due to an earlier volunteer interaction with a few social organizations, nationally and internationally, there was personal awareness of certain visual communicational challenges that need to be addressed while designing messages for culturally diverse audiences. I agree with McCoy when she says that while dealing with this kind of an audience, the entire equation of sender-message-receiver needs to be reconsidered. Frascara further stresses it by highlighting the importance of the inclusion of receiver component in the design equation. In his following statement, while addressing the designers particularly those who are working in the social domain, he drew attention to an important aspect of listening to those for whom we design.

> One of the valuable resources of creativity and skill is our ability to listen and learn from those for whom we design. (Frascara, 2000)

Krippendorff (2006) further elaborates that for designers, listening may take several routes from engaging in ethnographic research to inviting those interested to participate in a development team. He professes that participatory design starts with overcoming the voiceless user.

Susann Vihma in her essay about design semiotics compares design, which is a sort of symbolic system, with verbal narrative and storytelling. She explores the reason for associating [visual] forms with speech and verbal communication. She suggests that form in material and visual presence always expresses something to somebody. As Krippendorff mentions three concepts that are central to the semantic turn; the concept of human beings in human-centered design, the concept of knowledge and the concept of culture that nourishes design. The project research premise here is that:

- there is a need for a culturally effective and appropriate visual vocabulary for immigrant women of ethnically diverse backgrounds
- and that immigrant women themselves (for whom the poster is being designed) can contribute positively in developing an effective visual vocabulary

Research Methodology

The aim of this participatory and collaborative design research project was to explore an effective visual vocabulary for posters, being designed for an ethnically diverse audience of immigrant women in Edmonton, Canada. This research study was planned in collaboration with a community service provider, a Centre for Immigrant Women. An attempt was made to understand the wisdom embedded in respective cultural discourses, which could inform the overall learning outcomes of the project.

The project follows the basic design research process model, which involves the steps of problem identification, investigation, analysis, planning, synthesis and evaluation. However the research study employs different methods of design research techniques including observational research, a short visual analysis and a participatory design research workshop.

The research methodology combines visual ethnographic methods, observation techniques, and participatory design workshop approach into visual symbol development for the poster, which supports and utilizes the diverse cultural context of the users. (Fig.1)

The research in this situation is not market research or an audience study but rather practitioner-based participatory design research in which the engagement actually enables insights that contribute to the ongoing development of visual communication elements and the practice of collaborative design techniques. The initial focus is not the provision of data or information. Rather it is an attempt to work with the stakeholders to create an opportunity for a longitudinal study not only of the practice and reflection on the practice, but in order to build iterative cycles in information and communication design processes that, over time, will support the accounts of phenomena in the field and also provide a deeper understanding of the complexities of communication design for multicultural communities, in this case the one in Edmonton, Canada.

Project Participants

Immigrant Women

Immigrant women, who come from all over the world and represent diversity in cultural and linguistic backgrounds and form more than 50% of the immigrant population in Canada. Immigrant women from the centre 'Changing Together' were identified as a group for the participatory design workshop. Women in this study were females from 25 to 65 years of age. The focus on this group was not intended to generalize this wide age group, but rather to allow for opportunities to work with authentic groups that may include individuals between those ages faced with the challenges of immigration and language barriers.

Criteria for selecting the group

After discussing with the 'Changing Together' professionals, it was suggested that selecting a mix of new and experienced immigrant women from different groups of classes being offered at the centre might lead to more authentic outcomes. Collaboration with these identified student and teacher groups from ESL (English as Second Language) Basic Computer Literacy and Seniors Social class were sought.

Informed consent

Consent forms were administered to each participant. For those who not very comfortable with English language, the forms were translated to their own spoken language where necessary, with help of a fellow colleague translator.

Defining

Formative stage of my exploratory research defines my research and the design problem. The significance of research problem was established, based on the information gathered from the brainstorming, reframing, visual analysis, and observational research. The basic challenge was to handle the multicultural aspect of the visual communication vocabulary for the ethnically diverse target audience with varied literacy levels. Approaches based on different cognitive devices were employed to develop an understanding of the social design problem to define the design exploration**.**

Diverging

Divergent research approaches were applied to help develop an understanding of the problem, basic quantitative and qualitative data about the immigrant women was gathered and then strategy was devised to explore a commonly understandable vocabulary of images and symbols. Different methods for inquiring into the stakeholders' concepts and motivations were employed, these included unstructured interviews, observational methods like photographing different activities at the centre, visual ethnography by converting photographic data into digital stories and stakeholder participation in the design process through participatory design exploration workshop. As Krippendorff (2006) articulates that human-centered design methods, therefore weave available knowledge of how meanings arise within relevant stakeholder communities into the design process in order to assure that a design encourages the meanings that lead to reliable interfaces.

During this participartory design process, the focus was on generating words and images which were understood across various cultures, for the poster. It helped the image bank development and the ideation for the final inerpretation of the poster. It also helped in creating an emotional resonance in the prototype designs, which were later taken back to the group for testing and evaluation.

Visual symbols and Images were explored and developed through the technique of adjective attribution to concepts of *immigration* and *Changing Together* during the participatory design exploration workshop. All the adjectives and synonyms contributed by participants, who came from varied cultural backgrounds, were written on flip charts for recall during the later visual concept sketching exercise. The group was also encouraged to explore the agreed upon adjectives in the form of *an act*, for example how can we all together show *Changing Together*. And the group of participants responded by first holding hands and then they tied their colorful scarves to make a circle of different colors while holding them together (Fig 2). An image bank emerged from which symbols and images could be applied in the prototype posters. (Fig 3)

The above discussed, diverse steps helped to clarify, root and expand the range of options for designer's imagination but these were guided by how the stakeholders conceptualize the effective visuals for the poster. The next stage was about what designers traditionally do to synthesize apparently disparate elements into a new unity. So accordingly based on the identified visuals from the participatory workshop, three poster prototypes were designed. (Fig 4 a, b and c)

Earlier, a visual survey of the public spaces, which are frequently shared by the identified audience, was also conducted and shared with the group. This helped in identifying and agreeing on the channels of distribution for the poster. According to Timmers research (2003) one important factor in understanding the continued power and appeal of the poster is the accessibility of its physical deployment.

Transforming

Once a substantial amount of information, from the above-discussed modes of research, was collected it was synthesized into rough prototype designs for three posters. A testing session with the same audience of stakeholders was conducted where the poster designs for their visual vocabulary were tested in the form of a written evaluation of individual poster symbols and their comparative visual analysis was also made (Fig 5). This step in the research brought the stakeholders back into the process to test the extent to which the design and visual vocabulary was effective. While the posters were being tested, participants were encouraged to think aloud and their responses and observations were noted down for further analysis. As noted by Krippendorff (2006) data obtained through the method of Protocol analysis (Newell and Simon 1972) provides the design analyst with records of correlation between verbal accounts of what users see and think about their interactions. Which leads to adding valuable specificity to the otherwise 'meaning-dry' observational record on the one hand and abstract verbal accounts obtained during interview on the other

These initial findings will be used for the design of further poster iterations and to achieve a set of culturally agreed upon visual images, which have effective messages for a diverse audience, through the resultant poster design.

Triangulation of methods like protocol analysis with visual ethnography and observational methods offered an opportunity to overcome uncertainties afforded by the use of a single method. Based on the observation of research findings it is concluded that user-centered approaches to design can work effectively for developing a visual vocabulary for a culturally diverse audience.

Observations about prototype poster designs

Prototype posters served as carriers, and realizing these shared experiences facilitated communication in the evaluation and testing phase. Stappers (2007) in his essay on *Doing Design as a part of Research* maintains that Prototypes speak the language of experience, which unites us in this world. The method of knowledge generation through the design of working prototypes based on participatory design exploration session, helped in gaining fundamental understanding of a multicultural group. (Fig 4 a, Fig 4 b, Fig 4 c)

All together, the exploration in the formative and summative stages was successful and confirmed some of the assumptions that were made at the beginning. Most of the testing session participants responded positively toward the proposed prototypes and contributed in generating a succulent discussion on the merits and demerits of the chosen visuals. Interesting patterns were observed in the choice of prototype design.

- Mostly participants who were the staff members (of diverse cultures) had a preference for the Poster C and agreed that a knot of different colors is a symbol which accurately represents the concept of engage, encourage, empower which in turn symbolizes immigrant women's lives.
- Staff participants also identified with a circle of hope in the Poster B, but the black color was strongly disagreed upon by most of the participants.
- Images of Poster A, were found highly representative of the concept and almost 90% of those who represented the audience /users found this option the most convincing.
- Regarding the Centre's identity, mostly commented that the overall Poster Design was the centre's identity, and they don't see the logo a separate element.

Discussion of the Findings

Based on the observations and synthesis of research findings, it was concluded that user-centered participatory approaches of design could work effectively for developing a visual vocabulary for an audience of culturally diverse women. The user participation in the generative research stage definitely provided invaluable information in understanding the users perceptions, dreams and needs. This helped in creating a basic image bank, which was mutually agreed upon and was well accepted by a large representation of various cultures.

Some contradictions surfaced to the earlier assumptions from before this research exploration activity. The main assumption that displaced women would have a preference for nostalgic images and colors were proven completely wrong.

The majority of people in a group had preference for a certain visual, thus creating patterns of behavior. As in the case of Poster A, most of the participants who were ESL (English as Second Language) or basic computer literacy students, could relate to the symbol of butterflies and threads more than any other visual. Clearly the visual preference had two highlighted poles. i.e. Poster A and C. However a complete consensus in cultural sensitivity towards colors and symbols was found.

Concluding Reflections

The nature of this study was exploratory from the beginning. It also demonstrated the effectiveness of using generative, participatory methods in design research that helped in creating a sense of ownership and responsibility in the end users by making them stakeholders and design participants. Additionally it gave the design researcher, the opportunity to initiate a capacity- building process in a social services scenario, which can offer sustainable solutions for collaboration in the design-for-social-change process. The project outcomes reinforced Manzini's (2004) concept of "designing to enable people" rather than "designing to solve problems."

The method of knowledge generation while developing community collaborations, through the design of working prototypes based on participatory user-centered exploration session, assisted in gaining a fundamental understanding of the audiences' responses and needs.

This study also established that communication design could play an essential role in motivating and facilitating the social development and integration process of immigrant women in Edmonton, Canada. The research direction in this project until now has been based on the idea of shared creativity. This implies a deep transformation in the user's role as well as the designer's role of taking social responsibility. UNFAP-IOM jointly acknowledged, that Women's immigration has received very little attention, which apart from having other social consequences also holds back development. So the process of design where a subject facing a problem is not only 'the part of the problem' but 'also a part of the solution' contributes in building confidence of the participant stakeholder. One positive occurrence that was witnessed was significant increase in vocal skills and confidence level of the stakeholders. Many women from *participatory design workshop* and the *testing session* shared that they felt more important and respected when they were asked for an opinion or independently entrusted with a 'responsible' task such as that of visualizing a poster the centre.

The participatory design research methods can be seen as concrete steps towards the participation of these immigrant women in the local social development process while simplifying the cultural complexes.

A more immersive and reflexive role for the designer was explored – that of participating in a social process to facilitate in the emergence of effective communicable visual ideas for a local multicultural micro-community of immigrant women in Edmonton, Canada. This concurs with Poggenpohl (2002) when she says that it leads to the development of knowledge gained through pragmatic observation that is actionable. The role of a communication designer to identify problem-oriented activity, and to develop participatory strategies to address the real issues will provide a chance for them to contribute to the social process concerning cultural diversity in a constructive and sustainable manner.

The research project also helped in developing insight firstly, about of the role of multicultural user participation in the design process, in addition to identifying visual representations that communicate to a culturally diverse audience. And secondly it demonstrated that embracing diversity of human experiences facilitates in the emergence of focused visual messages for multicultural immigrant community. The project promoted awareness of contemporary social issues of immigrant women from the perspective of a design research student, in today's global village scenario, where we are striving to understand the wisdom embedded in respective cultural discourses. Future investigations can lead to design communication projects, which can improve various services for these social groups of culturally diverse communities of immigrants in Edmonton. It has to be seen whether such graphic communication design projects can change patterns of behaviors, acquire knowledge and empower these diverse communities while fostering their creative expressions, in the long run. If yes, then can the above discussed project methodology serve as a model in that scenario?

Author Biography

Naureen Mumtaz

She is a Graduate candidate in Visual Communication Design at University of Alberta, Edmonton, Canada. Being a visual communication designer/instructor, community volunteer and an active citizen, her teaching, practice and research interests are grounded in the notion that design can influence social transformation. She intends to explore sustainable collaborative design methods and generate new knowledge to discover and harness the power of design within the field of 'design for community development' in a diverse cultural context. Her work considers endless possibilities of affecting change through the focused use of design and powerful conceptualization, which she also experimented-with during her teaching 'Visual Communication Design' at a Women University in Pakistan.

In her ongoing graduate research project she is focusing on collaborative/participatory design methods through digital story telling process with an aim to contribute and nurture creative expression while accessing critical knowledge and perspectives in relation to immigrant communities' identified socio-cultural health services access problems.

Transitions Heuristics in the Pursuit of Well-being: Situating Interactive Products and Services in Transitions

Fatih Kursat Ozenc, Carnegie Mellon University, School of Design, kursat@cmu.edu

Abstract
Transitions in people's lives take shape in the roles they enact, and the environments they inhabit. In these transitions, people encounter the paradox of changing and unchanging happenings, occurring simultaneously at multiple channels with differing magnitudes, and through immediate and long-term interactions. In this multiplicity of dimensions, transitions bring complexity while they emerge, throughout their occurrence, and while they resolve. Dealing with this complexity oftentimes results in stress, decline in emotional and social qualities of experiences. Interactive products and service systems play an important role in transitional experiences, by providing support for people to hold on to during the transitions. However, they are not explicitly designed with transitions and their complexity in mind. In this paper, I introduced *transitions heuristics* stemming from the *modes of transitions framework*, to understand and act on the complexity behind transitions. Transition heuristics leads the inquiry to discover principles at work in the existing interactive products and services and unveils the functioning principles that transforms these products into transitional experiences. The discovery unveils four threads of transitional products: routine, performance, ritual and narrative, which encompass a hierarchical and concentric relation with each other.

Keywords
Interactive products and service systems; heuristics; experience design; routine; performance; narrative; ritual; case study; analysis; principles; methods

People live with transitions both rooted in human nature and in culture. These transitions affect people's lives in two dimensions; roles people enact and environments people inhabit. As an example, take a dual-income family who has just moved to a new city due to a job change, right after they had a new baby. This couple is dealing with the transitions both between their work and parental roles and in becoming a new parent: environmental transitions both in switching between work and home and in inhabiting a new city. Looking at their experience across immediate and long-term interactions, one can identify transitions phenomena oscillating between changing and unchanging traits, fluctuating in implicit as well as explicit processes; and happening at micro and macro levels. Transitions such as marriage or parenthood are intentional, however, loss of a loved one or an unexpected illness is an accidental transition. Moving from one city to another can be initiated directly by the person; however, it might also be indirectly related to a job change triggered by an employer.

Transitions can resolve as growth, continuity or decline. In the case of decline, transitions affect people's well being in at least three ways: an increase in stress (George, 1993), a decrease in felt-life qualities (Mccarthy & Wright, 2005) and establishment of a social order (Goffman, 1967). Oftentimes these transitions do not emerge consecutively but happen simultaneously at multiple-channels, and they affect people in similar ways but at different magnitudes. There are four kinds of transitional experiences that can be defined on top of four types of transitions, affecting people's lives. Mobility is the self-changing locations; adaptation is the self's quest for familiarity in unfamiliar roles; habituation (socialization) is the self's development of new patterns of interactions in a new individual or social setting; and adoption is the transformation of the self into a new environment. Immediate interactions arising from mobility and adaptation shape our daily transitions. There are *spatial* transitions, such as commuting between work and home, and *social-role* transitions, such as switching between parent and employee roles. Long-term interactions, characterizing habituation (socialization) and adoption, shape both life-stage transitions such as retirement, and environmental transitions, such as *migration*. These transitions in return shape our experiences through their qualities. Simply put, transitions bring complexity while they emerge, throughout their occurrence, and while they resolve.

Interactive products and services play an important role in these transitions. They provide people with tangible means to hold onto during periods of transition (Belk, 1988). Communication services are good examples as being support for transitions. Think of a mobile phone service that our imaginary family begins to use in their transition. With its phone capability, it supports families in mobility in between locations. With its GPS application, it serves as a resource for adaptation in the city. However, transition as an experience has not been considered explicitly among the experience design community. Moreover, the fact that people have changing and unchanging character traits is underestimated. Ironically, interactive products, which are dynamic by nature, have been designed according to the static character traits of people or the environment. There is a need both to reconsider experiences from the perspective of transitions, and to harmonize changing and unchanging character traits. In this article, I develop a transition heuristics based on the modes of transitions perspective (Ozenc, 2009) and heuristic approach (Young, Pecker & Pike, 1970) used in rhetoric, then I apply the heuristics on the interactive products and service systems (IP&SS) in transitional contexts. The inquiry concluded with the new kinds of transitional IP&SS, their principles, and insights, which can be used as a ground for developing products and service systems for transitions.

Modes of Transitions

Issues around transitions relate both to the changing and unchanging traits of people as well as the variations of changing and unchanging, including the new and old, strange and familiar, unconventional and conventional. These traits reveal a paradox: How can people possess both changing and unchanging traits? To overcome this contradiction, people make transitions with 'character,' or actions rooted in moral and intellectual virtues that harmonize the changing and unchanging dimensions in one's life (Goffman, 1967). Prior work on transitions has identified distinct perspectives on how people encounter the challenges of transitions, including *coping stress mechanisms* (Folkman & Lazarus, 1994), *adaptation processes* (Ashford & Taylor, 1990), *role-boundary models* (Ashforth, Kreine & Fugate, 2000, Clark 2000), and *moderation of transition stages* (Allen, 1984). Each perspective can be situated into a certain understanding of the concept of character, and its unique set of principles can be applied to people's understanding and deliberative action.

With ‘character’ one can deal with transitions. It allows a person to pursue continuity and stability during and after transitions, and through the means and ends of transitions. Means can be the logistics in a spatial transition, such as commute choice of a daily worker, whereas, ends can be the purpose in an adaptation, becoming a public transportation user. The means is the determination of character with actions, and also the determination of actions with character (Mckeon, 1968). Mckeon clarifies what is meant by actions in the determination of character:

> An action is right if it is well adapted to the circumstances, resources, needs, and purposes of the agent, that is, if it is well done; an action is right if it improves the circumstances, realizes the potentialities of available materials, orders needs, and develops the abilities and interests of the agent, that is, if the end achieved is good. All actions, even erratic and neurotic actions, are reasonable, since they have discoverable causes of which the agent is frequently explicitly conscious. An action is rational when it is well adjusted to the character of a person and his purposes under the circumstances; an action is rational when the reasons for the action and the values achieved by it have been examined and judged (Mckeon, 1968, p.113).

There are several different ways to approach the determination of character and of actions in transitions, each of which spotlights different aspects of the process. A focus on human nature emphasizes the unchanging qualities of temper and coping traits in transitions; the dramatic approach emphasizes the changing qualities of the persona and its adaptation and moderation processes; the ethical approach prioritizes the merging of changing and unchanging qualities of habits; and the social approach highlights the turn (tropes) of character traits in a social environment. Approaches that focus on habits and social turns are more holistic, encompassing aspects of coping, adaptation, and moderation processes.

The hypothesis that character helps people facilitate their transitions is followed by a second hypothesis. Products with character can support people in transitions, as their relationship is a reflexive one (Buchanan, 1995). In rhetoric, one can talk about character in the voice of the designer, the product, and the audience (Buchanan, 2001). However, regarding technology’s intervention, obvious manifestations of such reflexive relations in social media products (i.e., Flickr, Youtube, Facebook, etc.) hint at a radical emerging quality. In these examples, the character of the product is defined by the mergence of the designer, product, and the people using the product. With such a move in the emergence of character within interactive products and services, we can discover an insight that merging the characteristics of people and products composes character elements in interactive products and service systems, defining an experience. Evoking an Aristotelian tradition of poetics, Moholy Nagy unfolds the material, formal, efficient and end causes as the ‘character elements’ of products. In this way, he explains the dynamics of a maturing industrial design field and how such a relationship results in a unified whole (Nagy, 1944). In a parallel mindset of poetics, McKeon explains the character elements of people with ‘temper’, ‘persona’, ‘habits’, and ‘social turn’. Thinking of an experience as a means of the formal, material, efficient and end causes can help us to ground the character elements in an experience. In the discovery of these character elements, merging the character elements of people (McKeon, 1968) and products (Nagy, 1944) leads the inquiry to discover the character elements of experiences: routine, performance, narrative, and ritual. These are the frames that constitute the modes of transitions (Ozenc, 2009), which compose experiences (Fig.1).

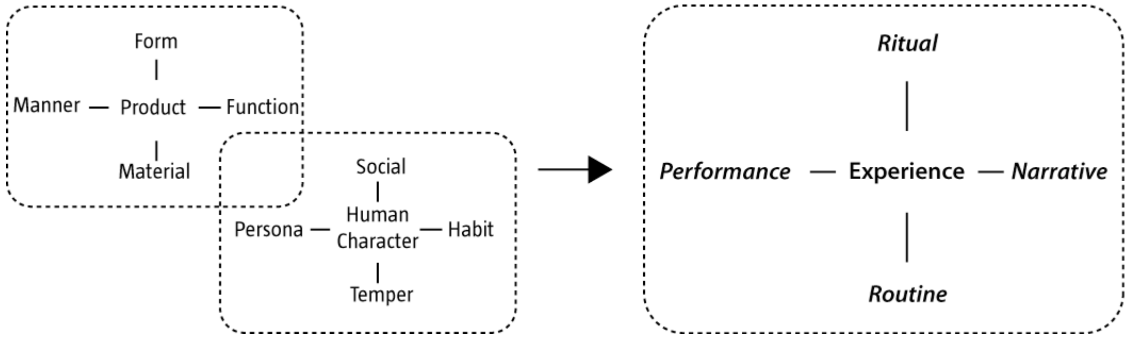

Figure 1: Modes of Transitions

Having identified the modes that define character elements in an experience taking shape through IP&SS, the next questions would be what kinds of products are particularly relevant, how these products support people in transitions, why they are relevant to the transitions, and what kinds of principles are guiding them? To inquire into these questions, developing a heuristics is useful to make a systematic inquiry that provides the necessary tools to ask questions using principles and methods (Young, Pecker & Pike, 1970). In describing a heuristic mindset, they made the following statement:

> A unit of experience can be viewed as particle, or as a wave, or as a field. That is, the writer can choose to view any element of his experience as if it were static, or as if it were dynamic, or as if it were a network of relationships or a part of a larger network. Note carefully that unit is not either a particle or a wave or a field, but can rather be viewed as all the three (Young, Pecker & Pike, 1970, p.).

In approaching an experience, one can approach the experience as part of bigger whole, as dynamic relationships between parts, or as a unified and integrated whole encompassing the parts and their relationships. These are conceptually hierarchical and one does not necessarily prevent other perspectives but might dominate them. In order to make experience approachable, one needs to segment the experience into units. And to understand a particular unit adequately, the heuristic approach suggests looking at that unit's contrastive features, variant forms, and distributions. Contrastive features can be summarized as the features that distinguish the unit and reveal distinct qualities of the unit from the other units. For instance, a wireless router can be distinguished from other routers with its cable-free quality. Variations are the changing qualities that are built on top of the contrastive features. They create diversity by suggesting different versions. Returning to our example, it might be the range, modem connection, or multiple-entry-allowance qualities of a wireless router. Distribution defines how the unit is situated in a bigger context. In the example of the wireless router, distribution would entail the Internet provider service in a home or office context.

Elaborating on the possibility of a transitions heuristics, one can easily find the correlation between the heuristic elements of parts, wholes and relationships and the transition phenomena. Transitions happen in parts (self) and wholes (environment), and in the relationship defined between them, regarding people's emotions and social qualities. Products are introduced into these transitions at all levels, in the immediate term (like with mobile phones), and in the long-term (as with health-care services). Since they mostly exist in-between contexts, and experiencing a transition by themselves due to the immaterial materiality (Ozenc, Kim, Zimmerman, Oney & Myers, 2010) of interactive products and service systems, defining archetypes for transition products to build a transition heuristics is challenging. However, we can attempt a typology of products based on the type of transitions mentioned earlier. The typology is malleable and one product can fall into multiple categories. I map the space of transitional products in Figure 2.

Spatial Transition	Social-Role Transition	Life-stage Transition	Environmental Transition
Transportation and Communication products, (i.e. Ubicycle, Merian, Telenav, Zimride, Nuride, Goosenetworks)	Communication and Personal care products (i.e. Helicor Stress Eraser, Emwave, Zipcar)	Health-care and other Care services, Collectives (i.e. Nala Patient Chair, Direct-life, Keas, Good Grief Center, I –am-too-young-for this! Cancer foundation)	Community services, Collectives (i.e. Activmob, Open door, Patients like me, Cure Together, Community-revolution health, Lotsa helping hands, I –am-too-young-for this! Cancer foundation)

Figure 2: A typology based on the types of transitions.

Inquiring into these products for emerging patterns, IP&SS situated in transitions can be viewed as units of experiences, which are open to be viewed as particle, wave and field. Thinking through the lens of heuristics, there emerge three product families, which provide a means to make a systemic inquiry using principles of transitions. These product families are the mobility, care, and community products. Mobility products are examples of the part, care products are the wave, and community products are the field. These are however the existing state of products that have been used in the context of transitions, which haven't been yet explored through the lens of modes of transitions.

To inquire into the particle, wave and field means, in other words, the parts, relationships, and the wholes in transitional products, there is a need for discovering the guiding principles in transitions. Principle is defined as "a comprehensive and fundamental law, doctrine, or assumption" (Webster, n.d.), which defines the beginnings and ends of phenomena. Watson makes a distinction between the first principles and secondary principles in his inquiry (Watson, 1970). First principles are principles that cause the beginnings, and secondary principles are functioning principles that are caused by first principles. He then identified four kinds of principles: elemental, reflexive, comprehensive, and creative principles. Elemental principles are analytical composed of functioning parts. If these parts are functioning for the sake of functioning, they become reflexive principles. Comprehensive principle states functioning principles are inherently part of a designed bigger whole. Creative principles are arbitrary in its relating to functioning principles (Watson, 1970). In approaching the transitions, I followed a similar approach to the guiding principles and discovered that each frame embodies one kind of principle characterized by Watson, and each kind consists of first and functioning principles. Each mode the frame itself is the first principle, followed by its functioning principles.

Looking at the core of transitions, there are embodiments of several functioning principles. At the center of a transition, there is an experiencing *self* in a dialogical relationship with the *environment.* Transitions occur in the swing of *changing* and *unchanging perceptions* and *interactions* of the *self* with the *environment*, defined with *emotions* and *reason* at *immediate* or *long- term time intervals*. This twisted swing affects the logistic, emotional, and social qualities of people's lives at differing magnitudes. To address these challenges, the habitual (narrative) and social (ritual) modes of transitions bring a holistic grasp on the rational, emotional and social dynamics in transitions.

Principles derived from the framework illustrate a diversity based on the character frames of routine, performance, narrative and ritual. Routine is the elemental first principle: Its functioning principle involves changing versus unchanging, role versus environment, immediate versus long-term, emotion versus reason, perception versus interaction, individual versus social, and reflection versus participation. Performance embodies the reflexive principle: its functioning principles are the integrity and finding harmony. Narrative embodies the comprehensive principle; its functioning principles involve *quality of life and well being*, and ritual embodies the creative principle, its functioning principle involves the *participation*. There is also a stratum, with layers of comprehension from routine to the ritual. While routine covers the natural tendencies and performance the nurturing, the narrative and the ritual cover both the nature and nurture aspects of transitional experiences. In these layered compositions of character elements of experience, routine and performance provide the means of immediate interactions, whereas the narrative and ritual provide the means for long-term interactions (Figure 3).

	Contrast	Variation	Distribution
Part	Routine	Procedure, Repetition	Order in Changing versus unchanging, role versus environment, immediate versus long-term, emotion versus reason, perception versus interaction, individual versus social, and reflection versus participation
	Performance	Enactment	Integrity and harmony
Wave	Ritual	Reflection, Interaction	Participation
Field	Narrative	Expression, Emplotment	Well-being, Quality-of-life

Figure 3: Transition Experience Heuristics schema

In exploring the transition heuristics through product examples, I describe the type of transitions and its characteristics; highlight the type of products people use in that transition; continue with the experience frame people prioritize during their use; and finally give specific product examples followed by the variations and distributions. In exploring the different kinds of transition products, from part to whole, I use the hierarchical relationship between the products to tie the argument to the principles, which suggests that one kind of product can fall into other characterizations, and that they have an intertwining and concentric relationship.

Routine and Performance products

The spatial transition means the changing environments, whereas the social-role transition means the changing of roles in relation or independent from environment. In the past decades, these transitions went through revolutionary changes, especially with the advances in the transportation and communication domains, which provide physical and performative mobility for people to navigate in their everyday lives. With the help of the technological advances, both transportation and communication domains now define product ecologies that involve not only products both also services and systems. Transportation ecology spans from bikes to cars; from ridesharing services to public transportation systems. Communication ecology spans from mobile phones to the Internet, personal wake-up services to the SMS systems for public awareness and collective action. In the richness of these ecologies, there also exist intersections combining both transportation and communication domains. This mergence between domains results in services that help people *plan, coordinate* and *use* the transportation services with the support of communication products. In some of these services, the focus is on the logistics of the transportation, i.e., helping people find matches regarding where, when, and with whom to go, and in some other situations, creating behavioral change for healthy life styles.

Mobility products include transportation and communication uses, routine materiality, and performative manners to frame experiences. Routine materiality of an experience is built through the planning, coordinating and repetitive use of a product (Wakkary & Maestri, 2007). This helps the transitioning person to build order in everyday life. The performative manner of an experience is a mechanism that enables a person to enact different roles and scripts in order to form consistency among routine materiality and ritual forms. People use routine and performance constructs in a dialogical relationship and in experimental ways. For instance, once the person finds resources for routine materiality, she can practice this materiality with small performances. If the performances fit to the context of the transition, the person gradually works through the routine materiality with repetition to form experiences.

Transition products in this type of situation illustrate richness with the ride and car sharing products. They are composed of both communication and transportation aspects of mobility. The idea behind ridesharing is to match people who are travelling to identical or near-by destinations. And the idea behind car sharing is to optimize the car use through offering membership-based car sharing. The higher goal for this type of product is to create more sustainable communities through leveraging spatial transition into a lifestyle transition. The challenges of such motives are several; they include planning, coordination and use. The use of such products seems to be the most critical challenge, as it needs habitual change. For instance, once people have built their routines using solo driving or owning a car, it is hard to change those routines unless there is a substantial intervention into their routines. To address these challenges, designers deploy strategies and interventions through online and physical media.

Goose-networks (n.d.) help people to find rideshares and alternative ways of commuting, thereby is providing a commute trip planner tool. The tool is flexible enough to provide not only rideshares but also public transportation and shuttle services. Goose-networks works with the routine frames. By situating the product in an office setting, Goose-networks increase the logistic reasoning while decreasing the emotional and social barriers. The variations of this type of service include Zim-ride (n.d.), a ridesharing service that supports people finding rideshares in campus environments; Nuride (n.d.), an incentive based rideshare program giving rewards whenever people use alternative ways of commuting. Goloco (n.d.), a rideshare service providing rideshare groups based on different roles, like attending church or concert. Among these variations, the possibility of leveraging the spatial transition into a lifestyle transition depends on how effective the product can use routine and performance frames as principles and strategies.

Zipcar (n.d.) is a membership-based car-sharing service providing hourly or daily car rental in designated locations of a city, whenever people need to become mobile. The Zipcar merges an interactive product and a service system to allow a person access to a car whenever she needs it, instead of owning and maintaining a car. From the perspective of transitions, Zipcar is a good example of a product that uses the performance frames. The service positions itself through the role performances rather than the routine frames such as commuting. To actualize the performance frames, they build personas around the vehicles that they provide for car share. Having segmented the cars by following trends, they present unique car personas as a person's neighbors. Mini Convertible Mollie organizes an annual block party, whereas Honda Civic Carlos teaches yoga, and loves to kayak, Prius Ping jogs in the morning and doesn't say much; Toyota Tacoma Tony is good with power tools but single. Each car represents a certain kind of prop that will facilitate different kinds of lifestyles, helping a person to adapt to the environment.

Products that use routine and performance frames as their principles for strategy and intervention functions at immediate-interactions level. However, once they are thought as part of a bigger context, they point out the long-term life-style and life-stage transitions, to be considered (later in the paper, or later in some other context?

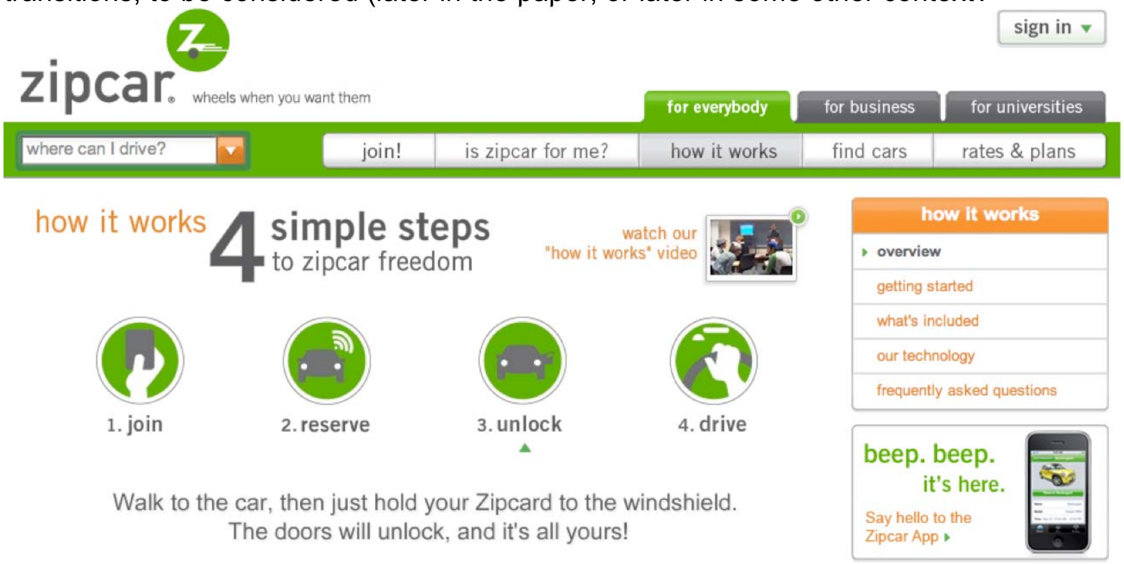

Figure 4: Zipcar, helping people to enact different roles through performance frames

Ritual Products

People experience intentional changes, such as acquiring a new habit for a healthy life style, or unintentional dramatic changes in their lives, such as loss of a loved one, serious illness, or losing a job. These transitions affect people's lifestyles and life-stages, requiring them to reconsider their roles and/or their environments. People need to perceive and act on the situation appropriately in order to continue their lives. Care products intervene in people's lives in these kinds of transitions. They can be personal or social, depending on the nature of the transition. When it is a personal one, care products help a person to reflect and act on the situation. Reflection provides the awareness, and awareness in turn triggers emotions to become actions, helping the person to overcome the turmoil. In case of social ones, they work through engagement and participation.

Care products use ritual frame constructs to form an experience. For ritual form, there needs to be a focus of attention, presence, and engagement in the activity (Collins, 2005). Once the ritual form is built, there emerges an emotional energy that provides the social turn for the person to transform according to the new situation. In a social setting, such ritual form needs to have a mutual focus of attention, co-presence, and participation, to create an emotional energy. Such ritual frames need performative constructs to provide focus of attention, and to build the stability that has been threatened by the changing roles and environments, and routine constructs to sustain this stability. For performances to create mutual focus of attention, ritual frames need symbolic props to enact, such as a university banner pole for a graduation ceremony. Ritual frames can function both as reflexive and also participatory constructs, based on whether it is an individual or social one.

As an example to a lifestyle transition, *Direct-life (n.d.)* is a personal care service that can track people's health and exercise records for a healthier life style. This service works over long-term use, and with reflexive principles. Compared to Direct-life, Emwave (n.d.) and Helicor Stress Eraser (n.d.) provide an immediate feedback for breathing patterns, and they aim to decrease stress by reflecting on the breathing. These products deploy ritual frames, in the sense that they aim to create awareness. They provide an emotional turn to transform the person into a new being who can adapt to the circumstances of the new situation.

Figure 5: Good-Grief center helping people in grief through ritual frames

There are also services of care that focus on unintentional changes, such as loss of a loved one. *Good Grief Center* (n.d.) is a bereavement service located in Pittsburgh (USA), which gives personal and social support for people who have lost their loved ones. For personal care, Good Grief Center provides care packages that include a handcrafted journal, a music and meditation CD and good grief cards that supply reflection pieces. For social care, they provide social support groups and organize workshops and meditation sessions for people who are in transition. There are variations to the Good Grief Center, such as Center for Loss and Life Style Transitions (n.d.), The Compassionate Friends (n.d.), Healing Hearts for Bereaved Parents (n.d.), etc. In these services, care comes after a dramatic unfolding, in which an overload of emotions has arisen.

The challenge in these kinds of transitional services is to address the emotional turmoil, which can easily turn into depression. The ritual frame construct can push the passive emotions to transform into active emotional energy. They can achieve this only if the person in loss can engage and participate in the service. There are many ways of participation, including a reflexive one, or a social one that happens through expression. Expression to another kind of product, namely narrative ones, which help people participate in the change through expression.

Narrative Products

Some transitions require a social turn that intervenes in the long-term and that helps people to adopt themselves to the new situation. Community domain does this by leveraging care products into another level, helping people not only to interact but also to participate in the services for change. They achieve this through expression, with narrated stories of each person allowing them to participate and become part of the community.

Community products function through narratives frames. Each person shares stories through the product, letting others know, be aware, and act on the situation. Through stories, a common sense is created based on participation. In a transition, the materiality of the story is out there, with the routines and performances. The transitioning person takes this temporality and performance, which emplots them in a dramatic construct, composing a unified whole that will create meaning and stability in the transition (Ricoeur, 2005).

I'm Too Young For This! Cancer Foundation (n.d.) (i[2]y) can be characterized as a community product that positions itself as an advocacy organization that serves the next generation of cancer survivors and their caregivers in their late teens, 20s, and 30s . i[(2])y sets its mission as “empowering young adults affected by cancer, by reducing late detection, ending isolation, improving quality of life, and providing meaningful survivorship. i[(2])y uses music, the arts and social media to organize, energize, mobilize and activate young adults to the cause, build community, end stigma and make it hip to talk openly about stupid cancer.” i[2]y takes the narrative medium with a broader perspective and use these media as functional frames for individuals and for the community.

Figure 6: i[2]y functions through narrative frames

Lotsa Helping Hands (n.d.) is another community product, which aims to create a platform for caregivers, volunteers, and people who are in transitions. They position themselves as a facilitator, providing communication resources that support family caregivers and volunteers by empowering their community circles who want to help those in need. *Patients Like Me* is a disease based community platform for people to congregate and share stories around diseases (n.d.). *Cure Together* (n.d.) and *Community-Revolution Health* (n.d.) also use narrative frame constructs to engage people in conversations. The medium of the narrative frame is diverse among the community products. Revolution-Health Service, for instance, provides blogging resources for people to express themselves and share their stories. In the bigger context, there are several motives behind these narratives: for inspiration, for learning, for creating social change through participation.

Considering the range of transition products and how they intervene in transitions at different levels, there emerge three high-level insights:

1. People compose their experiences with products using principles as strategies. These principles are the modes of transitions and their variations. For instance, Zip Car uses a performance frame as a strategy to facilitate the principle of finding harmony and

integrity among many different roles, whereas Goose-networks uses a routine frame as a strategy to build the principles of order and stability.

2. In deploying strategies, people are not bounded to one typical frame, they are open to maneuvers and making strategic moves to the extent of their principles. For instance, Good Grief Center provides the resources for both ritual and narrative frames. People can make strategic moves concerning how to deploy them in their transitional experience. They can either use the product as a reflexive one through cards and meditation CDs, or a participatory piece, engaging in workshops, and using not only ritual but also narrative frames.

3. The dynamic and cross-boundary uses of frames are possible with a unifying quality of character. Character helps people to prioritize the principles so that it affects the strategies at work. Character in that sense is a unifying principle for people who are in transitions. It houses order, integrity, quality-of-life, wellbeing, and participation as its principles.

Reflecting back on the inquiry, transitions heuristics begin with the typology of existing products that are in use for different types of transitions. The principles that are informed by the modes of transition reveal the future qualities and dimensions of new kinds of transitional products and services. These are the *routine*, *performance, ritual* and *narrative* products, embodying first and functioning principles that are hierarchically nested with each other. The transitions heuristics contributes to the design and research practice in several ways. First of all, it gives the competency to develop a systematic inquiry identifying issues for the complexity of transitions; then it provides efficiency in defining sweet spots with the frames in the process for actionable findings; and finally as being a design driven heuristics, it bridges the analysis and synthesis phases in the designing of strategies, products and services for transitions.

Involvement in the design student approach

Heliana Soneghet Pacheco, Universidade Federal do Espírito, Santo, Brazil

Abstract

This paper is about the methodology used in the first six months of the Design course at my university in Brazil. This was inspired by the so called Social Design methodology developed in another Design course where I previously worked as a lecture and researcher.

Educating designers is a complex subject because it is a matter which integrates techniques to help the students to develop their observational skills, creativity, social awareness and individual talents.

A student who arrives at the university has already skills, knowledge, and the capacity to project their life according to his/her education. Including this fact in the class's approach is the first step of this methodology.

The students are told to look for a group outside the university with an interlocutor, where they will develop a real design project. The purpose here is to guide the student, not to propose a problem or even resolve it, but he or she will be able to develop the capacity to identify fertile areas for action. Thus a constructive atmosphere will develop with the aim of bringing new benefit for the group, rather than the more negative mindset concerned with fixing a perceived problem. The student designs an object and tests it in order to get feedback from his adopted group. The student is encouraged to get as much feedback as possible in order to challenge his preconceived ideas and promote double-loop learning.

This paper shows the techniques used by the students related to data collection as an attempt to generate a "model 2" operating system as advocated by Schön and Argyris (Smith, 2001), and some of the projects developed during 10 years of the university design course.

Keywords

participatory approaches, design methods, design and society

Since 1997 I have worked at the Univeridade Federal do Espírito Santo - Ufes, in Brazil, with the students who are starting their first term, or semester. During the first four months the students develop a design project, construct and test it. This is a complex subject because it is a matter which integrates techniques to help the students to develop their observational skills, creativity, social awareness and individual talents. The objective is to give the student an experience of how designers act in a project, to what should attention be paid, how the data can be collected, and in which areas a designer can be useful. This shows the student part of the world he or she will be involved in for, at least, their next 4 years.

This paper will show the methodology used during 10 years of activity using examples of the projects developed by students over these years individually or in groups of 2 or 3 students.

The approach

The student arriving at university for the first time already has a skill set, and knowledge from their experience thus far. We recognize this, and it is the starting point of our methodology.

Here we believe education can enhance the existing capacity of students to allow them to become more aware of how an individual's personal experiences are connected to larger societal circumstances, according to the approach of Paulo Freire, the well known Brazilian educator (Nogueira & Freire, 1966).

The first step for the students is to find a group with whom they will develop a real design project. This group can be a school, a company or any organisation, but it must be outside the university system, and there must be an interlocutor to provide a link between the student and the group. People share and integrate knowledge best in social environments (Nonaka and Takeuchi, 1995) and a good interlocutor is essential for the project. As recommended by C. Alexander (1975), the involvement of the users, the interlocutor, and the student all together will be necessary for a successful experience.

The lack of a formal previous study in this area is substituted for by intuition, involvement with this group (at least 2 times a week) and curiosity. The real life situation instigates in the student the development of his/her capacity to look at the surrounding world when taking decisions. The format is to go to a place with plenty of activity in which the subject is new for the student, because previous knowledge could interfere in their observations.

The interlocutor is a person who is already involved in a project, in a work, in some movement towards getting a result. It is never a person who is waiting for something to happen, or somebody who has a complaint, but is not doing anything to resolve the situation. Engagement with an action is the basic requirement for the profile of the interlocutor. We used to say that the student has to find a person who has “shining eyes”. Shining eyes produced by enthusiasm and engagement. The reason is that we believe that it is important that the student, at this initial point, learns to identify fertile fields within a project, identify situations that work and people that will be working WITH them and not people that the student will be working FOR (Pacheco,1996:23).

The steps for the student making the project are:

1) Find a locale with an interlocutor, collect the data, and visit the place at least twice a week over the four months period of the project.

2) Define the general objective of the project

3) Research the subject

4) Elaborate the hypotheses, classify them in groups and test them.

5) Define the specific objective of the project

6) Generate alternatives and test them

7) Define the final alternative

8) Construct it

9) Experiment it

10) Form a conclusion

To find the locale is a very important step, because without a good environment it is very difficult to work well. It is preferable to delay finding a suitable locale and find it, than to work in the first place found just to start the project early. There is an example of a student who was part of a group of the university that started to work in a locale where people were involved in a campaign “if you drink, do not drive”. This student was not satisfied with the locale because she could not identify the objective of the interlocutor's actions, since these actions were not very clear to her. Instead of insisting more and trying to identify his objectives later, she resolved to change to another place and there, unfortunately, the interlocutor did not have “shining eyes”. This was a physical education class and it seems that the teacher (the interlocutor) was doing a work almost mechanically and her eyes were not “shining” because of this. Then she changed again to another place where the interlocutor had “shining eyes”. However, the student could see, in time, that this was because the interlocutor saw in the student somebody to work for him. His eyes were shining not because he was involved and happy with his job, but because he had seen in the student somebody who would follow his orders. By this point the student had concrete experiences of this abstract condition: “to find shining eyes”. She had a conception about what this was and she was following her intuition. The result so far was that she had had a number of unpleasant places to work. Despite this, she did not give up and later she found a very interesting interlocutor, a teacher who worked in the interval between formal classes, called “recreação” (this word comes from a two word junction: recreate and action). This interlocutor was somebody very creative and involved with her work, she had a clear objective and accepted the design student to her classes in order to develop a project. It was not easy for the student to find a nice place, but the guidance she received and her own understanding, and fidelity with her understanding, were responsible for the success of this first step of the project.

Once the locale and the interlocutor are found, data must be collected. Beyond natural observation, and records made with pictures and/or drawings, some other techniques are used.

Techniques related to data collection

There are basically 3 techniques used by the students to collect data about the interlocutor and his or her work. The point here is to collect valid data, which is connected to the real world, not to the student’s preconceived ideas. So, the strategy is to encourage feedback and outside input. This is an attempt to generate a “model 2” operating system as advocated by Schön and Argyris (Smith, 2001). In other words, to encourage open communication and minimize the influence of predetermined mindsets from either the student or the interlocutor.

The first is called “Listing beliefs and actions”. Along side observations of what is happening in the locale, the student starts to make a list of what the interlocutor says about his or her work and what the student can see about his or her actions, comparing one to the other. At one level this is important because, as Bregman and Haythornthwaite (2001) point out, conversations are ephemeral. However, more importantly, this is an attempt to determine the position of the interlocutor. It is common for people to have a mental map on how to deal with situations (Argyris and Schon 1974). However, frequently people’s perception of how they deal with situations is different to how they act in reality - espoused theory and theory in use (Smith, 2001).

Making this list is a useful tool for determining the position of the interlocutor at the start of the project.

Example of a classroom teacher as interlocutor is shown in table 1.

Table 1: List of beliefs and actions

Beliefs	**Actions**
I am very organized.	The interlocutor uses a class plan in which the periods of activities are distinct and she follows what is written in the order it was written.
It is important to stimulate creativity.	The interlocutor holds the hands of the students and shows how to paint a picture.
I prepare each class the night before.	--------------------------
	(The cell above is blank because this action was not seen by the student.)

What this example shows is that the first statement was observed by the student, and the interlocutor's action was related to the statement. Reading the report, anybody would agree with the statement that the teacher is organized.

On the other hand, the action related to the other statement is not an action which illustrates the stimulus of creativity. The result is that the action is not related to what the interlocutor said about her work.

The third statement has an action which happens at a time to which the student has not access and because of this, cannot be considered in the final analysis.

This technique is very important to 2 goals. The first one is to be conscious of to what extent the interlocutor is aware of his/her actions, to be able to select a subject to work with which would be possible in the local universe. The second is to identify which subjects would be under the student's observation. What is done in another locale, or another time, can be interesting, but without the direct observation of the student, cannot be used in this context.

The second technique is another list. A "List of good things at the locale". This list is about everything good that had drawn the attention of the student, about the work being done and the environment around. It is important here to select only examples that are effective. Students always seem to have the habit of observing what is going wrong in a place. They arrive at the locale with the idea that they will resolve a problem and consequently the problem has to be found. The exercise here is different. We stimulate the students to, first of all, pay attention in everything that shows that actions have worked.

Example from a project made with a teacher of Capoeira *(an Afro-Brazilian art form that combines elements of martial arts, music and dance):*

. teacher uses discipline successfully.

. joy in the faces of everybody.

. practice using repetition.

. students respect the teacher.

. students smile when face difficulties.

. abundance of wishes to learn and to teach.

Example from a project made with a teacher who works in the interval between formal classes, called "recreação"

. the teacher explores creativity modifying the use of traditional tools to other functions.

. the teacher talks to the students to reflect about what they are doing.

. the children have a lot of fun in the class.

. the students are stimulated to socialise.

Here we diverge from the intervention strategy of Schön and Argyris (Smith, 2001). Instead of aiming to identify problems in communication within the organistion and intervene to correct them (Argyris and Schon 1978), the case here is to teach students who will in the future have a positive approach to helping the client with design. Thus, we argue that in this context it is more important to identify when and how something goes right, or in other words, produces what is being expected, than to look for negatives.

This list gives the student a lot of inspiration when he or she develops their project because both the list and the final product of this design exercise are linked to the success of the project. We used to say that we work with joy, not with problems. With movement, not with stagnation. We also used to say that we work with what is in abundance, not what is missing. In all of the examples above, the resulting products were linked in some way to each environment as will be seen at the end of this paper.

It is at this point that we differ from traditional approaches in design, because at the same time as the word "problem" means opportunity, it also carries a meaning linked to stagnation and missed opportunity. On the other hand, the word "joy" is suggestive of something going well, movement being made.

So, the "fertile field" can be identified by the student and there is the "gold". There is the solution. The student is stimulated to start seeing the solution, not the problem.

In any given moment a "problem" will not be sought. Instead, only opportunities will be considered according to the behaviour and actions of the interlocutor. The idea is: if the interlocutor is already involved in some project, action, or objective with enthusiasm, and the student works with him or her, this situation will not be called a "problem". It will be called a "project situation".

Still with the aim of developing a model 2 situation, with a maximum amount of feedback, the third technique is the "Word game". This is a visual conversation between the student and the interlocutor. It also derives from another list. In this case, a list of key words related to the universe of that locale. There is no limit to the number of words, but it has to be done after a period observing the place to be as complete as possible. Ideally, someone who knows the locale should be able to say where, when and with whom the student is working by only looking at the list. Verbs and nouns can be used.

After this list is made, the student prepares each word individually on a separate piece of paper, each piece having the same size and typeface in order not to produce any impression of hierarchy. This collection of papers is then given to the interlocutor and he or she is asked to organise them according to his or her own criteria. The interlocutor can take out words that he or she does not believe make sense, or put new words that he or she believes are missing, in order to organise according to his or her logic.

What is the point here? The students, when organizing the list, are making visible what they have in their minds/thoughts. When the interlocutor organizes the words, he or she makes visible what is in his or her mind/ thoughts. So, this visual conversation is used to clarify a lot about the place, the work that is being done and the characteristics of these two people, the student and the interlocutor.

These examples show different kinds of organization. Sometimes the interlocutor organizes by order of importance, by groups, writes a story or uses different approaches (figure 1).

Figure 1: An interlocutor organizing the word game.

The definition of the objectives

These techniques help the student to analyse the situation, the communication codes, daily life, routine, and in general how the things happen, in order to have material to identify the objective of the project. So, the general objective of the project is only defined after about three weeks of observation. It is never decided on before this because it would be a result of conjectures not certified by the student's observations. A conclusion is only reached after a study, after an analysis, after a period of familiarity between the student and the locale and interlocutor, in order to allow him or her to make conscious choices. This objective is then defined by the students, in conjunction with their interlocutor. The objective is not given to the students as a task to be done.

The students have to put all the data to be analysed together, because they are connected. It is then easy to choose a pertinent objective when this objective is related to a lot of actions of the interlocutor, it is clear in his or her mind and so it can be seen by the student. When analysing it is important to consider the context in order to interpret well the data. Sometimes the objective is not very clear. The list of actions, for instance, is not linked to the word game and this can be result of either a poor level of observation or to an unclear situation. Normally the unclear situation happens when for some reason the real objective of an action cannot be said. For instance, in a fitness academy when the reason for some action is to get money, instead of producing healthy clients. It was common over these 10 years to see students changing the locale because, at this point of collecting data, it appears not to be a good place. It is very possible to make a mistake and what happens is that the group of students has to start a new project in another place. The good part of this is that they carry with them the learning of this experience and this new place is better chosen and the data collection is faster.

The first hypotheses

With the general objective defined, hypotheses are formed and here the student can formulate strange or impossible ideas. All that is required is that all of them must be linked, clearly, to the general objective. We believe that it is important that the student must be free of self-reprimand (a model one value in the Schön and Argyris schema -

Smith, 2001) in order to be creative. Normally the students have difficulty in doing this because they want to be "reasonable". Because of this, it is stipulated that they have to form and draw 20 hypotheses. This number has to be large enough to allow interesting ideas to appear (figure 2).

2.1 2.2

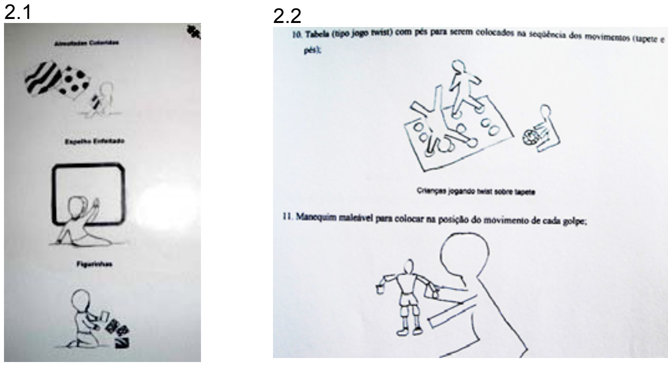

Figure 2: Examples of the first hypotheses 2.1) In a project developed with people with visual deficiency. 2.2) In a project in a class of Capoeira.

The tests

From these 20 hypotheses, the students separate the similar ideas into groups and test these groups with the real users. This test is done in order to see if the group is valid, so only a basic mock up is used.

The results of these tests will allow the student to chose the best way forward. The student and the interlocutor will analyse the results together.

In the case of the Capoeira class, the possible objectives defined were to work with either the teaching of the movements of the “dance”, the names of the movements or the music and rhythm of the dance. Three possible approaches were tested with the capoeira group based in the three situations: in the first one, the children were stopped in a place and learning, in the second, they were making movements, and in the third working specifically with rhythm.

In the first one, the students should link the name and the movement as playing cards (figure 3). The result was not satisfactory because the drawings of the movements were sometimes confused.

Figure 3: The student tries to associate the name of the movement in Capoeira with the drawing of it.

In the second one a cube/die was used. The child had to throw the cube/die and the face would show the movement to be done. Whoever knew how to do the movement presented himself and did it. This was ok, but the children were more showing what they knew rather than learning something new, and the interlocutor thought that this was outside of his present objective.

The third one was a test to help the children to drum correctly through visual hand guides on the table. This test was very well accepted by the children, and the interlocutor had identified it as the best one (figure 4).

Figure 4: The interlocutor (standing) and the children in Capoeira class.

In the case of students who worked in a school for people with visual deficiency, there was another set of circumstances. The challenge was to stimulate children to identify contrasts and some experiments were done with contrast gloves, a contrast rug and a contrast cube/die.

It was observed that the cube/die and the rug were efficient and then a rug was constructed that could be transformed into a cube/die according to the interlocutor's exercise proposal.

5.1

5.2

5.3

Figure 5. 5.1: Tests with the glove. 5.2: The rug and 5.3: the cube with the interlocutor holding the child in front of the mirror.

Defining the specific objective and generating alternatives

Once the specific objective is known, it is time for the students to generate alternatives, now with their “feet on the ground”, considering viability, price, material and dimensions of everything they are thinking of.

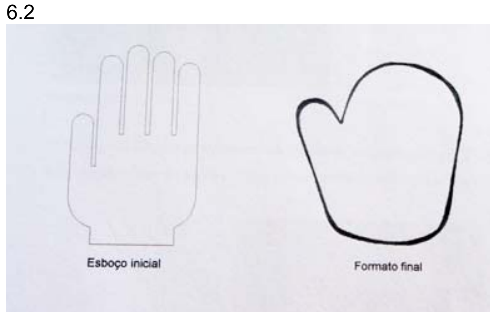
At this point, practical tests are again necessary because the next step defines the final alternative to be actually constructed and they need to know which one is the best. In all of these moments, the interlocutor is participating of the decisions and if other people are involved, they are also aware of what is happening.

The following images show the alternative tests and studies used in the Capoeira example above, until the final product was decided, including a bag to carry the “hands”. A design product made by this methodology should include the context. In this case, a complete product should have the tools to guide the children to drum (the “hands”) and a place to keep and carry these.

Tests included “hands” with numbers (figure 6.1) and later a study of possible combinations of numbers and colors. Faced with the construction, the students realized that the “hand” should be easier to cut in wood and the form of the hand was simplified (figure 6.2). After tests of the alternatives, it was resolved to use the system of colors and numbers seen in figure 6.3. It was also seen that it was necessary for a bag to be constructed to keep the material together (figure 6.4).

6.1

6.2



6.3

6.4

Figure 6: Tests and studies made until the definition of the final form of the product in Capoeira class.

In the case of a circus school, the issue was to rank the students according to their skills in order to stimulate them to learn what they didn’t yet know, or improve what they needed to.

The idea tested was to put on the wall 2 types of display. One showing, individually which type of performance each student knew (figure 7), and another showing each type of performance, with which students knew them, in order. The best student in the first place (figure 8).

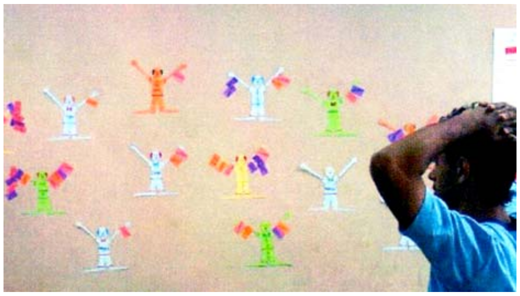


Figure 7: Test of a possible individual performance register design. This was changed to the final product after the test.

Figure 8: Test of the ranking of each exercise and the names of the students in order.

Once the definition of what actually will be constructed has been settled, the next step is the construction itself which can use a workshop at the university with the help of an instructor.

Preparing the observation of the final product in use

The experimental part is done over 3 weeks. In order to help them in the observation of what is happening and study the impact, 3 tasks have do be performed before starting the experimentation period;

i) a list of <u>which</u> points they will pay attention to,

ii) a list to <u>how</u> they will pay attention and

iii) a chronogram of <u>when</u> this will happen over the 3 weeks.

They have to include: taking pictures of the final object in use, time for any possible adjustments and time for the object to be left at the locale to be used with and without their presence, so that later questioning can determine it's usefulness. At the end, a letter from the interlocutor is required reporting on the development of the project.

The final result

The experiment is done with the final material in the real situation.

In the case of the Capoeira class, “hands” in wood were developed, marked with numbers and colors, in the size of the hands of the students, with a sand paper underneath and a special table cloth in order to not slip when beaten (figure 9). Some of these objects were developed over the experiments. Part of this development was also a bag to carry the objects.

Figure 9: The interlocutor and the children of the Project in a Capoeira class using the hands to guide then in drumming.

In the case of the circus class, the final product was a panel with two type of register. The individual performance of the students (figure 10.1) and their positions in the different categories of the course (figure 10.2). One was on the left hand side of the panel and the other on the right hand side. Over the experimental period it was possible to see students improving their performances because they would like to occupy more spaces on the panel

10.1 10.2

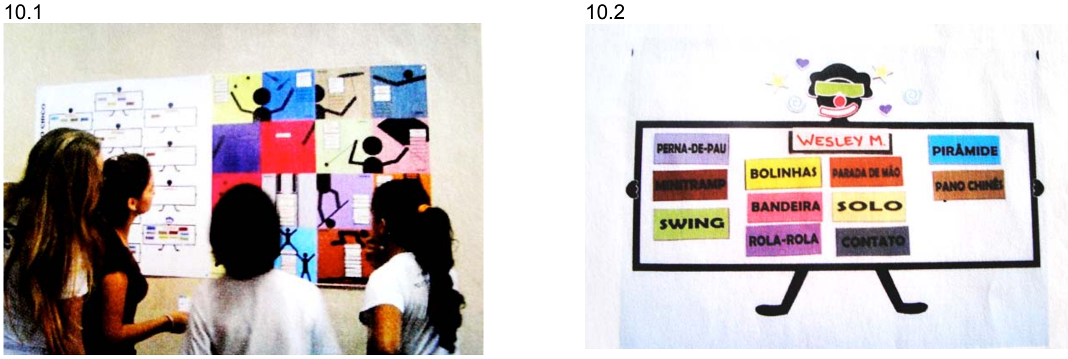

Figure 10: 10.1) The panel in which the performance of the students in the Circus class is registered in order to stimulate them to learn and exercise more. 10.2) The detail of the individual skills. The name of the child can be changed to another in order to be used over the years.

In the case of the work project made with people with visual deficiency, the product was a flexible rug that could become a cube (figure 11). The necessity for some three-dimensional stimulus was seen over the experiments.

11.1 11.2 11.3

Figure 11: The final product and its flexible format in the project with people with visual deficiency. 11.1) Rug, 11.2) Rug and “wall”, 11.3) Cube.

Conclusion

This method seems complex mostly because it is new for the students. Normally they come from a education model in which it is the teacher who brings the subject to be studied and not the student who brings the subject to be discussed in class. Our method can be applied to a lot of situations, but has fitted best mostly in situations of classes where there is a teacher as the interlocutor. The interlocutor can be another person, like a seller, a social care person, etc, but with teachers application seems to be easier in this new approach. In a situation in which the interlocutor is a teacher there is a clear objective, a predefined schedule and the student has only to find somebody who likes his job, who has "shining eyes". This makes the exercise less complex and still keeps the purpose of the discipline.

This participatory approach of the student, with an outside interlocutor and group, is an important exercise for them. Over the rest of their course they will experiment with other types of approach, but this was chosen as the first one for them to work with. Among other aims, the reason is that this approach stimulates questions, a wish to research, and produces a type of individual experience in which each student will have their own learning. Experience over 10 years has shown that this overall approach, which is similar, but not identical to the strategy of Schön and Argyris, can produce in the student a positive and productive approach to communication with the client.

She is *professor adjunto* at the Universidade Federal do Espírito Santo, Brazil, where she is responsible for the initial and final projects of the undergraduate students. In addition, she is coordinator of the Laboratory of Instructional Design for Distance Learning (LDI) and the Graphic Identity of Espírito Santo research group (Nigrafica).

Discovery and Creation: Explaining Collaboration between Designers and Scientists in Scientific Research

Carlos Peralta, IfM, University of Cambridge, United Kingdom/ cmp60@cam.ac.uk

Alex Driver, IfM, University of Cambridge, United Kingdom

Dr. James Moultrie, IfM, University of Cambridge, United Kingdom

Abstract

This paper examines the role of product/industrial design in scientific research. It reports the results of three case studies in which designers and scientist collaborated. The paper presents the initial findings of these cases, and reflects on the designers' contribution to research, and on those aspects that can act as a barrier or as a facilitator in designers and scientists' collaborative endeavour.

Keywords

Product design; industrial design; science; scientific research; interdisciplinary; collaboration; participatory approaches.

Design has the potential to play an important role in scientific research by linking it to people's day to day lives, but also to steer research in new and unexpected directions. Attempts have been made to discuss the commonalities and differences between design and science (Cross, 2001; Willem, 1990; Bonsiepe, 2007) and to compare design research and scientific research (Krippendorff, 2007; Glanville, 1999) and to reflect on how design can be complementary to research practices (Rust, 2004). There have also been attempts to study the impact that designers collaborating with scientists can have on public perception of science (Beaver, et al., 2009) and there is extensive literature about the interaction between art and science that occasionally mentions design[1]. However, there is little empirical evidence of product/industrial designers[2] having an active participative role in scientific research, and few studies of the role that product/industrial design could have in the practice of scientific research.

This paper illustrates the initial findings from three case studies undertaken to explore the impact that product/industrial designers might have in scientific research addressing the questions:

- Can designers meaningfully contribute to scientific research, and if so, what would be the nature of such contribution?
- What would be the main aspects that can act either as a barrier or as a facilitator for collaboration between designers and scientists, in the context of scientific research?

---

[1] The cited authors seem to use the word design as an overarching concept that covers different design disciplines. In this paper, it is assumed that the discipline of product/industrial design is included in that design overarching concept.

[2] In this paper, the term Product/Industrial design refers to the Industrial design definition of the ICSID (International Council of Societies of Industrial Design): "Design concerns products, services and systems conceived with tools, organisations and logic introduced by industrialisation - not just when produced by serial processes. The adjective "industrial" put to design must be related to the term industry or in its meaning of sector of production or in its ancient meaning of "industrious activity". Thus, design is an activity involving a wide spectrum of professions in which products, services, graphics, interiors and architecture all take part. Together, these activities should further enhance - in a choral way with other related professions - the value of life. Therefore, the term designer refers to an individual who practices an intellectual profession, and not simply a trade or a service for enterprises." (ICSID, 2010)

Background

Although there are known examples of collaborative interaction between designers and scientists in commercial, academic and institutional contexts[3], access to useful information about these initiatives is limited.

Interaction between social scientists and designers in the context of product development has been well documented in Squires and Byrne, (2002). Although the book covers several aspects of collaboration between social scientists and designers, it does not focus on collaboration in the context of scientific research, remaining instead in the realm of product development.

A meaningful contribution to the subject of collaboration between designers and scientists has been made by Rust, (2004 and 2007). In the first paper, Rust claims that although scientific pursuit is different from that of design, it may be possible to initiate collaboration between both “traditions” that serves both of their aims. The author proposes that designers’ abilities to “image new scenarios”, and to create a “practical environment” and “experimental artefacts” may be of use to scientists to select or even generate routes of scientific enquiry. Rust sustains that there is a “creative dimension” in scientific research and that designers can contribute to it. Rust presents examples of collaboration between scientists and designers, and concludes that designers can contribute to scientific research.

Even though Rust offers an interesting perspective on interdisciplinary collaboration, identifying both opportunities and barriers for designers in collaborative research, he does not present firsthand empirical evidence to sustain his claims. Although some of the papers cited in support of his argument show a reflection on research outputs and research methods, they do not look at the specifics of interdisciplinary collaboration, or reflect on the experiences of the researchers in the context of interdisciplinary work. This opens up opportunities for further empirical exploration of collaborative work between designers and scientists.

In his 2007 paper Rust reflects on how creative disciplines (art and design) can contribute to scientific research. He argues that designers may be better suited to undertaking research activates than artists. Rust points out that participant in design and science research projects may experience difficulties because of the absence of a “shared formal language”. Rust also formulates “tentative principles” for interdisciplinary research between creative people and scientists.

Although Rust develops interesting ideas, most of the evidence that supports his claims (personal conversations with artist and designers), is not presented or accessible. It is apparent that further study on collaboration between designers and scientists that presents “first hand” evidence may help to find new insight on the subject.

Approach

In order to fill the existing literature gap in collaboration between product/industrial designers and scientists, and with the purpose of obtaining empirical evidence to support claims on this theme, initial case studies, involving designers collaborating with scientists on their research work, were carried out, observed and analysed. Three case studies were selected from a range offered by a university technology transfer office. These studio cases were selected so that a) the design team (composed of the two main project researchers) could provide a meaningful design intervention, and b) the nature of the research needs, and subsequently of the design intervention, would be different in each case.

---

[3] *A few good examples of commercial and academic design and science collaboration that can be found on the web are: Simbiotica (University of Western Australia http://www.symbiotica.uwa.edu.au/welcome), Material Belief (Goldsmith Univ. http://www.materialbeliefs.com/), Biomimicry Guild (http://www.biomimicryguild.com/)*

Case 1 (Mask project) entailed the development of a device for the testing of a medical scientific hypothesis; *case 2* (Immuno project) included the design of systems and devices to reduce the time taken to perform a laboratory analysis technique. *Case 3* (Multistable project) involved developing a new technique of forming multistable structures from a variety of materials.

Different activities were carried out in each case study, and the project stakeholders' participation changed for each activity. Stakeholders can be divided in two different groups: Project Team (Scientist(s) + University technology transfer officer(s) + design team) and Design team (2 main project researchers + project director).

In each of the three case studies, the main activities were:

- *Preliminary meeting:* to understand the nature of the scientific project, to understand the perceived design need and to determine whether the project matches the research team expectations. (Project team)
- *Briefing meetings:* To discuss and agree on the design brief for the project (Project team)
- *Visits to labs/field:* To understand scientist/user requirements (Project team, or Design team + scientist(s))
- *Desk work:* To prepare presentations, reports, papers, briefs, computer drawings/plans, etc. (Design team)
- *Brainstorm/design focus sessions:* To generate/discuss ideas (Design team, or Project team, or design team + invited designers)
- *Workshop/lab work:* To make sketch models, to produce prototypes and to test ideas. (Design team, or Project team, or Design team + Scientist(s))
- *Interim meetings:* To report, discuss project developments. (Project team or scientist + Design team)
- *Presentations:* Formal communication of design work/ideas (Project team)

Notes, tape and video recordings were taken during meetings and work sessions. Initial and follow up semi structured interviews with the participant scientists were recorded and physical collection of cognitive artefacts and design outputs was undertaken. Design team follow up discussions were systematically carried out immediately after each meeting, presentation and work session. Written case reports were produced and the project team was invited to comment, and check for any errors in perception or interpretation.

The mixed data sources were analysed by the research team, to determine patterns, common issues and differences among the case studies. Analysis was carried out mainly through the narrative reconstruction of the study cases, using recordings, documents and design outputs as to trigger memories and reflections.

Case 1 Mask Project

Project Background

The scientist was conducting research in gas delivery for patients with respiratory problems. In order to perform experiments with patients, a mask was needed that would provide a perfect seal against the patient's face. However, the scientist found that the masks available on the market do not provide effective sealing or are not sufficiently comfortable for the patients over lengthy periods of study.

To address this problem, the scientist, using materials readily available at home, created a first prototype to solve the problem.

However, the mask was manufactured with materials not suitable for a clinical environment and medical trials, was not designed in a way that production of a standardized small batch (for clinical trials) was possible, and it was not comfortable enough to try on patients.

Scientist Requirements

The scientist required his concept be developed into a mask that could be tested on users. He was interested in finding materials that would make the mask comfortable to wear, and that allowed the manufacture of a batch of 30 masks for use in:

- Clinical trials and experimentation leading to the development and improvement of oxygen therapy techniques

- Accurate gas measurement for early detection of respiratory problems.

He was also seeking to use them as the basis for the development of a mass produced mask, to target the medical research market in the first instance, and then the clinical and therapeutic market.

The Design Team Approach

In a preliminary meeting, the design team agreed on producing a working design brief so all project stakeholders could discuss and agree on the project programme, its tasks, objectives and deliverables. The brief also helped to ensure that the designers had a clear understanding of the project design parameters and the mask's potential primary and secondary users (patients and clinicians) and context (labs and hospital wards) characteristics. At this stage while a collaboration agreement was in principle tacitly accepted by all participants, internally the design team further discussed the suitability of the project as a case study, because of doubts on two aspects. Firstly, the main concept of the mask seemed to be quite developed as an idea, so the design task appeared to be limited to finding materials and ergonomic adaptation. The design team was concerned that these were minor tasks that didn't offer enough opportunities for a meaningful contribution to scientific research. Secondly the project seemed to be too similar to those that would frame a normal product design consultancy commission. Rather than being involved in the scientific research process, addressing research questions, the designers felt that they might be solving a standard product design problem in which the customer happens to be a scientist.

However on further consideration, the project appeared to provide an opportunity to understand what the impact of a "normal product design project" would have in scientific research. In addition, the project would provide a good opportunity to demonstrate to the gatekeepers (university technology transfer officers) the design team's capabilities. Finally as the design team had been recently formed, this project would be "safe" enough to allow team members to develop working and collaborative practices.

The designers felt it necessary to directly observe patients in their environment, and to be able to revisit the information received, in the field. For this reason, the design team also conducted a guided visit to the hospital in order to observe patients with different levels of respiratory problems.

The Design Process

A first draft of the brief was presented including a detailed work programme and product specification, a description of who would be using the device and the context in which the product would be used. The brief was approved and it was agreed that the design team would focus on developing a mask for clinical trials and experimentation (leaving the potential development of a mask for commercial purposes aside). The focus on trials and experimentation meant that the project was no longer primarily concerned with exploitation.

After a brainstorm session involving other design researchers, the design team decided to follow the main principles of the scientist's idea, but to explore new materials options. This resulted in a mask that looked substantially different to the one developed by the scientist, but promised to meet all the criteria of the design brief.

Although the scientist's reaction towards the new design was positive and he eventually gave his approval to proceed with the construction of a prototype, he brought up for discussion some discarded features from his original design. He seemed not completely convinced by the design team's arguments, although samples of materials and drawings were presented to him alongside the explanations of the new design.

The designers proceeded to build a prototype of the mask. Once finished, the design team presented it to the project team. The prototype was tested by the scientist during the presentation and it become evident that it met the design parameters. It was agreed that the scientist would carry out formal tests with a sample of healthy people with different face shapes. After the tests the scientist reported that the new mask satisfied his technical requirements.

Nevertheless when further testing was carried out on cadavers some minor problems of sealing were observed. On this occasion, the scientist's response was to modify the mask to overcome these newly detected problems. This new feature implied a departure from the design team's ideas. Furthermore, in a later meeting, the scientist suggested incorporating some of the features of his original prototype. At this point the design team chose to incorporate ideas from both the scientist's and the design team's prototypes.

Case 2 Immuno Project

Project Background

A team of scientists built a fluid handling device based on a commercially available plastic component. They believed that their device could form the basis for a safer, cheaper and faster method of performing an immuno assay (a common laboratory test) compared with existing techniques. However, the device was not easy to handle, it did not allow multiple tests to be performed on different samples simultaneously, and it did not fit other standard components for carrying out immuno assays (microtiter plates, multiple channel pipettors, etc). These problems made it difficult for the scientists to prove their idea by making a reliable and credible comparison with other existing immuno assay techniques.

Scientists' Requirements

The scientists were looking for the development and fabrication of an improved version of their handling device so they could:

- Develop the new Immuno Assay procedure.
- Measure its levels of safety and reliability, its cost and its speed, so a comparison could be made with other existing competing procedures.
- Have the main underlining design principles ready for the development of a commercial version in the near future and for a fully automated version in the long term.

The Design Team Approach

In the first meeting of the project team, the designers were given an explanation of the fluid handling device and were introduced to the general principles of immuno assays. However, conducting an immuno assay in practice is a lengthy process that involves several steps. Also, a number of key aspects of the process had a scientific basis and were not directly observable, requiring an explanation in scientific terms. The designers asked for an observation day so they could have a real sense of the immuno assay process, and be able to associate the theoretical aspects of the process to the actual stages of it. The observation day was carried out and helped the designers to fully understand all the steps and the main scientific principles of the process. A diagram prepared by the scientists with scientific symbols was used during the day to explain those aspects of the process that were not directly observable. Some days later, the designers created their own diagram of the process, assigning a pictogram to each stage of the immuno assay, identifying its name and its corresponding scientific symbol. This diagram was shown to the scientists and it confirmed that the designers had achieved a good understanding of the process and its associated scientific concepts. Although at the beginning of the project, the design team was not familiar with the scientific concepts and vocabulary related to immuno assays, this mix of observation, scientific explanation and visualization of the process through diagrams, helped to establish effective communication between scientists and designers.

The Design Process

The design team started their design process by borrowing some standard equipment used to carry out immuno assays. They intended to use these in combination with sketch models to test some initial design concepts. The design team soon realized that any idea they might develop should be proved beforehand as being as efficient at handling liquids as the model developed by the scientists. However, the reduced scale of the components and parts they were designing did not permit them to use the sketch modelling techniques they were used to. So the designers had to resort to computerised rapid prototyping techniques to create the models. Since these techniques are considerably more expensive than normal sketch modelling techniques, the processes of consultation with the scientists was more thorough and intensive than usual. Interestingly, the presentations of the prototypes, carried out in the scientific labs, became almost “design sessions” were the scientists and designers considered different ideas and took key design decisions. Of equal importance was that the designers developed competing ideas, and subjected them to group scrutiny.

After a few prototype iterations and a number of discussions with the project team, the design team proposed a more radical version in which a set of objects formed a fluid handling system. A prototype was made, the scientist carried out some tests and they found that the system successfully met the design parameters. The scientists decided to take this idea forward, by applying for additional funding for the further development and production of 100 test devices.

Case 3 Multistable Project

Project Background

A scientist has patented a process for producing structures that can be configured into a variety of stable shapes without plastically deforming the material (e.g. a metal sheet that can be rolled into a tube). These structures are named multistable structures. The scientist has developed a number of samples and sketch models that have been used to show the potential of multistable materials to different potential industrial partners. In particular, he has built a sketch model of an accessory using bistable hinges (Bistable is a form of multistable material that changes from one shape to other as a consequence of a mechanical effort). However the size of the hinge seems too large and not easily adaptable to the accessory body. An accessories manufacturer has taken interest in this product and the scientist and the university technology transfer officer believe that manufacturing a more sophisticated and “designed” model of the accessory will help to cement the interest of the accessories manufacturer. They also believe that this material will allow the production of low cost accessories for people with limited purchasing power.

Scientists’ Requirements

The scientist was looking for the development of a bistable hinge of an appropriate size to be used in an accessory. He also wanted to build a new model of this accessory made out of metal with an integral bistable hinge, in order to use it as an example of the potential use of multistable technology in industry. Lastly they wanted to expand the range of possible applications for multistable structures.

The Design Team Approach

In the first meeting with the project team, the scientist explained the principles of the process that he developed to bring multistable properties to metallic sheets, and he showed some samples of multistable and bistable materials. He also brought the accessory's hinge sketch model. After this first meeting, there were discussions amongst the design team about the suitability of this case, since it seemed that the scientist's need (and the university technology transfer officers' needs) for design input, was more focussed on attracting commercial interest in his patented process than progressing his research activities. However, the designers thought that during the process of developing the hinge, questions would arise that may foster new thinking and encourage new directions in the scientific research. On this ground, the designers engaged in collaboration.

The Design Process

Soon after starting the development of some initial concepts the designers realised that it was necessary to have access to the multistable materials and to learn the multistable forming process in practice. For this reason, the scientist granted the designers access to the workshop in which the multistable samples had been made, so the designers could learn and practice the multistable forming process, and use multistable material for sketch modelling.

During this period of experimentation it became clear to the designers that although the nature of multistable materials was well understood by the scientist, the process of formation of multistable material was not standardized, and the tools used for it did not allow a precise control of the process. Furthermore, knowledge about the process of achieving multistability has been developed only for one type of material, and any idea that implied the use of a new material would first require the development of a new material-specific process. The project team met to discuss these issues. Through the discussion it became evident that any development of applications for the multistable process would need further development of its theoretical base, and would need the intervention of engineers with the expertise to perfect the process and make it more precise, and to develop more adequate tools for the experimental production of multistable material.

Regarding the development of the hinge, the designers also pointed out at that the rationale of using multistable material to produce accessories for people with limited purchase power may have not been appropriate. Producing accessories with multistable material would probably be more expensive than doing it with other competing materials, for example injected moulded plastic. Furthermore, developing accessories using bistable material would not necessarily be the right strategy to raise interest from the accessories manufacturer. A working model of a bistable hinge should be enough to show the potential of the process.

At the end of this meeting, the project team realized that on one hand it was too early for the type of collaboration that has been set up, and on the other hand, the planned project outputs were not adequate for its aims. At this point it was agreed that the collaboration should be postponed.

Initial Findings

The case studies have offered insight related to the questions into the initial research questions:

- Can designers meaningfully contribute to scientific research, and if so, what would be the nature of such contribution?
- What would be the main aspects that can act either as a barrier or as a facilitator for collaboration between designers and scientists, in the context of scientific research?

1. Design Contribution

Although the designers contributed to scientific research, the nature of this contribution was different in each of the studies.

Case 1: Mask Project

By developing the mask, the design team contributed to the scientist's research by delivering a suitable design proposal for experiments to be conducted. Also, the designers contributed to the scientist's understanding of the differences between developing a mask for experimentation and a mask for commercialisation. Additionally, the design input affected the scientist's understanding of his mask original idea and opened his mind to new possible solutions.

In addition the designers enhanced the commercial potential of the research, by providing a model that can help the scientist to attract partners or investors. In this way, the designers set the foundations for a viable product, potentially useful for other researchers, and for clinical applications.

Case 2: Immuno Project

By delivering a new system for Immuno Assay tests, the design team developed a tool that will potentially make the scientist's research procedures faster, safer and less expensive. If commercially exploited, these benefits can extend to other research and clinical laboratories around the world.

The designers also helped to bring the scientists' idea to a level of development advanced enough to make it easier to apply for a grant for funding further development. Finally, the designers' intervention brought the project closer towards commercialisation.

Case 3: Multistable Project

Even though the collaboration did not have any specific design output, the designers made a contribution to the scientist understanding of his own research. By specifying to the project team what was needed before designers could make a meaningful intervention in the project, the scientist was able to reassess his research priorities in regards to the development of the multistable production process. Thus, the designer's intervention triggered the project team's reassessment of their strategy towards the commercialisation of the multistable application in the accessories industry.

2. Barriers and Facilitators

Some common issues arose from the case studies that can be identified as barriers or facilitators for collaboration between designers and scientists in scientific research.

Communication

Some issues regarding communication acted as a barrier in the projects. For example, the designers' understanding of some important aspects and features of the projects was slowed down at the beginning by the scientists' use of specialised vocabulary and acronyms. However, this was quickly solved by the designers using different resources including direct questions to the scientists, internet searches, and elaboration of written summaries and graphic diagrams. An example of this was seen in the Immuno project, in which the designers created a diagram of the immuno assay process, associating scientific nomenclature, pictograms and text. The scientist also helped to overcome this problem by making an effort to filter out some technical expressions from their vocabulary while talking to the designers, but sometimes this resulted in key pieces of information being partly communicated. These omissions were later found to be critical to the design task. But on the whole, the combination of the efforts of designers and scientists allowed the creation of a basic vocabulary kit that permitted a fluent exchange of ideas.

Standard design communication tools such as drawings, sketches and models were useful to facilitate communication during the collaboration. Also, the design brief became instrumental in ensuring that all project stakeholders had a mutual understanding of the project main features and the nature of the collaboration. It helped to make explicit any misunderstanding that problems of communication may have produced.

Roles

Understanding of roles by all members of the project team became a fundamental aspect of collaboration between designers and scientists. Lack of clarity on the roles that scientist and designers play in regards to the design activity, can become a barrier for collaboration. In the Mask Project for example, the scientist independently made design changes to prototypes that compromised some of the basic principles of the designers' concept. Although well meant, these changes sometimes created tensions between the scientist and the designers. However, they proved to be useful in the long term, since a final solution was reached by combining both the designers' and the scientist's ideas.

The Immuno Project was different in this aspect. Even though the scientists had produced some design ideas before the beginning of the collaboration, they kept them aside during the project. Interestingly, during presentations and interim meetings while testing the prototypes produced by the designers, both designers and scientists agreed on design direction by consensus. This was a form of co-design with scientist and designers sharing the design role. However, it was the design team who pushed the ideas forward and when necessary, changed the project direction.

Another issue that can become a barrier in designers and scientists collaboration was the preconception that scientists had about a designer's abilities. At the beginning of the Mask Project for example, the scientist said that he was looking for design input since he did not "know anything about materials and (he was) not good with (his) hands". This view did not change: He stated at the end of it that the designers' main contribution to the project was related to the new materials they found and to their professional standard of prototype.

On the other hand, designers failing to be explicit about their role and capabilities can also become a barrier for collaboration. In the case of the Multistable project, the scientist expected that the designers would be able to do a job that should be actually done by a manufacturing engineer (develop multistable elements from new materials). An early conversation about the designers' capabilities and limitations would have been useful and would have saved time.

Preparedness and relevance

Another aspect that potentially can hinder collaboration between designers and scientist is the project's readiness for design intervention. Design development input can be limited if certain preconditions are not met. For example in the multistable project, the requirement of developing a new product (hinge for accessories) was not timely since the process to produce multistability was not fully developed and multistable materials were not standardised. On the other hand, the immediate need of that project was related to the further development of a production process, which made the product design input irrelevant at that stage. This highlights another aspect that can become a barrier for collaboration; there may be certain stages in projects for which Product/Industrial Design input is not relevant.

Conclusions

This paper has examined three case studies of collaboration between designers and scientist in the context of scientific research. It described their background, the scientists' design requirements and the design team approach. It also offered details about their design briefs and design processes.

This document has also summarised the initial findings of the research, specifying the design contribution to research in each of the projects, and the possible barriers and facilitators in collaborative effort between designers and scientists.

This work provides an initial step towards understanding the ways in which designers might contribute to scientific research and to its related activities. By developing this understanding further, it is expected that strategies that facilitate collaboration between product/industrial designers can be developed. In the long run this might also influence the way in which scientific research proposals and funding applications are made and the way in which scientific research teams are configured. Most importantly, the results may change scientist and designers' perception of each other, potentially fostering collaboration.

While this paper has attempted to outline aspects such as communication, roles, preparedness and relevance to highlight possible barriers and facilitators in collaborative work between designers and scientists, other equally important aspects such as personal characteristics and personal attitudes have been left aside. Questions like: How do personal characteristics such as age, interests, personal views or working habits affect the success of collaboration, or what is the importance of designers' and scientists' attitudes towards other disciplines and ways of working when they engage in collaborative endeavour.

Although this paper has provided some initial examples of the potential role of designers in supporting scientific research, they are based only in a type of collaboration in which designers engage with scientist in a form similar to that of the client and the design consultant. The nature of these case studies, in which the scientists identify a design issue and seek design professional intervention, implicitly excludes the designers from a direct intervention in the core of their research.

Future case studies may team up designers and scientists to meet the needs of a mutually agreed research project based on a scientific question, so that in this way, the role of designers may switch from that of a design provider to that of a researcher with a design background. In this manner, new and unexpected ways of design contribution to scientific research may be revealed.

Author Biography

Carlos Peralta

Carlos Peralta is a product designer currently reading for a PhD at Cambridge University, examining the ways in which designers and scientists interact and collaborate. He also teaches at Central Saint Martins College of Art and Design in London on the BA Product Design course and the MA Innovation Management course. Carlos was the head of the Product Design Department at the Glasgow School of Art between 2003 and 2007, and has worked in design education in Colombia, England, Singapore and Spain. His professional design experience includes work for industry, design consultancy and design entrepreneurship.

Alex Driver

Alex Driver is a Research Associate in the Design Management Group within the Institute for Manufacturing (IfM) at Cambridge University. Alex has a background in mechanical engineering and industrial design, and worked in industry for several years as an industrial designer for Atkins. He is currently researching the potential role of industrial design within scientific research.

Dr James Moultrie

James Moultrie is a Senior Lecturer in Design Management. His research interests seek to understand and improve the utilisation of design at project, firm and national levels. James is head of the Design Management Group within the Institute for Manufacturing (IfM) at Cambridge University. James is a Chartered Mechanical Engineer (IMechE) and has many years industrial experience as a project manager, senior engineer and marketing product manager. He has also been awarded a 'Scientific and Technical Academy Award' (Oscar) and an Emmy for previous work on a range of lenses for professional movie making.

Cognitive Biases and Design Research: Using insights from behavioral economics and cognitive psychology to re-evaluate design research methods

Nikki Pfarr, Institute of Design, Illinois Institute of Technology, nikki@id.iit.edu

Judith Gregory, Institute of Design, Illinois Institute of Technology, judithg@id.iit.edu

Abstract

In light of well-established principles in behavioral economics and cognitive psychology, we consider how minor variants in the structure, framing, and phrasing of several common design research activities may unintentionally elicit more biased participant responses than currently recognized. To begin investigating the relationship between minor modifications to design research activities and changes in participant responses, we propose designs for three experiments, and then explore their weaknesses and limitations through a short-term pilot study.

In our discussion, we suggest that a better understanding of cognitive biases may be used to produce more accurate and salient participant responses – either by minimizing or by explicitly eliciting activity- and context-induced biases as appropriate to the research at hand. Additionally, we propose that recognition of context-dependent preferences could lead to more holistic models of user behavior.

This early research is a work in progress. The principle aim of this paper is to provide a conceptual foundation for additional research into how participants' cognitive biases might influence the outcome of design research activities, and related implications for research activity design.

Keywords

Design methods; Cross, trans, inter, multi-disciplinarity; Cognition; Behavioral economics; Cognitive biases

Seemingly irrational behavior is pervasive in everyday decision making. People routinely make decisions that are not in their own best interests: they fail to participate in company-matching 401(k) programs despite being essentially offered free money; they smoke despite knowing the long-term risks of lung cancer; and they volunteer to work for free.

As design researchers, we strive to develop holistic models of human behavior within specific domains. Our models, and the methods by which we seek to discover, challenge, and extend them, will be most effective if they take into account both the conscious and unconscious 'irrational' behaviors people exhibit daily.

The field of behavioral economics, which draws upon both classic and contemporary cognitive psychology, offers substantial experimental data that help explain the ways in which irrational decision making is influenced by seemingly minor and irrelevant factors (see Rabin, 1998).

Literature review

Judgmental heuristics

Psychologists Tversky and Kahneman[1] (1974) proposed that irrational decision making can be partially understood in terms of judgemental heuristics and the cognitive biases to which they lead. *Judgmental heuristics* are the mental shortcuts that help our brains process information and quickly make decisions. Without these heuristics, we would be faced with the insurmountable task of evaluating every small piece of information we encounter every second of every day.

In particular, Tversky and Kahneman (1974) identified three heuristics commonly used to estimate probabilities and values: representativeness, availability, and adjustment and anchoring. *Representativeness* is defined as assessing the likelihood that a person or item belongs to a particular group based on how closely it aligns with one's existing understanding of that group; such assessment often involves drawing upon stereotypes. *Availability* is defined as estimating the frequency or probability of an event based on how easily examples of the event come to mind. Examples that are particularly visceral or salient are more likely to stand out, thus causing people to overestimate the frequency of their occurrence. *Adjustment and anchoring* is defined as estimating a probability or amount by starting from an initial reference point and then making adjustments in the direction that seems most appropriate.

Judgemental heuristics enable us to function efficiently in the face of large amounts of information and stimuli. However, reliance on these shortcuts can lead to systematic *cognitive biases*, i.e., tendencies to evaluate information, exhibit behaviors, and make decisions in consistently biased ways.

Cognitive biases and common behavioral tendencies

Substantial work in behavioral economics and cognitive psychology has been devoted to exploring, challenging, and uncovering the scope of cognitive biases, including those that stem from judgemental heuristics (see Rabin, 1998). Many of these findings suggest that what people think they like, need, and want – topics particularly relevant to design research – is often influenced by the way their options are framed.

Previous studies, such as those discussed below, have focused on the application of this knowledge to the domains of market research, consumer decision making, and product appraisal. However, we argue that there is greater relevance to the larger domain of design research: cognitive biases not only provide insight into participants' decision-making behavior, they can inform how we attempt to elicit and understand participants' preferences.

The following overview is organized around seven behavioral tendencies, selected because they have been widely circulated in behavioral economics discussions and because they are particularly relevant to design research. These tendencies are summarized in Table 1.

---

[1] Kahneman was awarded the 2002 Nobel Prize in Economics for his contributions to the field (Nobel Foundation).

Behavioral Tendency	Description	Sources
Loss Aversion	Tendency to avoid options that result in a loss relative to one's current reference point, and to perceive losses as more impactful than gains of equal value	Kahneman & Tversky (1979); Tversky & Kahneman (1991); McNeil, Pauker, Sox & Tversky (1982); Tversky & Kahneman (1986); Wertenbroch & Dhar (2000)
Endowment Effect	Tendency to attribute increased value to an owned item or entity	Thaler (1980); Kahneman, Knetsch & Thaler (1990);
Status Quo Bias	Tendency to select a default option when one is present	Samuelson & Zeckhauser (1988); Madrian & Shea (2001)
Affective Forecasting Error	Tendency to inaccurately predict future emotional states	Loewenstein & Schkade (1999); Simonson (1990); Gilbert et al. (1998); Loewenstein (1996)
Context-Dependent Preferences	Tendency to change one's preferences based on context, including how many options are being compared and the nature of their comparison (joint or separate)	Simonson & Tversky (1992); Tversky & Simonson (1993); Hsee & LeClerc (1998)
Affective-Cognitive Decision Making	Tendency to be more influenced by affective reactions than cognitive reactions when cognitive resources are limited	Shiv & Fedorikhin (1999)
Introspection and Consideration Override	Tendency to alter one's preferences when prompted to analyze them	Wilson & Schooler (1991); Amir & Ariely (2007)

Table 1 Summary of relevant behavioral tendencies

Loss Aversion: Is it a loss or a gain?

Kahneman and Tversky (1979) found that the framing of decisions, prospects, and possible outcomes influences the way people make decisions. People tend to evaluate options in terms of whether they result in a loss or a gain relative to a starting reference point. Losses are seen as being more impactful than gains of equal value, and as such people tend to avoid outcomes that involve loss. This behavioral tendency is known as *loss aversion* (Tversky & Kahneman, 1991).

Typically, people do not fully consider a given option in terms of both potential loss and potential gain; instead they generally accept the loss or gain frame in which the option is initially presented. Framing the same option in terms of a loss or a gain has been found to substantially change the perception of its desirability (McNeil, Pauker, Sox, & Tversky, 1982; Tversky & Kahneman, 1986). For example, McNeil et al. (1982) found that framing the same medical treatment option in terms of probability of living versus probability of dying substantially affected the perceived attractiveness of that option relative to other treatment options.

The hedonic versus utilitarian nature of an item can impact the degree of loss aversion. Wertenbroch and Dhar (2000) found that, when choosing to acquire either a hedonic item (like an apartment with a nice view) or a utilitarian item (like an apartment with a short commute to work), people usually choose to acquire the utilitarian item. But when choosing to give up a hedonic item or a utilitarian item, people usually choose to give up the utilitarian item.

The Endowment Effect: Is ownership involved?

Thaler (1980) identified the *endowment effect*, related to loss aversion, in which the sense of loss associated with giving up an item is greater than the sense of gain associated with receiving the same item; ownership increases the perception of value. Aligned with this concept, Kahneman, Knetsch and Thaler (1990) found that the seller of an item is more likely to ask for a price that is higher than a buyer would otherwise offer to pay.

The Status Quo Bias: Is there a default choice?

Samuelson and Zeckhauser (1988) identified the *status quo bias*, in which people overwhelmingly tend to select a default option when one is available. For example, Madrian and Shea (2001) found that 401(k) plan enrollment substantially increases when enrollment is the default option.

Affective Forecasting Error: Are participants attempting to predict their future emotions?

Numerous experiments have found that people's predictions of their future emotional states tend to be inaccurate, even in the short term (for an overview, see Loewenstein and Schkade, 1999). For example, Simonson (1990) found that when people make long-term decisions, they tend to favor more variety than they actually want when the future outcome occurs. Specifically, when people purchase several items in advance and consume them over time, they tend to seek more variety than when they purchase items with the intention of immediately consuming them. Gilbert et al. (1998) found that people tend to "overestimate the duration of their affective reactions to negative events" (p. 617) that might occur in the future, for example, a romantic breakup or the death of a child. Loewenstein (1996) found that, when in a "cold" state, people have difficulty predicting their feelings in a "hot" state (such as hunger or sexual arousal).

Context-Dependent Preferences: How many options are there?

Several experiments indicate that the number of options present in a decision-making scenario can influence preference. Simonson and Tversky (1992) found that intermediate options, in general, are most appealing; people tend to exhibit *extremeness aversion*. In another study, Tversky and Simonson (1993) found that, when selecting between two options, the introduction of a third option can greatly influence the way the original two options are perceived in comparison, and can even cause a reversal of preferences relative to the original two options. Additionally, Hsee and LeClerc (1998) found that comparing two attractive items in a joint evaluation decreases their overall attractiveness, whereas comparing two unattractive items in a joint evaluation increases their overall attractiveness.

Affective-Cognitive Decision Making: Are cognitive resources limited?

Shiv and Fedorikhin (1999) found that when cognitive resources are limited, people are more likely to be influenced by their affective rather than cognitive reactions when making a decision. Specifically, they conducted an experiment in which participants were told to memorize either a two-digit number (low cognitive load) or a seven-digit number (high cognitive load), and then walk to a different room and tell the number to another researcher. While walking to the other room and keeping the number in mind, participants were asked to select a snack, either fruit salad or chocolate cake, that they would receive for having participated in the study. Participants with the higher cognitive load were much more likely to select chocolate cake over fruit salad; they were more likely to be influenced by their affective reactions because their cognitive resources were limited.

Introspection and Consideration Override: Are participants being asked to analyze their preferences?

Numerous findings suggest that what people think they like, need, or want can change depending on whether or not they are instructed to analyze their preferences. In most cases this appears to result in more rational decision making, by overriding cognitive biases like loss aversion. For example, Amir and Ariely (2007) found that people tend to exhibit inconsistent preferences when primed to think about the pleasure (gain) associated with an option, versus the payment (loss) associated with an option – but when participants are asked to carefully consider their preferences, that inconsistency is reduced. This concept is referred to as *consideration override*.

But heightened rationality may not always result in optimal decision making. Wilson and Schooler (1991) found that asking people to analyze their preferences for strawberry jams caused “them to base their subsequent choices on [non-optimal] criteria” (p. 181), thus resulting in less optimal choices, compared to those of an expert. This suggests the possibility that people are not always aware of the motivations for their preferences, and that asking them to analyze those preferences may result in post-rationalization that causes the initial preferences to change.

Implications for design research

In light of these and similar findings, it is possible that minor variants in the structure, framing, and phrasing of design research activities may unintentionally elicit more biased participant responses than currently recognized. In particular, design research activities that require participants to make and analyze preference decisions should be thoughtfully examined with an eye toward the cognitive biases they might unintentionally induce.

In the next section, we evaluate three design research activities through the lens of behavioral economics and cognitive psychology. In the following section, we propose experiments to test the implications of our evaluations. Finally, we discuss insights into the challenges and limitations of the experiment design, which were identified during a short-term pilot study.

Evaluating three design research activities

We set out to evaluate the following design research activities through the lens of behavioral economics and cognitive psychology:

1. A product comparison task, in which participants indicate which product they prefer;
2. A feature selection task, in which participants construct a set of desirable product features from a provided list of possible features;
3. A storytelling task, in which participants tell stories about previous life experiences.

In this evaluation we identified three concepts from behavioral economics as particularly relevant: context-dependent preferences, loss aversion, and anchoring and availability (see Literature Review).

Evaluation of research activity 1: A product comparison task

Consider a design research activity related to product comparison in which participants face a set of items to compare and are asked to indicate their preference. Such a scenario may occur as part of a structured activity, for example during a lab-based prototype test, or more informally, for example during a shop-along in which participants decide which items to purchase.

Two behavioral tendencies discussed in the literature review are particularly relevant to such an activity: context-dependent preferences and extremeness aversion. Previous research related to these tendencies (Simonson & Tversky, 1992; Tversky & Simonson, 1993) leads us to believe that the number of items being compared in a product comparison task may substantially impact a participant's preferences. Specifically, we hypothesize that in a three-item product comparison, participants will be more likely to express a preference for the intermediate option than when that same option is included in a two-item comparison.

Evaluation of research activity 2: A feature selection task

Consider design research tasks in which participants are asked to indicate which features they like most from a provided set of features. The activity could easily be framed as a gain ("Which features would you keep?") or as a loss ("Which features would you get rid of?").

Loss aversion, a behavioral tendency discussed in the literature review, is particularly relevant to such an activity. Previous research on loss aversion (Kahneman & Tversky, 1979; Tversky & Kahneman, 1991) leads us to believe that framing a feature selection task as a loss may result in fewer items being selected for removal because participants attempt to avoid losses. Specifically, we hypothesize that framing a feature selection task as a loss will result in a larger set of desired features than when the task is framed as a gain.

Evaluation of research activity 3: A storytelling task

Consider design research scenarios in which participants are prompted to relate personal stories. This commonly occurs during contextual and ethnographic interviews.

Availability, a judgmental heuristic discussed in the literature review, is particularly relevant to storytelling activities. Previous research on availability (Tversky & Kahneman, 1974) leads us to believe that design research activities requiring a participant to tell a story could increase the participant's perception of the story's saliency, particularly if the story involves hedonic or visceral elements. Storytelling activities might increase the availability of the recounted and similar memories, thus affecting the participant's perception of the probability of similar events occurring. We hypothesize that storytelling could act as an inadvertent form of priming – that anecdotes brought up during storytelling have heightened saliency, and therefore may influence participant responses during subsequent research activities.

Experiment design

Following the evaluation of the three design research activities above, three experiments were developed as a first step in exploring how minor variations in framing, phrasing, and execution of these design research activities might lead to consistently biased results. All three experiments were designed to be part of a hypothetical design research study related to the iRobot Roomba, a robotic vacuum cleaner.

Design of experiment 1: Variations on a product comparison task

We hypothesized that in a three-item product comparison participants will be more likely to express a preference for the intermediate option than when that same option is included in a two-item comparison.

Thus, we propose an experiment in which half the participants engage in a two-item comparison (Group A), while the other half engages in a three-item comparison (Group B).

Participants in Group A will be presented with worksheets containing images and feature descriptions of two robotic vacuum cleaners (see Figure 1) – a low-feature, low-price product and a medium-feature, medium-price product – and asked to indicate their preference. Participants in Group B will be presented with worksheets containing image and feature descriptions of three robotic vacuum cleaners (see Figure 2) – the two options presented to Group A plus a high-feature, high-price product – and asked to indicate their preference.

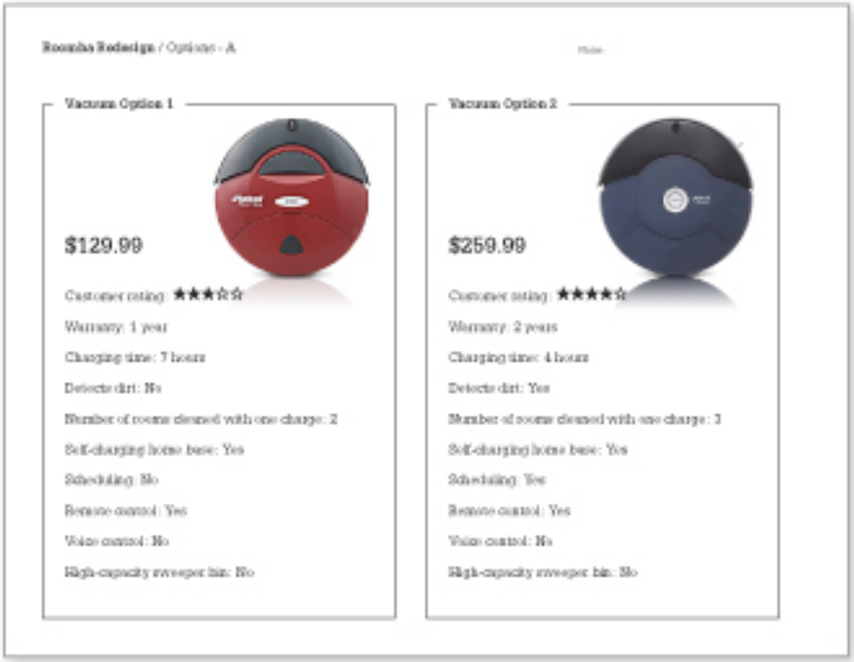

Figure 1 Product comparison worksheet for Group A

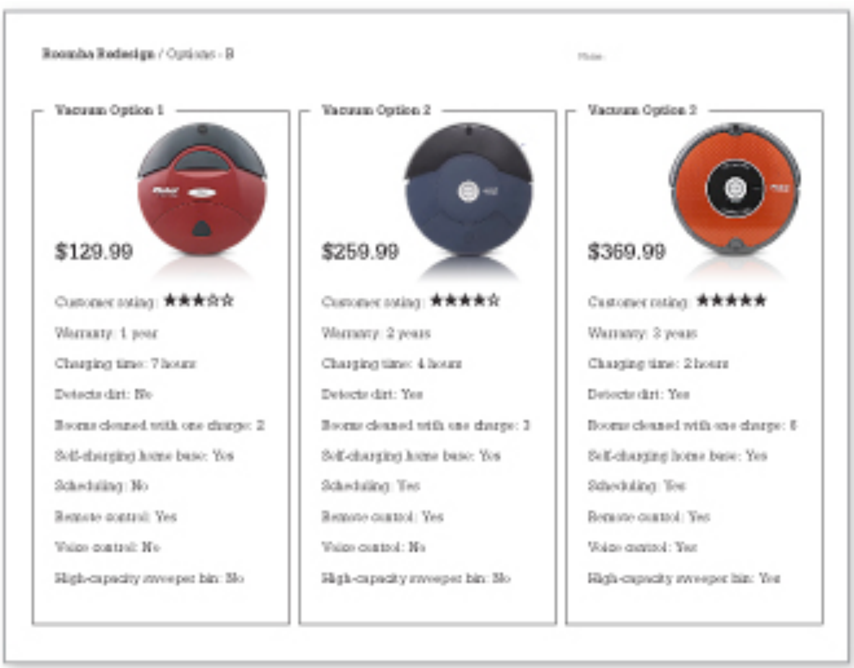

Figure 2 Product comparison worksheet for Group B

Design of experiment for activity 2: Variations on a feature selection task

We hypothesized that framing a feature selection task as a loss will result in a larger set of desired features than when the task is framed as a gain.

Thus, we propose an experiment in which half the participants engage in a feature selection task framed as a loss (Group A), while the other half engages in a feature selection task framed as a gain (Group B).

Participants in Group A will be presented with a set of 18 possible features for a robotic vacuum cleaner and asked to remove the features they would not include in the final design (the loss frame). Participants in Group B will be presented with the same 18 possible features and asked to select the features they would include in the final design (the gain frame). Each participant will receive 18 strips of paper naming the features along with a worksheet upon which to arrange them (see Figures 3, 4).

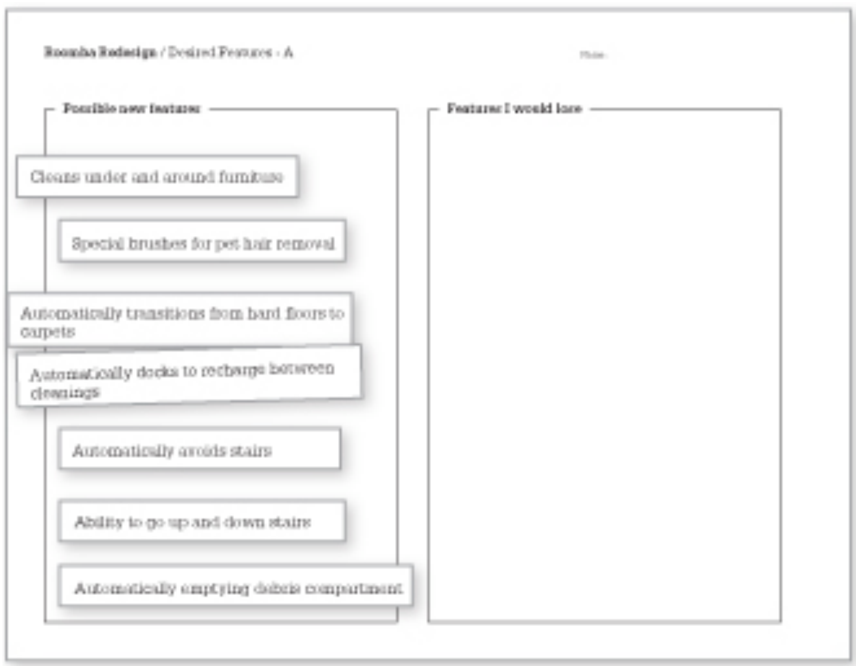

Figure 3 Feature selection worksheet for Group A (loss frame), showing a subset of features

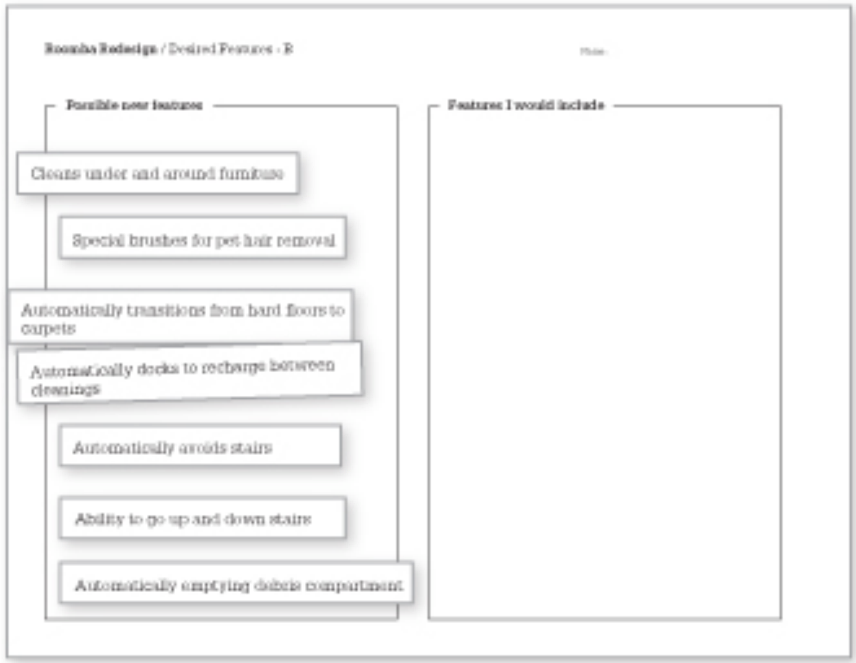

Figure 4 Feature selection worksheet for Group B (gain frame), showing a subset of features

Design of experiment for activity 3: Variations on a storytelling task

We hypothesized that storytelling could act as an inadvertent form of priming – that anecdotes brought up during storytelling have heightened saliency, and therefore may influence participant responses during subsequent research activities.

Thus, we propose an experiment in which half the participants describe positive memories indirectly related to a product (Group A), and the other half describe negative memories indirectly related to the same product (Group B). All participants are then asked to evaluate their interest in purchasing that product now or in the future.

Participants in Group A will be asked to recall and describe a time when their home was clean and it made them happy (see Figure 7). Participants in Group B will be asked to recall and describe a time when they had a frustrating experience with technology (see Figure 8). All participants will then be asked to rate their interest in purchasing a robotic vacuum cleaner now or in the future, on a scale of 1-5 (5 being most interested).

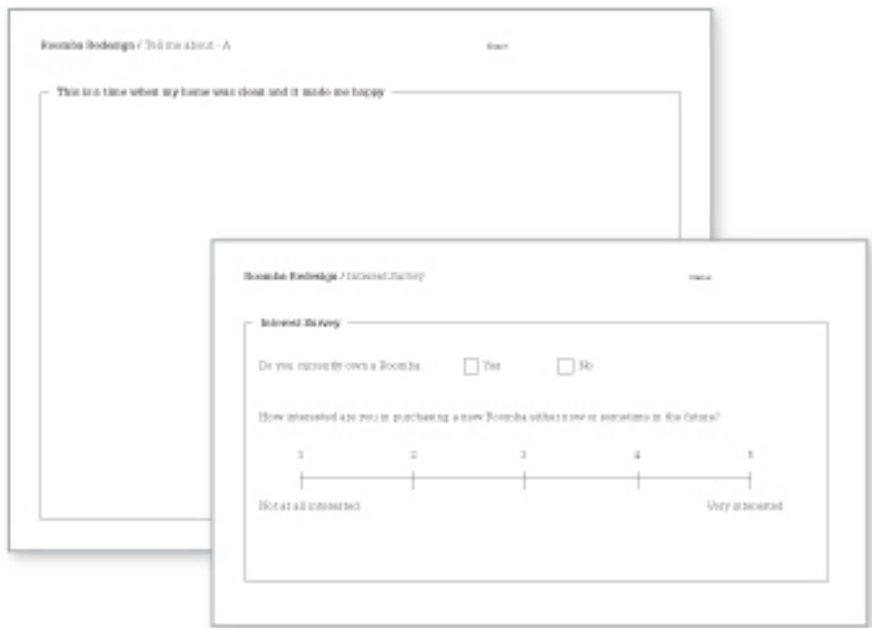

Figure 7 Storytelling and interest rating worksheets for Group A (positive story)

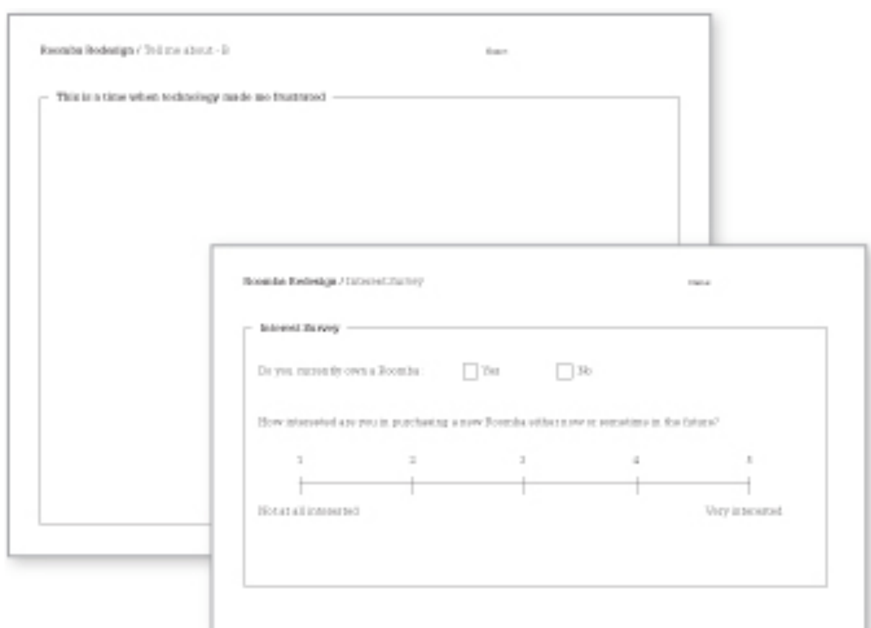

Figure 8 Storytelling and interest rating worksheet for Group B (negative story)

Note that in real one-on-one design research interviews, the storytelling prompts would likely be less leading. For the purposes of this experiment, we specifically wanted to compare the effect of a participant recalling and sharing a positive story versus a negative story on his or her subsequent behavior and decisions.

Challenges and limitations identified during a pilot study

After designing the three experiments described above, the first author executed an exploratory pilot study in November and December 2009. The primary aim of the pilot study was to identify challenges and limitations related to the design and conduct of the experiments, which could inform future work.

For the pilot study, ten Master's of Design student participants (three males, seven females) were recruited from the IIT Institute of Design. They were invited to participate in a study about Roomba vacuum cleaners and were not aware that the study was actually concerned with the evaluation of design research activities informed by behavioral economics and cognitive psychology. Of the ten participants, three were Roomba owners.

Pilot study sessions were conducted one-on-one (one participant with the first author as facilitator). In each session, participants completed the three design experiments described above[2]. The order of the activities remained consistent across all sessions. While it may have been desirable to randomize the order in theory, the placement of the storytelling activity could affect the outcome of the other activities in a session. The A/B variation within each design research activity was randomly determined for an equal distribution of the variations across participants.

Reporting on the pilot study is intended only as an exploratory foundation for additional research in this area; given the small number of participants, the pilot study was not intended to provide conclusive, robust or statistically significant results. Future studies should be planned that feature revised and more extensive experiments, utilize a much larger and more diverse sample, and are potentially double blind to prevent facilitator behavior or knowledge of the experiment from influencing participant behavior.

While they are neither conclusive nor statistically significant, findings from pilot study experiments are aligned with the initial hypotheses.

Reflecting on experiment 1: Variations on a product comparison task

In the pilot study, Group A (n=6) was presented with the two-product comparison, and Group B (n=4)[3] was presented with the three-product comparison. In Group A, two participants selected the low-feature option, and four participants selected the medium-feature option. In Group B, however, all four participants selected the medium-feature option.

We recognize that special care needs to be taken when selecting the products and features to be included in the product comparisons. For example, if one product appears more utilitarian or hedonic than the others, or if one product evokes a sense of ownership, preferences may be additionally impacted by loss aversion and the endowment effect, respectively. While these would be interesting effects to consider in the context of a product comparison activity, their presence in this particular experiment

---

[2] In between the second and third experiments described above, pilot study participants also completed a point distribution activity, which we do not discuss here due to space limitations.

[3] The 6-4 breakdown of participants, as opposed to a desired 5-5 breakdown, was the result of human error during the random group assignment.

may make it difficult to evaluate the impact of changes to the number of products being compared on participant preferences.

Additionally, during the pilot study participants referred to their current vacuum cleaners and their budgetary constraints in relation to their preferences; these variables should be controlled for in future studies.

Reflecting on experiment 2: Variations on a feature selection task

In the pilot study, Group A (n=5) was presented with the loss frame and Group B (n=5) was presented with the gain frame. Out of 18 possible features, Group A produced a feature inclusion set of average size 11.2, whereas Group B produced a feature inclusion set of average size 8.8.

We recognize that participants' starting reference points may be influenced by their current vacuum cleaner in addition to the 18 product features presented. Removing a feature may not only represent a loss relative to the starting set of 18 features, but a loss relative to the features on their current vacuum cleaners, amplifying the overall sense of loss. To better understand results from this experiment, information about participants' current vacuum cleaners should be collected.

We also note that the type of features presented may affect participant preferences. According to Wertenbroch and Dhar (2000), when people are faced with acquiring either a utilitarian or hedonic item, they tend to select the utilitarian item. But when people are faced with forfeiting either a utilitarian or hedonic item, they tend to keep the hedonic item. As such, the hedonic/utilitarian nature of the features may impact preferences, particularly as they relate to participants' current vacuum cleaners.

Reflecting on experiment 3: Variations on a storytelling task

In the pilot study, each participant in Group A (n=5) was asked to recall a positive memory whereas those in Group B (n=5) were asked to recall a negative memory. Group A indicated an average interest rating of 4.3, whereas Group B indicated an average interest rating of 3.1.

Moreover, non-owners' interest ratings seemed to be more affected by the impact of telling a negative story than those of Roomba owners. Of the non-owners, those who told the positive story (n=4) indicated an average interest rating of 4.125, whereas those who told the negative story (n=3) indicated an average interest rating of 2.5.

This may suggest that when an existing reference point is lacking, storytelling may have greater influence on a participant's behavior during subsequent research activities. This may also be indicative of owners post-rationalizing their purchases, or attributing increased value to the Roombas they already own (viz. the endowment effect). Current Roomba ownership, then, would be an important factor to control for in future studies.

We also note that, while the storytelling worksheet for both groups in this experiment provided a space for sketching a picture to go along with the story being told, only a few participants made sketches. It's possible that the act of sketching increases the saliency of a story – and as such all participants in future experiments should be instructed either to sketch or not to sketch along with their stories.

Discussion

As design researchers, we attempt to plan and conduct user research activities that help us uncover participants' underlying desires and latent needs. Given the prevalence of cognitive biases, we need to carefully plan the tasks and contexts involved in design research to understand how the structure and conduct of design research activities may influence the ways participants perceive information, assess options, and ultimately make decisions. We argue that small changes in design research activities may lead to predictably biased participant responses, aligned with findings from behavioral economics and cognitive psychology.

Failing to understand cognitive biases in the context of design research could lead to: (1) inaccurate research findings because participants are being unintentionally and unknowingly influenced into producing biased responses; (2) inappropriate interpretations of research findings that fail to account for cognitive biases that may be induced by the task or context at hand; or (3) inappropriate extrapolation of research findings to other contexts without an understanding of how cognitive biases may change across contexts.

An awareness and understanding of cognitive biases will allow design researchers to better avoid unknowingly influencing participants in subtle and non-obvious ways via activity- and context-induced biases. Changes in research techniques and activity design may be necessary to produce more accurate participant responses. However, it is natural to ask: is it possible, or even desirable, for design research activities to be truly neutral? Is it possible for our research to avoid inducing any and all cognitive biases, in favor of strictly rational decision making?

Given the directionality and intention of design projects, there likely does not exist a design research activity that exerts no influence on participants, nor one that reveals direct insight into a participant's true preferences. But this should not discourage us. Based on research from behavioral economics and cognitive psychology, it seems that user preferences are not stable but rather that preferences change based on context, framing, and the set of options being considered at a given time. Amir and Levav (2008) propose that, rather than ever really deliberately constructing preferences, people often "learn context-specific choice strategies without ever really engaging in difficult subjective value assessment… they simply learn to repeatedly use contextual cues" (pp. 155-156).

Assuming that participant preferences are dynamic in nature, and both affect- and context-sensitive, design research has an opportunity to explore the nuances of how a preference changes across contexts. This might suggest a shift in the way we model users' preferences: rather than assuming that users have inherent preferences, we should recognize and take advantage of the fact that users have dynamic and context-sensitive preferences.

Finally, a deeper understanding of cognitive biases could allow design researchers to explicitly design research activities that induce certain biases, in order to mimic biases present in other real-world scenarios or contexts. For example, when attempting to understand preferences as they exist in the current marketplace, design research activities should attempt to evoke the conditions of the marketplace. Given that consumers' choices are affected by cognitive biases that may result in seemingly 'irrational' decisions, it would not be beneficial to artificially de-bias users during a design research activity and then take those results as representative of real-world behavior.

Findings from behavioral economics may offer new insights into how to better replicate and model participant decision making in real-world scenarios.

Conclusion

In this paper, we evaluated three common design research activities in light of experimentally documented cognitive biases and judgemental heuristics. Whether or not existing design research protocols could be improved given this knowledge, it will benefit design researchers and designers to be informed about – and possibly participate in – ongoing research in the realm of behavioral economics and decision making. Hopefully this paper will spark additional discussion and research in this space.

Designing for the periphery of our attention: a study on Ambient Information Systems

Mauro Pinheiro, Universidade Federal do Espírito Santo (UFES), Brazil

Abstract

This article discusses a specific category of information systems known as Ambient Information Systems. These systems present information in a non-intrusive manner, acting mostly on the periphery of our attention, following Mark Weiser's concept of *calm technology*.

The major concern that drives the development of these systems can be summarized in two aspects: first, as pervasive computing increases, ordinary objects are becoming capable of processing and displaying data, thus the consumption of information will occur in many different contexts, which may contribute to an information overload, generating stress. The second aspect is that Design plays a major role in developing better ways to deal with this information overload. For a long time designers have been studying how to design communication systems that drive our attention, but little research has been done in exploring how to design communication systems that act upon the periphery of our attention.

In this article four Ambient Information Systems are discussed, highlighting their characteristics and limitations. As a conclusion, the author proposes an agenda of topics that should be tackled to advance future research on this subject.

Keywords

Pervasive computing; interaction design; information design; preattentive processing

Amid the rush and bustle of urban centers, we are exposed to many different information systems[1]. Although the presence of such systems can be easily perceived, it is possible to go by without noticing them, usually because we don't feel the need to consult the data they present, or because we have our attention focused on other tasks. Public clocks, traffic status displays, are some of the most obvious examples of these systems. Advertising posters and outdoors that populate our urban landscape are also information systems with which we deal every day and often go unnoticed. Their presence does not require our immediate attention, staying mostly on the periphery of our perception. When these information systems are augmented with computer technology, they are also called peripheral displays (Mankoff & Dey, 2003).

Much has been said about the overwhelming amount of information to which we have been exposed lately. This is partially due to the increasing use of computers in the beginning of this century, which not only has made it easier to produce and distribute data, but also has increased the connectivity between different systems, cultures and people all over the world. The changes we experience are so intense that it is common to use terms like "digital revolution", "information technology revolution", "information revolution" to describe them. The word "revolution", common

[1] **Information systems** refers to all the persons, procedures and equipment designed, built, operated and maintained in order to collect, record, process, store, retrieve and display information, using different technologies (Houaiss & Villar, 2001). In this article we are especially interested in (but not limited to) systems that use computer technology to collect, record, process and display information.

to these definitions, implies that radical changes are underway, in the sense that there is a rupture, which extends from the global economy to the private activities of an individual.

As a side effect of this digital revolution, information now comes from many sources and in different formats, such as text messages and Twitter tweets in our mobile phones, RSS Feeds, Facebook friend's updates, instant messages on our desktop computers, e-mail, and so on. Although it seems to be almost impossible to keep track of this amount of data on daily basis, as Hemp (2009) points out, we're still compelled to do so, even if it make us feel uncomfortable:

> The flood of information that swamps me daily seems to produce more pain than gain. And it's not just the incoming tidal wave of e-mail messages and RSS feeds that causes me grief. It's also the vast ocean of information I feel compelled to go out and explore in order to keep up in my job (Hemp, 2009, p.2).

As ubiquitous and pervasive computing increases, ordinary objects are becoming capable of processing and displaying information. Therefore, the consumption of information will occur in many different contexts and situations, which may contribute even more to this information overload, generating stress in a higher level.

Design plays a major role in developing better ways to deal with this information overload. Although designers have been studying how to design communication systems that drive our attention for a long time, little research has been done in exploring how to design communication systems that act upon the periphery of our perception. Considering that not all information needs to be in the center of our attention all the time, we should investigate innovative ways to present information into the periphery, taking advantage of our preattentive processing. As Weiser and Brown described, "By placing things in the periphery, we are able to attune to many more things than we could if everything had to be at the center. Things in the periphery are attuned to by the large portion of our brains devoted to peripheral (sensory) processing. Thus, the periphery is informing without overburdening" (Weiser & Brown, 1996, p.9).

Ambient Information Systems describe a set of applications that publish information in a non-intrusive manner, mostly acting on the periphery of our attention. The community of Human-Computer Interaction professionals has been exploring this subject for a while, but with little participation of the Design community. Although there are already interesting results on ambient information systems, I believe that Design has much to contribute to advance the research in this area. In this article, some ambient information systems are discussed, highlighting their characteristics and limitations. As a conclusion, I propose an agenda of topics that should be tackled to advance future research on this subject.. In order to be able to deal with this increasing information overload, we should have a better understanding of what it means to design for the periphery of our attention.

Ambient information systems

Ambient Information Systems are information systems that continuously present information that can be monitored by people without requiring the focus of their attention. In these systems data is presented mostly to the periphery of human attention. Presenting outside the main focus requires less cognitive effort for its consumption. This form of information delivery has manifested in several different implementations, but the overall theme revolves around how best to embed information into our surroundings (Hazlewood et al, 2008).

In these systems the major concern is how to present information in a discreet way, without being necessary to stop any activity to perceive them. In a world with an increasing number of information sources, which can be accessed from many devices and in different contexts, Ambient Information Systems represent an attempt to minimize the effort required to keep up with so much data. This concern is intensified with the rise of pervasive computing, as the most common objects may become information systems. It is necessary to find alternatives to prioritize the sources of sensory stimuli around us. An interesting strategy is to relegate to the background of our attention the information that is not essential, but which we can access at any time.

One of the earliest known examples of this type of information system is the Dangling String (also known as Live Wire), a project developed by artist Natalie Jeremijenko at Xerox Palo Alto Research Center (Xerox PARC). This system was in fact an installation in which a plastic wire was connected to an electric motor installed in the ceiling of a room. The engine was connected to the network of the institution by an Ethernet cable, so that the flow of network data directly interfered in its motion: when there was a heavy data flow, the engine turned faster, while a reduced flow caused the motor to turn slowly. The plastic wire followed the movement of the engine, producing a noise when moving fast. The combination of movement and noise was easily perceived from a distance, without interfering in any action that was occurring. The idea of the installation was not to accurately report the amount of data traveling through the institution network, but to give a sense of its flow and enable people to have a visual cue that could be associated with data traffic.

Figure 1: Dangling String (http://nano.xerox.com/weiser/calmtech/calmtech.htm)

The Dangling String is a typical example of an ambient information system. These systems usually present information in a discreet way, without drawing too much attention to itself, giving constant support to the monitoring of non-critical information.

This concern with discretion and with a non-intrusive information presentation has its roots in the work of Mark Weiser, precursor of research in ubiquitous computing. Unlike much research on computers occurring at that time, when he started the program on ubiquitous computing in the late 80's, Weiser was less interested in technical issues and more in the context of use or the impact that the increasing presence of computer technology would have on our lives:

> The program was at first envisioned only as a radical answer to what was wrong with the personal computer: too complex and hard to use; too demanding of attention; too isolating from other people and activities; and too dominating as it colonized our desktops and our lives. We wanted to put computing back in its place, to reposition it into the environmental background, to concentrate on *human-to-human* interfaces and less on *human-to-computer* ones (Weiser, Brown & Gold, 1999, p.693).

In anticipation to the proliferation of information sources competing for our attention due to the integration of computing devices to everyday objects, Weiser showed special interest in making the use of these systems simple. The goal then was to make the computers "disappear" into a given task and become as a simple tool that could be used without demanding our attention:

> In the last several years a few of us at PARC have begun to speak of *calm computing* as the goal, describing the desired state of mind of the user, as opposed to the hardware configuration of the computer. Just as a good, well-balanced hammer “disappears” in the hands of a carpenter and allows him or her to concentrate on the big picture, we hope that computers can participate in a similar magic disappearing act (Weiser, Brown & Gold, 1999, p.695).

Weiser, Brown and Gold believed that the most profound technologies are those that "disappear" by being so embedded in our lives. As stated by the authors, the idea of calm technology indicates a stage of computing evolution in which we use this technology without realizing it. It is precisely the idea of calm technology that underpins many of the ambient information systems. The information almost "disappears", being presented in a discreet manner, but can be easily brought to the center of our attention and used whenever necessary. This displacement between periphery and center of our attention is one of the main features of calm technology.

It's important to notice that in what regards Ambient Information Systems, information is meant to be perceived, which implies a specific type of communication. Ambient Information Systems are not suitable for complex data, which require detailed analysis. Rather, the intention is to present data in a subtle way, so that the information is perceived without effort and causes no disturbance. Normally, the Ambient Information Systems are used in situations that are not task oriented, that do not require immediate action in response to the information displayed. This type of interface does not apply, for example, to an air traffic control terminal, where operation requires a high level of attention from its operator. As highlighted by Weiser and Brown (1996), not every situation is suitable for a calm technology approach. Designing systems that act on the periphery of our attention requires special care:

> Not all technology need be calm. A calm videogame would get little use; the point is to be excited. But too much design focuses on the object itself and its surface features without regard for context. We must learn to design for the periphery so that we can most fully command technology without being dominated by it (Weiser & Brown, 1996).

As previously noted, the ability to move information between the center and periphery of our perception is a central issue for the calm technology concept, one that still guides the research on ubiquitous computing. Much research in this field seeks to develop "intelligent" products and systems which can operate independently, without our assistance. In theory, while at the same time the advances in technology allows the creation of objects with computational and informational resources, capable of communicating with each other constantly, this interconnected environment would not be a burden to us precisely because it would be possible to move the information provided by these systems to the background, without requiring our direct attention.

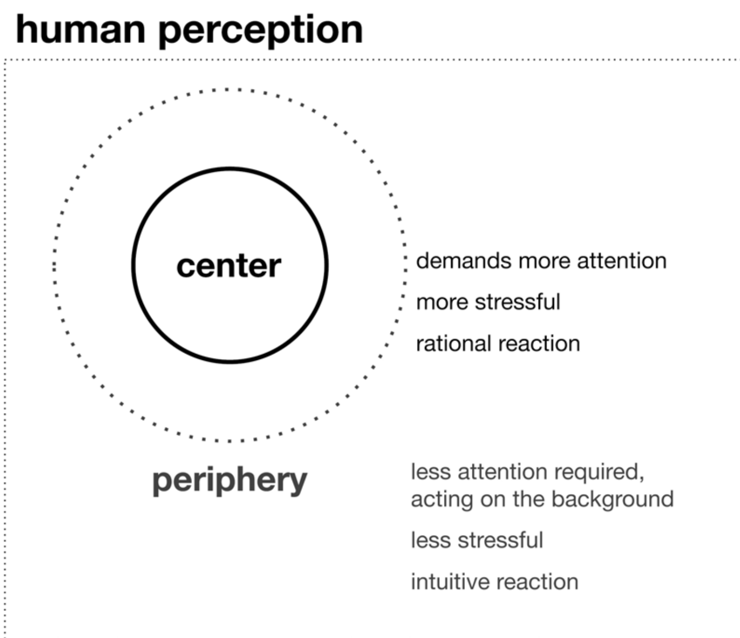

Figure 2: the center and periphery of human perception

From a more modest scope, yet aligned with the idea of reducing the cognitive effort required for information consumption, the Ambient Information Systems are an application of the calm technology concept, without requiring complex contextual data analysis or advanced artificial intelligence systems. Many projects on this field are based on the enrichment of our peripheral attention, presenting information in such a way that it can be perceived without demanding effort, assisting in the intuitive understanding of a more complex situation. This approach is also based in our preattentive processing (Healey, 2007; Healey et al, 1996), which is normally associated with visual perception, but may also occur through the stimulation of other senses (Lima, 2005).

Consider the communicative act itself, occurring through different media, as an example of this enrichment of our peripheral attention. In a telephone conversation, part of the understanding of what is said occurs by the way we talk. That is a level of information that goes beyond the "text" that is enunciated. Subtle variations in the intonation of the speech can bring more information, underlying what is said. In a similar way, in a videoconference, the image of the speakers provides more information that acts upon the periphery of our attention. By viewing the subjects and their behavior, we can have a better understanding of the discourse, even though we're not focusing our attention to this subtle information. In e-mail communication, which relies solely on the written word, disagreements often occur due to the reduced peripheral information that could help in understanding the message, demanding greater attention to the writing of the text, what probably wouldn't be required in a face-to-face conversation. Voice inflections, body movements and facial expressions are peripheral information that help us to communicate without requiring greater cognitive effort, as they are perceived intuitively.

To better understand how we can apply these principles to the design of Ambient Information Systems, four projects are described bellow, which in different ways deal with non-intrusive presentation of data. The limitations of these projects will be highlighted and possible improvements discussed.

Ambient Umbrella

The goal of this product is to solve a trivial problem: decide whether or not to take an umbrella when leaving home. Normally, a person would try to get informed about the weather conditions of the day to decide that. This could be done by reading the weather forecast in the newspaper, or accessing a website that provides the weather forecast, or watching the weather channel on the TV. In addition, of course, one could look through the window to see if there are any signs of rain.

In any of the options described above on how to get informed about the weather conditions, some steps would be necessary before taking a final decision on whether or not to take the umbrella. If a person does not have the signature of a daily newspaper, would have to go out and try to buy one. Another alternative is to consult the Weather Channel on TV. In the absence of a television channel with the weather forecast, and without a newspaper at home, one would have only left the option to look out the window and make a guess, or use the computer to seek the information on a website which presents the forecast for the day. This operation in turn requires more time and energy: it would be necessary to turn on the computer to access a particular site, request the information, interpret the information received, and only then would one be able to know what would be the chances of raining on that day. A series of steps to get some basic information, which would take time, require cognitive effort and certainly a good dose of patience.

The Ambient Umbrella addresses this issue in a relatively simple way. The umbrella actually "tells" you if it will rain. If the weather forecast for the day is rain or snow, the umbrella illuminates its handle. The concept is similar to the Weather Rooster (see Figure 3), which changed its color according to the humidity in the environment, indicating the possibility of rain.

Figure 3: The weather rooster (galinho meteorológico) is an interesting Brazilian predecessor of the Ambient Umbrella, without needing any computing device. The rooster is coated with layers of cobalt chloride, a chemical with the property of

changing its color depending on the humidity of the air. The blue color indicates low humidity, while the shades of pink indicate an environment with higher humidity in the air. Obviously the accuracy of this system is limited, since the humidity of an environment is not related only to the weather conditions, hence the cobalt chloride could be affected by other factors than climatic conditions. (Personal archive)

While the weather rooster has a relatively simple operation, its modern equivalent is based on a more complex system. The Ambient Umbrella receives weather forecast from a specialized website through radio waves. Depending on the forecast, the handle lights up indicating rain, drizzle, snow, and thunderstorms. From the user's standpoint, it is an umbrella, which simply lights its handle when it will rain. The idea is really that the technology involved in the process should not be perceived.

Figure 4: The Ambient Umbrella lights its handle when there is chance of rain, thunderstorms or snow. The system is connected to a weather service. (http://www.ambientdevices.com)

The information here is presented in a discreet, non-intrusive way, without disrupting any activity that occurs simultaneously in the environment. Whenever one needs to decide if taking the umbrella would be necessary, a quick look at the handle already gives the answer in a prompt, accurate and intuitive way, without requiring any effort. That's an exemplary application of the calm technology and pervasive computing principles, using computational resources to turn an ordinary object into an information system that requires little attention to be used.

The Good Night Lamp

This project seeks to communicate the act of coming home to loved ones, making use of an object as simple as a lamp. When one gets home and turns on the lamp, a signal is sent to other similar devices remotely connected to the emitter, and the light of these receptors is simultaneously lit. This way one can tell when he/she is "connected". The remote lamps, with their lights on, show that one person turned on his/her lamp, which by convention indicates their presence at home.

Figure 5: The Good Night Lamp: each lamp has a corresponding lamp in a different scale, which are connected remotely. When lighting the lamp, its correspondents will also have the light turned on, indicating that the person is at home.
(http://www.goodnightlamp.com)

The designer Alexandra Deschamps-Sonsino, who created the lamp, believes that the way people live in society is changing; we now have a constant need of being accessible. In fact, in recent years it's noticeable the growing popularity of social network sites like Facebook, Orkut, Twitter and instant messengers such as MSN Messenger, Skype, from which it's possible to keep in touch with our friends, even those that we don't see very often. Using these services it is possible to monitor the daily routine of our friends, expressed through their posts, their comments, photographs and other personal information made public online. Similarly, the increased use of mobile phones has generated a sense that we are always accessible, traceable, linked to these devices in such a way that they have been called "digital leashes" (Weerakkody, 2008). This type of behavior reinforces what Deschamps-Sonsino calls a feeling of being always on, sometimes off. The designer believes that in the future "we will learn to share parts of our lives with our families, friends and lovers in more subtle ways with the help of an ever sensitive, invisible and intelligent technology". (Deschamps-Sonsino, 2008)

Here we see the application of a principle present in many instant messengers, in which the interfaces usually present a list of the user's acquaintances, named "contact list". Each person in the contact list has his/her status indicated by an icon. If a person is online, with the program running, but is busy on other tasks, he/she can change his/her status so that the program will display an icon indicating that the person is busy. Similarly, there are visual conventions for different states of the users (online, invisible, busy, available, away, etc.).

The appropriation of this principle, used in instant messengers, to visually indicate the status of a person in the system (in the case of Good Night Lamp, the light turned on indicating the presence, the light turned off indicating that the person is absent) applied to an object as ordinary as a lamp is an example of an ambient information system. An information system integrated to the environment, with the amount of data reduced to a minimum so that the communication does not interfere with other tasks, staying on the periphery of our attention. The instant messengers, so far, are computer programs that run mostly in "conventional" computers and imply particular contexts of use, which in no way resemble the calm technology approach. The Good Night Lamp becomes part of the house, working without interfering with the actions of its residents, and conveys the sense of presence and proximity with people far away. Although in the current proposal only two binary situations are represented (on/off or present/absent), it could be possible to create other states, using variations in brightness, glowing effects, so that each light situation would indicate a different state of the user (present but busy, for example).

Thirsty Light

This project aims to help on the maintenance of houseplants by constantly monitoring the plant's soil to check its moisture, and warning when it is necessary to water the plants. The apparatus consists basically of a rod with a bulb containing a LED alert at one end and a humidity sensor at the other end. The operation is relatively simple: bury the pod with the sensor in a potted plant and it will measure the soil's moisture. When the moisture reaches a certain level, considered low for the maintenance of the plant, the light at the opposite end of the probe starts blinking. The lower the humidity of the soil, the faster the LED flashes, indicating the urgency of watering the plant. The whole system is based on technology called Drypoint, consisting of the humidity sensor and the digital circuit contained in the upper bulb, which receives and interprets the information sent by the sensor, and makes the LED flashes according to parameters received. The sensor works with 5 different levels of moisture, allowing it to be adapted to specific plant's needs.

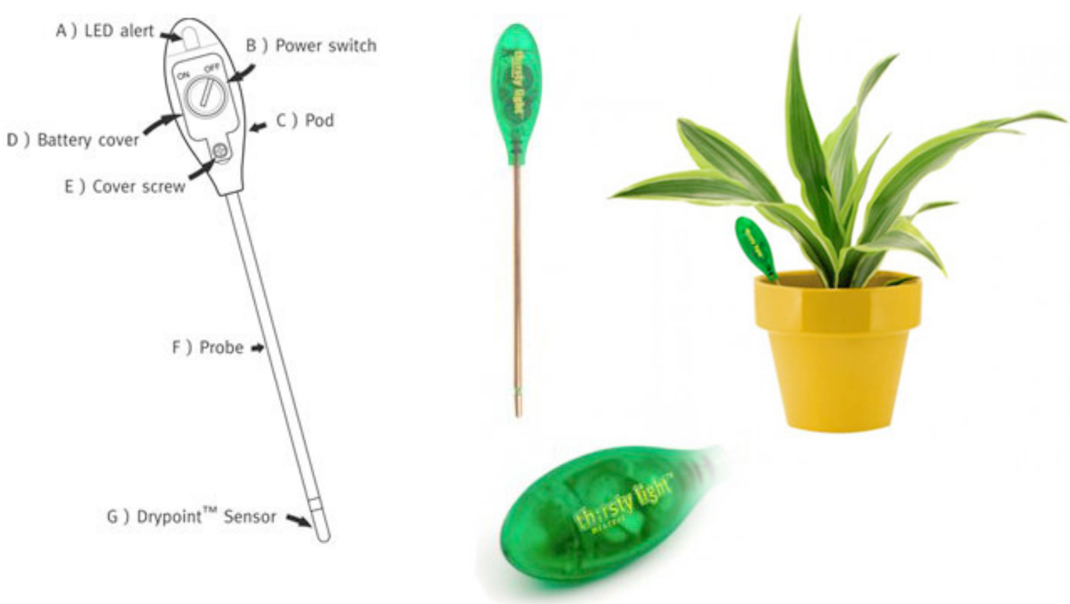

Figure 6: Thirsty Light, appliance designed to monitor the moisture of the soil and alert you when the plants need to be watered. (http://www.thirstylight.com)

Although the system is relatively simple, it is still necessary that the person pay attention to the plant's characteristics and specific needs. While some species prefer more moisture, others survive better with less water. On the product's website there is a disclaimer, advising the user to pay attention to the behavior of the plants in order to set the device properly, according to the characteristics of each species. If a plant absorbs moisture faster than others, the rod should be positioned with the sensor closer to the surface, a region that tends to dry faster.

As we can see, even though the Thirsty Light can assist in the maintenance of home plants, it is still necessary to have some knowledge about each plant's needs, at least on the early stage when it is necessary to perform a "fine tuning" on each probe, by placing the sensor on a position that best responds to each plant. But once these initial adjustments are made, the behavior of the system is quite non-intrusive, blending into the surroundings while at the same time constantly monitoring the condition of the plant's soil, and thus, acting as an ambient information system. It gathers data and presents it to its user without disturbance.

Ladybag

Developed by students of the School of Interactive Arts and Technology at Simon Fraser University, Canada, this project is about an ordinary object, a woman’s handbag. Using electronic components, the proposal is to make a bag as a mirror of its user's emotions. In this case the bag is classified as an Affective Communication System (ACS). In addition, the bag is able to identify the presence or absence of the most important items normally found in a woman’s handbag, according to its creators: keys, wallet and cell phone[2]. In this case, the bag acts as an Effective Organizing System (EOS).

To act as an Affective Communication System, the bag has to be pressed on specific points, where pressure sensors are located. Once pressed, the sensors trigger the bag's LED screen, on the outer surface of the bag, displaying an icon corresponding to a different emotional state. For each sensor there is a set of emotional states, which vary according to the applied pressure. The user must memorize the location of each sensor, and the corresponding emotional states, so she can express herself correctly through the Ladybag.

[2] Curiously, the three items selected as essential items to be tracked by the Ladybag system, were also identified as the most frequent items to be found in the bags of people from different cultures around the world, according to the research conducted by Chipchase et al (2005). The date of the creation of the Ladybag project is prior to this research, discarding the possibility that the authors of the Ladybag have selected these three items based on the findings of the research conducted by the Nokia research group. The choice of which items would be essential to keep tracking, however, was similar to what was identified by the Nokia research group. The difference is that in the study conducted by Chipchase, besides the cell phone and keys, money was the third item, instead of the wallet.

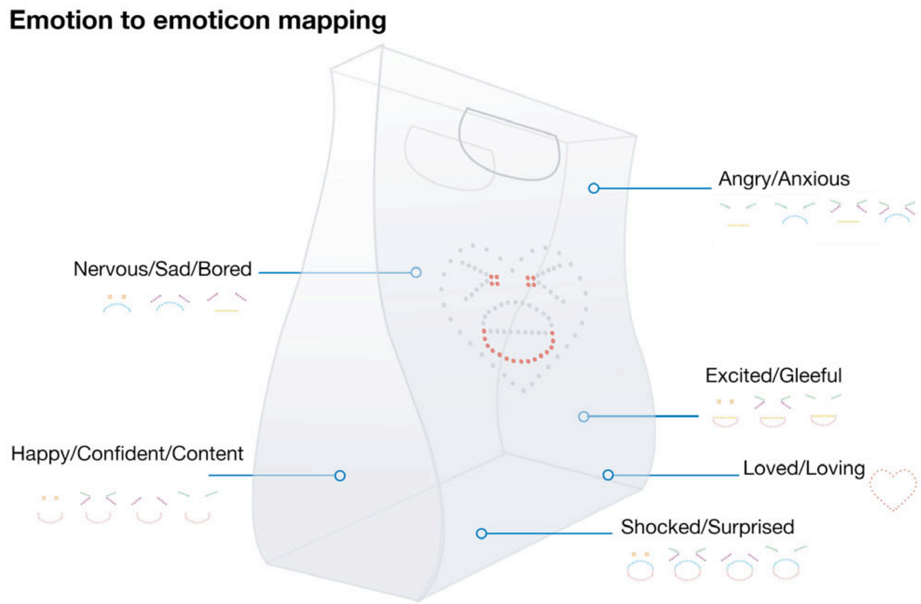

Figure 7: Ladybag: diagram showing the location of the sensors and the corresponding emotions (http://www.ladybag.official.ws/)

To operate as an Effective Organizing System, the bag uses RFID technology to keep track of the objects placed inside, depending less on the user's action. Basically, objects with radio frequency identification tags (RFID tags) are tracked by a RFID reader in the bag. If one of the items is out of reach, the sensor activates the bag's LED screen on the outer surface, indicating which object is missing.

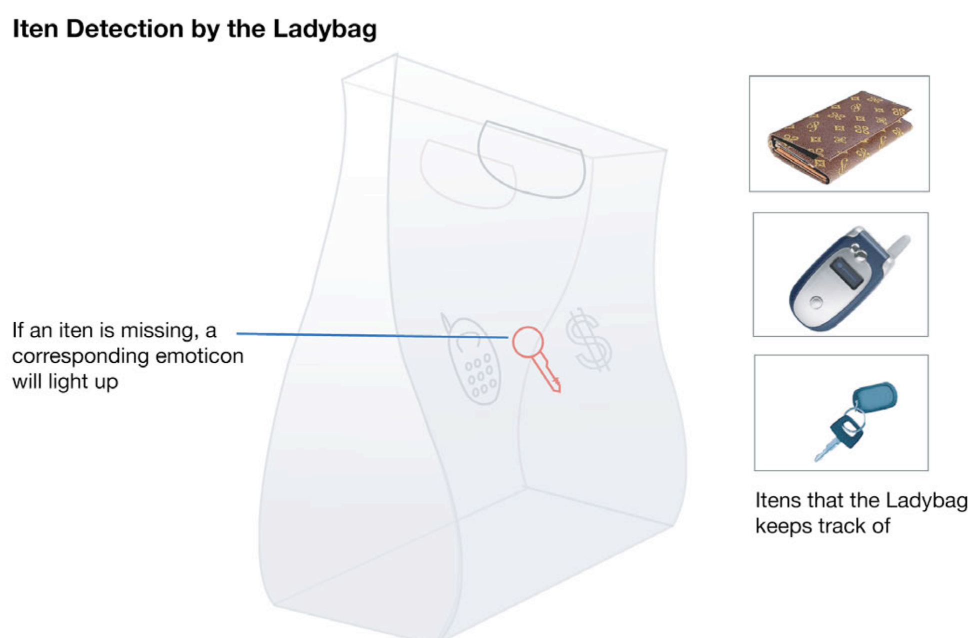

Figure 8: Ladybag as Effective Organizing System (http://www.ladybag.official.ws/)

In both versions of Ladybag, either as an Affective Communication System (AOS) or as an Effective Organizing System (EOS), the outer surface of the bag works as an ambient information system, providing information on the status of both the user's emotional state or the absence of objects linked to the system, in a discreet and unobtrusive way.

It should be noted that the AOS version of the Ladybag depends on a direct action of the user to enable it to express her emotions. So, while it may be seen as an ambient information system, since it presents information in a discreet way, it is necessary a conscious action from the user for the system to act. This way, it is possible to argue that this project cannot be classified as calm technology[3]. Alternatively, to make the system less depending on the user's action, biometric sensors could be used to constantly monitor the user's body, in order to notice changes in her emotional state without requiring a conscious action to display this information.

Discussion and further research

The projects described above have in common the fact that they present non-critical information in a discreet manner, acting mainly into the periphery of our attention. As we have seen, this is particularly interesting considering that computer technology and information systems have become widespread in our lives, and will increase even more in the years to come. Pervasive computing opens up new possibilities for accessing information, by augmenting ordinary objects with computational resources, allowing them to perform many different tasks such as warning us about weather change, letting us know when our friends come home, reminding us that plants needs to be watered, communicating our emotional state. On the other hand, ubiquitous computing also increases the amount of information to which we are exposed. Design has much to contribute in creating novel interfaces that can guarantee that this information overload won't turn into noise, generate stress or become a burden.

There are many issues that still require research regarding the design of Ambient Information Systems. How to evaluate the effectiveness of a system that should not be intentionally perceived by its users? The most known evaluation methods, which usually are task-oriented, don't seem to be suitable for this kind of system. Which metrics, heuristics and evaluation methods should be used, considering that in most cases there isn't an explicit task to be performed by users? Research in the field of visual perception and cognitive psychology (Healey, 2007, 1996; Lima, 2005) and specific studies on Ambient Information Systems (Hazlewood et al, 2008, 2007; Mankoff & Dey, 2003; Tomitsch et al, 2007) are being conducted, bringing a better understanding about this subject, but much remains to be investigated. Is there some kind of information that is more appropriate for this type of system? What does it mean to design for the periphery of our attention, considering that we are not restricted to our vision, that we could also explore the sense of touch, hearing and smell?

The answers to these questions are beyond the scope of this article. It is clear, though, that the design of Ambient Information Systems is a relatively new field for designers, and thus it is essential to deepen the research on this subject. This article is a preliminary result of an exploratory research being conducted on this subject, and the main intention was to stimulate the debate on the Design community about Ambient Information Systems, whose importance tends to grow in the near future.

---

[3] After performing some user tests, the authors of the Ladybag found that using pressure sensors to report emotional states was considered relatively complex, due to the difficulty of memorizing their location, and to relate each pressure point with a corresponding emotion. As it turned out to demand the user's attention to fully operate the system, the Ladybag cannot be considered a calm technology device, at least from the standpoint of its users. However, it can be considered an ambient information system as it communicates the emotional state of its user discreetly for those who are around.

Abstract

In the current experience economy, some retailers and retail designers aim at triggering customer experiences by associating the retail store's design with 'authenticity'. The notion of authenticity, however, is complex and layered and has been studied in several scientific disciplines. But within retail design, only limited research on authenticity is available. This paper aims to clarify the complex concept of authenticity in relation to retail design. Retail design as part of interior architecture is an emerging discipline. By establishing its theoretical basis, authors mostly rely on the knowledge of background disciplines; as in this paper, where we look at theories developed in marketing and philosophy to investigate how (staged) authentic retail settings be can situated in relation to the current experience economy.

The paper contains three large sections. The opening section presents a review of literature on retail design and the experience economy in relation to authenticity. The second section explores authenticity as defined through the theory on simulacrum by Plato, Baudrillard en Deleuze. In the third section, these theoretical insights are translated to the actual retail environment by surveying (staged) 'authentic' retail stores in three shopping cities in Flanders (Belgium). Based on this survey, seven different groups of authentic stores are defined, moving from 'real' to 'hyperreal'. This grouping should not be seen as a classification system but rather as a mental scheme to investigate and report on different approaches towards authenticity in retail store environments. The scheme can be applied in the field of consumer research as well as in retail (design) practice.

Keywords

Authenticity; Retail Design; Simulacra; Experience Economy

Authenticity is a layered concept, which has been studied in different scientific disciplines, such as philosophy, architecture, heritage conservation and marketing. Yet, to the authors' knowledge, the notion of authenticity in the design of retail environments has not received similar attention. Retailers and customers increasingly label retail stores 'authentic', irrespective of its historical, cultural and architectural background (Pine & Gilmore, 2007).

Competing in today's global market is becoming increasingly difficult. Since customers often perceive products and services as homogeneous, retailers and manufacturers continuously need to look for differentiation strategies (Petermans & Van Cleempoel, 2009). Differentiating oneself from the competitor by creating memorable customer experiences is therefore becoming one of the central objectives of many retail store environments (Verhoef et al., 2009). In the current experience economy, customers ask and expect more than just being satisfied with the purchased brand or product and the delivered service level. Instead, they look for personal, intuitive relationships with brands and retailers (Van Tongeren, 2003, 2004). Directing the store's retail design towards the creation of memorable customer experiences by appealing to customers' senses, emotions and values can contribute to the creation of such company-client relationships. Since customer experiences in retail settings appear to immerse customers at a cognitive, emotional and intuitive level (Healy et al., 2007), they can be considered as a new source for value creation. A retail experience which succeeds in delivering value to the customer can become the key to long-term retailer success. One approach which seems successful in Western economies today, is focusing the retail store's design on '(staged) authenticity'. Besides 'truly' authentic retail stores, retailers increasingly focus their retail store's design on staging authenticity in the stores' interior, exterior and/or the products sold in the store.

The research question is the following: How can (staged) authentic retail settings be situated in relation to the current experience economy? As retail design in interior architecture is an emerging discipline, theories are build by utilizing theoretical approaches of background theories. The purpose of this article is to (a) explore issues related to the design of a (staged) authentic retail environment through a literature review, (b) present cases of Flemish retail stores that were designed to be perceived as (staged) authentic retail settings and (c) describe and discuss the implications of these approaches for retail designers. The opening section of the paper discusses literature on retail design and customer experiences by focusing on the importance of designing appealing retail environments in the current experience economy in relation to authenticity. The second section approaches the concept of authenticity through the theory of simulacra by Plato, Baudrillard and Deleuze. The third section translates this theoretical framework into retail design practice by analyzing an inventory of (staged) 'authentic' retail stores in the three most important shopping cities in Flanders: Antwerp, Ghent and Hasselt (Llo, 2009).

Designing retail environments in today's experience economy

In the contemporary market, consumer choice is often emotionally guided and based on values (Holbrook & Hirschman, 1982; Babin et al., 1994; Mathwick et al., 2001). Hence, retailers need to be aware of the importance of designing retail environments, creating personal and memorable customer experiences. But what is retail design and how is it linked to the concept of an experience economy.

Retail design

Retail design refers to various aspects that deal with the interior and exterior of commercial spaces. There is particular attention as to how a store will work commercially through a functional and aesthetical environment. It entails, for example, an understanding of customer behaviour in relation to tangible (material) and intangible (atmospheric) design elements. Equally, the store's interior has to meet regulations concerning the use of a public space (Kindleysides, 2007; Petermans & Van Cleempoel, 2009, 2010).

When customers visit a retail store, they immediately make an association between the products sold in the store, their price, the store's 'tone of voice' and ambience and the retailer's presence and identity. As a result, retail design and retail branding can not be disconnected from each another (any more). The role of retail design is to translate and develop retail branding into the practice of a retail store environment, in accordance with specific societal and temporal conditions (Van Tongeren, 2003, 2004).

Authenticity in the experience economy

The concept 'customer experience' was formulated in 1982 by Holbrook and Hirschman as a new experiential approach to consumer behavior. However, it lasted until 1999 before the 'experience' concept came to the fore in the management and marketing discipline with the publication of Pine & Gilmore's book on the Experience Economy. They present experiences as a new economic paradigm, which emerges as the next step after an economy of commodities, goods and services. They were the first authors to describe the contemporary market culture as an ‘experience economy’.

How can retail stores appealingly be ‘designed for experience’ in the current experience economy? And how do individual customers perceive these retail environments? Until now, most of the existing literature on retail stores has focused on the isolated testing of individual in-store atmospheric stimuli, such as lighting (Areni & Kim, 1993). However, experiential elements do not work in isolation; rather, they function as a holistic mechanism, driving the customer’s experience (Healy et al., 2007). Customer experiences originate from the interplay between a personal, social and physical context (in casu: the retail store) a consumer finds him- or herself in (Falk & Dierking, 1992).

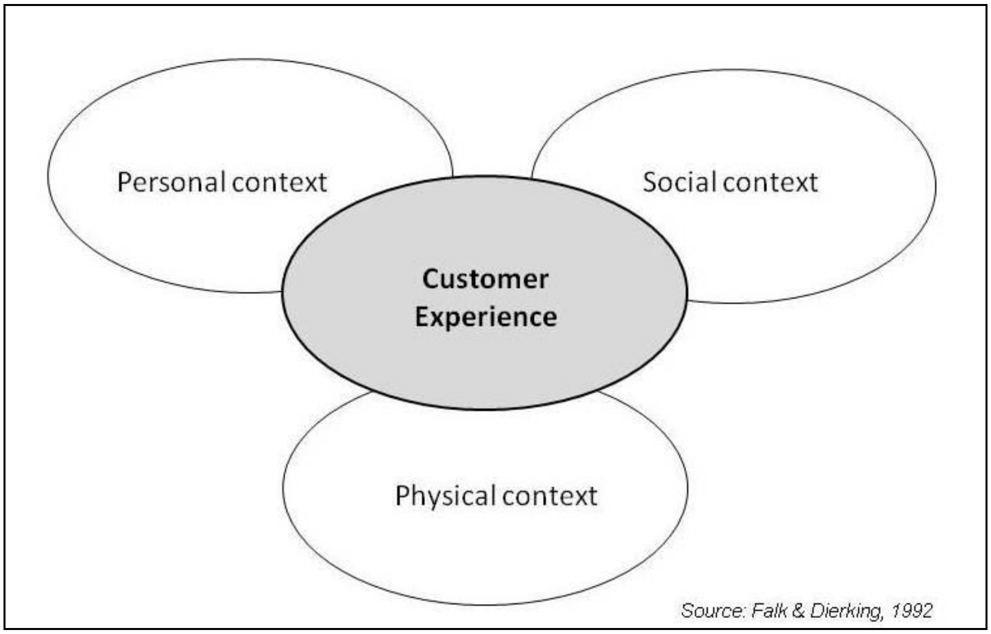

Fig. 1 Interactive experience model

The concept of ‘personal context’ refers to the personal, emotional, cognitive and socio-demographic characteristics, attitudes, norms, values, … of the individual customer. The concept ‘social context’ does not only concern the people, accompanying the customer on a store visit, but also the presence and behavior of the in-store personnel. Finally, the ‘physical context’ encompasses different elements: (1) architecture and design (2) the lay-out of the environment (in and outside the store) (3) the feeling the environment invokes with its users (4) the objects and activities, present within the physical environment.

The combination of these three contexts continuously influence the individual customer. The interaction between these contexts ultimately results in customer experiences. Hence, customer experiences are always personal and subjective: each individual comprehends, organizes and interprets in-store information in a unique way, reacting with a different interpretation to in-store stimuli because of his or her particular cultural, social and personal backgrounds (Klingmann, 2008).

Consumers’ holistic attitudes about a given store can influence their overall preference for that store (Thang & Tan, 2003). When consumers perceive a store environment or element of that environment positively, they are more likely to remain in a store for a longer period of time, to touch or examine merchandise and to indicate an intention to purchase (Hyllegard et al., 2006). Orchestrated experiences can encourage loyalty, not only through a functional design, but also by creating emotional connection through an engaging, compelling and consistent context (Pullman & Gross, 2004).

In today's retail practice, different kinds of experiential retail settings seem to exist. Kozinets et al. (2002) differentiate between flagship brand stores (eg. Nike Town), themed entertainment brand store (eg. The Hard Rock Café) and themed flagship brand stores (eg. The World of Coca Cola Museum, Atlanta). The spectacular and entertaining aspect, used by these kinds of stores to differentiate from competitors, has inspired an increasing number of retail stores.

In today's experience economy, customers in Western Europe want retailers to take into account their true and authentic feelings, desires, and personalities. Customers no longer want to be considered as mere 'consumers'. They want to achieve goals in life, realize ideals and contribute to aspects they value important (Pine & Gilmore, 2007; Petermans & Van Cleempoel, 2009). Retailers and retail designers need to take this evolution into account when designing appealing experiential retail environments.

Currently, the concept of 'authenticity' is being used as a way to answer these customers' concerns. Retailers try to appeal to customers by for instance choosing historic locations for their retail store, by integrating authentic elements in their retail store's design, or even by designing completely new 'authentic' retail stores.

The simulacrum: Plato, Deleuze and Baudrillard

The paradigm of the simulacrum has been discussed in relation to postmodern consumer culture to explain that the boundaries between real and imaginary are becoming blurred and how this effects the marketplace (Firat & Venkatesh, 1995; Hollenbeck et al., 2008). So far however, this theory has not been applied to the actual retail environment. In this paper, the theory on simulacrum creates a better understanding of contemporary retail settings in relation to authenticity and staged authenticity.

Plato and the simulacrum

The concept of authenticity originated in Plato's theory of Ideas which distinguish the true (metaphysical) object and its image, the original and the copy, the model and the simulacrum, the authentic and the inauthentic (Deleuze, 1983, pp. 45-46). The distinction moves between two sorts of images: on the one hand iconic copies, on the other hand phantasmatic simulacra. Icons are good, well-founded images of the Idea, endowed with resemblance. An iconic copy is 'modeled' in the Idea. Simulacra are insinuations, subversions and are made without passing through the Idea. However, a simulacrum is not a copy of a copy or an endlessly degraded icon. Where the icon is an image endowed with resemblance, the simulacrum is an image without any resemblance (p. 48).

The whole Platonic motive is a matter of distinguishing the good from the false copies. For the observer, to judge on an image, one should have true knowledge of the Idea. But *'the simulacrum implies great dimensions, depths, and distances which the observer cannot dominate. It is because he cannot master them that he has an impression of resemblance. The simulacrum includes within itself the differential point of view, and the spectator is made part of the simulacrum, which is transformed and deformed according to his point of view'* (Deleuze, 1983, p. 49).

Baudrillard: reality and hyperreality

In contrast with Plato, Baudrillard does not believe in objective reality or truth but only in the individual interpretation of it (Lepers, 2009, p. 122). He approaches the concept of simulacra within his critic on the consumer society. According to Baudrillard, we live in the era of simulation, inaugurated by a liquidation of all referentials: the model of the real has no origin or real anymore. It is no longer a question of imitation, nor duplication, nor even parody. He described this 'decay of the real' in four steps:

'Whereas representation attempts to absorb simulation by interpreting it a false representation, simulation envelops the whole edifice of representation as itself a simulacrum. Such would be the successive phases of the image:

- *It is the reflection of a profound reality*
- *It masks and perverts a profound reality*
- *It masks the absence of a profound reality*
- *It bears no relation to any reality whatever: it is its own pure simulacrum'* (Baudrillard, 1994, pp. 16-17)

This final phase is supposed by Baudrillard to supersede all others. Where in the first phase there is still a real to refer to, in the final phase simulation no longer copies anything and reality is replaced by nostalgia which is the plethora of truth, of secondary objectivity, and authenticity (Hegarty, 2004, pp. 50-52).

Baudrillard argues that in the era of nostalgia, reality is replaced by hyperreality. He gives Disneyland, among many other examples, as a perfect model of the hyperreal. In the first place, Disneyland is an imaginary world which ensures the success of the operation but it also is a social microcosm, a miniaturized pleasure of real America. Disneyland is presented as imaginary in order to make us believe that the rest is real; whereas all of Los Angeles and the America that surrounds it are no longer real, but belong to the hyperreal order and to the order of simulation (Baudrillard, 1994, pp. 12-14).

Deleuze and the upgrading of the simulacrum

In his article "Plato and the simulacrum", Deleuze takes the theory on simulacra even further (1983). He starts from a similar definition of simulacrum as Baudrillard but he undermines the very distinction between copy and model (Massumi, 1987). Deleuze says the simulacrum is not a degraded copy, rather it contains a positive power which negates both original and copy, both model and reproduction; the simulation is a process that produces the real. Deleuze describes the era of simulation as the 'overthrow of Platonism' which means to raise up simulacra, to assert their rights over icons or copies (Deleuze, 1983, p. 53).

Understanding the retail environment

The distinction between real and hyperreal can be recognized in contemporary retail settings.

Today, we can still find some "real" authentic stores which have a continuous, and even renewed, attraction on consumers. In such stores there is emphasis on original characteristics, tangible as well as intangible, of the retail environment and their design has remained unaffected in the course of time (Grimmeau & Wayens, 2003). The designers and retailers of such stores often deal with aspects of conservation taking the international documents on heritage conservation as a reference (ICOMOS, 1964, 1994, 1996). An interesting example is 'Galeries Saint-Hubert' in Brussels, a 19th century shopping arcade (Galeries Saint-Hubert, 2010). The program of the passage was threefold: a well-thought combination between a public space meant to solve traffic problems, a commercial, sales oriented space and an official national monument expressing a new politic reality after the independency of Belgium in 1830 (Geist, 1979). From its foundation, the Galeries Saint-Hubert was continually in use and in 1997, the buildings were completely restored (Dienst Monumenten en Landschappen van het Brussels Hoofdstedelijk Gewest, 1998). The restoration project preserved both the versatility of the initial project as well as the physical architectural qualities of the building (Plevoets & Van Cleempoel, 2009a).

On the other side of the spectrum, there exist “hyperreal” retail settings. An example is ‘Bataviastad’, an outlet shopping village in the Netherlands (Bataviastad, 2010), created as a themed park around the shipyard of the 17th century vessel ‘Batavia’. The design of Bataviastad is conceived as a reconstructed fortified town; aesthetically the village is a pastiche of historicised architectural elements inspired partly on Marken Island and partly on colonial architecture from the Caribbean where the original ship Batavia used to sail to (Groenendijk & Vollaard, 2006, p. 93).

Fig. 2 Galleries Saint-Hubert

Fig. 3 Bataviastad

But as suggested by Baudrillard (1993, p. 38; 1994, p. 6) and Deleuze (1983, p. 53), in contemporary society the borders between true (i.e. ‘real authentic’) and false (i.e. ‘staged authentic’) are becoming blurred. As one of the goals of this paper is to present cases of retail stores that were designed to be perceived as (staged) authentic, the authors want to test the value of Baudrillard and Deleuze’s idea in contemporary retail practice.

To gather relevant data, (staged) authentic retail settings in the three most important shopping cities in Flanders - Antwerp, Ghent and Hasselt (Llo, 2009) – have been surveyed. Two students from the master (interior)architecture helped to collect data. After the completion of the survey, all studied retail settings needed to be classified according to the developed theoretical framework. Our attempts in doing so soon made clear that most studied stores could not be classified as ‘truly’ or ‘falsely’ authentic; they mostly represented an intermediate type of authenticity.

As a consequence, the authors distinguished different groups of authentic stores. Three parameters were used to inform the different groups: the (staged) authenticity of the store interior, the (staged) authenticity of the store exterior and the (staged) authenticity of the products sold in the store. As a result seven different groups of authentic stores, moving from ‘real’ to ‘hyperreal’ were distinguished. These groups can be put into an axe on which retail spaces can be organized. Figure 4 presents a classification of retail settings based on the shifting between ‘real’ and ‘hyperreal’:

- *Historically authentic*
  Despite retail being a rapidly evolving business subjected to constant change (Christiaans & Van Amerongen, 2004), some stores survived the course of time and remained unchanged since their foundation (Grimmeau & Wayens, 2003). These 'historic' retail settings can be considered heritage and as such their authenticity can be evaluated by applying heritage-related definitions such as these implied by international documents on heritage conservation (ICOMOS, 1964, 1994, 1996). In many cases, the preserved historic elements are limited to the store front (English Heritage, 1999, 2002) but some examples exist where both the exterior and interior elements are kept and where the store is still selling the original product.

  An example is 'Tierenteyn-Verlent', founded in 1790 and located in the historic centre of Ghent. From its foundation, the store specialised in producing and selling home-made mustard. Over continuous generations, its owners have maintained the original shop front and store interior (Tierenteyn-Verlent, 2009). Today the stores exterior and interior are protected as a monument by the Flemish government.

- *Historically authentic setting*
  Increasingly retailers look for existing buildings that are historically or architecturally significant. Reusing significant buildings have advantages as to differentiating oneself against competitive retailers as well as to sustainable design. Moreover, historic buildings are often located on A-locations inside the city centre which make them very attractive for the retail sector (Plevoets & Van Cleempoel, 2009b, 2009c). Although the hosted building can often be considered authentic from heritage perspective, it does not obviously imply that the store is considered 'authentic' from the point of view of retail design.

  Bookstore Selexyz Dominicanen in Maastricht (NL) is an example of a store located in a historic building; the host space of the store is the 13th century church of the former Dominican convent. The casco of the church was completely restored and contrasts strongly with the contemporary design of the bookshop's interior. In the centre of the church, a large bookshelf of two floors high is build up as a steal construction. On the one hand this volume stresses the dimensions of the church and on the other hand, from the upper floors of the bookshelf, visitors can observe the architectural details from the church. As a result, host space and contemporary interior enhance one another (Merkx+Girod Architecten, 2010).

- *Historically authentic interior*
  Just as retailers use historic exteriors to render an authentic store image, also authentic interiors can be introduced for creating an atmosphere of nostalgia. Many examples are at hand where historic furniture aims to ad a sense of timelessness to the store.
  Daniel Ost calls himself a floral artist and sculpture (Ost, 2010). His store in Brussels is located in the former Chemiserie Niguet, designed by the art nouveau architect Paul Hankar in the late 19th century. Not only the shop front but also the interior elements of the store were restored in all their details (Heymans, 2006).

- *Authentic product*
  Some retailers or brands distinguish oneself by offering traditional, often handicraft made products that are appreciated by customers still today for reasons of quality, originality or even rareness. To survive increasing market competition, these retailers often present themselves through an innovative retail design that represents the taste of their target public (Berckmans & Gaiardo, 2003).

The Belgian *chocolatier* Neuhaus has more than 150 years of experience in producing high quality chocolates. Although the process of production has evolved since its foundation in 1857, the quality of the used ingredients, the recipes and the production techniques are still given major attention today. The oldest store of Neuhaus is located in the Galeries Saint-Hubert in Brussels and its interior dates back to the early 20th century. But other Neuhaus stores have been founded all over the world and their design is adapted to contemporary fashion, taste and techniques (Neuhaus, 2010).

- *Staged authentic*
  Beyond using buildings and interiors that are authentic from heritage-perspective, retailers also 'stage' authenticity in their new design. The new design can be staged in different aspects: firstly it can stage a historic architectural style, secondly it can stage a regional architectural style from a specific area or country or thirdly it can stage a specific atmosphere.

  The bakery chain 'Le Pain Quotidian' stages authenticity in the products they sell, but also in the design of their retail spaces. Their bread and pastry look traditionally produced and are served hand cut. The interior of the store and the adjoining tearoom have a domestic atmosphere; the furniture is made of reclaimed massive wood and customer's can have breakfast together at the long table, centrally in the tearoom (Le Pain Quotidien, 2010).

- *Pastiche*
  A pastiche is a combination of various historic and historicized elements. Axel Vervoordt for instance is a collector of art and antique objects from a large variety of periods and regions. When furnishing or decorating a space, he aims to give the space its own identity by bringing together objects from different cultures; hence, a certain tension is created between the different objects and between the objects and the room. Most of his projects concern private houses and apartments. His personal residence is a castle in s' Gravenwezel, near Antwerp, and is opened for the public twice a year. At these occasions, people are free to buy certain objects (Vervoordt, 2010).

- *Hyperreal*
  A hyperreal retail setting does not refer to any profound reality but aims to create a world of phantasm. An example, Bataviastad (NL), has been given above.

But as suggested in figure 4, the different types of authentic stores should not be seen as a classification system with strict borders between the different groups. The scheme can be used as a mental scheme to investigate and report on different approaches towards authenticity in retail store environments. It can be used as a transparent interdisciplinary communication tool. It is, however, not meant as a quantitative methodology that would allow 'measuring' the level of authenticity in retail spaces.

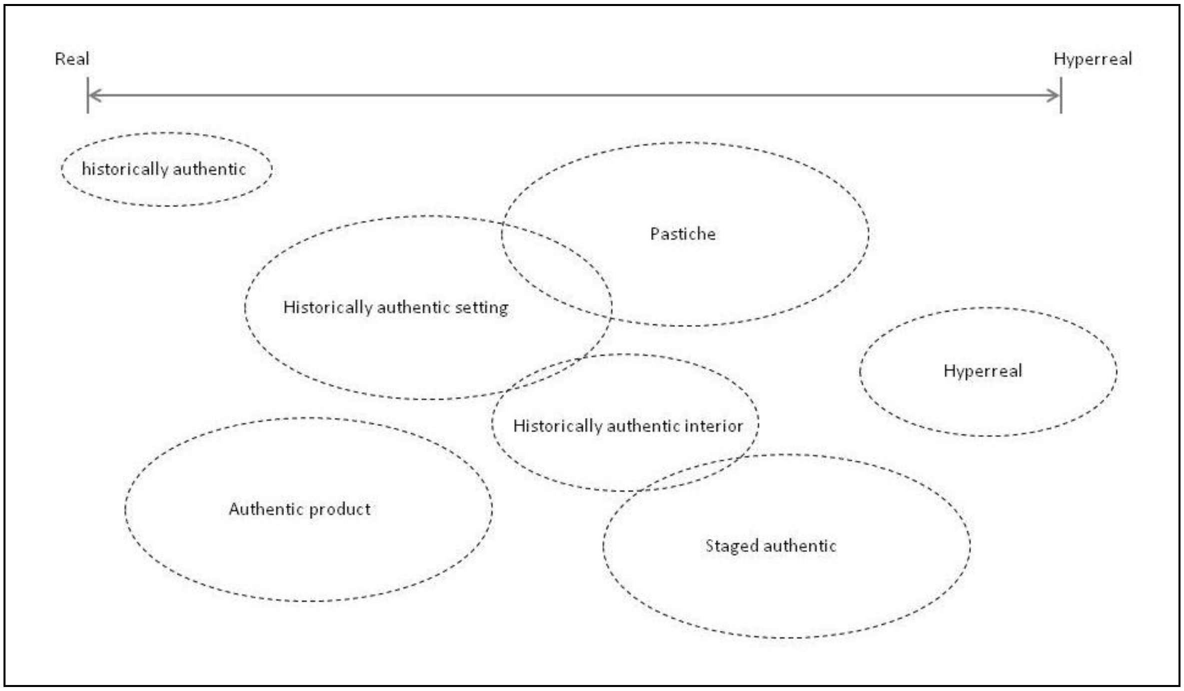

Fig. 4 Groups of (staged) authentic retail settings

Conclusion

This paper aims to present a first attempt in developping a theoretical framework on the complex concept of authenticity in relation to retail design. Although in certain disciplines a definition of authenticity could be formulated (e.g. heritage conservation: ICOMOS, 1994), the authors did not, as yet, aim to develop a normative definition of authenticity for the retail design discipline. More than defining the meaning of authenticity in retail design in this paper, the authors firstly studied the concept through the theory of simulacra as developed and described by Plato, Baudrillard and Deleuze, and secondly, described and clarified the concept by studying retail design practice in Flanders.

Based on the intermediate positions between 'real' and 'hyperreal' (Deleuze, 1983; Baudrillard, 1994), the authors have presented a classification scheme which can be used to study 'authentic' retail settings. However, the authors do not take a dogmatic position in favor of one of these two approaches to authenticity, all the more since recent consumer research illustrated that people's perceptions on authenticity vary (Beverland & Farrelly, 2010). Beverland and Farrelly's research (2010) demonstrated that the process of authenticating an experience is contingent on consumers' goals. After in-depth interviews with 21 informants about their understanding of authenticity, some labelled ubiquitous, mass-market objects as 'authentic'.

But Beverland and Farrelly's results contradict with results from earlier consumer research that illustrated that commercialisation can have a negative effect on the way consumers experience authenticity (Grayson & Martinec, 2004; Maclaran & Brown, 2005). One of the possible explanations of these contradicting results may be caused by the lack of a clear definition or delineation of the concept of authenticity in retail design. As such, a first application of the classification scheme could exist in the field of consumer research; In future consumer research on authenticity in retail setting, the proposed scheme may be used to indicate more specifically the meaning of authenticity in the researched setting. As such the internal validity of results could be enlarged (Yin, 2009).

Further research could investigate if the type of customer differs between the different groups of (staged) authentic stores. If this should be the case, a second field of application of the scheme may be in the retail (design) practise; by knowing who their target customers are, retailers and designers could adapt their retail store's design to their customers' current needs and wants.

Given that the survey of the actual retail environment in this contribution only covers three important shopping cities in Flanders, the valorization of results is limited to the Flemish retail context. As consumer preferences are strongly culture specific (Millan & Howard, 2007), results could be different when studying actual retail settings in other cultural environments. Hence, further research could focus on developing a comparative study between the actual retail settings in different cultures or geographical regions, to provide a better understanding of the implications of cultural differences in consumer preferences for retail design. Another possible direction for future research could be the elaboration of the scheme, here presented.

Author Biography

Bie Plevoets

studied Interior Architecture at the PHL University College in Hasselt (BE). Already during this study she showed interest in heritage conservation, making her master thesis on 'Re-use of convents: a social and architectural challenge'. After finishing her study in Interior Architecture at she followed a postgraduate master in Conservation of Monuments and Sites at the Raymond Lemaire International Centre for Conservation (Catholic University Leuven). Currently Bie Plevoets is working on a Ph.D research at the PHL University College and Hasselt University dealing with the tension between heritage and retail in historic city centres in Europe.

Ann Petermans

has a Master's Degree in Communication Sciences. Since research has always fascinated her, she started her career in a Market Research Company. After having worked there for 3 years, in 2004 she turned to scientific research at PHL University College. Recently, she started working on her Ph.D. research at the PHL University College and Hasselt University. Her research focuses on the relationship between Experience Economy and Retail Design whereby she focuses on conceptualizing and getting an insight into customer experiences in holistic retail settings.

Koenraad Van Cleempoel

studied art history in Louvain, Madrid and London, where he obtained his Ph.D. degree at the Warburg Institute. Since 2005 he is engaged in establishing and directing a research unit in interior architecture at PHL-University College. He is the supervisor of four Ph.D. students on subjects of retail design and domesticity. Previously he has published on the relationship between art and science during the renaissance period, especially in the field of scientific instruments. But currently he shifted his attention to the modernist period. He currently looks at polychromic interiors of Le Corbusier and De Stijl and tries to understand its influence on Belgian modernists. Another area of research is the presence of the occult in the discourse of several modernist artists, Mondrian in particular.

A new atlas for abstract spaces. Visual tools for the exploration of complex contexts.

Marco Quaggiotto, Politecnico di Milano, INDACO Dept., Milan, Italy
ISI Foundation, Complex Networks and Systems group, Turin, Italy

Abstract

In the tradition of research, text is the preferred solution for research and communication. The linear sequence of writing explains reality: it transforms synchronic scenes into a sequence of codes that describe it diachronically. Nonetheless, while textual representation still remains extremely useful in scientific communication, the linearity of writing is lately appearing as inadequate to the latest models of science and to the representation of current knowledge systems.

In this context the language of cartography in particular seems to be fit to work as a structural model for the representation of complex systems, and Design can find in the atlas a model for the communication of complex contexts. As a tool designed to describe and act upon complex context, the atlas provides a model to strategically describe highly heterogeneous knowledge spaces. As a communication device, the atlas sets up a strategic network of images in order to achieve a set of communicative goals: maps, illustrations, graphs, and texts work together to describe and act upon space.

In the first part of this paper, we examine the structure of the atlas in order to expose the mechanisms that allow actions of exploration of complex and heterogeneous contexts. In the second part of the paper, the format of the atlas is discussed in its transfer to the digital domain and in its application to knowledge contexts. The first experimental results of such an approach are displayed by presenting a software tool for the collaborative management of design knowledge resources.

Keywords
Communication Design; Interface Design; Knowledge Visualization; Information Visualization; Cartography; Atlas.

In the tradition of research, text constitutes the preferred solution for research and communication. The linear sequence of writing *explains* (from the Latin verb *explico:* to unfold) reality, it transforms a synchronic scene into a sequence of codes that describe it diachronically, slicing it in discrete elements. The subdivision of reality in discrete elements allows the reasoning of scientific thought: logical reasoning, proof and deductive processes build upon the linear narrative created by writing to give an order to the scientific process. The linearity of the text, in other words, matches perfectly the logical nature of the scientific-deductive method, which ultimately represent the ultimate expression of historical consciousness (Flusser, 1997). Nonetheless, while textual representation still remains an extremely useful in scientific communication, the linearity of writing is lately appearing to be not enough to the latest models of science, and to the representation of current knowledge systems.

The changes that the current knowledge paradigm is undergoing can be summarized in two main aspects. On the one hand, the developments of systems theories and epistemologies of complexity are transforming the scientific discourse in a model that aims to describe complex phenomena in their entirety. The focus is not so much in the sequence of an explanation, but on the relationships that link the components of a system irreducible to its analytical decomposition. On the other hand, the explosion of social knowledge paradigms that surpass the models of idealism are changing the structure of knowledge itself, exposing the social and relational dimensions of cultural processes that were gradually hidden by writing and printing technologies.

Knowledge is less and less considered in terms of *possession*, and increasingly in terms of *access* to information and skills. Knowing means having access to social and technological networks able to provide necessary information and insight at the time of need. The rigid and permanent structures of disciplines and subject areas are therefore progressively replaced by fluid and dynamic spaces in permanent movement and evolution, able to define cross-cutting paths, areas of interest and clusters.

Although a new paradigm for knowledge is clearly emerging, appropriate narratives for its representation are still lacking. Traditional interfaces based on the linearity on text or the hierarchical models of knowledge struggle to meet the needs of increasingly complex and ever-changing research contexts, in which relationships between elements part of the knowledge system are as important as the elements themselves.

Maps for the exploration of complex contexts

In this context, design is involved on two different levels:

On the one hand, the nature of design process requires the designer to be confronted daily with complex and transdisciplinary systems, in which the different design dimensions cannot be analyzed separately. As a synthetic discipline, Design is focused on keeping together, rather than distinguishing between heterogeneous elements. Social, semiotic, linguistic, cultural components appear as an irreducible system that has to be synthesized in the design process.

On the other hand, Design in general, and Communication Design in particular, is responsible for the creation of formats and tools able harness the characteristics of images in order to address this kind of communication needs. Designers are responsible for the creation of a new rhetoric of complexity, a visual rhetoric not limited to the elusive search for scientific neutrality, but a language aware of its involvement in the creation of a cultural artifact in which the author is an expression of a cultural and social context.

The challenge to be addressed is no longer that of creating better analytical structure to subdivide and classify elements of reality. On the contrary, the current urgency is to ‘keep together’ the elements of the system in a single representation.

In this context, the languages of visual communication acquire a role complementary to textual communication, and the language of *cartography* in particular seems to be fit to work as a structural model for the representation of complex systems. In the history of image-tools, for thousands of years maps have been providing an interface to describe and act upon the complexity of the territory.

As narratives, maps are the expression of communication goals: they operate selections on reality, distort events, classify and clarify the world in order to better tell a particular aspect of a territory. Maps, in other words, can be seen as a ‘visual narrative’ of space: cultural artifacts created by an author in order to describe a space in terms of a goal.

As instruments, maps are tools that allow to reach otherwise unattainable goals. They allow not only to do things better, more efficiently, but also to create new realities. Maps describe the territory, highlight positions, distances, spatial distributions, groups, boundaries. They serve as tools to act on the space: to orient navigations, to mark paths, to plan trips, to explore territories. Or they can be used as design tools: plans for the construction and modification of space.

As with all codes that can boast such a long history, the cartographic representation of space has come to be regarded as a “natural” match between the represented space of the territory and the representing spaces of the map. However, nothing is natural about cartographic representation. As cultural artifact and political tool, maps create a virtual reality that allows the user to perform operations on the area represented. Exploration maps, nautical charts, building plans and world globes all carry with them an intended use and a number of functional purposes.

Building on this heritage, the operative concepts, tools and formats of cartography provide a perfect match for the representation of complex contexts, and their application can be extended to spaces that are no longer strictly geographic spaces. By looking at the theoretical critique of cartography developed by the critical cartography movement, the definition of the map takes on the connotations of a much more general cultural artifact. Moving away from the geographical space as its only object of investigation, maps becomes a “graphic representations that facilitate a spatial understanding of things, concepts, conditions, processes or events in the human world” (J.B.Harley and David Woodward, 1987, p. xvi). Space becomes an abstract substrate similar to the anthropological space defined by Levy as “a system of proximity unique to the world of humanity and thus dependent on human technologies, signification, language, culture, conventions, representations, and emotions” (Levy, 1997).

This metaphorical space fits perfectly in the realms of research and science. Unlike the structures used over the centuries to manage knowledge by subdividing it in discrete areas, space is a continuous substrate: it doesn’t divide culture in sections, it doesn’t create hierarchies or define order in absolute terms, but on the contrary, it defines relations, proximities. Space creates clusters, identifies pathways and highlights priorities in a dynamic structure, and likewise it allows to locate, to remember, to relate.

From the moment in which the complexity of the knowledge structure becomes untamable, the metaphor of the ‘journey through the territories of knowledge’ replaces the institutionalized metaphor of the ‘tree of knowledge’ that in turn loses most of its ability to provide tools for interpretation of reality. Even D’Alembert, in the prologue to the *Encyclopédie* feels the need to suggest an image that goes beyond the typical representations of the time, proposing a representation of a territory that expresses perfectly the complexities of the project:

> [The Encyclopédie] is a kind of world map which shows the main countries, their position and their mutual dependence, the road that leads directly from one to the other. This road is often cut by a thousand obstacles, which are known in each country only to the inhabitants or to travelers, and which cannot be represented except in individual, highly detailed maps. These individual maps will be different articles of the Encyclopedia and the Tree or Systematic Chart will be its world map.
>
> But as in the case of the general maps of the globe we inhabit, objects will be near or far and will have different appearances according to the vantage point at which the eye is placed by the geographer constructing the map, likewise the form of the encyclopedic tree will depend on the vantage point one assumes in viewing the universe of letters. Thus one can create as many different systems of human knowledge as there are world maps having different projections, and each one of these systems might even have some particular advantage possessed by none of the others. (D'Alembert, 1751)

Knowledge becomes impossible to draw as a whole in a truthful manner, but only through the choice of a point of view that is both arbitrary and inevitable. Like the geographical and human space of territory, the complexity of knowledge needs useful abstractions, cultural interfaces able to transform the space in map. Although the maps of D’Alembert never actually found any representation beyond the linguistic metaphor, the idea of an atlas of possible trees and maps already emerges as a possible approach to the representation of tightly interconnected knowledge spaces.

An atlas for knowledge spaces

The Atlas as a communication format

Like any good metaphor, the cartographic analogy applied to knowledge is not limited to a lexical transfer from a proper domain to a figurate domain, but it allows the transfer of knowledge from a known field to one yet unexplored. In the context of knowledge representation, the Atlas is here proposed as a tool and an approach capable of exploiting the representation codes for complex realities developed by cartography in its thousands-years tradition. Just like traditional atlases, these ‘new atlases’ provide a format to represent heterogeneous and complex territories, creating a tool to allow a connection, a comparison, a relationship.

The concept of ‘atlas’ in this context doesn’t depict so much a list of maps, as rather a system for the representation of space, a communication device aimed at representing complex contexts through the use of many partial overlapping narrations. A tool combining multiple images with the aim to describe the many aspects that make up a space.

> Atlases belong to a particular type of communication formats: as containers they collect information and visual documents about territorial entities. In the same manner, they are also containers of viewpoints: they expose different dimensional scales, techniques and languages of representation, and they express different subjectivities: readings and interpretations that mix descriptions in order to create stories. They have a strong intermedial nature: different media interact with each other in a dialectic relationship (the story told by one media, is confirmed, strengthened, completed by the other media) and they contribute to the construction of a single communicative framework. (Baule 2007b)

In opposition to the totalizing approach of hierarchical models that try to present in a single image the ‘true’ structure of knowledge (in the Middle Ages) or its most useful representation (in the Enlightenment), the atlas presents a network of partial (incomplete and biased) stories, expressing authorial points of view with no claims of objectivity or comprehensiveness. The ‘description of the universe’ proposed by the first cartographic atlases is the result of a complex work of collection, amendment, interpretation and comparison of maps, indexes, diagrams, pictures and stories gathered over time from various sources.

The reason for this approach is clearly exposed in one of the definitions of complexity itself, which finds the core of complexity in its inability of being adequately captured in all of its properties by any one formalism (Vries e Goudsblom, 2002). Any given model of any complex system will be ‘by definition’ partial, unfinished, and incomplete. Only a system of representations, carrying different views of the same real-world phenomenon will have enough information to be useful, if not exact. The structure of the system is not depictable by a single image or even by a formal description, but it needs a multiplicity of views, a system of descriptions, a network of texts.

From this perspective, the atlas as a communication device *arranges* the elements of a speech, and “the practice of arranging embodies the idea of structured organization, planning and articulation of the elements that defines the communicative discourse” (Baule, 2007b). The arrangement, in this context, is not a simple list or enumeration, but a strategic placement focused on the achievement of a goal.

> The term ‘device’ – writes Agamben (2006) in his analysis of the use of the same term by Foucault (2001) – seems to refer to a set of practices and mechanisms (both linguistic and non linguistic, legal, technical and military) that are designed to cope with an urgency and to achieve a more or less immediate effect.

The strategic dimension of the atlas is therefore reflected in its design dimension: maps, diagrams, text and peritexts are arranged together in order to allow not only the description of a space, but also its use. Just like the map itself, the atlas is a communication tool with its own mechanisms, materials and supports, an instrument that enables users to act on space: it allows navigation, exploration, change of scale, comparison.

As an interface for space, the cartographic atlas anticipates the mechanisms of digital interfaces: browsing through the pages, following links, looking up its indexes, the user can explore complex contexts by moving thorough different views of a single subject. The world, at first displayed as a whole, is then described in its details by different maps designed with many different objectives. Physical, political, geological and economic maps of the same territory are put side to side on the same page to allow comparison. On one side diagrams, histograms, tables and explanations make visible the invisible, on the other side alphabetical indexes and tables of contents and figures allow the navigation of the volume, providing the opportunity to identify the geographic location of a city known only by its name.

Unlike a simple collection of maps, the atlas and holds together the different narrations of the same territory in the creation of a format for the description of space. Through the careful design and layout of its elements, of the consultation mechanisms, of the graphic and symbolic characters, the heterogeneity of its components becomes a browsable and navigable system, a polyphonic narration, a mosaic made of different tiles that give shape to a single picture.

The Knowledge Atlas

This concept of atlas as a model for the representation of complex contexts, as already foreseen by D'Alembert (D'Alembert, 1751) and later recovered in the '900 by other actors in the field of knowledge (Rayward, 1994), has been the subject of an experimentation in the context of design research. The *Knowledge Atlas* is a prototype of a software platform for the management of research systems (i.e. resources, actors and relationships that interact in the creation of new knowledge), designed to support research of common tasks such as survey, mapping and analysis.

The software, built on web-based technology, is a social web application that allows researchers and students to build their own bio-bibliographic database by adding five main types of resources (authors, texts, projects, conferences and research groups) related to the research field that's being investigated. Each resource in the system can be then described collectively by the users (as in a wiki) in its essential features (such as date, description, location ...) and individually, by each user, through the definition of tags, comments, and through the establishment of relationships between entities (e.g. relating a text to its author, a person to a research group).

The aim of this management structure, expanding beyond classic bibliographic management, is to adapt to contemporary forms of cultural production: to collect not only explicit knowledge, but also implicit knowledge embodied in people, in communities and in objects. Traditional bibliographic models are therefore hybridized with a model for the mapping of social, cultural and scientific contexts. Using this management structure for research ecosystems, all the resources inserted into the database are shared at different levels between the users. The resources are not limited to their individual use, but instead they represent the nodes of a big network that ties together users, resources, and keywords. On the other hand, the wealth of information available in the network that links resources, users and descriptions makes it impossible to create a single image able to express its complexity.

In order to address this issue, the cartographic metaphor has been applied to the design of an interface to research spaces, with the aim to create not so much a single totalizing view of the observed area, as a series of maps designed to describe the relationships between its components, the pathways develop between them, and the transdisciplinary themes that emerge.

The complexity of the information gathered by the system is represented through a series of partial maps, held together by an atlas, a representation system that acts as container of points of view. Building on a cartographic rhetoric of knowledge spaces, information and data entered by the users are selected, filtered, prepared, screened and symbolized in order to create specific images of the research designed to present specific view of the space.

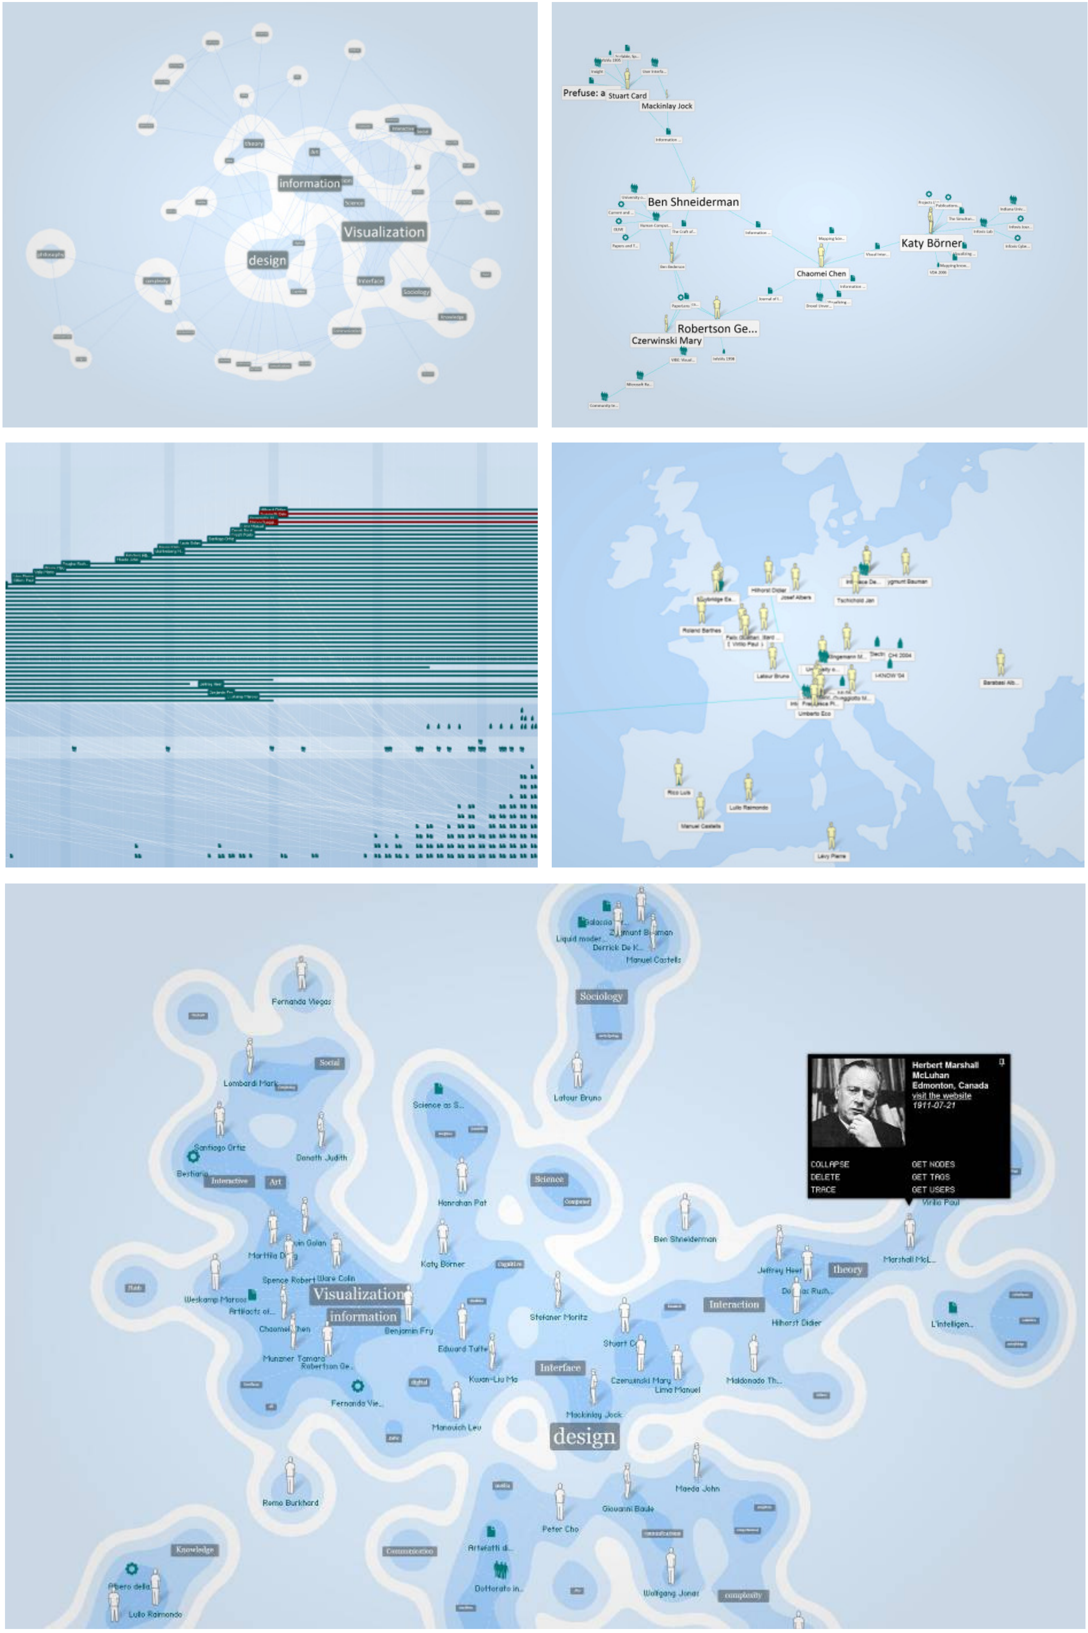

Figure 1 – Sections of the Knowledge Atlas.
Each map displays different aspects of the same complex space.

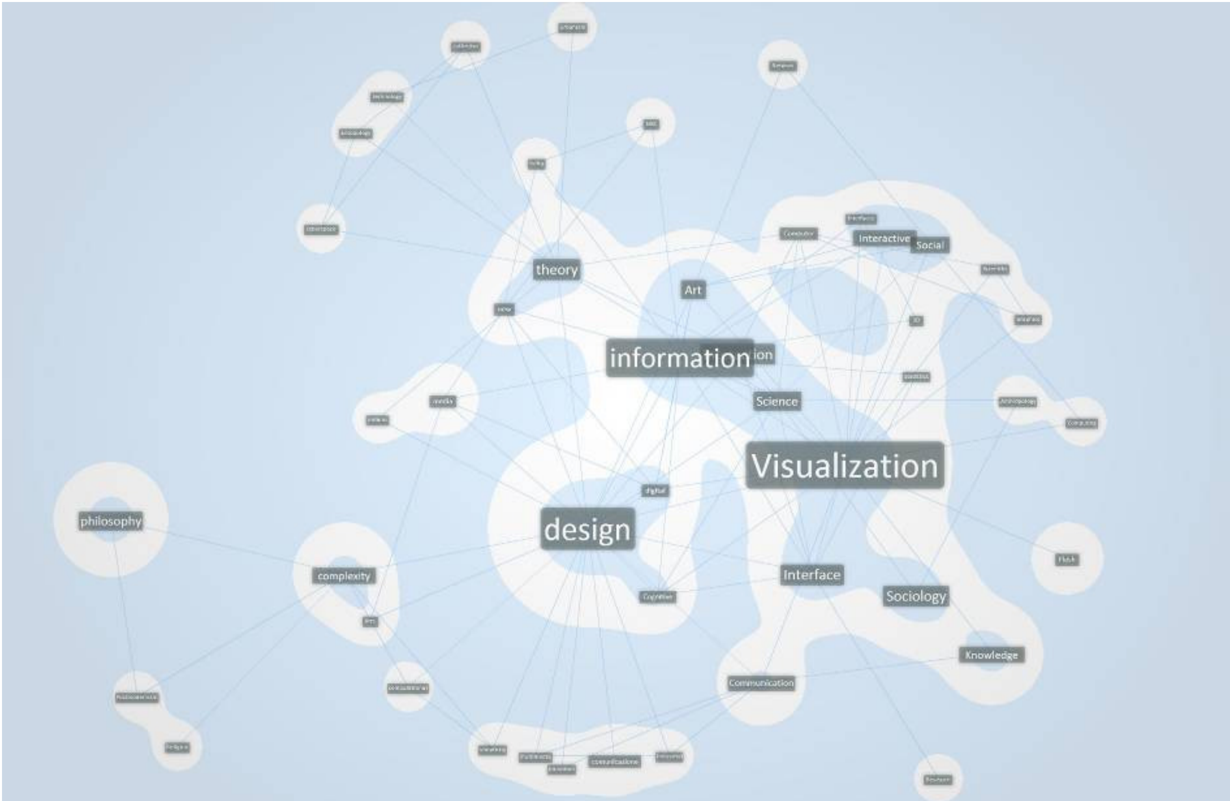

Figure 2 – *Thematic map*. Example typology characterized by focus on themes, subject clusters and implicit domain relationships.

As in traditional cartography, by combining the tools made available by the representation system, the user/designer can manage the rhetorical operations that lead to a potentially unlimited amount of maps. The most successful and most useful combinations eventually will be coded in relatively stable typologies that (with some variability) will be defined by their properties, their role and their use. Despite these typological forms, in the context of *knowledge cartography,* are not as stable as the typologies culturally defined by traditional maps (political, geological, physical maps are defined by strict rules governing their modalities of representation), the *Knowledge Atlas* attempts to propose some typological forms that seem to emerge from the international research on research representation. The atlas format becomes therefore container of *co-authorship maps* that show the relationship between authors, *geo-relational maps* that display the spatial distribution of research-related resources, *events timelines* aimed at describing the sequence of events, *thematic maps* designed to show the subject clusters of research, *relational maps* of the scientific community, etc. (Figure 2)

The connection that links maps and views, which in the paper version of the atlas is served by print-based mechanisms such as indexes, geographic reference systems (grids) and tables, in the digital version of the atlas is expanded to become a set of techniques for the navigation and exploration of space. The static shape of traditional maps is replaced by a map able to change borders, to increase level of magnification, to show or hide details. Areas of particular interest can be enlarged in order to show smaller details by exploiting the mechanisms of scale, or they can be reduced in order to obtain a general overview of the territory heavily focused on the global look of the 'landscape'. Similarly, just as easily it becomes possible not only to switch between visualization models at any time, but also to share with the final user the fundamental operations of cartographic rhetoric. Operations such as those of comparison, navigation and change of viewpoint, find new potentials in the digital tools: the user isn't bounded to a navigation bounded by the cartographer's maps, but he himself is able to create his own maps, aimed at communicating the most interesting, useful or clarifying aspects. The power of maps, historically at the service of power (king, government, church, military) is shared – in some part – with the user.

The Atlas format, once transferred into the digital contexts of software applications, finds its hidden nature: it becomes a meta-interface aimed at providing tools for the representation of complex contexts, a device for the creation and connection of different interfaces. It is not so much artifact as ‘graphic machine’, a system able to articulate set of individual artifacts as expressions of a systemic logic (Baule 2007a). The maps, their typologies and their sequence is generated from time to time according to the user’s needs and directions. Building on the potentials of digital systems, the atlas becomes a potentially unlimited network that collects and links a wide range of maps and pictures that can be modified by users to create narrations, reveal patterns, explore unknown territories or communicate the size and extent of their knowledge space.

Understanding Team Design Communication through the Designer's eye: a Descriptive-Analytic Approach

Chrysi Rapanta, Università della Svizzera italiana, Switzerland, chrysi.rapanta@usi.ch

Luca Botturi, Scuola Universitaria Professionale della Svizzera italiana

Andreas Schmeil, Università della Svizzera italiana, Switzerland

Abstract

The present study is an example of an empirical design research project based on design teams. Our main goal is to describe, understand and analyze the communication processes which take place inside a design team working on a design project for a short period of time. This paper presents the main observations and results of two case studies based on two design fields: Architecture and Graphic design. The paper's contribution lies on the methodology used, combining qualitative and quantitative methods of analysis, and involving the designers' point of view at various steps of the research process. In this way, we consider the value of this study twofold: first, it served as a 'vehicle of communication' between the research team and the design team and second, the structured methodology followed taking into consideration recognized methods, such as Linkography, and adapting them to the communication focus of this study.

Keywords

Design methodology, Team design, Communication, Case studies, Content, Structure, Linkography

The evolution of Team Design research can be marked by two main landmarks, which changed the view of how to focus on design processes: the Delft protocols workshop in 1994 (Cross, Christiaans & Dorst, 1994) and the DTRS7 common dataset analysis (McDonnell & Lloyd, 2009). In the two corresponding collections of papers written by diverse authors focusing on a big range of methodologies, a common tendency can be seen: the more complex the design process gets, the more effort is required by the Design research community to describe and analyze this complexity.

A major aspect of design complexity lies on the fact that design is nowadays mostly carried out by teams, including also others than the designers (e.g., the users) and consisting of people with different backgrounds and disciplines. This has generates an heterogeneity in the communication processes emerging during the meetings in which everyone involved in a specific design project has to be present but is not necessarily active and, even worse, not necessarily 'effective' for the production of the final product. As effectiveness we understand the relation of individual contributions at a cognitive-communicative level with the final team design result.

In order to judge this effectiveness, which additionally forms the basis of the team's best communication practices, an external eye, rather than the designers', is needed. At the same time, the designers' eye on the research processes is the other half of the judgment as they are the ones who know the specific characteristics of their work better than anyone else and the requirements they have to confront also outside the design meetings. For this reason we consider their involvement in the methodology presented below as an essential aspect of the research design process.

Method

Research questions

Having as main goal to describe the effective communication processes taking place in a team of designers, in a brief, as the projects considered were also brief, and communicable way, we posed the following research questions:

1) Are there moments in the team design interaction that can be characterized as more effective than others?
2) Which aspects of communication are relevant to this effectiveness?
3) Are there significant correlations between them?

Participants

The data used for this study is taken from two teams of professional designers at work on real design projects. Both projects had a short overall duration and were completed with the achievement of their goals, i.e., the creation of specific design objects.

In the first case, a team of 6 architects designed a Cultural Center for an international contest. This project ran for 4 months and generated a full submission for the contest, in the form of plans and model pictures. Overall, this project included 6 team design sessions for a total of nearly 10.5 hours. In the second case, a team of 2 graphic designers and their client designed a multiple-content book, authored by the client. The project ran for 3 months, and generated as final output a book on a famous film director. This project included 6 team design sessions for a total of nearly 8.5 hours. For the remainder of this paper the cases will be referred to as case A (for Architecture) and case B (for Book).

Data collection

According to Nardi (2006), in order to best describe an activity taking place in a specific context the following methodological implications have to be taken into consideration:

- A research timeframe long enough to understand actors' objects, which in Activity Theory also represent the goals-objectives (Leontev, 1979);
- A broad data collection, that allows paying attention to broad patterns of activity;
- The use of a varied set of data collection and analysis techniques;
- A commitment to understanding things from the actors' points of view.

Following the above principles, our method of analysis can be summarized in four steps, which are presented and discussed in more detail in the following paragraphs:

1. Following the participants during the whole duration of the project, understanding its context and specific features from the point of view of the professional life of the designers. In particular, we audio- and video recorded all team meetings for later analysis.
2. Focusing on the activity of participants both as individual contributions (moves) and team processes and interactions, namely by coding the recorded protocol in *cognitive-communicative acts* and then segmenting the coded protocol in *design episodes.*
3. Analyzing design episodes according to a number of parameters, blending different design analysis methodologies.
4. Discussing the content, structure and significance of these episodes with the designers themselves, in order to reach a level of consensus on their own communication processes.

STEP 1: Starting from the beginning

Following the principles stated above, to the purposes of this research study, we contacted designers which were about to start new projects with a duration compatible with the time constraints of our research. We then engaged the participants in a conversation about the project, asking them to present the project and identify its specific features from two points of view: the project itself (e.g., the peculiar kind of content for the book in Case B), or its position in the professional career of the involved designers (e.g., the fact that it was the first submission to an international contest for the team of Case A). Collecting such information was important for defining the framework of the design projects, along with the frame of mind of involved designers. This was indeed central for being later able to interpret their feedback on the analysis and to identify the relevant design features of the output.

We then video-recorded all design meetings. While large part of the activities carried out within design projects are individual activities, when a team is involved, design meetings represent project milestones: it is there when individual contributions come together and are shared and blended, when tasks are assigned, when ideas must find effective expression and representation in order to become shared and actually contribute to the project.

STEP 2: Segmenting episodes and coding acts

Following the nature of the projects, video recordings were organized in *design sessions*. Our main unit of analysis was the *episode*, intended as a significant temporal segment of a design session. Other scholars in Design Research have also chosen design episodes as the main units of analysis (in Cross, Christiaans & Dorst, 1996; McDonnell & Lloyd, 2009). In short, the granularity of episodes and the criteria for their definition (i.e., for segmentation) remain under-studied issues both in Conversational Analysis and in Design Research.

Our definition of episode is very similar to Wheatley's (1995) *topic type*, which refers to "a unit of talk that shares some of the attributes of Levinson's *activity types* and discourse *topics*" (in Firth, 1995, p. 379). The equivalent of our design episodes in discourse analysis would be what Sinclair and Coulthard (1992) call *transactions*. However, in our study we did not follow strictly these authors' indications for two reasons: (a) because of the lack of analysis of the transactions' main components, i.e. *exchanges and sequences*; and (b) because of the so-called "anarchy" in the design discourse, due to an "opportunistic movement between topics" (McDonnell, 2009, p.252).

Given this situation, we defined two criteria for the distinction between episodes: (a) topic-shift and (b) goal-shift. This means that each time that an explicit introduction of a new topic happens, or a new goal emerges during the interaction, a new episode begins.

Each video-recorded session was therefore transformed into communication protocols, which were composed of design episodes, each composed by several moves. *Moves* refer to each participant's contributions in the interaction and correspond to the smaller unit of analysis after acts (Sinclair & Coulthard, 1992). As these authors declare "a move boundary signals a change in the speaker who is composing/creating the discourse, and therefore a move boundary is a potential change in the direction of the discourse" (p. 23). In Design Research, Goldschmidt's (1992) description is one of the most representative: "The meaning of a 'move' in designing is akin to its meaning in chess: a design move is a step, an act, an operation, which transforms the design situation relative to the state in which it was prior to that move" (p. 72). As for episodes, for the granularity of the moves we again consider two main criteria of change of state: topic-shift and goal-shift. The difference here is that for moves, topics refer to individual representations and goals to person-derived goals.

Each move was then tagged with a *theme* and a *keyword*. This protocol, and not a full transcript, was used for coding and analysis.

Finally, each move was coded according to a framework of cognitive-communicative acts, to which the moves correspond in a design interaction. Each act is described by an action (e.g., *present*) and an object (e.g., *data*). The framework included the categories presented in Table 1. An example of a coded episode can be seen in Figure 1.

			Object			
			Data	*Solution*	*Plan*	*Goal*
Action	*Present*	make explicit, generate	P(d)	P(s)	P(p)	P(g)

STEP 3: Episode analysis

The main focus of this paper is on communication episodes as main unit of analysis. This was operationalized as a threefold analysis, which included their *content*, *structure* and *relevance*.

Content. As we already implied above, content refers to two main entities, distinguished for the purposes of this study: the *theme* and the *keyword*. The *theme* refers to the context or to the common ground of the discourse (Hajicova, Hall Partee & Sgall, 1998), whereas the notion of *keyword* was created to refer to Akin's (1986) *thing* or *relationship* to which a move is focused on. The theme is related to the topic in the following way (Katz, 1980): "The notion of a discourse topic is that of the common theme of the previous sentences in the discourse, the topic carried form sentence to sentence as the subject of their predication" (p. 26). Perfetti & Goldman (1974) add: "By thematisation we mean the discourse process by which a referent comes to be developed as the central subject of the discourse" (p. 71). In conclusion and according to our use of the notions *topic* and *theme,* topic refers to a more general conversational object, usually composed of many themes, which in their turn consist of at least one referent – what we call *keyword* for reasons of simplification- which has become part of the common ground of the speakers.

Structure. As far as the structure of an episode is concerned, we were mainly interested in:

1) *Time duration*: absolute and in relation to the whole session.
2) *Number of active participants*: absolute number and in relation to the total number of team members present during the session.
3) Identification of *the person(s) who initiates and finalizes* the episode (related to roles).
4) *Number and type of cognitive acts* belonging to the episode.
5) *Number of links* among identical keywords inside an episode; this measure is an adaptation of the method of linkography which is already applied on team design protocols (e.g., Goldschmidt & Weil, 1998). Our adaptation consists in considering only inter-episode links, taking therefore into consideration that the topic currently under discussion, which is usually the same during one episode, promotes the use of certain keywords and prevents others.
6) the *type of links* belonging to an episode. We mainly distinguish between two types of links: neutral and relevant links. Relevant links in this study are those which link between relevant keywords, i.e. keywords directly referring to aspects of the final design object.

Relevance. To the purposes of this research study, we defined relevance as the relationship between episodes and the final design product. Conceptually, an episode is relevant to the design project if it provided ideas, features or decisions that were eventually positively reflected in the final product. In order to determine relevance, after the design projects were concluded, we had a special session with the lead designers, and asked them to select relevant features of the final design product from the list of keywords from our protocols (see below). This served as a benchmark for the analysis. Relevance can refer either to content or to structure. In the case of content, we consider the *relevance of keywords* in relation to the final product; in the case of structure, we consider *relevance of links* in relation to the number of linked relevant keywords inside an episode. Formulas are presented in Figure 2.

$$\frac{\text{\# relevant keywords in episode}}{\text{\# keywords in episode}}$$

Formula for relevance of keywords (content)

$$\frac{\text{\# links to/from relevant keywords in episode}}{\text{\# links in episode}}$$

Formula for relevance of links (structure)

Figure 2 Formulas of "relevance" used in the study

STEP 4: Feeding back to the designers

The participant designers were involved in the research process mainly in two ways: deciding on the relevance of the keywords and discussing the choice of some episodes as more relevant than the others.

Deciding on the relevance of the keywords

After having tagged each one of the protocol's moves with a keyword, we came up with a list of all the keywords referred during the six sessions of each project and their occurrence in the whole protocol. In the following table we show the keywords with the highest occurrence of both analyzed projects.

CASE A: Architects		**CASE B: Graphic designers**	
space	access	images	cover
shape	building	contents	texts
dimensions	texture	dimensions	pages
performance hall	patterns	structure	translations
wrapping	internal-external	corrections	order
piece of city	stone	history	poetries
volume	«souk»	report cards	family images
empty space	continuity	authors	PDF
underground	route	index	costs
facade	square	position	titles
quality	symbols	scripts	form
surface	external	material	color
internal	green	father	notes
costs	requisites	format	tetralogy
materials	structure	images	interviews

Table 2 Some of the keywords emerged

The second step consisted of a grounded analysis (Glaser & Strauss, 1967) based on the produced list of keywords and their corresponding theme, according to the already coded protocol. This kind of qualitative analysis permits both to define categories as emerging from the data and to classify contents into these categories and not according to pre-defined and frequently biased taxonomies. Finally three big categories emerged for both projects, named: Problems, Solutions and Constraints-Requirements. In Case A, another small category was added called 'Examples'. Solutions were further categorized as belonging to one of the problems.

In the third step, the responsible of each design team was asked to help the research team in defining the integration of the keywords emerged into the final product. This co-decision turned out to be necessary, especially in the case of Architects as their final product was a projected model and not a physical building. During our discussions we mainly defined the use or non-use of each solution proposed, which of the requirements-constraints were related to which solutions and finally, only in Case A, which of the examples emerged during the discussions served as base for which implemented solution. Having done all that, we were able to determine the relevance of the problems, solutions, examples and requirements-constraints discussed throughout the projects.

Feedback to and from the designers

Once the most significant episodes were selected, a Focus Group session was organized with the design teams. The structure of these sessions followed the basic steps of an ordinary Focus Group meeting (Morgan & Krueger, 1998); however, the content of discussion was formed on the basis of Video Interaction Analysis methods (Jordan & Henderson, 1995).

More precisely, we showed the team the video clips of the episodes we selected and we discussed their content and structure, the other two measures of our analysis. Some representative issues of discussion brought up during the Focus Group sessions are:

- What is happening in this episode?
- How would you evaluate the team's communication in this episode?
- Is this episode relevant to the final solution? If so, how?

One of our goals was also to give and get feedback on the types and identification of the 14 cognitive-communicative acts we selected as codes for the protocol construction. We consider that the predominance and sequence of these acts gives a first image of the team communication dynamics constructed around a complex cognitive object, such as the design object. Moreover, the categories selected are understandable and communicable also to non-experts. However, we could not be sure about the adequacy of our selection until we tried out a test of inter-rater reliability having as raters one of the authors and 5 members of team A. The results were satisfying (K=0,65) considering also the difficulty of agreement in such types of coding schemes (Goldschmidt & Weil, 1998), and the lack of clear explanations for each category. The improvement of the coding scheme is one of our future goals.

Results

From the analysis described in the previous section, a respectable amount of data regarding team communication processes emerged. However, their treatment and statistic analysis was adapted to this study's goal and more precisely to give answers to the following main questions:

- Which are the characteristics of the episode with the highest structure and content relevance?
- Is there a significant correlation between these characteristics?

First of all, we needed to know which of the 206 episodes in total (of both cases) were more relevant in terms of content and structure. In order to do that, we selected all cases which appeared having very high structure and content relevance at the same time. Our analysis turned out with 7 out of 85 most relevant episodes for Case A and 12 out of 121 for Case B. These episodes where the ones which formed the base of discussion with the two teams during the focus group meetings.

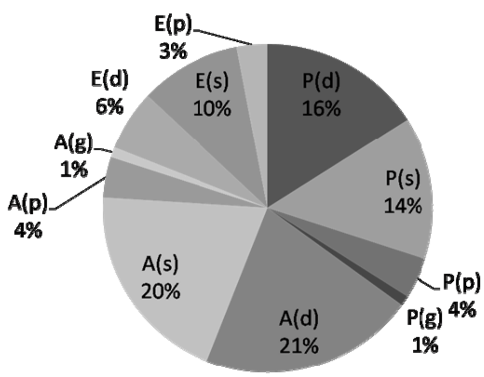
Secondly, we were interested in describing these highly relevant episodes using the measures discussed previously. Table 3 shows some general characteristics we considered representative of the team communication process such as the session in which the episode appears in, the number of active participants, the time proportion that the episode occupies in the whole session etc.

Case	session	active participants	duration in session	first speaker	second speaker	last speaker	total acts	predominant act
A	2	4 of 5	12.7%	3	2	3	33	A(s), P(s)
A	3	4 of 6	4.8%	1	2	2	26	A(s)
A	3	5 of 7	6.4%	1	2	2	31	P(d)

A	3	3 of 6	7.4%	1	4	3	27	E(s)
A	4	4 of 6	7.7%	3	1	3	25	P(s)
A	4	4 of 6	8.2%	1	3	1	30	E(s)
A	6	4 of 5	9.9%	1	4	1	25	P(s)
B	1	2 of 3	8.4%	1	2	1	22	A(d)
B	1	3 of 3	2.4%	1	2	2	16	E(p), P(p)
B	1	2 of 3	4.1%	1	2	1	19	E(d)
B	2	3 of 3	13.0%	1	2	2	13	E(p), A(p), A(d)
B	3	2 of 2	5.0%	1	2	2	10	-
B	3	2 of 2	4.8%	1	2	2	19	P(s)
B	4	2 of 3	7.4%	2	1	1	25	P(s)
B	5	2 of 3	3.3%	1	2	1	14	A(d), P(s)
B	5	2 of 3	8.4%	1	2	1	32	E(s),P(s)
B	6	2 of 2	2.3%	1	2	1	22	P(s)
B	6	2 of 2	4.2%	1	2	1	16	P(s)
B	6	2 of 2	2.5%	1	2	2	10	-

Table 3 Some descriptive characteristics of the most relevant episodes

These descriptives were used as a “vehicle of communication” between us and the designers at the time we wanted to make them reflect on their communication processes. We also considered necessary to give them a more detailed image of their use of cognitive-communicative acts during these highly relevant instances of the project. Figure 3 shows the distribution of the appearing acts in both cases always inside the 19 episodes’ time.



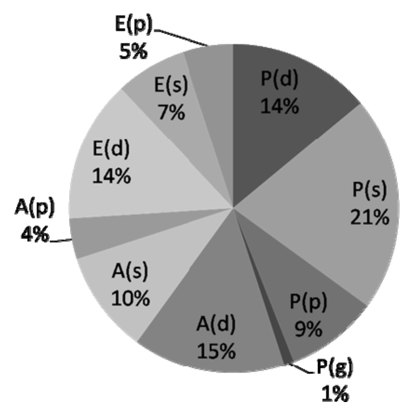


Figure 3 The distribution of the appearing acts during the most relevant episodes in Case A and Case B

Significance of correlations was also examined in order to check the reliability of the methods used. Table 4 shows some of the significant correlations emerged between the variables used.

	Duration in session	Active participants	First speaker	Total acts	Total links	Content relevance	Structure relevance
Duration in session	-						
Active participants	.035	-					
First speaker	.139*	-.091	-				
Total acts	**.851****	.119	**.154***	-			
Total links	**.310****	**.425****	-.131	**.458****	-		
Content relevance	-.103	**.377****	**-.223****	-.067	**.368****	-	
Structure relevance	-.027	**.310****	**-.135**	.014	**.303****	**.791****	-

Table 4 Pearson correlations for the sample N= 206 (* p > 0.05, ** p> 0.01)

Discussion

First of all, some interesting comparisons between the two cases emerge regarding their relevant episodes. The distribution of the relevant episodes among the sessions doesn't seem to follow any general rules. We can assume that it depends on the very specific characteristics of the project and the team. In Case A, for example, session 5 was dedicated to the application of solutions already discussed and this could explain why relevant episodes do not emerge. In Case B, the first and last sessions seem to be the most relevant: the first session was dedicated to the explanation of the project from the client to the designers and the final solutions were mostly presented in the last 2 sessions, after the complexity of the material was more or less resolved.

It is interesting that in all relevant episodes half or more of the participants are active. However, our small sample does not allow considering this observation as a pre-condition. Also, the type of participation has to be controlled before getting to generalizations.

The length of duration of these episodes, compared to the total duration of the corresponding session, does not seem to be significant as it is also confirmed by Table 4.

As far as the identity of the first, second and last speaker is concerned, it is interesting to notice that in all cases the second speaker is different than the first. Given that in our study 'speaker' corresponds to a person who makes a move, it is possible that a sequence is composed of more than one moves of the same speaker. Another interesting observation is that the last speaker almost always, in 17 out of 19 cases, corresponds to one of the two initiators of the episode.

No reliable observation can be made about the influence of the number of total acts, as this measure is significantly subject to the episode's duration as we can see on Table 4.

Nonetheless, the type of cognitive-communicative acts inside the episode seem to have some comparable characteristics between the two cases: a) in each episode distribution, 'solution' is the main action's object in both cases, and b) in all episode distribution, the action of 'analysis' is most predominant one and together with the action of 'evaluation' overpass the action of 'present'. This is interesting if we consider that in Case A the most frequent act is ‘present’ rather than ‘analyze’ and in Case B the most predominant object is ‘data’ instead of ‘solution’.

The most significant correlations, marked in bold in Table 4, turn out to be:

- Between Content Relevance and Structure Relevance: the more relevance there is between the content of the discussion and the final design product, the more this content is linked with other episodes before and/or after the episode under analysis.
- Between Total links and both Relevances: this is a confirmation that the method of Linkography is a representative measure of both the content and the structure of a design process.
- Between Total links and Active participants: the more participants are active in the episode, the more links in the structure of the process are created.

Conclusions

The present study’s goal was to construct and apply a method of description and analysis of the team design processes sufficient and adequate enough to respond to two requirements: (a) to shed light onto the communication processes of two diverse teams designing a specific design object in a short-time period and (b) to describe and analyze this process in a meaningful way for the designers involved.

Taking into consideration that this paper forms only a part of an ongoing research on team design processes, we should mention that the present focus is limited to some macro-observations without getting into further detail which we consider to be necessary in order to be more precise in our results and communications to the designers. In addition, this paper’s contribution should be seen considering the notable lack of precise and efficient methods in both fields of Small Team Communication and Team Design Research. Regarding the limited literature and confrontation, especially in the latter field, we conclude with mentioning our contributions and implications for further work.

Regarding the method used, it can be broadly considered as an extension of the Linkography method (Goldschmidt, 1992; Goldschmidt & Weil, 1998). Our innovation lies on the following facts: a) we didn’t transcribe the whole discourse; instead, we coded the whole communication that took place for both studies creating in this way an extended protocol to work on, b) our coding relies entirely on natural setting communications – no thinking aloud protocols were used and c) the links were constructed between keywords to which the moves were referred; these keywords sometimes were uttered exactly the same by the designers and some other times we had to infer them from the context. In this way, we gave a pragmatic dimension to the concepts used and, as a result, their connection with the final characteristics of the design object made more sense.

Moreover, the combination of the method described above with other methods deriving from the Cognitive Ergonomics field, regarding the use of the coding scheme, and from the Communication field, regarding the granulation of the episodes and their discursive structure, resulted in the production of various observations, with a high significance in a great number of them. Finally, the introduction of the measure of ‘relevance’ and its double definition as ‘content relevance’ and ‘structure relevance’ was proven efficient at the time of selecting a small number of episodes as more representative of the team design process. A constraint of this research device is the need for active involvement of the participant designers and their collaboration during the entire research timeline.

Future work includes adding more cases from other design fields, further controlling the reliability of the coding and segmenting methods and analyzing the most relevant episodes also from dialectic and argumentative points of view so that a more detailed view of the micro-communication processes can be given. Participant roles is another issue not thoroughly considered by this paper and which needs further characterization regarding not only the behavioral aspects but also the epistemic dimensions (as in Baker et al., 2009).

Diagrams for socio-technical controversies

Donato Ricci, Politecnico di Milano, donato.ricci@mail.polimi.it

Abstract

The opening of enormous databases and the possibility offered by new tools to access the heterogeneous flows of data and information emerging from the Internet could be seen as an innovative mode also to observe and represent social complex systems. The *cartography of controversies*, the applied version of the Actor-Network Theory (ANT), is one of the examples of this new way of exploring and understanding these new information and knowledge domains. The cartography of controversies also aims at overcoming some of the limits of the traditional description of social issues by exploiting the potentialities of the *information visualization* and of the *information design*. In this framework visual models and diagrammatic devices are assumed as useful tools to describe the different position assumed by the actors of controversy. A distinctive feature of these, heterogeneous and non-isotopic, spaces is the absence of *unique metrics* to deal with them. The absence of reference points requires endowing with technical and conceptual tools for understanding and grasping the dynamics and the processes, which characterize them. Diagrams are here considered as operating devices able to describe and unveil the nested and latent connections of a system.

A real case has been choose to develop and test the capability of diagrammatic models to observe and describe controversies and to show the point of view of the actors involved in it: the remote control of dangerous materials transportation in road.

The research is strongly related to the development of the *Turtle Project*: a series of visual tools and diagrammatic devices able to explore controversies. It could be defined as an observation environment of the discursive knowledge flowing through the Internet, offering the possibility to make profit both from quantitative and qualitative research methods.

Some results about the chosen controversy are discussed as well as the limit of the tools.

Keywords

Social Complexity, diagrams, controversies, Actor-Network Theory, cartography of controversy, content analysis, discourse analysis.

New domains to visualize

It seems that the traditional modes of accessing, observing and representing social complexity are changing thanks to the opening of enormous databases and new tools to access heterogeneous flows of information (Latour, 2007).This hypothesis, supported also by Lev Manovich (2001, 2006), redefines a new emerging cultural form to capture, explain and discuss the complexity of reality, but it should be reshaped and extended. A more accurate analysis should be carried on two aspects strictly related to design discipline and more specifically to communication design practice. Communication design tools could be used as strategic devices able to read and narrate the dynamics that shape the current space of information and knowledge (Bonsiepe, 2000). On one side, theoretical remarks should concern the access to data, which, gathered from different fields of study, produce a new relationship between qualitative and quantitative methods; on the other side, empirical experimentations should be deployed on the modes through which these spaces are synthesized and translated into narrative devices[1]. These two aspects, only apparently

[1]The key concepts about the capabilities of visual tools refer to some theories born in the cognitive sciences with Johnson-Laird and particularly on the effectiveness of images, graphs, maps and more generally the class of diagrams, not only in mnemonic tasks (Yates, 1974), but also in those of complex reasoning and orientation between

sequential, can be merged into a new dimension that overcomes epistemological borders: beside a strongly codified knowledge are associated new relational and dynamic ones. This new domain requires also new modes of observation and representation. Indeed, it is emerging an area study labeled as *knowledge visualization* (Okada, Shum, & Sherborne, 2008; Shum & Okada, 2008), quite similar to the *information visualization* and to the *information design*, that aims to depict spatially knowledge domains (Shiffrin & Börner, 2004).

From visualization to controversies

The *cartography of controversies*[2], developed by Bruno Latour as an applied version of the Actor-Network Theory (ANT) (Latour, 1999, 2005), is one of the examples of this new way of exploring and understanding these new information and knowledge domains. The ANT approach tries to comprehend social and knowledge issues as complex network made up by relationship between heterogeneous actors, objects and discourses.

One of the most innovative elements of cartography of controversies is how the description of the analyzed complex social system is performed. The limits of a pure analytical approach, based on textual forms, are also shown by the increasing achievement of system theories and of complexity science. Alongside to text and discourse, visual models should be a mode of representation that does not divides or analyzes the elements separately but studies them in an interconnected and indivisible manner. *Images* thus could assume a role of primary importance: able to describe elements as a whole without dividing them, it becomes an irreplaceable instrument for depicting qualities of systems otherwise difficult to interpret. The aim is to explore, to integrate and depict the enormous informative richness produced by the actors through communication devices able to assemble information and practices even apparently unrelated, in a single *optically coherent space* (Venturini, 2008). The cartography of controversies aims at overcoming some of the limits of the traditional textual narrative description by exploiting the potentialities of the *information visualization* and of the *information design* to observe social phenomena.

Smooth spaces and points of view

Under certain aspects ANT shares with Complexity theories, and particularly with social complexity, not only the interest in complex networks[3]. Indeed, some features of the complex systems[4] show resemblances with the controversies, as the dynamicity due to a high number of agents and actors and the non-compressibility due to non-linear interactions. Furthermore, the very same definition of controversy makes reference to open dimensions, with a priori non-definable boundaries. They are indefinable as the Complex systems are, bringing to an impossible exhaustive, stable and complete knowledge[5]. The possibility of understanding these systems depends also on the production of *dialogical* models able to compare different data, information and knowledge. The dialogical models configure themselves as a representation of *smooth spaces* (Deleuze & Guattari, 2006*)* animated by different tensions which do not appear as unique and compact realities, but composed by fragments and heterogeneous pieces (Marzocca, 1994). A distinctive feature of these, heterogeneous and non-isotopic, spaces is the absence of *unique metrics* to deal with them. The absence of reference points requires endowing with technical and

---

a high number of data and information (Berthoz, 2006).

[2]The *cartography of controversies* can be defined as a set of techniques for observing and describing, as well as to explore and visualize social issues, especially but not exclusively, *socio-technical systems*. The word controversy refers as a neutral term, to a shared uncertainty or to *«a debate surrounding a technique or scientific fact that has not yet been determined»*. Its aim is to open the *black boxes* of techno-scientific truth and observe empirically how they are constructed through a widened and non-linear process of negotiation. At a conceptual level all the controversies, even though each one is essentially unique, have some common characteristics (Law, 2004):

- A high number and high diversity of actors and agents involved;
- A high dynamics of relations between actors and agents;
- A marked non-reducibility and compressibility;
- A dialectic but conflicting form.

[3]In the *latourian* cartography every social event is described as a heterogeneous network of connections where actors are constantly working to bind or dissolve their mutual links.

[4]See also (Cilliers, 1998).

[5]Even if it is assume to be able to obtain all the data about a Complex system it would be impossible use them, coming to a situation of *information overload*. See in this regard (Ricci, Ciuccarelli, & Valsecchi, 2008; Scagnetti, Ricci, Baule, & Ciuccarelli, 2007).

conceptual tools for understanding and grasping the dynamics and the processes, which characterize them. Also according to the cartography of controversies, each approach to the knowledge spaces can exist only from subjective and partial point of views. The only objectivity accepted by the social epistemology is a second order objectivity, which is the attempt of understanding a system as a unique object through the highest number of possible point of views, even those in opposition. This position, often accused of radical relativism, is interested more in the *"truth of the relationships"* rather than in *"the relativity of the truth*[6]*"*. In this way the Latourian relativism is the opposite of the point of view absolutism, i.e. the evident willingness of not comparing or of not linking one of the vision of the world with the possible others, of not establishing a dialogue with them. It is a *dialogue* able to disclose a deeper knowledge of the analyzed controversy.

The bridging artefacts of communication design

The capability of the communication design of building languages and tools, first of all visual ones, should be oriented also to the construction of bridging artifacts, in order to connect different point of views, social contingencies and manifold interests, structural features of a Complex social system. One of the raising challenges is the representation of smooth and complex spaces (Scagnetti et al., 2007), which are also spaces of knowledge and controversies. Visual models could help in describing, in a tangible manner, the different position assumed by the actors of a complex system and their point of view, developing mutable explanations of the reasoning processes as well as the data cognition processes paths, which underpin their assertions. It is a very process of translating the actors' mental models (Laird, 1988; Norman, 1996; Preece et al., 1994) into a shareable form. It is a focus, which moves from identifying the possible controversies solutions to assisting the actors of the social transformation in underlining the social, economic and organizational dynamics through the constructions of artifacts:

- *open* to the possibility of recombining data and heterogeneous information;
- *inclusive* in the possibility of telling plausible visions regarding the system perception, offering an optically correct device, maintaining and preserving the multiple interpretations, produced by a space of controversies.

Diagrammatic devices

The challenge is that of showing the multiplicity of viewpoints and stressing the different narration typologies which underpin them. Besides, it has to point out where the different interpretations overlap and where they diverge. At the same time it has to be shown how the information characterizes the very nature of the system. It is, then, necessary a notation system, which explains the controversies dynamics. Diagrammatic modes of visualization (Scagnetti et al., 2007; Ricci et al., 2008; Ricci, 2009) seem to be particularly adapted to achieve the above mentioned goals. In this context diagram are considered as operating devices able to describe and unveil also the nested and latent connections of a system. When design is addressing complexity, diagrams could become generative tools that can be used to generate *metadata* relevant to the design process. Diagrams effectiveness lays in the ability to act as go-between with explicative functions of the different correlated quantities (Abrams & Hall, 2006; van Berkel & Bos, 1998; Corbellini, 2007), as a sort of *graphic short-cut* for the representation of complex phenomena. Indeed diagrams and maps are media between what is known about a system and what the system is; they could display not only quantitative data but also ideas, concepts, frames, schemes, viewpoints, perspectives and values of the system observer. The aim is not that of representing fixed positions in space and time, but rather of rendering in a visual language the actors' mutable tensions and the strengths fields produced during a controversy.

In this research field have been conceived, first conceptually and then in an empirical form[7], two diagrammatic tools to manage the three main dimension of a social complex system: time, actors

[6] See also (Deleuze, 1990).

[7] This research is related to a wider field in the framework of the DensityDesign Lab. The aim of this line of research is to verify the power of communication artifacts in helping decision making processes and their ability to facilitate dialogue within participatory design actions. For more information see densitydesign.org

and interactions. Each of them has the objective of transforming and formatting in a common form data and knowledge produced by each actor belonging to the system. The proposed approach discussed in this paper is different from others in which the main effort is to develop formal model and algorithms for computer simulations, and where visual codes are strongly codified. Here, the objective is to set up a visual language mixing up digital information to depict, through the observer interactions, how agreement areas and disagree ones are generated. The real goal is to build narrative models (Bruner, 2005) preserving the informative richness but bearing in mind that every analysis reduce and compress.

Choosing a real controversy

This research has seen, since the very beginning, a profitable collaboration with the Mobility and Transportation Laboratory (LMT) of the Politecnico di Milano, in order to test on a real case both the theoretical concepts and the diagrammatic tools of this work.

From a series of interviews and collective discussions with the LTM research group, it has been found the most interesting case to be tested: the remote control of dangerous materials transportation in road. The selected social-technical system is constituted by many actors, very different each other and facing a deep transformation. On one side the legislative modifications are causing a deep transformation of the entire industry; on the other the whole transportation industry has changed is dynamics, which are still facing a redefinition process. This industry is characterized by a hyper-fragmentation of the transporters, which are action as single firms. Another featuring phenomenon is the evolution of the shipment management technique, producing enormous data to be analyzed. If on side this could be interpreted as a raising efficiency but on the other as privacy and independence loss of the myriad of involved transporters. This is causing a lot of frictions both on the experimentations of the info-mobility technologies and to the implementation of clear and sustainable laws. The research effort is also to set-up tools useful for a profitable discussion among transporters, legislative and technological actors.

Setting up the research method and strategy

Once the observation field has been defined, an approach to generate the dataset and a method to elaborate them in order to observe the controversy has been chosen. Many are the difficulties linked to the direct observation of a controversy (Venturini, 2009) and in general to observe all the social complex system since expanding themselves in space and time. The observation of social and technical system is like a constant collection of materials produced by the actions of the several actors, present in different time and places. It is an integration work, which finds in the digital dynamics of the Internet an affinity almost elective (R. Rogers, 2002, 2004, 2009). Differently from many digital research methods, which by the automation of some mathematical algorithms build networks and rebuild connections, among the different actors of a controversy, in this research the aim is to try developing and testing semi-automated tools focused on the semantic content and structure of information. During a controversy every actors constantly leave some traces, which could be seen a potential heterogeneous database: made up by the interview transcriptions, official reports, statistical data, operating and normative procedures, and industry analyses and media news. All these traces share, regarding the research hypothesis, the shape in which they are generated. They belong to a social structure, reflecting also the point of view of each actor. They are part of different discourses by which each actor tries to further and enhance its position within the network and in the controversy developing path. Among the various qualitative research methodologies, through the use of discourse analysis[8], it is possible to try to

---

[8]The text, language and discourse are seen within the methodologies of *discourse analysis* as *objects* able to provide representations on how things are, how they were, and how they could be or should be. Discourse creates three types of interdependent social and cultural meanings that define a mental model. In our field of research:

- It creates representations of activities and events – it is the discourse "semantic function" through which we define the concepts, ranks them, they are enumerated and assigned attributes ;
- It constructs the viewpoint of each actor and social relations – it is "the pragmatic function" building social and emotional ties to some issues brought forward by other stakeholders, whether real or not, and to other points of view;
- It creates the relationship with the environment – it is the function that organizes the contents of the texts and discourses, that create the sense and narrative structures, it also related to other forms texts such as the data

understand, unveil and construct how the positions in the networks are related to this traces and discourses. The discourse analysis, in fact, examines how the social word is constituted by the meaning of discursive practices: it interprets them.

This work, from a technological point of view posits itself above information and discursive flows, related to a controversy developed in the Internet. With adequate tools, such as crawlers and ad hoc research engines the traces of a controversy emerge and they can be observed. The data gathering finds in the Internet not only a precious *box*, which contains the elements to reassemble the network and the dynamics of a controversy. Stemming from the previous statements, the *Turtle Project* has been conceived. It is made up by a series of tools and devices able to explore controversies and could be defined as an observation environment of the discursive knowledge flowing through the Internet.

Turtle is able to grasp significant discursive data exploiting the potentialities implicit in RSS feed system. For this project an RSS is a constant source of information related to specific actor. Each RSS feed is associated to an actor, vice versa each actor could be related to a more than one RSS feed. *Turtle* is periodically monitoring the feed list for each actor, and it finds relevant news and traces for the analyzed controversy thanks to a keyword matrix. In order to build an extensive list of RSS feeds related to each actor, some tools have been borrowed from the Digital Methods Initiative. They are complementary to the *Turtle* project: in particular the *Lippmannian Device* also knew as Google Scraper, which has been used to attain a series of valid URLs, from which extracts the RSS in relation to the dangerous goods transportations. This process has been carried on in the following way:

1. The first two hundred results of a traditional Google research with the query “Trasporti” have been selected;
2. The multiple hosts, the links from Wikipedia, images and videos have been deleted;
3. The remaining results have been processed by the *Lippmannian Device*, with the query “merci pericolose”*;*
4. With another tools have been extracted the RSS;
5. A weighted list of one hundred and sixteen results related to the controversy has been build;
6. The list has been enlarged by adding the most important Italian journalistic headlines;
7. Exploring this website list, have been generated twelve clusters of actors.

At this time *Turtle* is able to automatically perceive the information produced in real time by the actors. Since an RSS can produce information not strictly related to the observed controversy, a semantic correspondence between the information content and a list of keyword related to the dangerous goods transportation is performed. Furthermore, if an information is considered relevant, from it are extracted the most important words. To sum up, to each actor are associated some RSS feed from which are extracted the relevant information. The main contents come by the latter. Furthermore, performing a Content Analysis process *Turtle* is also able to give some quantitative insights about the observed controversy[9].

---

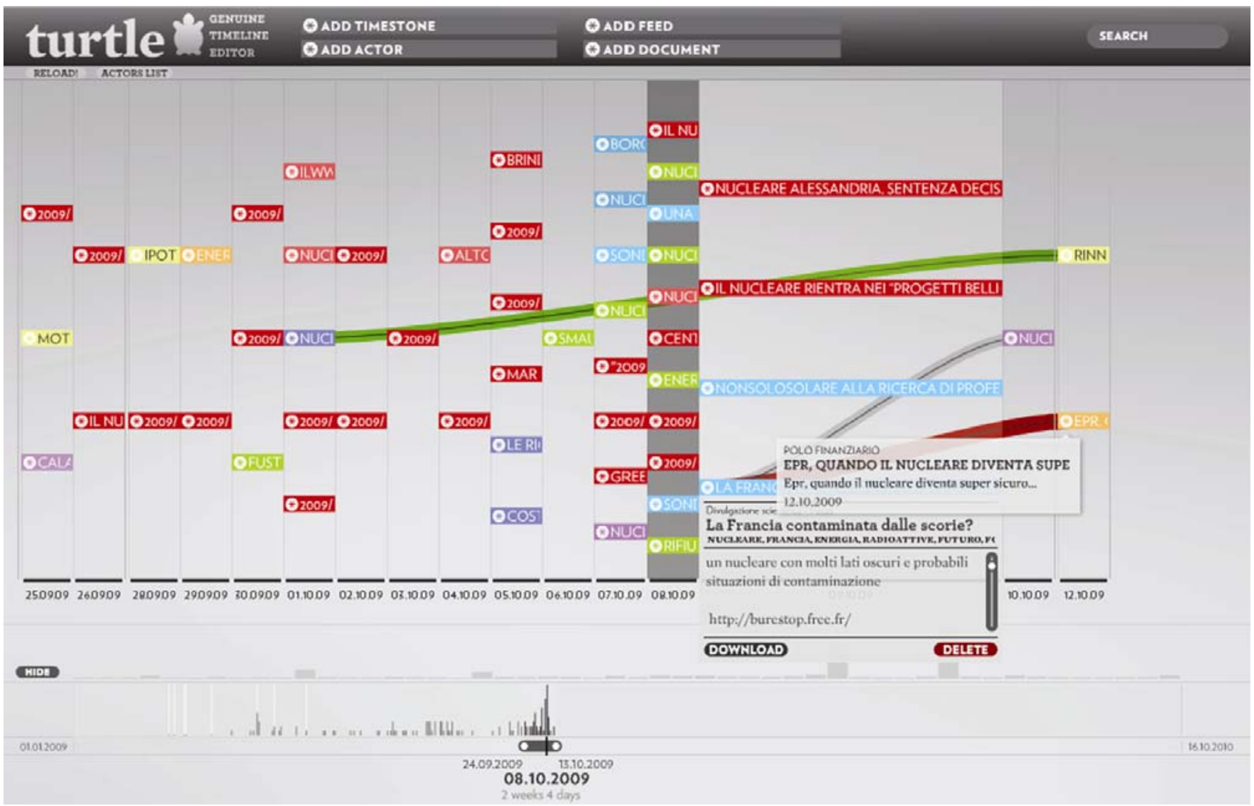
or images.

The concept is often vague, or used with different meanings depending on context. A useful description is given by Marike Finlay (1987): *«[...]discourse analysis is the study of the way in which an object or idea [...] is taken up by various institutions and epistemological positions, and of the way in which those institutions and positions treat it. [it] studies the way in which objects or ideas are spoken about [...]».*

[9]Content analysis is a method used to transform non-numeric and symbolic information for the purposes of statistical analysis. It follows explicit rules of coding and allows classifying large amounts of data. Because of its relative conceptual simplicity can be used to support other, more detailed textual information and discursive fragments. Are distinguished two main approaches in the use of this class of research tools (Shapiro, 1997) the instrumental analysis and the representational analysis: *«At issue in this distinction is whether it is the source's or the researcher's perspective that is used to interpret the texts under analysis. When a researcher understands texts representationally, they are used to identify their sources' intended meanings. When a researcher understands texts instrumentally, they are interpreted in terms of the researcher's theory»* (Smelser & Baltes, 2001).

Observe and visualize

After having described the technical and conceptual features of the research, it has to be pointed out that the *Turtle* characteristics are not exclusive linked to the RSS feed aggregator. Indeed, *Turtle* offers some useful tools to explore a controversy. To the traditional and digital filing documental functions are added explorative and narrative functionalities of visualization. From a graphic interface point of view *Turtle* is made by two explorative tools: *Turtle Timeline* useful to analyze data and observe the controversy, depicting the results of the automatic Internet information gathering; *Turtle dynamics* synthesizes information showing the position of the various actors, their relations and the most important content of their discourses. The potentialities of the visual models have been tested in the empirical study in a real controversy on a twofold floor: firstly, *Turtle* should clarify the specific contribution to the overall discursive structure of each single discursive fragment; secondly, it should underline the latent structure by synthesizing every single discursive fragment. Even if it *Turtle* seems to act in an automatized manner, each action is controlled by the controversy observer.



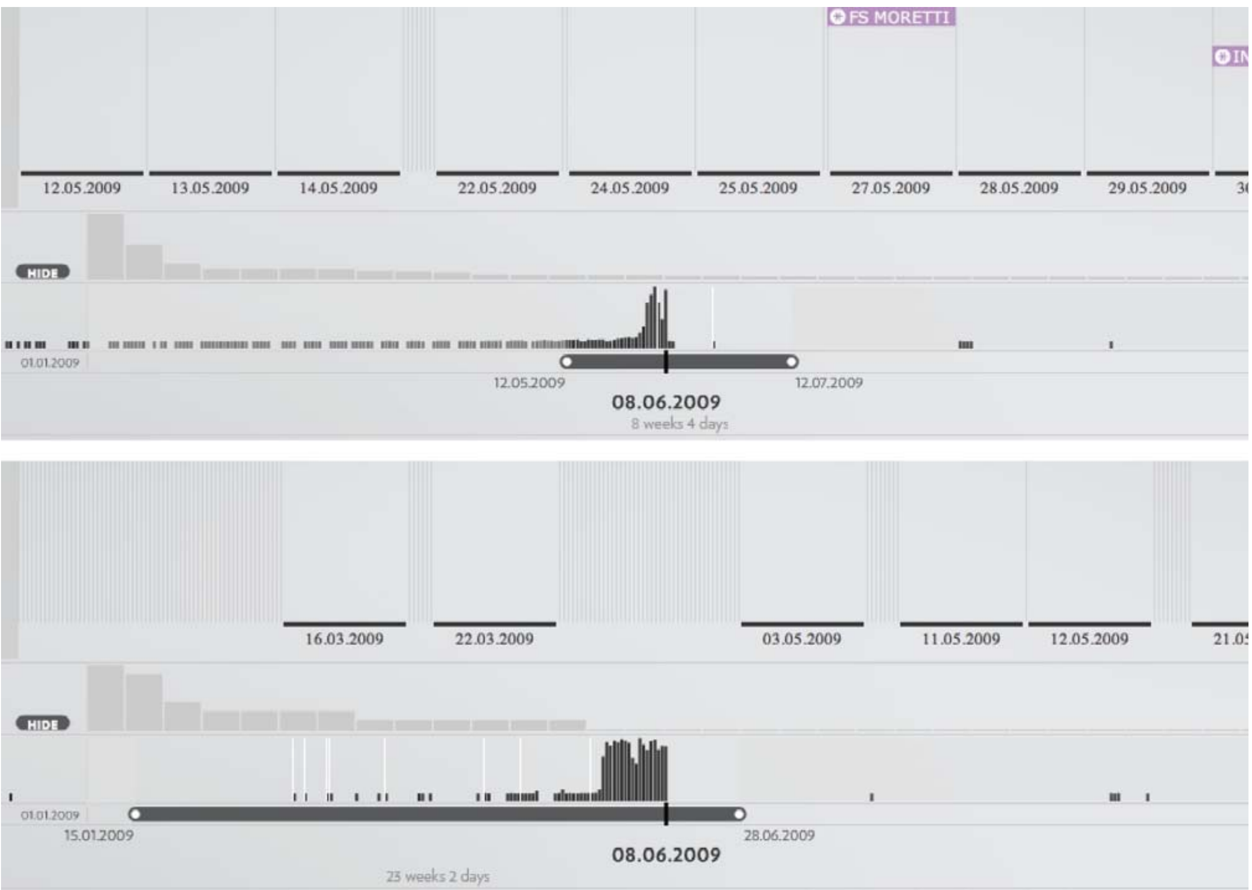
Turtle Timeline: Creating the relationship between discoursive fragments

For example, illustrating the interface characteristics and its features in visualizing information, it is possible to start from the actors identification procedure, which is a step by step process and it is able to guarantee a great flexibility. To each actor it is possible to associate a color, different shades indicate different groups of actors (e.g. the observer can choose the purple for the governmental headlines; blue for right news headlines; green for environmental associations). Different color graduation can indicate different actors, which tend to share their idea. To each actor the observer can associate some metadata. The specific aim of this software is to visualize the discursive fragments and stress their relationships, also with respect to time. The observer can link two or more fragments assigning to their relationships in terms of similitude or contrast. Three are the possible links: a generic one, depicted as a grey line; the second, an agreement link, assigned by the observer when he considers the content of two fragments as converging; the third one, a disagreement one when the observer states that the content of two fragments are in conflict or show two different opinions or point of views. Furthermore, the observer can assign a weight to the last two links, indicating the strength of the concordance and discordance.

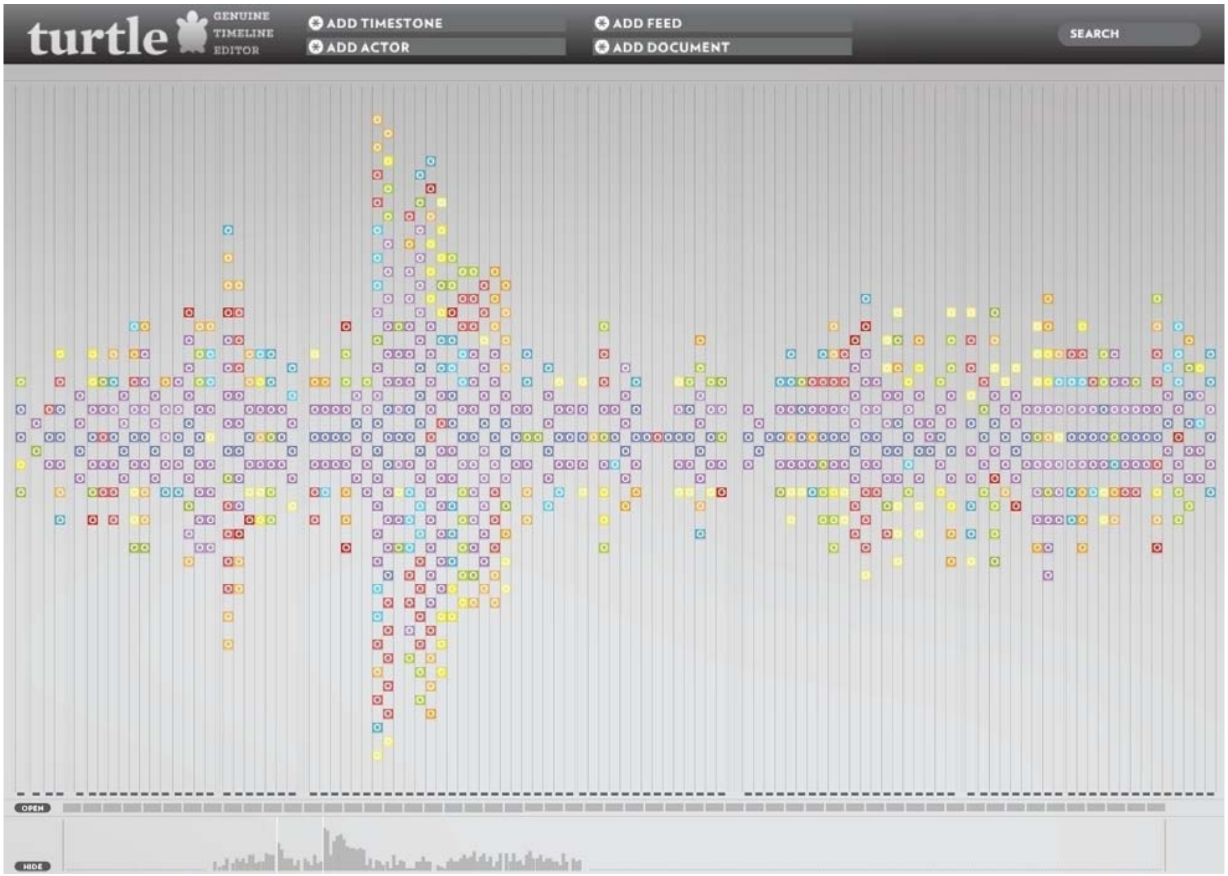
Turtle dynamics is the complementary device of *Turtle Timeline*. It gathers the fragments actor by actor and the relationships among them, proposed by the observer to visualize a synthesis of the controversy. It shows cluster of actors for a specific momentum as a graph; letting emerge the relationships among clusters of actors. The latter are visualized as circles, with a directly proportional to number of fragments produced by them. Each position on the graph is a function of the relationship built by the observer in *Turtle Timeline*. The distance among the circles decreases as the agreement links between actors increases. On the contrary the distance increases if two actors have lots of fragments in opposition.

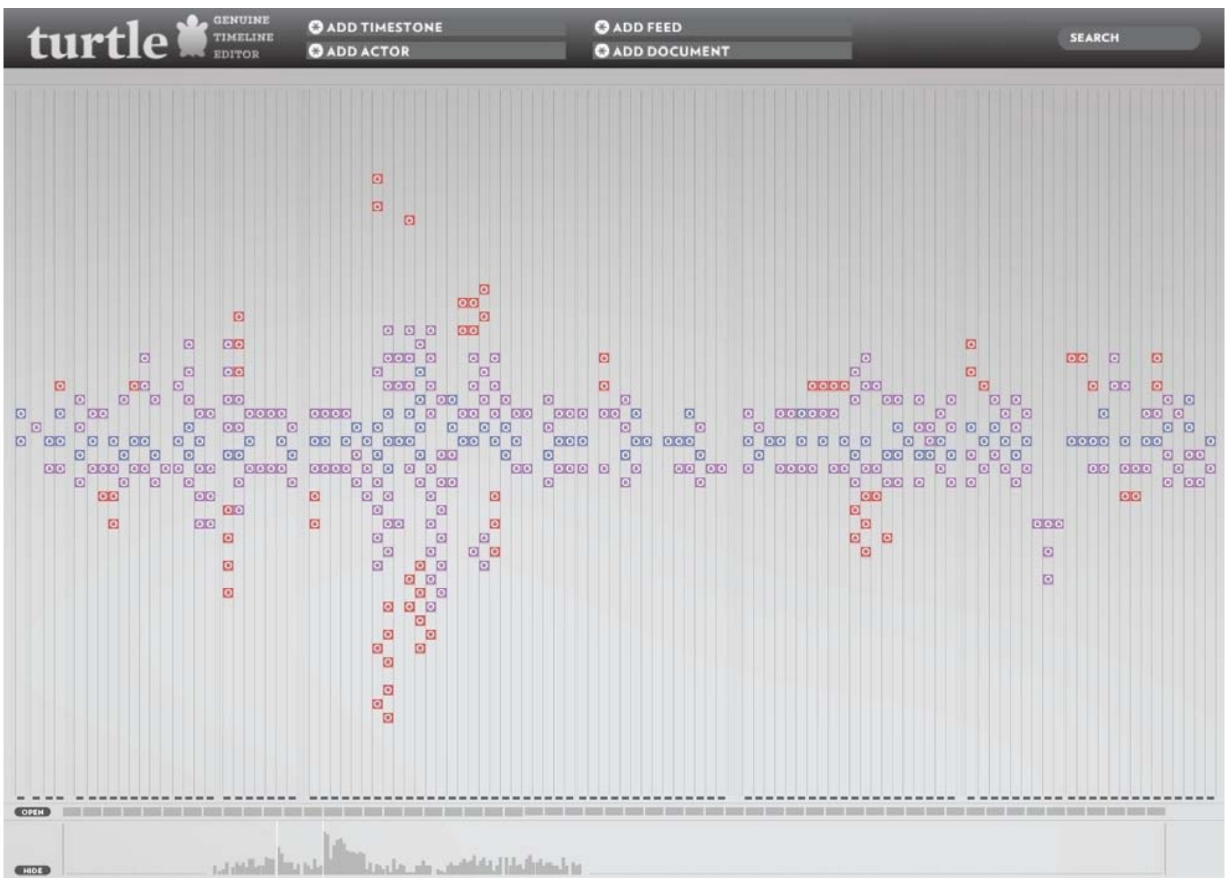
Some results about the controversy

In observing the controversy about the dangerous goods transportations *Turtle* has made it possible to enlighten some interesting dynamics. First of all, the dynamicity of the considered case has emerged thanks to its content analysis capability and from a comparative analysis with another controversy, i.e. the nuclear energy implementation in Italy. By observing the dimension of the flow through the time, it has been possible how the external events can affect the controversy. In this sense, the comparative analysis shows the *discursive flow volatility*: the increase or decrease of the discursive production in relationship with an external event. For instance, considering the last European poll, the two controversies showed a different behavior. The dangerous goods transportation one, as the elections were approaching, saw a rapid raise of the flow, which has been constant through all the poll period for plummeting at the end. On the contrary, the nuclear controversy the flow rose even before of the elections, and then stayed stable in the long run.



Turtle Timeline: Above the "dangerous good" information flow. Below the "nuclear" information flow. The considered period is related to the 2009 European poll

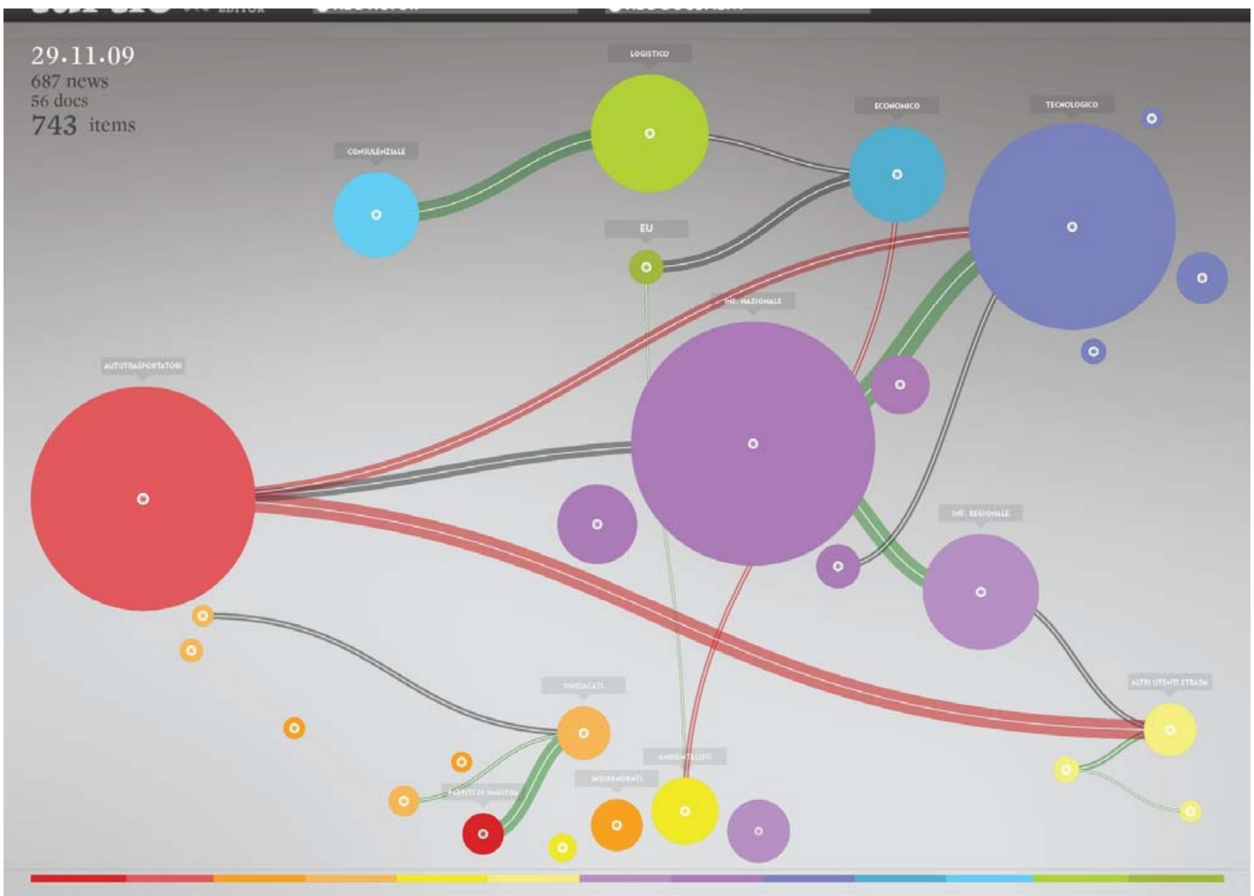




Turtle Timeline: Above the diagram after six months of observation. Below the diagram where the *discourse axis* is enlighten

Other observations have been performed in relation with events more germane to the specific controversy of the dangerous goods. On 29 June 2009, in Italy a tragic event took place in Viareggio, where a train transporting dangerous goods was involved into an accident. Although it was referring to a differing transportation system, this event led to a significant increase of the discursive flow, strictly related to the remote control of the transportation of dangerous materials in road. After this event, the flow remained stable. *Turtle* shows its capability of revealing the interdependence of controversies with other systems. By observing the lay out of the fragments into the interface, other patters emerged, both communicative and relational ones. *Turtle Timeline*, in fact, positions on the median area the fragments belonging to the actors, which in the observation time frame has the highest ratio between the number of fragments vs. number of days, so to identify the more active actors in the controversy, which constitute the *discussion axis*. In our case, it is represented by the technological actors cluster.

The most important qualitative and discursive results can be abducted by observing the diagram produced with *Turtle dynamics*. It shows in the upper part, really near among them, clusters concerned with the economic aspects of the controversy: the technological cluster, the logistic and the economic information one. Within this area, of great interest is the consultancy cluster, which represents those actors involved in the trucks and drivers certification. It is at the end of a chain starting from to the EU cluster, producing the laws and directive for the entire transportation industry. In other words it is evident a link between directives and their economic impact, the logistic and the bureaucratic issue, all of them are polarized by the technological aspect of the controversy. A weak link joins the EU cluster with the environmental one, even if the link is an agreement one.



Turtle Dynamics: the graph after six months of observation.

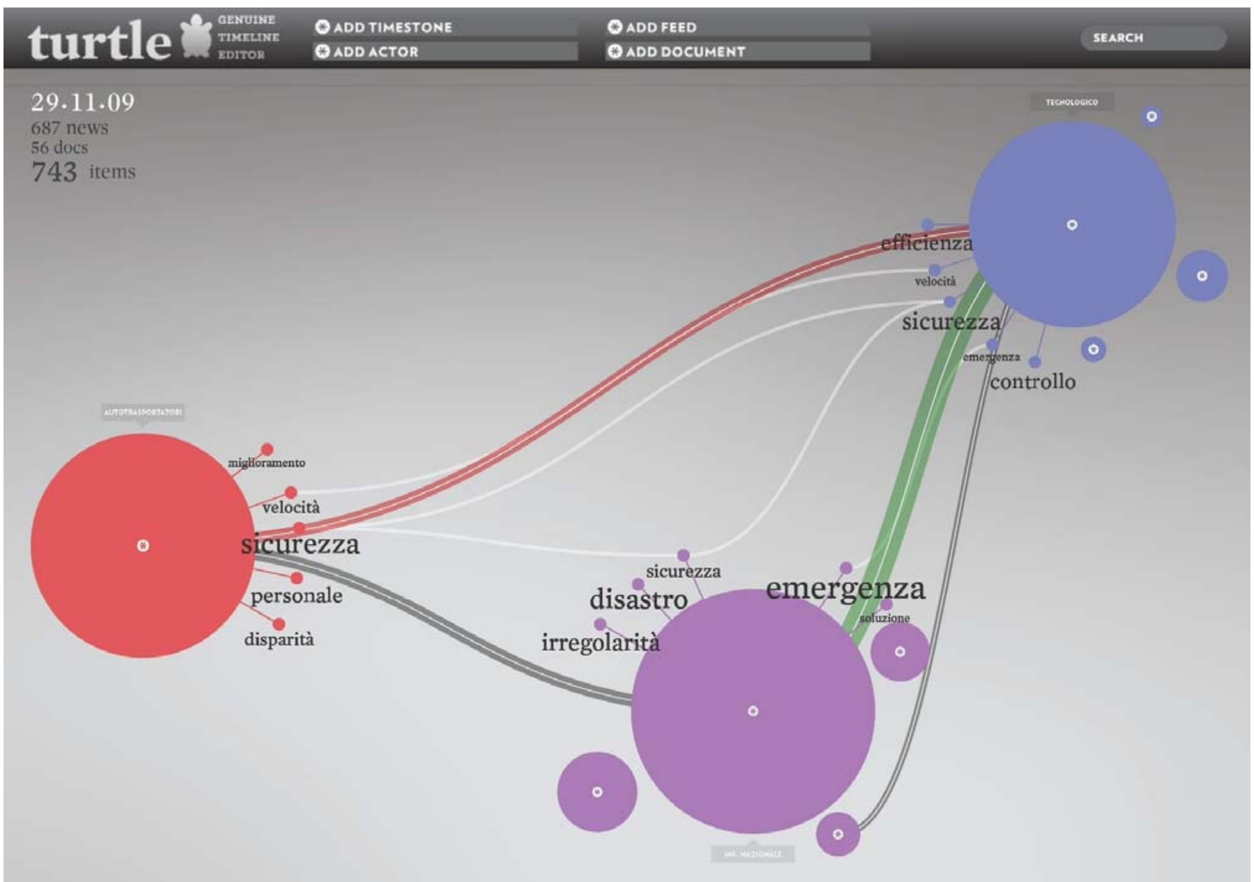
On the contrary, the environmental cluster has a disagreement weak link, with the economic cluster. In the middle of the graph, the national news headline cluster has a huge weight, strongly linked to the tech one. The regional news headline cluster, closed to the national one, has a generic link with the cluster pertaining to the car and motorcycle drivers. This relationship could mean that there is a mutual influence between the regional news sources and personal blogs and forums, which constitute the vast majority of the car and motorcycle drivers cluster.

The latter are clearly and strongly in opposition to truck drivers, which occupy the left part of the diagram. They are in opposition with the tech cluster as well.

At the diagram bottom are situated the labor unions cluster and the left party cluster.

This diagram lay out reflects some hypotheses emerged from the first and quick analysis of the controversy as well as the interview session with the researchers of the LMT. Expanding the *Turtle dynamics* diagram and letting appear the key issues concerning the three main clusters, even though they are in contrast, it is possible to point out where their point of views converge. Recalling the remote control of dangerous materials transportation in roads, jointly with the privacy issue, the diagram shows the tech cluster interest in safety, efficiency and dangerous goods transportation control. The national news headline is concerning with the need of finding solutions to prevent emergencies and accidents. Even the truck driver cluster is supporting the safety issue, but it is concerned also with the improvement of their working conditions. Safety is by far the major linking strength, even if it could be declined in various facets from the economic to the social one.

Taking into account what it can be observed through the diagram and triggering a *designerly* way of thinking, the clash between the need for a greater safety, achieved through the control and the tracing of the truck drivers, and the need for independence and privacy can be balanced considering the other drivers interests. The role of the remote control devices should be considered twofold: on one side it is perceived as invasive by the truck driver, on the other they can be used to increase their working condition. An issue, the latter, which is one their main concern.



Turtle Dinamics: The three main actors, and their issue relationship.

Some limits about the tools

The research results presents obviously some limits, which basically reflect all the three levels on which the empirical tests have been carried out: the technical one, the definition of observation area and the visualization one. Here will be discussed only the first, which has shown the more significant impact on the results achieved. The main limit has been represented by the *noise* of the information flow. It is an issue related to the automatic part of the gathering data process but it requires some reflections about the research methods. The researcher has to constantly monitor the results of the filtering process in order to overcome this limit. If one side it can be enhance by optimizing the algorithms, on the other it implies not to fully rely on the automatic procedure; therefore, it implies the need for exploiting the researcher cognitive capabilities to reassemble the puzzling fragments of a controversy.

Multiple perspectives

In developing the research, from a more abstract point of view three steps in *formatting* information and discursive fragments have been carried out:

1. From the textual fragment to a visual object. It has been sought the qualitative and quantitative data salience in order to convert them into nodes and elements referable to an optical space;
2. From the phenomenon implicit structure to an explicit and visual one. Analyzing one by one the visual objects, it has been tried to highlight their mutual significance as well as their overall sense, visually showing their relationships.
3. From a unique perspective to a multiple one. The possibility of not univocally linking the different fragments opens to more than one possibility. Moreover, it brings to further reconfigurations and multiple interpretations of the same phenomenon.

The possibility of another observer to build its own links would bring him to configure a different network and a diverse interpretation of the observed phenomenon.

The diagrams, presented in this paper, have not to be considered as devices able to provide the reader with definitive answers, but instead as tools to be used in drafting better questions to be asked to the system. Their novelty relies more on their capability of *formatting* data, rather than their visual aspects. On the wake of Bonsiepe (2000), it could be stated that diagrams are like *finding engines*, rather than searching engines. Rephrasing, they are able to provide entry points to better examine the faced issues. Diagrams are interfaces providing patterns where he observer is responsible of the assembly operations and of the meaning making operations. At the same time the reader is responsible for the sense making activity of the diagram. The logical path linking the observer-writer with the reader is featured by three questions: what do I see? What does mean what I see? What it might mean with respect to my issue?

In such a context *to see* acquires a key importance: it highlights the structural features, it describes distributions, directions, dynamics helping the observer in understanding a complex discursive space. In this researcher these possibilities are pursued differently from a pure algorithmic approach. The most important actions, as for instance that of building links among fragments, result from active actions of the observer. The observer is called to read and interpret every single information and data acquired about the controversy, producing a personal and non-linear discursive order. Through these actions, he increases his consciousness with respect to what it observes. This chance of arranging, linking and manipulating objects and discursive elements has not to be disconnected from the ethical stances. It is to be accepted the responsibility of the modeling operations and be aware of their imperfection. The overall process, in fact, identifies only what it is relevant to one observer. In this way diagrams incorporate also its point of view. This, which could mean a great limit, in the light of the Complexity, in which there is never an absolute point of view, could mean taking advantage the multiple interpretations and models, which can be built for the very same phenomenon. Every attempt to homogenize observations and, thus, interpretations would imply *violence* to the complexity in which we are immersed.

Author Biography

Donato Ricci

Donato Ricci is a researcher and senior designer at DensityDesignLab (www.densitydesign.org), where he carries out scientific researches, design project and teaching activities in the field of visual languages for complex decision making processes. In 2005 he graduated in Communication and Industrial Design at Politecnico di Milano. In 2010 he obtained a PhD degree cum laude in Industrial Design and Multimedia Communication at Politecnico di Milano with the dissertation Seeing what they are saying: Diagrams for social complexity and controversies. During the doctoral research he developed Turtle, an advanced prototype of a web-based platform for the visual exploration of socio-technical controversies.

His works have been featured in several conferences and exhibition (the MediaLAB Prado – Visualizar08, the SIGGRAPH09 Conference, the VirginiaTech Educate09 Conference, the MIT Humanities + Digital Conference) and publication and showcases (Data Flow 2, Visual Complexity.com).

Empreintes lumineuses nocturnes : Codes et représentations simplifiées appliquées au design de l'éclairage architectural et urbain

Victor Rodrigue, M.Sc.Arch. Université Laval, Québec, Canada, vserodrigue@yahoo.com

Claude MH Demers, Ph.D., M.Arch. Professeure titulaire / Professor

Résumé :

Cette recherche présente une méthode simple pour mesurer, analyser, représenter et comprendre la complexité des systèmes de lumière urbaine dans les grands espaces. Elle démontre les avantages d'un code simplifié de repérage et de représentation des ambiances lumineuses, appelé ici« empreinte lumineuse nocturne », pour l'intégrer dans l'analyse et la création des paysages, architectures et places publiques vécues la nuit. La recherche propose un outil d'analyse de la lumière urbaine à partir d'une technique photographique basée sur l'idée de mouvement afin de créer ces « empreintes lumineuses nocturnes». Celles-ci permettent de vérifier les conditions critiques des éclairages existants et d'améliorer les propositions de design étudiées.

Mots clés

ambiances lumineuses, photographie numérique, méthode d'analyse de la lumière, design urbain

Problématique

La ville nocturne se vit en mouvement, introduisant à plusieurs égards les notions de complexité dans l'appréhension visuelle des grands espaces. Cela est vrai dans les villes nordiques où le climat froid, présent plus particulièrement où la période nocturne hivernale occupe une grande partie du temps, génère des comportements favorisant la mobilité physique des usagers pour optimiser leur confort physiologique. Il existe donc, dans tout projet de design d'éclairage architectural et urbain, une complexité inhérente à la caractérisation des ambiances lumineuses observées dans le continuum de la perception visuelle. Narboni définit ces ambiances lumineuses comme le « résultat d'une interaction entre une ou des lumières, un individu, un espace et un usage. L'ambiance lumineuse provient d'un éclairage naturel ou artificiel et influence momentanément ou durablement la perception du lieu éclairé. » (Narboni, 2006, p.14)

Si les types de sources lumineuses sont nombreux et que la conception d'ambiances nocturnes occupe une place de plus en plus importante, les problèmes causés par la lumière sont de plus en plus complexes et difficiles à intégrer dans le processus de design, notamment en regard de la pollution lumineuse et du calibrage des contrastes. C'est dans ce contexte qu'il apparaît nécessaire d'adapter les méthodes existantes pour analyser les ambiances lumineuses de manière globale et dynamique.

Par ailleurs, l'espace urbain n'est pas perçu par les utilisateurs à travers des champs visuels statiques, mais plutôt dans son ensemble (Lou, 1996, p.29). Les places publiques sont vécues et perçues par le public selon des champs visuels qui diffèrent d'une expérience à l'autre et d'une personne à l'autre.

Si la photographie numérique est un support pour enregistrer les modèles lumineux dans l'espace (Demers, 1998), il n'existe pourtant pas de méthode photographique permettant de mesurer ou d'analyser la lumière d'un lieu dans son ensemble mis à part l'utilisation d'un objectif de type « fish-eye ». Les méthodes existantes analysent des points de vue particuliers, la capture des ambiances lumineuses se faisant à travers des photographies cadrant un point fixe du lieu ou de l'élément architectural à étudier. En d'autres mots, l'analyse de la lumière urbaine par la photo numérique reste encore limitée au « champ visuel » tel que définit par Lou, en raison, notamment, des limites de l'appareil photo.

Dans ce contexte, la méthode du balayage photographique se présente comme une méthode alternative d'analyse de la lumière afin d'optimiser son intensité pour améliorer le confort des citoyens, l'ambiance et la santé collective. Ce projet vise donc la création et le développement d'un outil d'analyse des ambiances lumineuses et la représentation visuelle des paysages nocturnes des places publiques. Cette recherche poursuit et approfondit l'analyse de la lumière présente dans les paysages nocturnes urbains à partir de la photographie en mouvement grâce à un procédé technique novateur, qui permet d'enregistrer et de capter la lumière des espaces dans leur ensemble par le biais de photographies panoramiques à 360°. L'outil développé porte le nom d'empreinte lumineuse nocturne.

La méthode du balayage photographique

L'empreinte lumineuse nocturne se présente à la fois comme une expérience, un outil d'analyse et une source de réflexion sur l'éclairage urbain. L'outil permet la mise en relation de données à la fois sensibles et quantifiables à partir de relevés photographiques de la lumière. Cette mise en relation tient compte de l'échelle et de la dimension des lieux, d'un parcours, d'une place publique, etc. Cette réflexion de recherche transpose photographiquement le ressenti en mouvement d'une ambiance lumineuse urbaine et permet une prise de conscience de l'importance d'harmoniser la lumière dans son ensemble.

Cette recherche introduit la photographie comme support d'information et instrument de recherche indispensable dans l'analyse des ambiances lumineuses urbaines. Les outils informatiques appliqués à la technologie photographique numérique permettent de créer le code simplifié de lecture et d'analyse de la ville nocturne. L'objectif de la recherche était d'évaluer le potentiel qualitatif et quantitatif d'une image balayant 360° d'un espace public à partir d'un point précis, pour en caractériser les ambiances lumineuses. Le balayage réunit sur un même plan vertical toutes les sources lumineuses et surfaces éclairées de l'espace qui entourent le photographe et sa caméra.

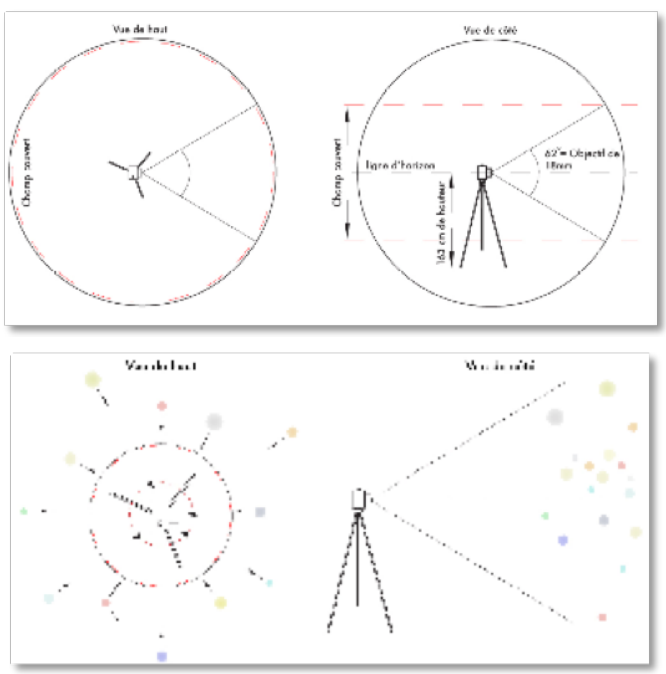

Figure 1 : Champ couvert par le balayage photographique

La méthode consiste en la capture de photographies reconstituant le spectre lumineux d'un lieu dont le mouvement en rotation du balayage photographique estompe l'environnement architectural pour ne percevoir qu'un ordre superposé des tonalités lumineuses d'une atmosphère. Cette méthode permet d'éviter que les formes architecturales n'interfèrent sur l'image et ne présente ainsi que les sources et les surfaces lumineuses du lieu étudié. Une bande significative d'un pixel de large, c'est à dire une bande où sont imprimées toutes les sources lumineuses, est sélectionnée sur toute la hauteur de l'image (figure 2). Cette bande est extraite au centre de l'image, afin de minimiser l'effet de la distorsion concave de la lentille et de conserver la hauteur réelle des sources lumineuses dans la photo. L'échantillon ainsi obtenu consiste en une tranche qui est étirée sur le sens de la largeur pour visualiser l'*empreinte lumineuse*. Cette empreinte, échantillon du balayage photographique, est transformée et analysée en se basant sur la méthode digitale développée par Demers [2007] pour quantifier les brillances et le contraste afin d'établir une classification des ambiances lumineuses nocturnes. L'ambiance nocturne du lieu ainsi fixée sur support photographique est prête à être réinterprétée. Les couleurs, les contrastes chromatiques et d'intensité ainsi que les brillances sont désormais lisibles et donc analysables.

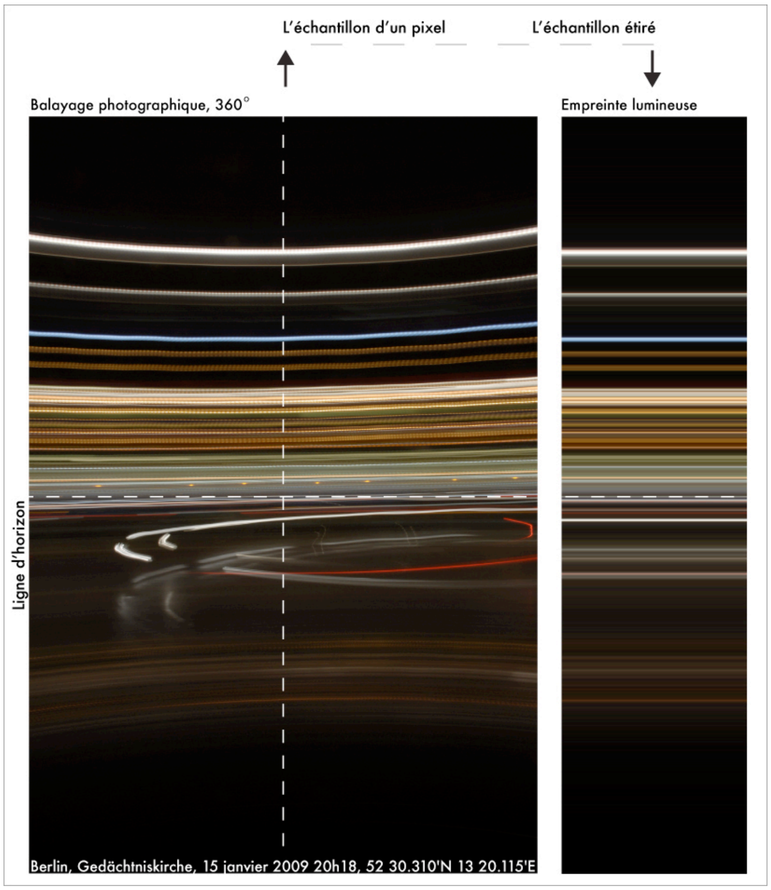

Figure 2 : Du balayage photographique à l'empreinte lumineuse - Un portrait abstrait lumineux condensé au pied de la Gedächtniskirche. Le résultat (balayage photographique) devient graphique quand la colonne d'un pixel est étirée.

L'analyse développée ici se base plus particulièrement sur les notions de contraste et de brillance, de couleur et d'angles de prise de vue. Le contraste est une valeur essentielle de l'image. Il permet de quantifier les données, de comparer différentes zones entre elles et de façon plus globale, différentes images entre elles. Une analyse du contraste par la méthode photographique offre une base critique pour l'étude des éléments urbains existants. Demers explique que le contraste d'intensité peut facilement être mesuré à l'aide de la photographie permettant une analyse quantitative de la lumière. Il existe deux types de contraste : le contraste d'intensité qui est quantifiable, puisque visible et le contraste chromatique, qui tient de la couleur, une mesure subjective et difficilement mesurable. La perception de la lumière dépend toujours du rapport existant entre les intensités lumineuses de diverse sources ou objets dans le champ de vision. Plus la différence de contraste est élevée plus la perception d'un objet par rapport à un autre se distingue. L'étude du rapport entre les éléments éclairés et non éclairés est une étape importante avant de procéder à la mise en lumière. (Demers, Potvin, 1997)

La recherche présente une méthode simple pour mesurer, analyser et représenter la complexité des systèmes de lumière urbaine à partir d'une approche originale de capture photographique et d'analyse numérique transposant des impressions visuelles en empreintes lumineuses. La méthode sert à mesurer l'intensité et le degré d'importance de la lumière et des couleurs dans les paysages urbains et permet d'appliquer plus efficacement les principes de design d'éclairage architectural et urbain. L'empreinte lumineuse réduit l'environnement aux éléments de base de la composition spatiale : les points, les lignes, les surfaces. Pour répondre aux particularités des compositions lumineuses urbaines, la notion de couleur s'ajoute à la réflexion spatiale. L'ensemble des points lumineux est ramené sur un seul plan, générant l'empreinte nocturne d'un point identitaire d'un parcours. L'absence de point de fuite des empreintes lumineuses (figures 4 et 5) procure une impression abstraite du mouvement de l'œil dans le champ de vision. L'approche du balayage photographique considère une ambiance comme une configuration ou un agencement de lignes lumineuses sur une échelle verticale correspondant à l'espace visé. L'organisation des lignes, des couleurs, ainsi que leur épaisseur créent une combinaison spécifique, propre à chaque lieu. Les empreintes lumineuses permettent donc de qualifier et d'interpréter de manière organisée les impressions ressenties des lieux. L'appréhension globale d'un parcours à l'aide de ce procédé peut servir à observer la progression des tonalités ressenties lors d'une promenade urbaine, puis à fixer les critères de design appropriés à une intervention dans le lieu visé. Dans l'ensemble, les empreintes lumineuses permettent donc d'établir une relation physique et abstraite entre l'espace, la lumière et le mouvement, essentielle à la perception visuelle de l'environnement et des ambiances.

Méthode & démarche expérimentale

Afin de confirmer la faisabilité et le potentiel de l'empreinte lumineuse nocturne comme outil d'analyse, nous avons procédé à des expérimentations sur le terrain. La méthode a été appliquée à deux projets d'éclairage urbain: Les champs Élysées, à Paris et Unter den Linden, à Berlin.

À Berlin, le projet d'éclairage urbain, qui s'étale sur un parcours d'environ 1,5 kilomètres sur l'avenue Unter Den Linden a été conçu par la firme *Kardoff Ingenieure lightdesign*. Il a été qualifié d'exemplaire par Christa van Santen, designer d'éclairage et professeure. Ce parcours a été choisi pour son importance comme axe dans la ville. Il a été comparé à l'avenue des Champs Élysées, son équivalent parisien, entrée monumentale de la ville lumière. La collecte des échantillons a été effectuée, en soirée, en janvier 2009. En vue de développer ce projet, 13 points de mesure ont été pris à Berlin et 11 points de mesure à Paris ont été choisis.

La prochaine section décrit avec précision la procédure suivie pour obtenir des empreintes lumineuses nocturnes pour les lieux sélectionnés.

1 Choix des emplacements

La première étape consiste à définir des points de vue représentatifs du lieu à étudier. Ceux-ci doivent permettre de saisir les espaces dans une cohérence photographique pour former un ensemble compréhensible et représentatif. Ainsi, la disposition de la caméra dans l'espace au moment de la mesure doit prendre en considération l'utilisateur habituel de l'environnement étudié. Le projet tient compte du champ de vision à l'échelle de celui du piéton. L'intention est de se rapprocher, avec l'outil photographique, des caractéristiques de l'œil humain afin d'établir le rapport entre l'observateur et la lumière.

Afin de prendre en photo une ambiance lumineuse, le chercheur, observateur/photographe doit sélectionner son emplacement avec soin, en fonction de ce qu'il souhaite étudier dans une scène L'avantage avec l'empreinte lumineuse, c'est qu'elle ne tient pas compte des points de vue des sujets dans une place publique, mais plutôt de la position spatiale dans l'espace. Il est à noter que le choix de l'emplacement reste subjectif. Les distances, donc les données, peuvent ainsi varier en fonction du point de vue du chercheur. Afin de standardiser les analyses, les lieux d'étude, s'il s'agit d'une étude comparative, doivent posséder certaines similitudes. Par exemple, pour les besoins de cette recherche, nous avons sélectionné des trajectoires qui occupent pour deux villes différentes une fonction similaire.

À Berlin, les lieux de mesure ont été choisis en fonction de critères spécifiques : ils devaient faire partie des quartiers centraux, avoir un usage multiple, présenter une concentration importante d'activités nocturnes et la lumière devait y jouer un rôle important dans la définition des ambiances. La position choisie permet, dans la mesure du possible, d'avoir une vue d'ensemble du lieu. À Berlin, la trajectoire Unter Den Linden est étudiée, à l'exception des empreintes 3, 4 et 5. À Paris, c'est l'axe des Champs-Élysées qui est la trajectoire empruntée, d'où l'importance de la séquence lumineuse.

1.1 La localisation de la mesure

Lors des prises de mesures, il est important de réaliser des photographies montrant les lieux afin d'en saisir l'esprit et de consigner certaines caractéristiques sur un support visuel. Ces photographies (figure 3) sont riches en informations qualitatives pour compléter une analyse complète des ambiances lumineuses. Une photographie montrant le contexte des lieux constitue une première source d'information et de repérage. L'image photographique est un outil indispensable pour l'analyse et l'observation de la lumière. Pour chaque empreinte saisie à Paris et Berlin, deux photographies de référence ont été prises pour situer et décrire visuellement les lieux où les points de mesures ont été pris.

Le plan de localisation des images (figure 3) précise le lieu exact des prises de mesure par balayage photographique. En plus des plans, des photos permettent de situer et de suivre l'évolution des conditions lumineuses sur un parcours donné. Il est effectivement possible de mesurer de façon globale la progression lumineuse des couleurs et des tonalités d'un parcours. Par exemple, le parcours emprunté à Paris permet d'observer que la séquence (illustrées par les empreintes) va du peu contrasté et peu brillant (cour carrée du Louvre), au très contrasté et très brillant, sur les Champs Élysées. D'un élément et monument urbain qui sommeille la nuit (musée) à l'activité urbaine grouillante (commerces), il y a là une gradation intéressante des ambiances sur ce parcours.

Figure 3 : Les points de localisation des prises de mesure à Berlin et Paris.

2 La technique du balayage photographique

2.1 Équipement

L'équipement nécessaire pour réaliser le balayage photographique est constitué d'un appareil photo reflex numérique réglé en mode manuel, d'un trépied, d'une rotule. Plusieurs variables techniques au moment de la prise de vue sont susceptibles d'influencer les résultats. Il s'agit, notamment, de l'ouverture focale, du temps d'exposition et de l'ISO, c'est-à-dire le degré de sensibilité du capteur de l'appareil photo.

2.2 Réglages de l’appareil numérique

Les mesures à Berlin et à Paris ont été enregistrées avec la plus petite ouverture (f/22), un temps d’exposition de 10 secondes et l’ISO à 100.

Plus l’ouverture de l’objectif est petite (f/22), plus les détails des éléments sources et des surfaces lumineuses sont précis. Parce que le temps d’exposition est relativement élevé (10 secondes) pour compléter une rotation, l’ISO choisie est 100. Avec l’ISO à 100, l’image possède l’avantage d’être plus nette et plus précise, avec moins de bruit visuel. Finalement, une rotation de 10 secondes est une durée qui offre un bon rapport entre qualité des résultats et facilité de réalisation.

2.3 Prise de mesure

Une fois toutes les variables techniques déterminées et l’appareil photographique fixé au trépied, c’est le moment de la capture d’images. Cette dernière consiste en une rotation de l’appareil grâce au trépied sur 360^{o}. Pour ce faire, il faut s’assurer que l’horizon est cadré au milieu du viseur afin de situer et repérer les lumières dans l’environnement avec plus de facilité. Lors de notre expérimentation, toutes les sources lumineuses du lieu ont été, dans la mesure du possible, captées par l’appareil. Par contre, ce n’est pas toujours possible en raison des champs visuels restreints de l’objectif. C’est le cas lorsque le point de mesure est situé au pied d’une source lumineuse ou d’un immeuble en hauteur et que l’objectif n’est pas en mesure de cadrer tout l’ensemble lumineux constituant l’espace public. Il est possible de limiter la portée de cette contrainte en utilisant un objectif grand angulaire.

L’idéal est de commencer et de terminer le balayage photographique à l’endroit le moins éclairé des surfaces ou de l’horizon de l’espace mesuré. Cela permet d’avoir une marge d’erreur dans l’angle de rotation et dans le temps. En effet, lors de la réalisation du balayage photographique, une marge d’erreur est à considérer lors de la réalisation de ce processus manuel. Il serait possible d’y remédier en élaborant un système motorisé.

Le photographe doit poursuivre la rotation pendant toute la durée du déclenchement de l’appareil, afin de créer un panorama de 360^{o}. La constance dans la rotation garantit une mesure exacte. C’est pourtant la considération technique la moins précise et la plus difficile à atteindre. C’est par essais et erreurs que cette synchronisation est atteinte par le chercheur photographe.

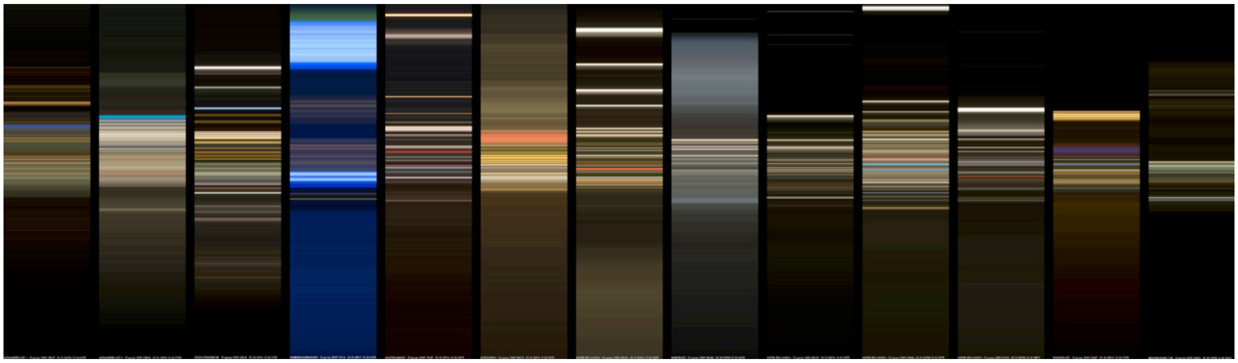
3 Traitement informatique des images

Une fois que le balayage photographique est réalisé, l’image est ensuite traitée à l’aide du logiciel *Adobe Photoshop*. Avec l’outil « rectangle de sélection » réglé à un pixel de large, on sélectionne une bande significative sur toute la hauteur de l’image (figure 2). Cette bande est extraite au centre de l’image, afin de minimiser l’effet de la distorsion concave de la lentille et de conserver la hauteur réelle des sources lumineuses dans la photo. Cette bande très étroite est ensuite étirée horizontalement pour créer une bande de 10 cm de large, qui permet visualiser ce que nous appelons une empreinte lumineuse nocturne. Cet étirement n’influence pas la résolution du document.

Les empreintes lumineuses nocturnes obtenues dans le cadre de cette collecte de données peuvent ensuite être comparées et analysées. Elles constituent chacune une unité qui se prête à la recherche. Elles se présentent de la façon suivante pour les lieux que nous avons étudiés.

Les empreintes lumineuses nocturnes

L’empreinte lumineuse réduit l’environnement aux éléments de base : les points, les lignes, les surfaces et les couleurs. Chaque ligne correspond à une source de lumière ou à une lumière réfléchie. Ici, le point de fuite n’existe plus, les impressions obtenues sont des images en deux dimensions. L’ensemble des points lumineux est ramené sur un seul plan. L’absence de point de fuite dans les images donne une impression abstraite du mouvement. Les résultats présentés ici portent sur les empreintes lumineuses de Berlin et Paris.



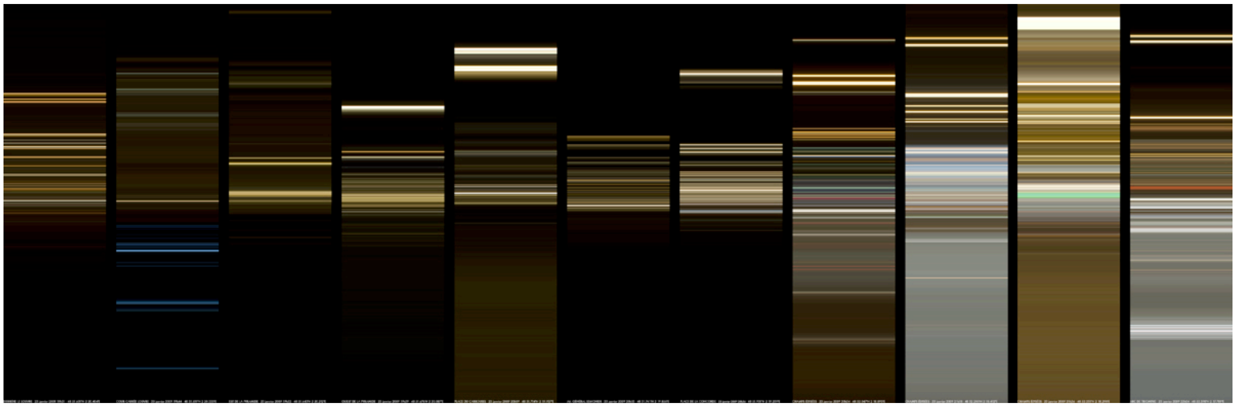


Figure 4 et 5 : L'ensemble des empreintes lumineuses prises à Berlin (haut) et Paris (bas).

Toutes les sources lumineuses perçues sur les empreintes lumineuses sont artificielles, à l'exception de la lune, dont l'intensité varie dans le temps. Les sources lumineuses proviennent des espaces publics (lampadaires, enseignes lumineuses, feux de circulation, etc.), mais aussi des immeubles résidentiels et commerciaux. Les sources proviennent de toutes les directions et hauteurs. Une étude qualitative des empreintes lumineuses nous permet de constater que lorsque des zones noires les dominent, cela signifie dans la majorité des cas que la mise en lumière de l'élément architectural et l'ambiance lumineuse du lieu reposent sur un contraste important.

Autre élément intéressant : la lumière indirecte affecte beaucoup moins l'empreinte et offre un éclairage plus doux et homogène dans l'espace.

Particularités de la lumière visibles sur une image balayée

La plupart des sources lumineuses dans l'espace public sont fixes, certaines sources sont mobiles (ex. véhicules routiers où les lignes sont surtout situées sous la ligne d'horizon, sauf si la topographie du sol est importante), alors que d'autres sources clignotent (ex. panneaux lumineux, enseignes publicitaires, etc…). Les distances, couleurs et intensités sont variables.

Dans la plupart des cas, la lumière blanche est émise par un lampadaire plus ou moins rapproché. (Exemple : images à Berlin 3, 7, 9, 10 et 11) La dimension des sources lumineuses varie en fonction de la distance d'observation, de la position relative de l'objet illuminé en rapport avec son milieu physique et des divers points d'observation, de leur dimension et de leur intensité. (DEMERS, POTVIN, 1997, p15) Il est impossible de connaître les distances à partir de l'empreinte lumineuse seule. Par contre, plus la concentration de lumière est forte et située au centre de l'empreinte et plus les sources lumineuses au loin sont visibles et nombreuses.

Application de la méthode

Étude de la variation du contraste en fonction de la brillance

La méthode Demers (1997) pour l'analyse des ambiances lumineuses nocturnes, qui s'appuie sur la brillance et le contraste des empreintes lumineuses nocturnes, permet une classification des empreintes lumineuses par catégories pour fins de comparaison. Les valeurs des contrastes et brillances des empreintes lumineuses sont classées dans le tableau suivant (figure 6). Les treize valeurs enregistrées à Berlin sont situées entre 8,62 et 44,91 pour la brillance et 19,7 et 45,01 pour les contrastes. On constate sur le graphique que plus le contraste augmente, plus la brillance a tendance à augmenter.

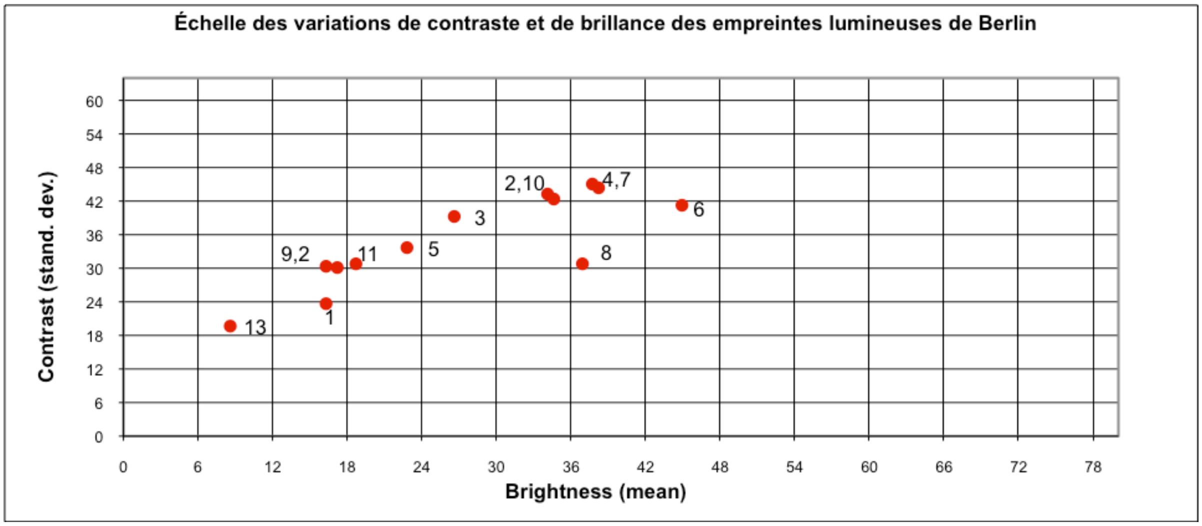

Figure 6 : Échelle des variations de contraste et de brillance des empreintes lumineuses de Berlin.

Les empreintes lumineuses nocturnes des deux symboles historiques allemands que sont la Porte de Brandenburg (13) et la Tour de Berlin (1) ont une brillance et un contraste faibles. Les images les plus contrastées et lumineuses sont les 4, 6 et 7, c'est-à-dire le musée Hamburg Hauptbahnhof, Altes Museum et la gare Centrale de Berlin. Les images 4 et 6 sont enregistrées devant les musées Hamburg Hauptbahnhof et Altes Museum.

Analyse des contrastes et des brillances

Le tableau suivant démontre que la brillance et le contraste d'intensité entre les différentes sources sont beaucoup plus élevés à Alexanderplatz qu'à la Cour Carrée du Louvre, ce qui n'est pas évident sur les photos panoramiques. L'avantage de l'empreinte lumineuse par rapport à une analyse faite sur une photographie statique tient donc à ce qu'elle permet de visualiser l'importance relative d'une source lumineuse par rapport à une autre. Par exemple, dans l'exemple d'Alexanderplatz (figure 8), l'entrée de métro (ligne bleue), qui n'est en définitive qu'un point de lumière dans l'espace, apparaît comme une signalétique forte, si on la compare aux autres sources de lumière de la place. En effet, lorsque ramenée sur un plan simple grâce à l'empreinte lumineuse, cette source s'avère importante.

Empreinte lumineuse	Brillance	Contraste	Ouverture	Temps d'exposition
Cour Carrée du Louvre	7,06	10,81	f/22	10 s.
Alexanderplatz	34,57	42,45	f/22	10 s.

Figure 7 : Comparaison des contraste et brillance entre les empreintes lumineuses et les panoramas.

La comparaison des panoramas et des empreintes lumineuses permet de déterminer la nature de chaque source présente sur l'empreinte (figure 8). Puisqu'il permet un repérage facile, le panorama demeure indispensable à l'analyse qualitative de la lumière. Le panorama et l'empreinte lumineuse se complètent. L'ouverture au moment de la prise de vue n'est pas la même pour le panorama que pour l'empreinte et varie d'un lieu à l'autre, tandis que l'empreinte lumineuse est constante à ce niveau.

Figure 8 : Panoramas et empreintes lumineuses – Cour Carrée du Louvre à Paris et Alexanderplatz.

La Cour Carrée du Louvre est un lieu fermé où toutes les couleurs, les contrastes et les tons forment un ensemble lumineux homogène et cohérent. L'empreinte démontre que la luminosité des façades est faible comparativement à l'empreinte lumineuse nocturne prise à Alexanderplatz. Pratiquement aucune source directe de lumière n'est visible à partir du centre de la place, sauf pour celles situées dans l'eau de la fontaine bleutée. Le point central de cet ensemble équilibré et homogène est marqué par la fontaine bleue, sur un plateau sombre. Les zones bleues dans la portion basse de l'empreinte sont les réflexions de la lumière dans la fontaine située au centre du lieu. Une caractéristique de cette place est l'absence de lampadaires. L'éclairage des bâtiments provient de luminaires montés sur la façade du Louvre. Les sources lumineuses sont discrètes. C'est pourquoi cette empreinte lumineuse est la moins brillante et la moins contrastée du graphique. Parce que l'intensité lumineuse est relativement faible et que la lumière est surtout réfléchie sur les murs de la cour Carrée du Louvre, une ouverture de l'objectif à f :13 permet de mieux lire les couleurs et les tonalités propres à l'ambiance par l'empreinte lumineuse.

À Alexanderplatz (figure 8), l'espace s'ouvre sur une variété de sources lumineuses beaucoup plus importante. La diversité des couleurs provient des commerces et des lampadaires tout autour de la place. L'espace central d'Alexanderplatz n'est pas éclairé, seule la ceinture commerciale illumine ce grand espace sombre. Alors que le brouillard épaissit la lumière dans l'air, le sol mouillé réfléchit la lumière des lampadaires. Le pourtour de la place publique au niveau des étages supérieurs des immeubles discret, sauf pour la tour « Park Inn » qui projette une auréole dans le brouillard nocturne. C'est pourquoi cette empreinte se caractérise par une concentration très forte de lumière juste au-dessus de l'horizon.

Les empreintes lumineuses nocturnes de Unter den Linden, à Berlin, révèlent une variété impressionnante de couleurs. Les commerces, les musées, les édifices, les infrastructures lumineuses jouent pour beaucoup sur ces variations. Sur les Champs-Élysées à Paris (figure 8), on constate une certaine homogénéité de la couleur de la lumière. Un blanc doré chaud illumine l'avenue. Les analyses démontrent également que la lumière s'intensifie du musée du Louvre à l'Arc de Triomphe.

Ambiances lumineuses

Lorsque la méthode est appliquée l'ensemble d'un parcours, la séquence des empreintes lumineuses obtenue on obtient le portrait d'une impression lumineuse d'un parcours et de ce qui est vu par les usagers. Les empreintes lumineuses permettent donc de qualifier et d'interpréter de manière organisée les impressions ressenties des lieux et des parcours. L'appréhension globale d'un parcours à l'aide de ce procédé peut servir à observer la progression des tonalités ressenties lors d'une promenade urbaine. Les figures 4 et 5 présentent l'ensemble des empreintes lumineuses prises à Berlin et Paris. Les lieux où on été prises les mesures sont indiqués sur les empreintes lumineuses. Des photographies des lieux prises à partir des points de mesure sont également présentées sur la figure 3.

Étude de la localisation des concentrations de lumière

À Berlin, les concentrations moyennes de lumière se situent surtout entre l'horizon et 10° au-dessus. La figure suivante présente la localisation du niveau de concentration de la lumière pour la moyenne des empreintes lumineuses, généralement situé entre 2° sous l'horizon et environ 10° au-dessus.

Le graphique suivant présente la distribution moyenne des brillances sur une échelle verticale des tons de gris des treize empreintes lumineuses prises à Berlin. L'analyse démontre que la brillance est à son plus élevé au niveau des yeux, c'est-à-dire environ 150 cm de hauteur (entre les valeurs de 1350 et 1950 px). Dans la partie supérieure de l'empreinte (0 et 1350 px), les valeurs sont plutôt fluctuantes, allant de faibles à moyennes, alors que pour la partie inférieure de l'empreinte (1950 et 3872 px), la brillance diminue de façon graduelle (20 à 10).

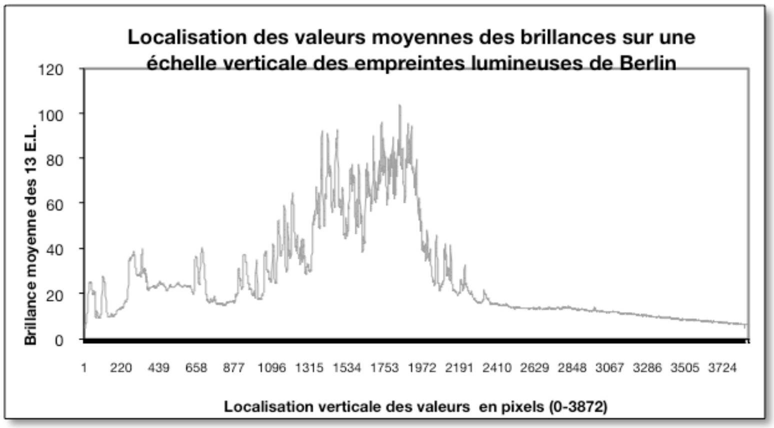

Figure 9 : Distribution moyenne des brillances sur l'ensemble des empreintes lumineuses.

Visualisation moyenne des couleurs

Le logiciel *Adobe Illustrator* CS3 et sa fonction « gradient mesh », permettent de créer des dégradés de couleurs à partir des empreintes lumineuses. Cette analyse sert à comparer les moyennes de couleurs obtenues sur l'échelle verticale d'une empreinte lumineuse. Les couleurs se fondent ainsi les unes dans les autres, ce qui donne une impression plus forte de celles-ci, en faisant abstraction des lignes. Cela simplifie la comparaison des couleurs pour l'ensemble des empreintes lumineuses.

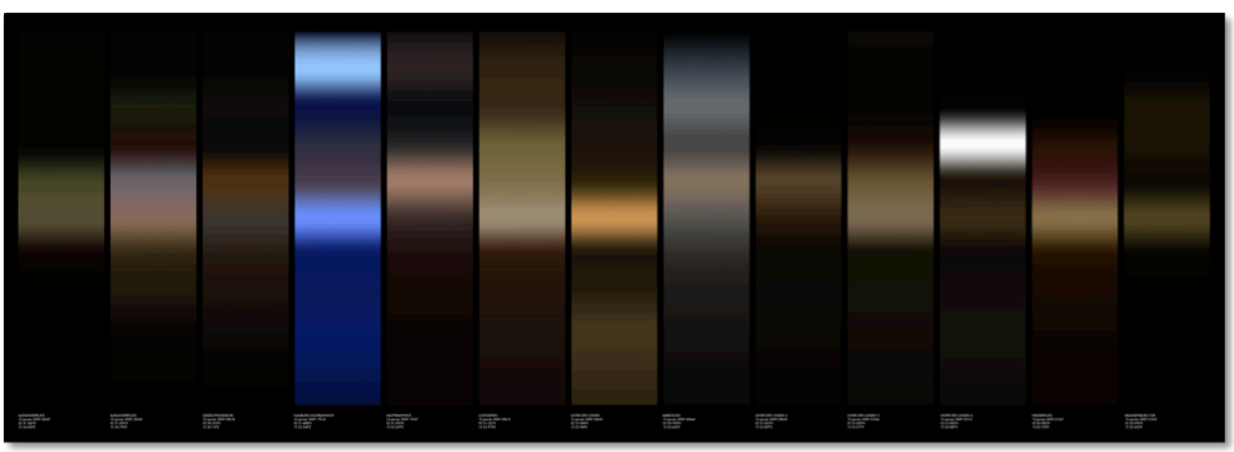

Figure 10 : Les 13 empreintes lumineuses couleurs de Berlin transformées en 10 gradients vectorisés.

En brouillant le paysage nocturne horizontalement, l'ordre vertical des couleurs et des tonalités prédomine sur les détails et les lignes. L'ensemble des couleurs devient par conséquent un matériel de travail et de réflexion.

Synthèse

La mise en application de la méthode sur des échantillons pris à Berlin et à Paris a prouvé que l'outil développé permet notamment d'étudier et d'analyser les ambiances lumineuses pour les aspects suivants:

- Transposer photographiquement des ambiances lumineuses urbaines dans leur ensemble.
- Extraire des informations qualitatives et quantitatives pertinentes sur l'ensemble d'un lieu.
- Étudier la couleur des sources lumineuses des espaces publics et obtenir des moyennes de couleur.
- Analyser les contrastes, la brillance et de les couleurs des sources lumineuses dans un environnement en entier.
- Évaluer l'homogénéité ou l'hétérogénéité d'un parcours lumineux.
- Comparer l'identité lumineuse entre plusieurs lieux.

L'étude a mis en évidence l'intérêt de développer la recherche sur la lumière urbaine. Il serait intéressant, par exemple, d'effectuer une analyse en fonction du zonage ou de l'échelle spatiale, des préoccupations de ses habitants, des spécificités des sites. D'autres expérimentations avec l'outil pourraient aussi être effectuées en vue de mesurer l'intensité lumineuse d'un environnement ou encore ses excès de lumière. Une adaptation du procédé du balayage photographique permettrait éventuellement de déterminer une corrélation entre le niveau de brillance et le niveau de pollution lumineuse dégagé par une source de lumière à partir de points précis dans l'espace.

Limites de la méthode

Il convient de dire qu'il existe une multitude d'approches pour cerner la lumière dans l'espace et qu'il n'existe pas une démarche exacte. L'empreinte lumineuse, même si elle est soumise à certaines contraintes, permet tout de même la précision dans certaines mesures.

Lors de l'analyse d'une empreinte lumineuse, plusieurs facteurs peuvent influencer la démarche expérimentale et l'interprétation des données. Cette synthétisation de la lumière comporte des limites. D'abord, elle ne s'applique qu'à des endroits bien précis dans l'espace. Le mouvement horizontal ne tient pas compte de toutes les forces lumineuses verticales qu'on peut retrouver dans le paysage. La superposition des couleurs par rotation affecte les rendus. L'imprécision des mesures d'un appareil à un autre ou d'un objectif à un autre peut aussi affecter les données.

Conclusion

Cette recherche exploratoire a élargi les possibilités offertes par les outils photographiques et informatiques pour l'analyse des espaces publics urbains. Elle tentait spécifiquement de développer le balayage photographique de la lumière, un processus d'analyse, de réflexion et d'exploration qui permet de réfléchir sur l'aménagement des paysages urbains nocturnes et la représentation des sources lumineuses pour un lieu dans son ensemble.

Le développement de cette méthode, où le lieu est appréhendé non seulement à 360^{o}, mais aussi en mouvement, souligne comment l'image photographique peut aider les différents acteurs du milieu à saisir l'impression ressentie par les utilisateurs des lieux publics. Les expériences et les analyses effectuées pour l'élaboration de cet outil suggèrent en effet que les ambiances lumineuses créées par la lumière artificielle peuvent être condensée sur une empreinte lumineuse. Le balayage photographique peut aider à mesurer certaines qualités lumineuses des espaces urbains. Dans l'ensemble, les empreintes lumineuses permettent donc d'établir une relation physique et abstraite entre l'espace, la lumière et le mouvement, essentielle à la représentation visuelle de l'environnement et des ambiances.

Les empreintes suscitent l'inspiration et peuvent se concrétiser en projets d'éclairage urbain. En effet, cette technique permet d'obtenir une composition propre et unique à chaque lieu et dans le temps. La lumière urbaine est une composition collective. Commerçants, citoyens et aménagistes participent à la créer. L'exploration présentée ici devrait ainsi permettre d'optimiser son utilisation par tous les acteurs du milieu.

Analyzing the Appearance and Wording of Assessments: Understanding their Impact on Students' Perception and Understanding, and Instructors' Processes

Stacie Rohrbach, Carnegie Mellon University, USA, stacie@cmu.edu

Abstract

In the context of a design studio, the study presented in this paper investigates the effects that appearance and wording of assessment forms have on design students' perception and learning. The project is motivated by hypotheses formed by a prior study, which revealed visual and textual components of assessment forms as possible influences on students' perception and learning. Thus, the goal of this project is to investigate their impact on students and offer the study findings to educators to help them better understand and construct effective assessment tools.

This paper argues that the appearance and wording of assessments convey meaning and must align with the activities and discussions that are common in design courses. This argument is supported by research that emphasizes the seamless integration of all steps of the learning process (Biggs, 2003) and the importance of students' learning preferences in developing lesson plans (Gardner, 1993). The paper explains the construction of four assessment forms. It also describes the post-evaluation self-reflections that students wrote and the questionnaire they completed at the end of the course. These project components were conducted to learn what students retained and how they perceived the assessment forms. In addition, the instructors provided their perceptions and time allocated to using each tool.

The outcomes of the study revealed that the digital assessments were more efficient to complete than the handwritten form. Students noted little difference in their satisfaction between the digital and handwritten forms when the wording stayed consistent. However, they did prefer comments that were personal and related to each specific project. The students retained more information from assessments that included a clear visual hierarchy and eliminated ambiguous titles. These findings informed the proposal of visual and textual considerations that should be taken into account when creating assessment forms for use in design classrooms.

Keywords

Visual design, rubrics, assessment, evaluation, pedagogy, education, learning, feedback

Throughout the past decade a large segment of professional design practice has gone from focusing solely on the creation of artifacts to also emphasizing the importance of collaboration within and among disciplines, applying a range of design processes, and engaging in projects actively throughout their duration (Poggenpohl, 2004). At the same time, government agencies are requiring the documentation of measureable outcomes (Middle States Commission on Higher Education, 2003). These changes require educators to not only rethink the ways they teach but also the ways they assess students' performance. Many educators are adjusting project plans and course activities to align with professional practice. (Heller, 1998). In contrast, based on the review of assessment tools used by design educators over the past several years, little has changed in the ways instructors evaluate students' performance. As a result, there is a misalignment between how design courses are taught and how students' performance is assessed, which in turn, negatively impacts the learning process. (Biggs, 2003). Assessments in design courses often focus on a review of an artifact instead of the learning process, which encourages students to work passively with the intent to please their instructors instead of striving to solve complex problems independently (Davies & Reid, 2000; Long, 2004). Research indicates that students devote much time and attention to the assessments that they receive and that these tools significantly impact students' learning (Brew, 1999). Hence, improving assessment processes to align with course activities is crucial to enhancing design students' learning.

Based on the survey of assessment tools conducted for this study, many design educators who have altered their evaluation process now utilize rubrics. In their book, *Introduction to Rubrics*, Stevens and Levi (2005) define the term. They state,

> At its most basic, a rubric is a scoring tool that lays out specific expectations for an assignment. Rubrics divide an assignment into its component parts and provide a detailed description of what constitutes acceptable or unacceptable levels of performance for each of those parts. Rubrics can also be used for grading a large variety of assignments and tasks: research papers, book critiques, discussion participation, laboratory reports, portfolios, group work, oral presentations, and more. (p. 3)

In addition to including a matrix of evaluative criteria and performance attributes, the structure of rubrics also stress the importance of aligning assessments to project objectives, and methods for translating performance ratings into grades (Stevens & Levi, 2005). It is logical for educators to explore the use of rubrics in the context of design courses based on learning science research that proves their success in assessing students' performance and applying them across disciplines (Goodrich, 2000). Although rubrics provide methods that are intended to help instructors develop and use assessments, discussions with design educators and students reveal a reluctance to adopt the suggested evaluation changes. A study that researched the actual and perceived effectiveness of rubrics in a design studio showed that students appreciate the clarity provided in rubrics but prefer less-informative feedback that poses questions and is personal, which matches the activity in design classrooms (Rohrbach, 2008). The outcomes of this study lead to the hypothesis that the form of assessments should draw on the teaching characteristics of design courses.

In his book, Frames of Mind, Howard Gardner explains that people learn best when information is communicated to them in ways that match their learning preferences (Gardner, 1993). Based on several years of teaching experience, information that is communicated to design students through one-to-one conversations and visualizations, such as sketches, appears to resonate with them more than densely written text and quantitative tests, which confirms Gardner's notion. Research that describes the use of rubrics explains the importance of clear wording in communicating evaluative criteria and performance attributes to students (Goodrich, 1996). Unfortunately, although this is informative, such efforts often lead to a document that is text-heavy and impersonal in its structure, which misaligns with the learning preferences of many design students. Hence, it is logical for them to prefer to receive feedback as handwritten comments as opposed to pre-formatted text because it appears more personal, matching their expectations, despite the fact that it often provides them with less information regarding their performance and ways to improve in the future. Thus, studies, which focus on improving design students' perceptions of assessments while maintaining the clarity and robustness of information provided via rubrics, must be investigated.

Another critical component of assessing the performance of design students is the appearance of evaluations. Visual perception and cognition are critical learning components for people who often have a heightened sense of visual acuity, such as design students (Kosslyn & Koenig, 1992). They spend a great deal of time analyzing design artifacts and constructing compositions. Hence, it is logical for design students to read the appearance of their assessments and gather meaning from them. Unfortunately, research that focuses on the impact of visuals on perception and understanding in the context of assessments has not been found. Thus, studying the effects of visual form on students' perception and learning is warranted.

This paper argues the need for assessment tools to reflect design students' learning preferences and expectations, and align with course activities not just in their content but also their form and delivery. This premise is based on research that stresses the importance of weaving together all the stages of learning (Biggs, 2003), from the onset of a project to the receipt of assessments (Wiggins & McTighe, 1998), and the value of visual perception to learning and understanding (Kosslyn & Koenig, 1992), especially for design students, who often prefer to learn visually. The study uses rubrics, which have been proven to provide design students with informative feedback (Rohrbach, 2008), as a basis for exploration, with each assessment form including slight modifications in wording and appearance. The outcomes generated in this project illuminate the impact that the visual tendencies of design students and the unique structure of design courses can have on the effectiveness of assessment tools.

The construction of four assessments forms that are based on rubrics but vary in wording and visual appearance is illustrated and described in this paper. The use of each form in relation to specific projects is explained and the findings gleaned from a questionnaire, a series of self-reflections, and documentation by instructors are also included in this paper. Study limitations and principles that inform the wording and appearance of assessments forms that are derived from the study outcomes conclude the paper along with projected next steps in the study of evaluation methods in the context of design education.

Background and Context

I received a fellowship in the summer of 2007 that enabled me to work with teaching experts and four professors positioned in other disciplines to investigate the development, delivery, and assessment of projects in the seminar courses that I teach. Although the assessment portion of the fellowship focused on evaluating students' writing by using rubrics, I began to question the application of rubrics in assessing design projects and the perception of rubrics by design educators and students. Therefore, I conducted a study that investigated these issues within the context of a design studio with 48 first-year design students and the two educators of the course. The results of the study showed that students perceived attributes of rubrics more positively than other forms of assessment but still preferred handwritten comments. Thus, there appeared a disconnection between assessments that aided learning and those that students preferred, which warranted further investigation.

Research Goals

The initial investigation I conducted shed light on the perceived successes and failures of a range of assessment tools. However, perhaps the most significant finding from this study was the difference between assessments that students preferred and those that they believed were most effective. Through an analysis of theses results I hypothesized that the disparity might be attributed to differences in wording and appearance, which inspired a second course of inquiry. Educators can assess the outcomes of design courses fairly and consistently using assessment tools, such as rubrics, that are proven successful in other disciplines (Ehmann, 2005). However, the individual attention that students receive in studio courses and their tendency to grasp information visually may warrant the delivery of evaluations in alternate forms to improve their learning, value, and understanding of assessments. Therefore, I developed a study that investigates the visual and textual forms of assessments.

The goal of the study presented in this paper was to gain insight into how the appearance and wording of rubric-based assessment forms affect design students' perception of the tools and support or negate learning in the context of a first-year studio course. Although studies exist that argue the success of rubrics across a range of disciplines based on systematic measuring of student learning (Fuchs and Fuchs, 1986), research that supports the notion that the appearance and wording of assessments affect students' learning and perception has not been discovered. Therefore, this project uses variations in assessment forms throughout a course, student self-reflection writings, a questionnaire completed by students in the class, and documentation provided by the course instructors, as research content. This paper then uses the analysis of the project outcomes to argue the importance of visual and textual attributes of assessment forms to students learning, understanding, and value of evaluations. The results of the project also inform the proposal of design considerations that educators may find beneficial when creating assessment forms for design students, and call attention to issues of assessing the outcomes of design courses that require further study. In pursuit of these goals, this project seeks to answer the following research questions:

- How does the appearance of information affect students' learning, understanding, and perceived value of assessments?
- How does the wording of assessments affect students' learning, understanding, and perceived value of assessments?
- How does the form of assessments affect the amount of time instructors allocate to the task and how they perceive the accuracy and consistency of their reviews?

Implementation

The study was performed during the 2008 fall semester in a required studio course for 45 first-year design students, which I taught with a colleague. Similarly to the first study, my colleague and I established a set of preferred outcomes for the course that would prepare students for their next stage in the curriculum. Our intention was to help students better understand the meaning of design, what designers do, and why they are needed. We sought to help them identify design opportunities, learn and employ strong design processes, evaluate work, and propose ideas for improvements. I constructed a course rubric that articulated these goals in written form for the students' repeated reference and guidance. The learning objectives were broken into four categories—process work, resolution, participation, and attitude—and four sets of performance attributes aligned to each criteria. We also explained the objectives to the students the first day of class and emphasized that through the design of two- and three-dimensional individual and group projects, they would strive to:

- develop appropriate ideas in response to project assignments
- build a process for working that enables consistent, incremental growth
- articulate their ideas well, both verbally and visually
- translate and communicate ideas into effective, well-crafted visual forms
- collaborate with their peers: share ideas and information
- understand and integrate feedback into their creative working process
- illustrate an understanding for how context shapes, and is shaped by design

Assessment Forms

In this study, the form that was proven the most effective learning tool in the prior assessment investigation—a rubric—was used consistently throughout the semester to evaluate project outcomes. The visual appearance of the information, the wording used to provided feedback, and the ways the forms were completed, varied. To limit the interference of the various project parameters on the study, students were divided into four groups, which would indicate the type of assessment form they received for each project (table 1). The first two assessments differed in visual appearance but did not vary in content or language structure. The assessments for the third and fourth projects functioned similarly. However, the division of groups changed to minimize the impact of the assessment instruments on the outcomes. It is important to note that the content and language structure of the first two assessment tools varied from those used for projects three and four.

	Assessment A	Assessment B	Assessment C	Assessment D
Student Group 1	Project 1	Project 2	Project 3	Project 4
Student Group 2	Project 1	Project 2	Project 4	Project 3
Student Group 3	Project 2	Project 1	Project 3	Project 4
Student Group 4	Project 2	Project 1	Project 4	Project 3

Table 1

The assessment form that I created for the first two projects consisted of the general rubric that was used as an overview for the entire course. It included the four sets of learning objectives—design process, resolution/final work, participation, and attitude—and four sets of performance attributes aligned to each objective. The text was written in paragraph form and cited general practices that applied to the course as a whole, as opposed to the individual project. As a part of our evaluation, my colleague and I checked a box next to a paragraph in each row that best described each student's performance. Each row included a space beneath it where project-specific comments could be listed. The feedback consisted of observations made during the corresponding project and suggestions geared toward helping students improve their performance in the future. Prior to our evaluating sessions, my colleague and I established a list of common comments that we would provide students. These aligned with the learning objectives that students received in the project briefs and were based on the work that we saw in development and our experiences with the students. I constructed digital versions of the assessment forms that enabled us to select several of the comments via drop-down menus (Fig. 1). The students received printed versions of these assessments where the comments appeared as typed sentences without the drop-down menu present. For the other project, students received a similar form. However, instead of typed comments, the same sentences were handwritten (Fig. 2). This enabled the comparison of handwritten to typed comments in a situation where the wording structure was identical.

The last two assessment forms that I developed consisted of a rubric that included performance attributes that were specific to the third and fourth projects. The content of each rubric matched the learning objectives listed in the briefs that the students received at the beginning of each project. The content structure of these forms differed from the first two in that their performance attributes weren't written as all-inclusive paragraphs. Instead, each comment was separated with a check box next to it but still resided in the columns and rows of the rubric. This enabled us to check one component of their process work, for example, as "excellent" and another as "good". The visual appearance of the assessments used in projects three and four differed, while the content structure and wording stayed consistent and students received printed versions of each assessment. One of the forms showed all of the text in black with comments relevant to the individual student checked (Fig. 3). On the other form, all of the text appeared as a 50% gray with the relevant comments shown in black and checked (Fig. 4). The goal of this part of the study was to investigate the effects of visual hierarchy on students' perception and understanding of the feedback they received.

This set of figures shows portions of each of the assessment tools that were used in the freshmen design studio throughout the duration of the course. Note that to enable the comparing of assessment tools, the segments shown here relate to the "design process" attribute in each project. However, students were also assessed based on their resolution/final work, participation, and attitude.

Process	☐ **excellent**	■ **good**	☐ **needs improvement**	☐ **unacceptable**
	breadth and depth of ideas generated and explored is extensive; evidence of steady progress shown through sketches, models, notes, etc. is clear and consistent; ideas are thoroughly evaluated and clearly used to inform steps taken in development and refinement stages	the required amount of ideas are generated and are moderately varied, some sporadic evidence of progress is shown through sketches, models, notes, etc.; ideas are evaluated and connected loosely to the development and refinement stages of projects	a few ideas are often generated; little evidence of progress is shown through sketches, models, notes, etc., ideas appear to be occassionally evaluated; loose connections of process work to the development and refinement of ideas is seldom visible	a single idea is typically generated; evidence of any progress is difficult to find; few sketches, models, notes, etc. have been made; evaluation of ideas isn't evident; connection of process work to the development and refinement of ideas is unclear
Photo composition	You generated a good quantity of quality sketches and notes.			
Type composition	You need to improve your use of sketches and notes as tools that aid your understanding and inform your next steps. You explored a good range of ideas. Keep it up.			

Fig. 1: Shown here is a portion of an assessment sheet that students received after conducting the first or second project in the course. It includes a general rubric that pertains to the entire course, which students received in the syllabus. It also provides students with project-specific feedback in the form of typed comments.

Process	□ excellent	■ good	□ needs improvement	□ unacceptable
	breadth and depth of ideas generated and explored is extensive; evidence of steady progress shown through sketches, models, notes, etc. is clear and consistent; ideas are thoroughly evaluated and clearly used to inform steps taken in development and refinement stages	the required amount of ideas are generated and are moderately varied, some sporadic evidence of progress is shown through sketches, models, notes, etc.; ideas are evaluated and connected loosely to the development and refinement stages of projects	a few ideas are often generated; little evidence of progress is shown through sketches, models, notes, etc., ideas appear to be occassionally evaluated; loose connections of process work to the development and refinement of ideas is seldom visible	a single idea is typically generated; evidence of any progress is difficult to find; few sketches, models, notes, etc. have been made; evaluation of ideas isn't evident; connection of process work to the development and refinement of ideas is unclear
Photo composition	You generated a good quantity of quality sketches + notes.			
Type composition	You need to improve your use of sketches + notes as tools that aid your understanding + inform your next steps. You explored a good range of ideas. Keep it up.			

Fig. 2: Shown here is a portion of an assessment sheet that students received after conducting the first or second project in the course. Similarly to Fig. 1, it includes a general rubric that pertains to the entire course, which students received in the syllabus. It also provides students with project-specific feedback in the form of handwritten comments.

Process	■ the quantity of quality sketches and models generated is extensive	□ the quantity of quality sketches and models generated meets requirements	□ the quantity of quality sketches and models generated is small	□ the quantity of quality sketches and models generated is limited to one or two
	□ an extensive range of ideas is explored	■ a moderate range of ideas is explored	□ a small range of ideas is explored	□ one or two ideas are explored
	□ ideas are thoroughly evaluated and clearly used to inform steps taken in development and refinement stages	■ ideas are evaluated and connected loosely to the development and refinement stages of projects	□ ideas appear to be occassionally evaluated and loose connections of process work to the development and refinement of ideas is seldom visible	□ evaluation of ideas isn't evident and the connection of process work to the development and refinement of ideas is unclear
	□ a working process that matches project specs is clearly evident	□ a working process that matches project specs is somewhat evident	■ a working process that matches project specs is diificult to find	□ a working process that matches project specs is not evident

Fig. 3: Shown here is a portion of an assessment sheet that students received after conducting the third or fourth project in the course. It consists of a project-specific rubric in which each comment is separated from the others but remains in the same column. Feedback that pertains to the individual student is noted by a black checkbox. All text is shown in black.

Process	■ the quantity of quality sketches and models generated is extensive	□ the quantity of quality sketches and models generated meets requirements	□ the quantity of quality sketches and models generated is small	□ the quantity of quality sketches and models generated is limited to one or two
	□ an extensive range of ideas is explored	■ a moderate range of ideas is explored	□ a small range of ideas is explored	□ one or two ideas are explored

Fig. 4: Shown here is a portion of an assessment sheet that students received after conducting the third or fourth project in the course. Similarly to Fig. 3, it consists of a project-specific rubric in which each comment is separated from the others but remains in the same column. Feedback that pertains to the individual student is noted by a black checkbox and black text. Comments that don't pertain to the individual remain gray.

Self-Reflections

At the start of the class following the receipt of each assessment form, students were asked to take ten minutes to jot down all of the feedback they could remember receiving on the sheet and to explain their understanding of the information and how they planned to use it in the future. This step of the study was intended to ascertain students' retention and understanding of the assessments.

Questionnaires

On the last day of the course, students completed a survey that asked them questions about their perception of each assessment form. The task, which took approximately ten minutes, was conducted via the internet and the students' responses were logged anonymously. The questionnaire was divided into four parts—each corresponded to a different assessment form but asked the same questions in a consistent manner. Most of the questions were followed by a set of pre-written responses and an area for students to enter their own comments, all of which were accompanied by checkboxes that students either ranked in terms of importance or selected all that applied.

In the questionnaire, students were asked how thoroughly they thought they read each assessment, how well they believe they understood the content, and what attributes of the assessment they thought infringed on their understanding of the information. Students were asked to consider the importance of individual assessment attributes to them and then rank each component, such as grade listings, and individual comments, on a five-point scale. The students performed a similar task when asked what they gained from the feedback, such as direction on how to improve in the future, and an understanding of what they performed well in the corresponding project. Disregarding their actual project grades, students were asked how satisfied they were with each of the assessments they received. If they weren't completely satisfied, they were asked to identify reasons that attributed to their dissatisfaction. Lastly, at the end of each section of the questionnaire, which related to a particular assessment form, students noted the grade they received for the corresponding project. This process enabled the examination of students' perceptions of visual and textual information and how the forms of the assessments impacted their preferences.

Study outcomes

The results of the questionnaire verified some hypotheses, revealed a few surprises, and fuelled a subsequent study. For purposes of clarity, I will identify each of the assessments throughout this section as:

- A: the assessment that includes a general rubric and typed comments selected from dropdown menus;
- B: the assessment that included a general rubric and handwritten comments that were identical to those selected from dropdown menus;
- C: the assessment that included a project-specific rubric that was separated into individual points shown in black text; and
- D: the assessment that included a project-specific rubric that was separated into individual points shown in gray and black text.

In each set, the first few questions referenced students' reading and understanding of the assessments. The vast majority of students noted that they read each assessment thoroughly (Fig.5) and that they understood all of the information (Fig.6). It is important to point out that although the distinctions are slight, students read assessments A and C, which contained a full page of black printed text, less thoroughly than B and D, which included handwritten or gray and black text. Students also indicated a slightly higher understanding of C and D—the detailed rubrics—than A and B—the general rubric. The students' lack of knowledge of design terminology may have attributed to their high rankings of ambiguous and unfamiliar language as causes of their misunderstanding (Fig.7). It's important to note that students found the amount of text on A and C more problematic than B and D.

The next set of questions in each section related to students' value and use of the assessments (Figs. 8, 9). Here, slight differences among the assessments became apparent. Students valued their grades on C and D, which didn't include column labels such as "excellent" and "good", more than on A and B. The placement of checkboxes was less important in C, which lacked visual hierarchy. In addition, individual comments were valued more on A and B, which didn't reference project-specific criteria in the rubrics. When asked which assessment provided specific information well, students noted B, which included handwritten comments, as best supplying suggestions for improvements and D, which utilized gray and black text, as best indicating their performance on the relevant project. Students pointed out that C and D, which included project-specific rubrics, listed important attributes of the corresponding project better than A and B, which used a general rubric, and that the translation of feedback to a grade was most clear in D, which used visual hierarchy to delineate content. Interestingly, students' consistent use of the assessments did not appear to be affected by the differences in the types of feedback they received—A and B pointing out project performance and offering suggestions for improvements, and C and D simply noting project performance.

The last section of each set in the questionnaire dealt with students' satisfaction of the assessments. Although differences among the four forms were evident, the discrepancy between printed and handwritten feedback was slight in comparison to a similar study that was conducted in the fall of 2007 (Rohrbach, 2008). In the study described in this paper students noted that they were most satisfied with C and D consistently, followed by B then A (Fig. 10). Their preference may be attributed to the detail, clarity, and specificity of the project-based rubrics used in C and D. Students who claimed that they were not completely satisfied with the results of the assessments, largely attributed their dissatisfaction to a lack of information (Fig.11). Many of them expanded on their notation, stating that they wanted more time to discuss their work with their instructors. Lastly, there was no noticeable correlation between students' grades and their responses to the assessment questionnaire.

Although students' self-reflections that were collected as part of this study were written in prose, similarities arose among the set. Students' retention of information from assessments A and B were consistent, indicating that the form, whether it was printed or handwritten, had little impact on the content that students remembered and how they planned to use it. Students were consistently focused on the performance headings shown on assessments A and B, such as "excellent" and "good", and seldom connected the titles to concrete information about their performance. Hence, the headings were dropped from assessments C and D, which marked an increase in students' descriptions of their performance in their self-reflections. Students also appeared to remember more information from assessment D, which utilized visual hierarchy, than assessment C, which lacked visual hierarchy.

The instructors documented the amount of time spent completing the various assessment forms throughout the duration of the course. Instructors spent approximately seven hours completing the handwritten assessments and four hours completing the digital assessments. In review of the first two assessments my co-teacher and I noted that the forms diminished our time on the task and reduced our tendency to scrutinize specific attributes of students' projects that often cause inconsistencies among our assessments. However, the necessity to check one paragraph that cited several performance attributes prevented us from commending specific successes or noting particular areas for improvement. In contrast, the last two assessments, which separate each individual performance attribute, required us to examine details more than we had in the past. This characteristic is not necessarily problematic but forced us to assess students' performance in an unfamiliar manner.

This set of figures illustrates students' perceptions of the four assessment forms used in the freshmen design studio. The data was collected via a questionnaire that the students completed anonymously at the end of the course. Moving from left to right, each column correlates to a specific assessment form—A,B,C,D, as listed at the start of the study outcomes.

Study Limitations

Although the structure of this investigation, which is illustrated in Table 1, limits the interference of the project parameters throughout the course of a semester on the study, it is important to reiterate that the investigation was isolated to the context of a design studio that included first-year students. The narrow pool of participants enabled the in-depth study of assessment tools without having to account for vast differences in students' design skills, knowledge, and experiences. Nonetheless, this is an inherent limitation of the study because students' placement within a curriculum may have a bearing on their assessment needs and desires. Their diverse levels of maturity and learning experiences may warrant different approaches to assessment. Hence, the outcomes of this study are intended to serve as a basis for further investigation.

Conclusion

This study and its outcomes are intended to serve design educators by providing them with clear and substantiated information that facilitates their rethinking of the assessment process and guides their decision-making when conducting evaluations. It proposes methods for studying the visual appearance and wording of assessments and informs subsequent investigations in this area of research. As a result of this inquiry, I believe the design education community will gain a better understanding of the critical components of assessments and how they can use visual appearance, wording, and form structure to improve students' understanding of feedback and inform their subsequent learning.

Supply feedback aligned to students' educational experiences.

The outcomes of this study show that the majority of students understood all of the feedback that they received. However, students who noted a lack of understanding cited their unfamiliarity with the terminology, ambiguity of the feedback, and structure of the comments as causes. Thus, to improve all students' understanding of the assessments they receive, it's important for educators to consider the words they use when providing feedback, verifying that new terms are clearly defined and matched to each student's level in the curriculum. In addition, students noted that they believed the handwritten comments provided them with more direction on how they could improve their performance, despite the fact that the handwritten and typed comments were identical. Therefore, it is important for instructors to consider the wording and form of assessments to which students are accustomed, and introduce new instruments slowly, clearly explaining any changes in the evaluation metrics.

Provide comments that address a specific project and student.

Students' responses to the questionnaire and the information culled from their self-reflections indicate that they most preferred and understood project-specific feedback that was geared toward the individual. For example, more students noted that the detailed descriptions of their performance were highly important on assessments A and B, which presented them with a rubric that related to the entire course, than in assessments C and D, which used a project-specific rubric. This indicates that students sought personal and project-specific information that wasn't readily available in the rubrics. Students also noted that assessments C and D gave them a better understanding of the evaluative criteria and listed important attributes of the corresponding projects more effectively than assessments A and B, attributing the majority of their dissatisfaction with the assessments to a lack of information and stating that they wanted more direct feedback. Thus, educators must consider how broad, course-based statements negatively impact students' perception and understanding of the feedback they receive.

Remove vague titles of performance.

The review of self-reflections that took place after each assessment indicated that most students focused on the performance titles that had been marked by instructors on assessments A and B, such as "excellent" and "needs improvement". Students often cited their rating at the beginning of their self-reflections but failed to link them to concrete information that described their performance or offered suggestions for improvements. Thus, I think the vague performance titles provided students little useful information and instead caused them to stop reading the supporting information and look for connections among the content. Therefore, I believe instructors should be wary of titling performance levels and instead focus on the clear definition and delineation of one from another. I think this process will help students grasp project and course objectives and outcomes, and how they relate to each other, more effectively.

Situate individual comments within a larger context.

The questionnaire outcomes indicate that students were most satisfied with assessments C and D. Students' reasons are illuminated by the written responses that they provided in the questionnaire and also by the review of their self-reflections. Students noted relationships between their performance and attributes of those levels that were above and below their position in the rubrics. They noted that this helped them articulate their advances and inform further improvements. As a result, I believe situating each student's performance attributes within the larger context of the class helps them understand grading metrics and provides guidance for improving their performance.

Deliver feedback in a form that is efficient.

Provided that a consistent language is used to assess students' performance throughout a course, the differences in students' perception of handwritten and typed forms appear slight. The questionnaire responses indicate that students were minimally more satisfied with the handwritten assessments. In addition, the self-reflections showed that students retained the same amount and type of information despite differences in the visual form of the assessments. In contrast, the amount of time educators needed to assess students using the digital forms was significantly less than the handwritten forms. Thus, I believe it is important for instructors to explore alternative assessment tools with the intent of making them more efficient without sacrificing the quality of information they provide students.

Use hierarchy to improve perception and retention of content.

Perhaps most interesting are the results of this study that deal with the visual appearance of the assessment forms. Students indicated that they read assessments A and C, which included little visual hierarchy, less thoroughly than B and D. They also noted that the amount of text of A and C, which was identical to B and D, prevented them from understanding all of the feedback the received. Lastly, a comparison of self-reflections showed that students retained a great deal more information from D than C. In all cases, assessment D yielded the most positive results, which I believe is due to the form's clear and prominent hierarchical structure that draws attention to an individual's performance among attributes that reflect the class as a whole. Hence, I think instructors can improve students' perception and retention of assessment information by using visual hierarchy to reduce the overwhelming appearance of a text-heavy document and highlighting content that is pertinent to the individual student.

Use placement of text as a form of communication.

Based on the results culled from the questionnaire, the placement of assessment content can also provide students with valuable feedback. Students indicated that assessment D provided them with the most information about their performance and that they best understood how the feedback they received translated into a grade via this form. I believe these outcomes can be attributed to the visual pattern that results from highlighting comments that pertain to an individual within the context of the greater rubric. Hence, students can see that their grade is likely to be in the B range if most of the second column is highlighted. They quickly gain an understanding of their overall project performance and individual components that may not be in line with the others just by glancing at the assessment sheet. I think educators can use this information to help students form an overall, accurate perception of their performance on a project and also invite them to explore the feedback more thoroughly, linking it back to the first impression they made.

Next steps

This research project uncovers the affects that appearance and wording of assessments forms have on students' learning, understanding, and perception of the feedback. The study premise, research structure, and outcomes function collectively as a base, on which additional research on assessment in design education can be conducted. Although this project presents visual and textual principles for design educators to consider when constructing evaluation tools, the outcomes also reveal specific areas of assessment that warrant additional investigation. For example, the alterations to conventional rubrics in this study are slight. Therefore, another project may seek to extract the essential components of rubrics that must be retained in assessing design students' performance and further alter the appearance and wording to best suit students' expectations and the design studio context. In addition, since this project consists of instructors evaluating students' performance, which does not match the peer-to-peer and peer-to-educator interaction that is often present in design courses, another investigation may study the roles of design students' in the assessment process. However, these are but two directions that this research can follow. The key point is that it is important for educators to understand the critical role that assessments play in students' learning and understanding and that further studies are necessary to improve the evaluation instruments used in design pedagogy, making educational experiences enjoyable and effective.

Author Biography

Stacie Rohrbach

Stacie Rohrbach is an Associate Professor in the School of Design at Carnegie Mellon University in the United States. She teaches studio- and seminar-based communication design courses at all levels of the undergraduate and graduate curriculum. Rohrbach's research investigates how combining design processes and learning theories improves the teaching of complex and abstract content—specifically visual communication. She explores the design of educational tools and methods for university students within and outside of design, in classroom and online contexts. Rohrbach also applies her new knowledge to areas outside of visual communication, such as the biological sciences. The nature of her work allows her to explore the relationships between print and digital media and the communicative value of sound, motion, and visuals as educational tools.

Prior to her current academic appointment, Rohrbach worked professionally in both print and digital media. As an art director, designer, and researcher she developed identity systems, corporate standards manuals, interactive websites, promotional materials, and product packaging. She also taught design courses at Lehigh University as an Adjunct Lecturer. Rohrbach earned a B.F.A. in Graphic Design from Carnegie Mellon University and a Master of Graphic Design degree from North Carolina State University.

CAPTURING AND RETAINING KNOWLEDGE TO IMPROVE DESIGN GROUP PERFORMANCE

Dr Seymour Roworth-Stokes
Pro Vice-Chancellor
University for the Creative Arts, UK

Abstract

This paper explores the management and organizational context for capturing and retaining knowledge transferred through the design process.

It is widely acknowledged that our ability to successfully organise and transfer design knowledge is dependant upon the context in which it is situated. Cross (1992) has also highlighted the normally unsystematic way designers work and the limited extent to which the knowledge contained within the products they create is made explicit.

Essentially design knowledge transforms as it transfers (Ashton, 2007) and the knowledge-based resources of a design group are socially complex. Successful exploitation of these knowledge assets can secure competitive advantage (Alavi and Leidner, 2001) yet, a systematic literature review of leading design and educational management journals found limited empirical evidence that shed light on the influence of knowledge management on design group development.

The paper addresses this weakness in the literature and suggests that design consultancies utilise cross-disciplinary knowledge to solve problems which could not be resolved by linear disciplinary frameworks (Gibbons et al, 1994). Based on two in-depth case studies with interior design companies implementing new digital asset management systems over a two year period, the paper explores the findings in relation to design practice and policy, alongside implications for the contribution of the Creative Industries to the knowledge economy.

Introduction

The companies under investigation were supported through the Knowledge Transfer Partnership (KTP) scheme in the UK which draws upon academic expertise to improve organizational performance.

These schemes have been running for over 30 years and have helped businesses develop and embed new technologies, products and production processes. There has been considerable growth in KTPs as organizations have sought to exploit university expertise towards strengthening competitiveness, wealth creation, and social and economic performance.

Previous design related KTP research has focused on the long-term impact of strategies to innovate new products and services after a ten year period (Hands, *et al*., 2004) but the emphasis has often been on economic outcomes rather than design knowledge and its contribution to organizational development.

This research aims to develop a framework to identify the knowledge being captured and retained as designers' progress from one phase of the design process to the next. The intention is to shed light on the complex interaction of phenomena during the creative process which relates to both individual and design team knowledge.

Managing knowledge in the Design Group

It is widely accepted that knowledge is a key market asset for design groups (as described by Roworth-Stokes, 2007 and Harvey *et al.*, 2002). This is evident throughout the design process from research to concept development, from detail design to manufacture – in fact all the stages that underpin new product development. Design groups help their clients exploit design knowledge in a market for design services which is worth £4.8 billion in the UK alone (DCMS, 2001).

Gibbons *et al.* (1994) suggest that the production of knowledge is becoming increasingly focused toward the solution of specific problems through teams at the expense of the individual interests. It is argued that a new production of 'cross-disciplinary' knowledge is emerging – termed Mode 2 – which is distinct from the more traditionally based and linear disciplinary frameworks – Mode 1. Clark (1998) has proposed that this is a characteristic of 'entrepreneurial' organizations and it mirrors the way design groups manage knowledge for organizational advantage. Teams are brought together with multi-disciplinary expertise, with backgrounds in psychology, engineering and management to solve client problems.

Robertson and Hammersley (2000) found that consultancies wanted knowledge workers to develop their own knowledge – by sharing their own expertise and learning from others – in order to satisfy client demands and to be part of what was termed the 'cultural fit' of the organisation.

> *'Thus project team working was not hindered by consultants jealously guarding their personal knowledge and expertise...Valuable organisational knowledge and skills were thus retained within the firm over time…Expert consultants were selected on the basis of their cultural fit…Cultural fit implied a willingness and ability to share knowledge and…which allowed them to work with others from different specialisms and further develop and enhance their own intellectual capital.'*
> (Robertson and Hammersley, 2000, p.251)

Yet whilst there is a burgeoning literature on the contribution of the Creative Industries to the economy, there is a dearth of empirical research which has specifically focused on the ability of design groups to capture and retain knowledge within the design process. This paper will explain the practical interventions which address this gap in organisational performance and will then go on to explore the implications for policy and practice.

Methodology

Universities play a significant role in national innovation systems and are regularly cited in economic studies concerned with improving competitiveness through innovation and technology transfer. The term 'knowledge transfer' has recently broadened the concept of engagement between higher education and business in recognition of the need to harness both new and existing technologies that add value to the business and its customers through new products, services and enhanced organisational efficiency.

Building upon data sets already developed by the author in a research study exploring university knowledge transfer (Roworth-Stokes, 2007) two KTP projects were selected in the same sector to explore organisational processes which support knowledge capture, retention and exploitation. The projects both required the implementation of digital asset management systems (including web-design, digital archives and intranet development) within architecture and interior design practices. Academics supervised each project and oversaw the appointment of an Associate responsible for the implementation of the technological infrastructure over a two year period. This allowed for a close investigation of factors associated with knowledge management.

A summary of each case is provided below.

Case	Background	Context and purpose	Outcomes and benefits
A	Services: • Interior design • Architecture • Retail branding/ environmental graphics Clients: • HMV • Selfridges • City Councils	Context: • 20 staff • Turnover and profit declining Purpose: • Intranet facility with office manual • Purchase and implement digital asset management software • Create digital archive of previouse client work	Outcomes: • 15 staff • Turnover and profit stabilised • Database driven web-site • Digital Archive • Updated corporate identity, logo and business plan • Competitor analysis/new business database in other sectors Benefits: • Staff able to access digital archive of previous 10 years work • Prospective clients search website by client/service etc. • Designers can work remotely through secure Web site • Staff have an IT Service Desk supporting the intranet • Efficiencies in physical (utilisation of space) and human time in accessing client information
B	Services: • Interior design • Exhibitions • Architecture • Multimedia and graphic design Clients: • The Natural History Museum/ Maritime Museum • Lottery Fund projects	Context: • 13 staff • Turnover and profit decreasing Purpose: • Digital archive intranet • Archive database • Improved client presentation and on-line marketing • Efficiencies in project delivery	Outcomes: • 10 staff • Turnover reduced and profit increased • Archive Intranet (Website) • Archive Database Benefits: • Digital archive of previous 11 years of client artwork/admin • Prospective clients can get information on intranet • Designers use the Intranet for credential presentations • Efficiencies in physical (utilisation of space) and human time in accessing client information

Table 2. Description of case studies

The inquiry focused upon the interaction of cause and effect relationships during three stages of the project – origination, implementation and development. Building upon Eisenhardt's approach to deriving theory from case study research (Eisenhardt, 1989), documentary evidence, autobiographical interviews and semi-structured interviews where conducted with a range of staff.

Interviews with both the KTP employee and the Director of the design group were explored in depth, to identify the key events, milestones and the forces at play. A key feature of this approach was to establish as full as an account as possible in the respondent's own words with minimal intervention by the researcher. This technique, as described by Plummer (1983), was employed to give 'voice' to each individual view. As Plummer (ibid, p.57) argues: *'views, truths and conceptions of the real can never be wholly ripped away from the people who experience them'*.

The interview commenced by asking respondents to consider the circumstances which led to the initiation of the project before describing its implementation and outcomes, highlighting any critical incidents or factors along the way. This was followed by a series of structured questions around the themes of leadership, management, organisational development and developments in the design sector.

Careful wording of each question within the interview protocol was critically important to attaining as full and 'open' a response as possible – striking a balance between the need to guide the discussion around topics whilst not wanting to 'phase' respondents with 'management speak' they might not relate to. For example the theme of management sought to clarify perceptions towards resources and communication which led to the question: *'To what extent has the scheme improved the sharing of information and knowledge e.g. client work, contacts etc?'*

All quotations were fully transcribed and pseudonyms and codifications were used for all people and places to provide confidentiality and anonymity.

Findings

As recognised by Eisenhardt (1989) and Miles and Huberman (1984) there is a risk that there can become a divide between the actual data obtained and the conclusions derived. The huge amount of qualitative data accumulated can mean a lack of clarity within the filtration procedure and a lack of consistency in the process of condensation.

> *'Analyzing data is the heart of building theory from case studies, but it is the most difficult and least codified part of the process. Since published studies generally describe research sites and data collection methods, but give little space to discussion of analysis, a huge chasm often separates data from conclusion.'*
> (Eisenhardt, 1989, p.539)

A process of coding was undertaken to develop 'nodes' by highlighting each element of text that had meaning for the respondent. For example: *'once I had got the commitment of the staff I got going'* was coded as 'trust'. Here, Strauss and Corbin's (1990) well detailed method of building substantive and formal theory from qualitative data was employed, whereby open coding was used to label discrete events or phenomena, and categories identified to group concepts identified through phenomena pertaining to common themes.

In order to summarise the relationships identified and to make sense of the complex interaction of nodes and themes a visual approach to the display of data was sought. As described by Miles and Huberman (1994) the causal connection diagram was employed and is presented below. This incorporates a chronological 'timeline' on the left hand side of the diagram whilst the 'nodes' on the right signify connections between the incidents, happenings and events identified.

Miles and Huberman (1994, p.227) suggest *'such a chain helps analysts lay out explicitly what may be causing certain phenomena. Although the chain does represent a simplification, that very simplification carries with it the seeds of a fuller explanation'*.

For example, node 3 and 4 refer to the need to recruit a new Associate with the appropriate technical and educational background. This was referred to by those interviewed as 'A LOW PERIOD' due to the need to manage knowledge more effectively throughout the organisation.

In determining the significance of a cause and effect relationship the author draws upon Flanagan's (1954, p.327) definition, in that it *'must occur in a situation where the purpose or the intent of the act seems fairly clear to the observer and where its consequences are sufficiently definite to leave little doubt concerning its effects.'*

These broad patterns of causality form the basis for the discussion which follows.

PATTERNS OF CAUSALITY

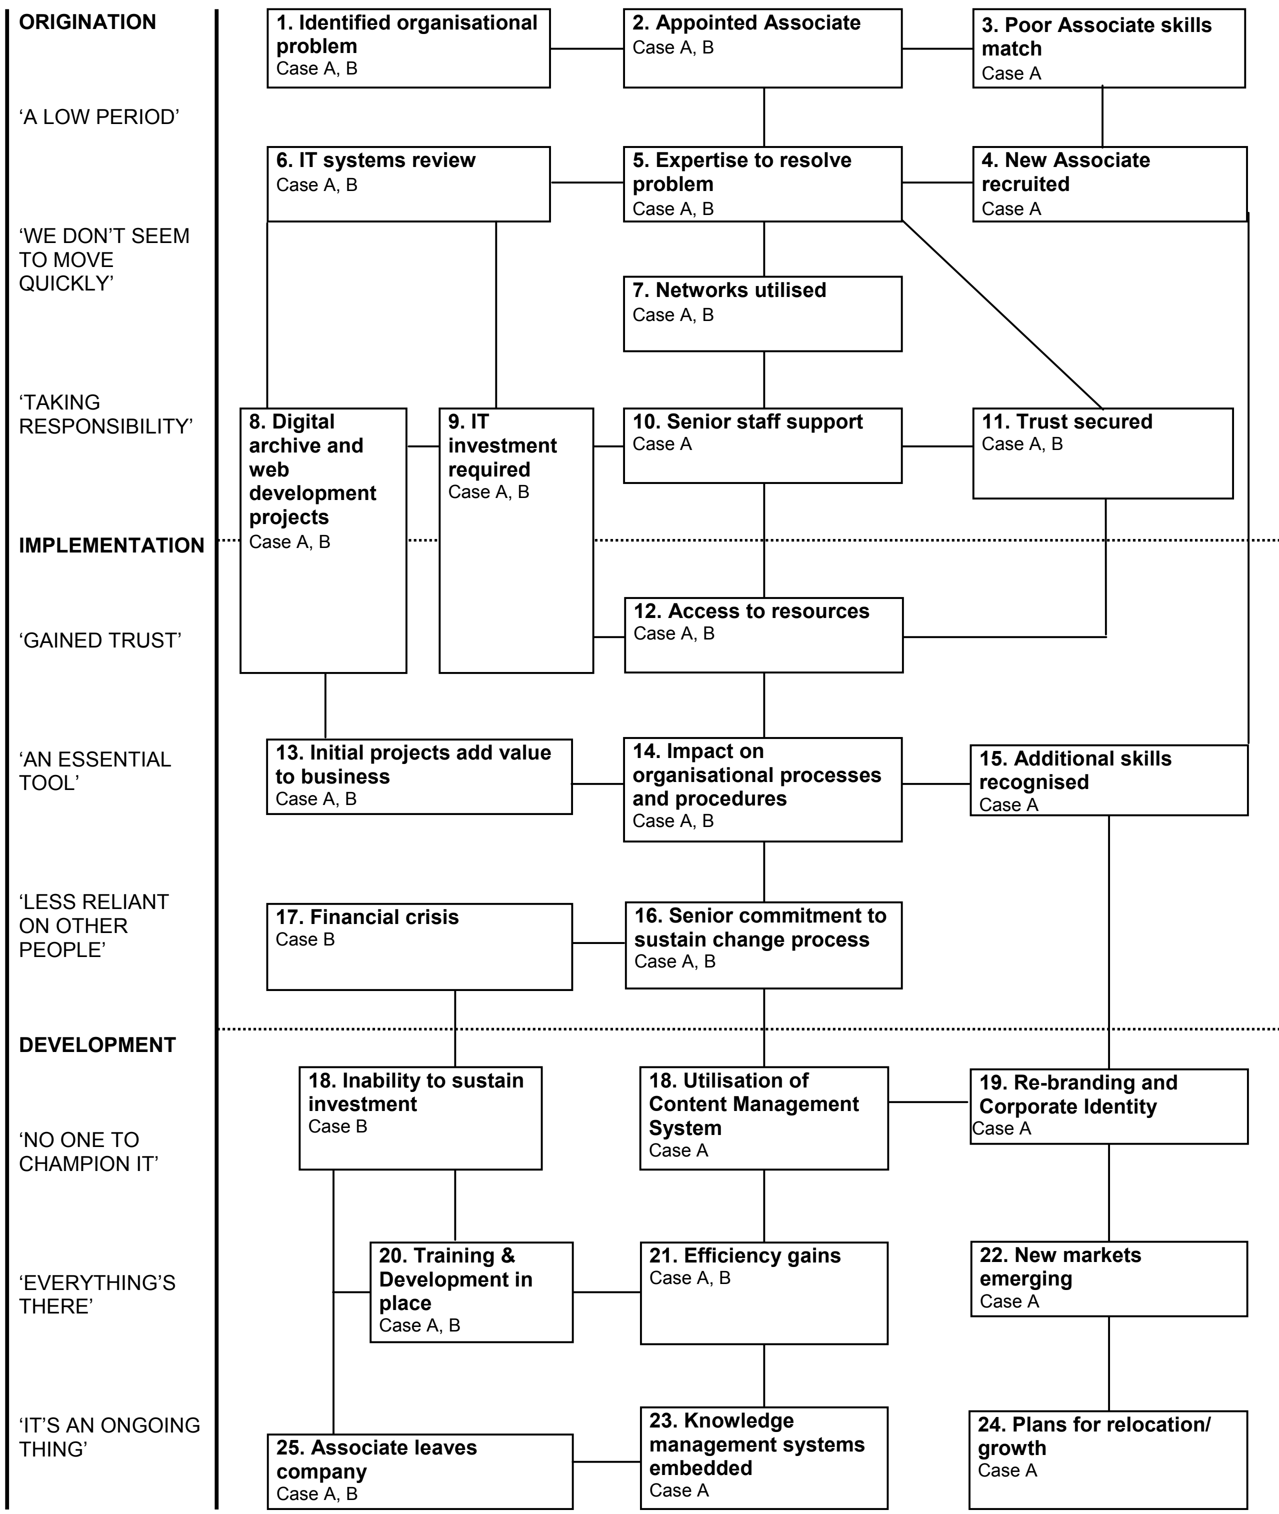

Figure 1. Cross case analysis of causal connections (modified from Roworth-Stokes, 2007)

ORIGINATION

'A LOW PERIOD'

At the point of origination both companies had identified similar organisational problems to improve efficiency (1) and increase competitiveness.

> *'the company had different digital assets which were difficult to find…over 10 years of data structures which were badly structured throughout the organisation…they were repeating a lot of information and designers couldn't find anything'*
> (Associate)

The need to improve digital asset management had the potential to improve communication and reduce duplication of client artwork between designers whilst enhancing awareness of design expertise through web based promotion and marketing.

Each associate (2, 3, 4) used their technical and educational background to conduct an audit of the organisations knowledge management systems.

> *'when I first arrived I was asked to look at the organisation and see what areas needed improvement…but there were various other problems such as the web-site needed upgrading and there wasn't any form of intranet.'*
> (Associate)

'WE DON'T SEEM TO MOVE QUICKLY'

As the Director of Case A pointed out, *'two years ago we could just about get by'* but the pressure to address this gap in performance had changed with a downturn in business following the millennium boom in regeneration work. A lack of in-house technical competence and expertise in web-design and intranet development had the potential to significantly reduce future success.

'TAKING RESPONSIBILITY'

The Associates, who were recent graduates, used their initiative to improve the level of awareness, trust and commitment towards the knowledge transfer project (7, 10, 11).

> *'I asked members of my family and friends to seek their advice, it was a challenge and whilst I had learnt the theory it felt like I had been thrown in at the deep end really…but once I had got the commitment of the staff I got going'*
> (Associate)

IMPLEMENTATION

'GAINED TRUST'

Commitment of resources to delivery the project (8, 9) begins to yield recognition by senior staff of the benefits of the new systems.

> *'the second year was a discovery, you suddenly understood what was going on, the work that had been put in…so I was as much a student as the Associate in that process'*
> (Director)

'AN ESSENTIAL TOOL'

Once the primary objectives had been achieved (15), attention turned to the need to fully embed the new technology within the culture of the organisation (13, 14). Concept and detail design work is recorded alongside client data as the design process unfolds. The web-site and the digital management system also facilitate access to files remotely through the internet, creating new working methods for the designers.

> *'We have a common international language of design…the systems have to be consistent and we are all scribbling away using the same tools…but we can now work together no matter where it is'*
> (Director)

'LESS RELIANT ON OTHER PEOPLE'

As knowledge assets are captured as part of the creative process there is less reliance on the Associates (16) to manage the process. However Case B highlights the fragility of the design services sector and when the company is affected by an economic downturn (17) staff resource are diverted towards new business development (18).

> *'involvement in the archive intranet was far greater than in the creation of the archive database, because the archive intranet was a greater priority to the practice in terms of generating new business'*
> (Supervisor)

DEVELOPMENT

'NO ONE TO CHAMPION IT'

The Associate in Case B completes the training and development of staff and is able to leave 6 months earlier than originally planned (20, 25).

> *'There has been a lot of internal efficiency, we have a few people leave and new people come in and they have been able to adapt quickly to the new structure'*
> (Associate)

Case A continues to invest time and resources into the partnership and there is a shared ownership over the knowledge management systems created (23).

> *'The Office Manager has learnt quite a bit…and her role has changed…she got through to the heart of the matter and set up the electronic document filing systems because she could see what we were trying to get at'*
> (Director)

'EVERYTHINGS THERE'

Benefits of the new asset management systems become apparent in both companies. The use of the intranet and the digital archives provide a platform to capture and retain creative and non-creative outcomes. Staff are able to use their time more effectively (21) and the Directors stress the importance of these systems in organizational development:

> *'There is less collective leadership and more autonomy…everyone knows what they are supposed to be doing and people have such access to information'*

> *'In a business sense it makes us much more effective…you are definitely more efficient'*

Case A utilises the enhanced understanding of its collective knowledge to revise its mission and purpose (15). The project becomes a catalyst for the company to align its business more closely with architecture, which also becomes a key feature of its brand and new corporate identity (19).

'IT'S AN ONGOING THING'

At the end of the project implementation (25) the emphasis has moved to the sustainability of processes and procedures which capture and retain knowledge. Investment in information management becomes an asset and driver for development rather than a risk to be managed. New market opportunities became evident through larger contracts (22) and the companies realise the potential for growth.

> *'we are now mature enough to accept bigger jobs…you can do a ten million pound job the same as you can do a hundred million pound job in roughly the same time with a few more staff…we can handle it and we will get a much better and consistent turnover for it.'*
> (Director)

Analysis

Before we consider the policy implications it is useful to reflect upon the findings of the research within the context of the design process.

There are many models to describe the design process originating from Archer's (1965) seminal work on design methods. More recently research conducted in the UK by the Design Council has proposed a simple double diamond diagram to explain how one might manage design more effectively. The diagram is used below to describe four distinct areas which show the different modes of thinking that designers encounter when they embark upon a new design project.

It should be noted that the purpose of these headings is to allow reflection on the findings, and their underlying cause and effect relationships, to inform design practice rather than a direct comparison with the chronological headings contained within the timeline in Figure 1.

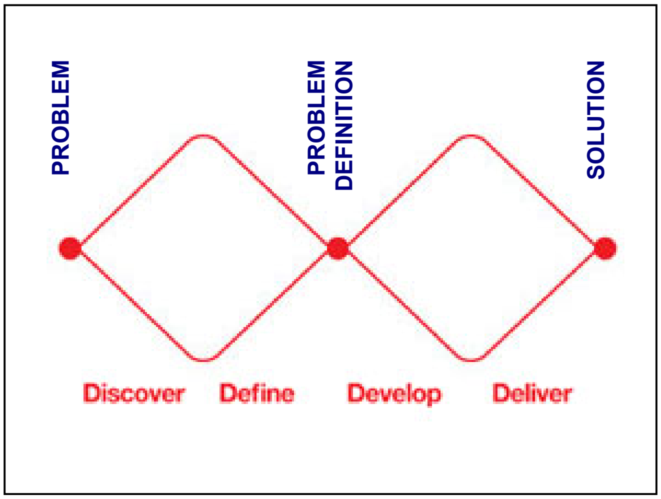

Figure 2: Design Council (2007)

The Design Council model offers an iterative process in which knowledge is captured and retained as designers progress from one phase to the next. The discover phase begins with an initial idea or problem identified from user need or demand before the second phase operationalises the design problem into a managed process. This is followed by the development phase based on the generation of concepts, ideas and potential solutions before the delivery stage when the product or service is tested, agreed, specified and launched in the marketplace.

In contrast the cases studies suggest that prior to the commencement of the digital asset management systems, knowledge appeared to being utilized in an unsystematic manner due to inherent problems with the operational structure and working practices.

The table below summarizes the model against the findings of the research and highlights the influence for each of the factors identified which are explored further in the commentary that follows.

Phase	Activities	Nature of influence
Discover	1. Market research 2. User research 3. Managing information 4. Design research groups	• 'Mood' and 'Theme' boards can be used in digitized format to express market context and consumer/audience profile • User research combined with visual content can enhance credentials presentations • Client details can be made easily accessible across the design group (even remotely) through customer relationship management systems • Understanding of new trends and market potential can be enhanced and retained even when individuals change within the team
Define	5. Business plan 6. Project development 7. Project management 8. Project sign-off	• Clarity over the knowledge assets of a design group can further organization purpose when seeking to grow the business • Concept develop can be informed by reference to previously archived work • Client access to project management information can support concurrent engineering/manufacturing processes • Enhanced information systems can reduce misunderstandings with clients and hence reduce lead times
Develop	9. Multi-disciplinary working 10. Visual management 11. Development methods 12. Testing	• Open and accessible working practices can facilitate multi-disciplinarily approaches to resolve design problems • Digital asset management systems can enhance remote working and efficiencies in preparing client artwork • Integrated IT systems which facilitate CAD/CAM file sharing with clients can improve efficiency • Prototyping and market testing can be used to effectively refine/redesign product proposals
Deliver	13. Final testing, approval and launch 14. Targets, evaluation and feedback loops	• Socially constructed knowledge (understandings, meanings or associations which underpin brand equity) can be retained or exploited for promotional purposes • Data can be used to evaluate the effectiveness of the design process and options or alternative design solutions can be captured to inform future product diversification

Table 2: Influence of interventions on design group knowledge

DISCOVER

The interviews demonstrated the importance of 'visualizing the brief' at the commencement of the design process. 'Mood' and 'Theme' boards are commonly used to communicate and clarify the market context, consumer/audience profile and style or finish being considered between client and design group. The analysis would suggest that the retention of these knowledge assets in digitization format can enhance communication throughout the project, providing clarity and purpose whilst ensuring common understandings or interpretations between designer and client which had been tacit, are retained even when individuals change within the team.

DEFINE

Case A highlights that clarity over the knowledge assets of a design group can further the strategic positioning of the organization in market terms when aiming to secure growth. In addition, both cases suggest that the efficiency of the design process can be enhanced by concurrent engineering/manufacturing processes whereby the design group integrates its own data with client production systems to reduce lead times.

DEVELOP

Increasingly the two design groups were moving towards open and accessible working practices to facilitate multi-disciplinarily approaches to resolve design problems. Specialist knowledge was drawn upon in the co-production of knowledge to resolve complex technical and operational problems. This included input from engineers, technologists, psychologists, sociologists and anthropologists amongst others as required.

Digital asset management systems were able to facilitate access and input to the design process, including remote working, in a cost effective way alongside file sharing for prototype development and market testing to refine/redesign product proposals.

DELIVERY

Case A suggests that the process of implementation of the digital asset management process had an effect on the design groups knowledge and understanding of itself within its sector. The recognition of a specific market proposition and subsequent rebranding exercise are evidence of socially constructed knowledge whereby the group collectiveness shares and operates within a common set of meanings and cultural processes underpinning the brand equity.

Equally both cases demonstrate that the management information systems offered further advantages in the evaluation of client work whilst the data captured throughout the design process could be used quickly to secure product diversification.

Conclusions

Business management factors are often characterised by strategies, processes and procedures to maximise market opportunity. Gibb and Davies (1990) suggest that this area relates to performance and the ability to operate at maximum efficiency levels.

Intrinsic to this area is the notion that business leaders are able to understand the market in which they operate and quite objectively undertake activities which improve competitive position. Hence, growth can be achieved by using appropriate business management tools such as business plans to set targets and overarching goals for the business. This pseudo-scientific approach to planning is often built upon the business development model identified by Ansoff (1965) by exploring development through market penetration; product development; market development and diversification.

The findings of this research would suggest that the business management of design groups can be enhanced by embedding sound ‘knowledge management’ in practice. In particular, technology which is geared towards the requirements of designers in capturing visual material and for sponsors to be able to utilise the knowledge derived from it (e.g. Ruggles, 1998; Bassi, 1997). However, Gumbley (1998) and Robertson and Hammersley (2000) have criticised the rather simplistic notion that technology is the means by which knowledge can be effectively produced and distributed due to the need for human and social aspects to be taken into consideration.

This study found that ad hoc management processes and procedures in the design groups combined with a lack of technical infrastructure to capture and retain knowledge reduced the potential to exploit a key market asset during the design process. The fluidity of the creative process and both individual and collaborative contributions towards innovative solutions can result in the retention of knowledge being overlooked. The objective to digitise outcomes led to a strategic change in working practices but this required an adaptive approach to the design process and new working practices. In summary, to translate ‘designerly ways of knowing’ (Cross, 1982) into tangible knowledge assets requires new ‘designerly ways of designing’.

Therefore, technical systems in themselves may only provide a means to facilitate effective knowledge production and dissemination. This research would suggest that a combination of trust in management and the intended purpose for the knowledge, as well as good social interaction (as suggested Robertson and Hammersley, 2000), may be necessary ingredients to its successful implementation.

In addition, the exploitation of knowledge is intrinsically linked to the ability to attract and retain design 'talent' or 'knowledge workers' as often cited in the knowledge management text. When asked to identify the major assets of the design group within the semi-structured interviews, the experienced research staff were invariable cited as the key resource of the organization.

The ability to capitalise on the knowledge of designers throughout the design process requires a balance to be struck between personal fulfillment (through high levels of autonomy and responsibility) and the need for regulation and control. Rotter for example (1966) suggests that 'locus of control' is higher for owner managers than the population average.

In this respect, this research supports the view of Robertson and Hammersley (2000) who found that knowledge workers (in management consultancy firms) are expected to act with a high degree of responsibility and autonomy which, if not forthcoming, may result in the departure of highly valued and talented staff.

From a policy perspective, if the contribution of the Creative Industries to the knowledge economy is to be sustained, leaders in design groups have to engender change in organizational culture towards knowledge management. Equally, universities have a role to play in supporting the design industry in the effective and sensitive implementation of management systems that can realise a positive influence on the growth of the business.

The author would like to thank the Associates and Directors for their openness and honesty during the interviews and in particular the supervisors and staff at the University for their help during the research.

Biography

Dr Seymour Roworth-Stokes is Pro Vice-Chancellor for Research and Development at the University for the Creative Arts in the United Kingdom and has responsibility for marketing and communications, research, knowledge transfer and cultural strategy. He is an industrial designer with many years experience as a design consultant for clients such as BT and BAA. He has published widely on design, teaching and learning strategies, and on art and design research management. His current research interests include design research methodologies employed with SMEs, creative entrepreneurship and the cultural economy, and managing design research teams. He is leading a major project on behalf of 13 universities in support of the Cultural Olympiad in the lead up to the 2012 Olympics and Paralympics.

Misfits, Balance, Requirements, and Systems: thoughts on Alexander's Notes on the Synthesis of Form

Filippo A. Salustri, Ryerson University, Canada, salustri@ryerson.ca

Abstract

The author examines the notion of misfit as presented by Christopher Alexander in his book *Notes on the Synthesis of Form*. We argue that from the point of view of our current understanding of design, the approach is flawed, but not flawed beyond use. In fact, the core concept of misfit, and how misfits can be addressed, remain as important to design today as when Alexander wrote about them. In this paper, a number of flaws are identified and explored. Subsequently, a new approach, which the author calls a *balanced systems approach*, is sketched. This approach preserves the intent and core of Alexander's work, while addressing the identified flaws. The main contribution of this paper is to indicate the shortcomings of Alexander's approach, but only for the sake of refining it and ensuring it remains relevant and useful.

Keywords

misfit; requirement; balance; system; Christopher Alexander; synthesis; function; form

In 1964, Christopher Alexander published *Notes on the Synthesis of Form* (Alexander, 1964), hereunder abbreviated as NSF. In that book, Alexander argued for a novel approach to design problems based on identifying and addressing misfits – mismatches between the capacities of and expectations on a form in a specific context. He also identified a change in the way design had been conducted that relates to changes in culture. His "unselfconscious" cultures designed primarily through a heritage of craft and artisanship where reflection and systematization were largely absent. These cultures have largely given way, in his view, to "selfconscious" cultures that reflect and systematize intensively. While he recognizes inherent design benefits from the move to selfconscious culture, he also advises that we have also given up certain advantages of the unselfconscious cultures. In particular, the responsiveness of unselfconscious design to externalities (the exigencies of the context and problem at hand) has given way to a more internalized and abstract perspective. He sees this as problematic because the internalizations are imperfect.

Alexander's relatively esoteric work on misfits and the nature of design problems as described in NSF has languished in comparison to his other work – e.g. the more pragmatic work on pattern languages, which has received broad attention in many disciplines.

The current author believes there is some benefit in revisiting NSF and considering its implications in the more sophisticated setting of contemporary design. We will argue in this paper that there are distinct benefits to Alexander's notion of misfits, and that the combination of (modified) misfits with systems thinking provides a valid framework in which to discuss modern design thinking and propose new potential avenues to improve how design is practised.

The paper is laid out as a series of observations about NSF and the notion of misfits. In each section, modifications are suggested that can address identified shortcomings in Alexander's original work. Finally, a new, balanced systems approach, is introduced. This approach appears to preserve the intent and core of Alexander's work, while addressing the identified shortcomings.

Set Theory in NSF

This is a fair amount of formal logic in NSF, in the form of set theory. The current author is well acquainted with set theory from his own research, and has identified three concerns with Alexander's work.

1. Alexander assumes the existence of the universal set; that is, the one set that contains every other possible set. However, the universal set is excluded from every standard set

theory, because its inclusion makes set theory invalid. An invalid theory is one that yields false positive results (i.e. the theory can prove true statements that are in fact false).

2. Godel proved that no formal system can be both complete and valid (Hofstadter, 1979). However, the current author has not found any evidence of a completeness proof of Alexander's logic. An incomplete theory is one in which there are some true statements that cannot be proved true within the theory. Thus, it appears that Alexander's work is neither valid nor complete.
3. Alexander's logic appears to be a many-sorted, first order logic. Every many-sorted logic has an equivalent one-sorted logic. One-sorted logics tend to be more stable and reliable, and more easily computed) than many-sorted logics. However, Alexander appears to have never translated his work to one-sorted form for the sake of establishing a completeness proof.

Of course, just because the appropriate proofs have not been provided does not invalidate all of his work – indeed, the current author believes NSF remains as relevant today as when it was originally written. However, there is no benefit in invoking set theory unless one seeks to establish a formal grounding for some undertaking. Therefore, this suggests that the formal aspects of Alexander's work should not be relied upon. In this article, the current author will not depend on these aspects of Alexander's work.

What is a Misfit ?

NSF provides no direct definition of *misfit*, but rather a number of characteristics scattered over several passages.

Alexander writes of "requirements or misfit variables" suggesting that there is some equivalence between the two terms. Indeed, although Alexander nearly always uses the term *misfit*, the text is best understood by reading *misfit variable*. The author suggests that the difference between misfit variables and requirements is that misfits simply describe a situation, whereas requirements constitute directives to the designer to address misfits to the extent described by constraints (either boundary constraints or minimization constraints).

Alexander also refers to a misfit (variable) as relating to an *ensemble*, which is the combination of a given form and the context in which it exists. This is very important because it connects a misfit variable to a particular situation; that is, *misfits are always situated*.

The importance of a misfit being a variable is easy to overlook. A variable has two elements: a named property, and a value for that property. If the variable's value is "bad," then it is a *mis*fit. The goal of designing, then, becomes the changing of the *values* of misfit variables so that they are no longer "bad," but the variables themselves must obviously remain.

This is reinforced by considering the partitioning and clustering tasks described in NSF. Networks of related misfits are mathematical graphs of nodes and links (a graph is a set of ordered pairs of nodes that represent the relationships between the elements of the node pairs). Nothing is said about the contents of the nodes or of the links.

Partitioning and clustering builds a hierarchy such that the top level of the hierarchy is the design problem as a whole. The network is one of misfits, or requirements, so the network is a model of the design problem.

The design problem is not something typically under the designers' control, although its model (as requirements/misfits) may change as the designers' understanding improves over time. Excluding changes arising from the imperfect knowledge and reasoning of human designers, the problem itself remains *fixed* (i.e. invariant). If the problem changes because of external influences on the existent ensemble (also not under the designers' control, but quite possible in the real world), then the original problem no longer exists and the designers must essentially begin again. For simplicity, we assume here that these kinds of changes do not occur.

If the problem is fixed, then the misfit network (the model of the problem) must also remain fixed.

The designers' goal, however, is to eliminate the misfits. If we eliminate the misfits, and the misfits are the network, then we must change the network. This contradicts the previous statement: we cannot change the network if it must remain fixed.

We can resolve the contradiction by realizing that the nodes in the network are variables and that misfits are just bad values of those variables. Thus, to eliminate a misfit, one must change the content of a node, not the node itself. In this way, we can remove misfits while keeping the network itself fixed.

There is another problem with the notion of misfits. As misfits represent only the "bad" aspects of ensembles, a network of misfits forms on a *partial* representation. If there are "good" aspects of ensembles, they will not be part of the misfit network. However, these good aspects will likely interrelate with the misfits, just as misfits interrelate with one another. Changing the values of misfit variables could adversely influence those good aspects, but the misfit network will not capture those influences.

This could be addressed by broadening the concept of misfits to include any property of an ensemble, not just those with bad values. The resulting network could then be described as representing *forces* at work in a situation that must be resolved, or *balanced*, by a design. In that case, one would end up with a network graph that describes how well *balanced* a form is with respect to a context, including both its good and bad aspects. The misfit network would be a sub-graph of the overall force graph. Conveniently, this viewpoint is quite consistent with Alexander's work on pattern languages (Alexander, Ishikawa, and Silverstein, 1977).

There is Always a Form

Misfits motivate designing, so misfit identification (and existence) must precede design. Over the years, some of the author's colleagues have argued that, because of the notion of starting from an existent form, Alexander's approach ignores the possibility of highly innovative design or invention. The argument hinges on the assertion that there is no form preceding the invention of a suitably innovative product.

However, the author believes that there is *always* a preceding form: it is the way that we do things "now," that we find inadequate, and that we address by innovation. Even for highly innovative forms, there is also a preceding form. In those cases, the preceding form is just substantively different from the innovative one.

For example, Jeff Hawkins led the invention of the original Palm Pilot personal digital assistant (PDA) by setting the device's main competitor as a leather-bound agenda (Rose, 2000). That is, the form that preceded the Palm Pilot was *not* a PDA but still shared aspects of functionality with it. There were a number of innovative technological elements in the Palm Pilot, such as the invention of the "graffiti" glyph language for stylus-based text input, and "instant on" technology. Palm developed these innovations for their product, without which the design team (led by Hawkins) believed the product would fail in the marketplace, to compete functionally with an agenda.

The forms before and after an innovative design do not have to share structure, but they *do* have to share some essential functional purpose. The Palm Pilot and the leather-bound agenda serve the same purpose, in context, even if the PDA expands on that purpose and opens the possibility of other functions.

Thus, while *form* is what one has at hand, one must really focus on the *function* that the form serves. The extant form is used to understand how the required function is *not* being fulfilled. These shortcomings are the misfits, and they drive the design of a new form.

In cases of high innovation, it may be difficult to identify (i.e. separate) the predecessor form within the context. This is solved by applying principles of systems thinking: entities are marked by boundaries; boundaries are where properties change; so identifying an entity means identifying key properties and then finding where they change. Even the act of drawing different boundaries can be enough to inspire innovation. For example, while the first attempts to build flying machines typically used flapping wings to generate both lift and thrust, success came relatively easily once new functional boundaries were drawn in the situation such that lift (via wings) and thrust (via propellers) were separated.

The Palm Pilot was not the first PDA to be designed, but it was the first *successful* PDA. This is because its designers found an appropriate balance point between all the factors that influence its success: cost, size, functionality, complexity, etc. To find an appropriate balance point, one must identify the appropriate systems, which in turn drives the identification of proper misfits.

The Problem of Form and Requirements

In NSF, Alexander refers often to an example of a kettle, and gives a rather extensive list of requirements that a kettle should satisfy. One of them reads "…should have a handle that…."

Alexander *assumes* that the kettle has a handle – thus implying that at least one design decision has been made (that there must be a handle) by the time the requirements were specified – even though specifying the requirements is supposed to *precede* designing. This is a logical contradiction. There may have been constraints on the kettle design problem requiring a handle, but this is not indicated in the text. This kind of logical contradiction is common in NSF; the kettle's handle is just one example of it.

More appropriate requirements would be functional, not structural, in nature; they would be more appropriate because they would make no assumptions about designed form. Two examples of how this might have been done for the kettle's handle include the following.

1. [The kettle must be such that] a person can easily carry/lift the kettle. (This begs questions about the capacity of the users, how far and how often they carry/lift the kettle, etc. Such questions should be answered with constraints.)
2. [The kettle must be such that] a person can pour the kettle's contents. (This begs questions about the position/location of the thing receiving the poured contents with respect to the kettle and its user, the rate of pour, etc. Again, these should be answered with constraints.)

There are other possibilities. The point is, however, that Alexander's requirements are not good ones. The lack of good requirements undermines his argument. However, one can recover, and at the same time refine, the overall process as follows.

Clients and users do not really know what they want. Designers serve that purpose. Clients and users *are* very good, however, at identifying what is wrong in how things are, what is wrong with the "as is" ensemble. This is precisely what misfits are for, so they are ideal for capturing what clients and users find wrong with the current situation.

However, designing requires production of form to suit function. An informal description of a process that can achieve this goal is discussed in a subsequent section.

Abstract Categories of Requirements

Alexander correctly observes in NSF that requirements are in practise often grouped according to abstract concepts like "safety" or "durability," and that such categorization is not helpful because it is arbitrary and constructed entirely by the needs of the designers rather than the needs of the situation for which the designers work. The arbitrary nature of the categorizations that designers impose only obscure the nature of the problem, which exists in an ensemble independent of the designer.

The author agrees with Alexander, that categorizations should be driven by the available information and not by the designers' needs or beliefs of what the categorization "should be." While the act of balancing will naturally include the designers' experience and perspective, the forces that are to be balanced must be those "observed" to exist in the extant ensemble.

Decomposing Misfit Networks

Much of NSF is devoted to establishing how and why networks of misfits should be decomposed and partitioned into a hierarchy. Alexander went so far as to develop software that could perform such decomposition and structuring work for a given misfit network – e.g. (Clark and Elms, 1976). Others, such as (Elms, 1983) and (Owen, 2007) have since tried to improve on Alexander's work.

Alexander states the purpose for decomposing misfit networks as follows. “We now have a graph G(M,L) which represents the design problem. …to solve the problem, we shall try to decompose the set M in such a way that it gives us a helpful program for design.” In other words, the decomposition is to help guide the designers to a solution.

However, to do this, he and all the others who have built upon his work rely on *cutting* certain links between misfits in the network graph to construct the needed hierarchical structure; this means that some relationships are ignored. Naturally, significant effort is made to identify the “weakest” relationships – those that can hopefully be ignored without invalidating the network graph itself as a representation of the design problem. More precisely, the graph is cut where the smallest damage to the network, and the greatest decrease in complexity, can be achieved. The complexity of the algorithms is driven by the need to identify those specific cuts.

The current author finds this approach problematic. In general, there is no way to know *a priori* what the impact of any change to a problem definition will be on the fitness of a designed solution. Alexander himself devotes a significant portion of NSF to arguing that design should be led by the facts, the data, the available information; so, to ignore information simply for the benefit of the designer seems inappropriate. One might make such an argument if a complete problem (as modelled by a misfit network) were demonstrably intractable – in which case, an approximate solution could be better than no solution at all – but no such demonstration is made.

There is another approach that should be able to help control complexity and organize design problems to facilitate their solution without ignoring any of its elements: a hierarchy of systems based on functional interactions, such that higher level functions emerge from, but are not necessarily directly produced by, constituent subsystems. This approach is based on recognizing properties of the entities described in a problem (the ensemble) in functional terms, and does not impose arbitrary structures on that problem. More information on this is provided in a subsequent section.

Setting these matters aside for the moment, let us examine Alexander’s two criteria for what constitutes a good misfit network decomposition, to determine if they are still reasonable given the preceding discussion.

First, with a good decomposition it must be possible to find “constructive diagrams” for each subset of misfits *individually*. This is what programmers call *encapsulation* and is inherently addressed by systems thinking, wherein a system is crisply demarcated by its boundaries with the environment and that one can swap one system for another so long as its interface (how it exchanges things with other systems) is the same.

Alexander also writes that a subset of misfits must “cohere somehow” and suggest “a physical aspect or component of the form.” The current author believes Alexander intends a coherence based on function: misfits in a set must all be functionally connected – which in turn would suggest kinds of forms. In this interpretation, systems, being functional entities, clearly fit well in Alexander’s approach.

Alexander’s second criterion is that a “useful” decomposition must be such that the representation (i.e. constructive diagrams) of a combination of two subsets of misfits must be “derived…in some simple way” from the representations of the two subsets.

This suggests that there must be a relatively straightforward superposition of representations to combine two sets of misfits. This in turn suggests that all the requirements (defined by misfits) must be known before a design solution is started. This is not generally possible because many requirements of lower level solution elements (e.g. the parts and sub-assemblies of a physical product) are derived from a combination of higher-level requirements plus design decisions that were made earlier in the process. This *co-evolution* of problem and solution (Dorst and Cross, 2001) is necessary because every design decision alters the specifics of the design problem.

However, it appears that Alexander is following a “waterfall model,” for instance when he writes in NSF that a decomposition must occur *entirely* before solutions are sought, which is not effective in design situations.

We can salvage this, however, if we admit a systems-based hierarchy. If we focus on only the requirements of one system at a time, and design as much as possible for it before moving to its subsystems, then we can implement co-evolution. At the same time, Alexander's misfit-based approach can be applied *to each level* in turn.

Thus, the author believes that a systems-based approach to misfit organization satisfies both of the requirements set forth in NSF for acceptable decomposition methods.

The author has identified one other problem in Alexander's method of combining subsets of misfits. His method does not seem to address that some properties of combined subsets are neither endemic nor constituent of the subsets; rather, these properties *emerge* from the combination itself. These emergent properties are very important for design. A systems-based approach treats these properties by associating them only with particular systems and not necessarily with their sub- or super-systems. For example, the drive train of an automobile enables the emergence of a key property of the automobile (its ability to move) without providing the property *per se*; but without the engine, that key property is not available.

Relative Independence of Requirements

Let us return to the sample requirements in NSF that Alexander gives for the kettle. Two of them are: "…must be comfortable…" and "…must be economical to heat." Alexander ponders the apparent independence of these two requirements, writing that it is hard to see if and how they relate.

Requirements can be uncoupled but still become coupled in a specific design; this is because the structure of the design may cause coupling to emerge only in that context. Borrowing from Suh's Axiomatic Design (Suh, 1990), one can demonstrate that one can decouple requirements by choosing the "right" design. That is, while it certainly is possible to develop functionally coupled requirements, truly uncoupled requirements depend on both the requirements *and* the design solution. This is evident in the kettle example: requirements that explicitly mention, for instance, the kettle's handle, create structural coupling that may not be present if the requirements were first treated functionally. The author believes this feature of how requirements couple via a design explains the uncertainty that Alexander expressed in NSF.

The distinction between functional and structural aspects is also evident in Alexander's own words: "Some sets of misfits, in view of their interactions, seem naturally to belong together, and, taken as units, suggest physical form very strongly." If there is a justifiable reason for using a certain form that causes requirement coupling, then so be it. It is still better, though, to be given the choice of deciding whether such a form is in the best interest of the designed object's users. To ensure that the designer at least has the opportunity to choose, it is important to distinguish between the form and the function – particularly in the requirements (or misfits) – so that coupling is not artificially introduced.

Balance, Misfits, and Systems

The foregoing sections presented a number of problems that the author has identified in NSF, and has suggested another approach, based on *balance* and on *systems thinking*, that could address those problems. In this section, the author will describe some further details about this balanced system approach.

A system is a set of interacting elements (which may be other systems) that provide defined functions and is crisply distinguished from its environment or context (Karnopp et al, 1990). Systems thinking is based on viewing a domain of interest as consisting entirely of systems. Systems encapsulate function, and interact physically by exchanging mass, energy, and information. System properties emerge from the interactions of subsystem elements with the system's context (which includes other systems). Changing the location of system boundaries can completely redefine the functionality and purpose of a system. A system that interacts with its context well is one that *balances* properties of the context with properties available by the system itself. The author has discussed the notion of balance in design elsewhere (Salustri et al, 2009).

The author therefore proposes that designing start with a study of the "forces" that exist in a given situation. These forces may be economic, technological, or based on needs and desires of clients and users; they may be beneficial forces or forces that give rise to misfits.

The needs and desires must be described in terms of what is "wrong" with the current situation. This requires identifying the properties that are perceived (by the designer working together with clients, users, and other stakeholders) to change in some detrimental way. Boundaries are marked where properties change. For instance, sufficient productivity at one point in a production process may become insufficient at another point; the boundary lies between those two points and identifies a poorly balanced property of one of the systems. Similarly, the layout of some architectural space may be sufficient for one population of users, but not for another; here the boundary lies between those two populations, and marks a lack of balance between the space and the user population.

Boundaries mark the interface between systems. By first identifying the boundaries, one can use them to derive systems that emerge from the situation rather than from some preconceived, arbitrary organizational structure.

Each system thus identified may be further decomposable, depending on the nature of the situation, into subsystems. Such decompositions should be again based on the study of the actual situation rather than what the designers think should be present. This results in a hierarchy of systems. Each level of the hierarchy can be a network of systems, but because the details of each system are encapsulated within them, the interactions will tend to be far fewer than has been suggested by Alexander.

This hierarchy of systems must then be functionalized (that is, changed into a network of functions, without reference to form, but still situated within the given context). When functionalizing a system network, each form element (e.g. the kettle's handle) must be treated separately because there may excellent reasons for some specific element to remain in the network. Examples of such reasons include: the client may be unwilling to assume the risk associated with removing a particular form element; or there may be safety regulations that require a particular element to be present (e.g. electrical cut-off switches, bulkheads, or warning signs). There is no way to know *a priori* if a complete functionalization of a network is possible; however, the more functionalized the network is, the less likely it is that the design situation will be over-constrained with arbitrarily assigned forms, and therefore the more likely that a good design solution will be found.

One then studies each level of the functionalized system hierarchy in turn. At each level, some interactions between systems may be quite beneficial, while others are in some kind of conflict. Those in conflict are equivalent to Alexander's misfits. Our goal then becomes to re-balance the systems to eliminate – or at least minimize – the conflicts, while causing the least detrimental change to the beneficial interactions. This requires, as Alexander has proposed in NSF, to build a network of relationships. Instead of just a network of relationships between *misfits*, though, we need a network of relationships between *properties* (i.e. including relationships that show good fit and not just bad fit). We do this one level at a time in the system hierarchy, so that we can use encapsulation to temporarily ignore the details that would cause the overall problem to become intractably complex. The details of methods suitable to assist in balancing an unbalanced system are still being developed by the author; their discussion goes beyond the scope of this paper.

The author is currently working on a demonstrative example of this approach, derived from the kettle example in NSF. Although the example is still a work in progress, it has some features that may help illustrate the balanced systems approach suggested above.

For example, if we begin by considering the kettle as a single system (i.e. we do not refer to its constituents, only to the kettle as a whole), the number of its basic functional requirements are very few: to allow water to enter it, to heat the water it contains, and to allow the water in it to come out. The *extents* to which these functions are exhibited are specified with constraints that arise from the context of the kettle-system. For instance, the amount of water to be contained by the kettle would depend on the ways in which it is to be used. If its capacity is not consistent with its use, then the design is not balanced. To re-balance it, either the kettle's capacity must be changed, or the kettle must be re-tasked to a different context.

Since the kettle's purpose is to provide hot water, we can describe its major functional elements (subsystems) as: an access system (to get water into and out of the kettle), a heating system, a containment system, and a control system (to control the kettle's dynamic behaviour). These subsystems interact to produce the required overall functions of the kettle. At the level of subsystems, further balancing will be required, but only insofar as interactions between specific subsystems are concerned.

Much more work remains to be done on this approach. However, insofar as it has been specified to date, it does appear to lend itself well to help structure design problems to facilitate creative design solutions.

Author Biography

Filippo A. Salustri

Filippo A. Salustri, Ph.D., P.Eng. has been teaching, researching, and practising design engineering since 1989. He has been involved with research and design of cars, aircraft, spacecraft, robots, temporary structures, toys, home appliances, and medical equipment. His research interests include formal and informal methods of designing, information visualisation, and web-based design tools. He is a member of the Design Society, the Design Research Society ASME, CSME, IEEE, and INCOSE; he is a founding member of the Canadian Design Engineering Network, and the Canadian Engineering Education Association. He is currently an Associate Professor of Mechanical Engineering at Ryerson University.

Co-design in Public Spaces: an Interdisciplinary Approach to Street Furniture Development

Maria Gabriela Sanches, Carleton University, Canada, msanches@connect.carleton.ca

Lois Frankel, Carleton University, Canada

Abstract

Cities are developing at a rapid pace. As a result of this growth, the importance of public spaces has increased. This paper intends to discuss the role that elements such as street furniture play in this context, whilst proposing a specific design approach to develop them. It attempts to analyze the distinct user-product relationship between people and the objects that occupy urban areas, and suggest ways to improve it. Co-design emerges as an alternative to involve all the stakeholders in the design discussion. The lay public, city planners, politicians and designers are invited to participate in the creation of pieces of street furniture. The interdisciplinary aspect of co-design becomes evident, once each actor contributes to the process with a different perspective on the urban spaces' needs. The association between co-design and street furniture development promises to be very beneficial to public spaces. Some of the positive outcomes of this association may be reduction of vandalism and urban alienation, and the enrichment of the community life. The co-design process affects, however, the roles that the referred actors play in the traditional context, and depends on the compromise of some power structures to be successful.

Keywords

co-design; co-creation; interdisciplinarity; public spaces; street furniture.

Approximately 3.2 billion people live in urban areas today (Kries, 2006). Whilst cities are developing and growing, public spaces are acquiring increasing importance. The urban elements that occupy these areas deserve major attention from designers, city planners, politicians, as well as the lay public. This paper aims to analyze the distinct user-product relationship that evolves from the interactions between the people and the elements they experience in public spaces. Since this relationship is not exempt from deficiencies, the study also intends to identify problems that might interfere with it as well as suggest ways of improvement.

Since community design approaches have met with success, it makes sense that co-design may emerge as a possible tool for street furniture development. Through literature research, this investigation attempts to explore the principles of co-creation, while analyzing their applicability to this context. Considering that co-design implies the participation of non-designers in the design process, the discussion about the roles that the lay public, politicians, city planners, and designers would assume in the co-design process becomes necessary. Designers share the creative process with the public, who is the *user* of the products. The non-designers are the most interested in the improvements of the urban areas. The changes depend, however, on the decisions of city planners and politicians, also referred to as the *choosers*. All of these actors play an essential role in this context and are invited to participate in the co-design process, using their distinct knowledge to complement the interdisciplinary experience.

The possible outcomes of the association between co-design and street furniture development are evaluated. Improvements such as the reduction of vandalism and enrichment of the life of the community are some of the advantages that the involvement of all the stakeholders in the creation of urban elements can promote.

Context

The relation between industrial designers and the urban space is recent. Even though today designers create urban furniture, playgrounds and parks, guidance systems and means of transportation, it was just in the course of the 20th century that they started to take responsibility for issues related to the city (Kries, 2006). According to Kries (2006), design received a great impetus in the post-war era. It was necessary to reconstruct the destroyed cities, and industrial designers, who before would collaborate with architects and urban planners, started to play an independent role, complementing the pragmatic and rational tendencies of Modernist architecture and urbanism.

From this time to now, much has changed. In 1950 there were 86 cities on earth with over one million inhabitants, today there are 400, and in 2015 there will be over 550 (Kries, 2006, p. 23). Cities are developing at a rapid pace, and it is clear that this growth poses challenges for designers. New demands on the design of public spaces are evolving and these professionals must be prepared to create products that satisfy the *users*' new needs. Kries (2006) exemplifies some of the new trends in public spaces by stating that “wireless Lan hot spots allow us to work and communicate anywhere within public areas” and “plasma screens and other façades transform high rises into communicative structures” (p. 23).

The new demands also affect the objects that occupy the urban areas: the urban elements. Creus (1996) defines urban elements as “objects which are used and which are integrated to the urban landscape” (p. 6). The expression ‘street furniture’ is commonly used to designate these objects as well. In this paper, both terms will be utilized as synonyms. In this category one can include benches, chairs, streetlights, flower boxes, bus shelters, bicycle racks, and litterbins, among others.

The importance of the urban elements to cities is evident. People are sometimes so accustomed to having them around that they do not even notice the role these elements play in their daily life. The significance of street furniture is strongly connected to accessibility. Urban elements make “the city accessible to everybody and easier to get around in” (Creus, 1996, p. 9). Ramps and sign panels properly situated can facilitate the public’s locomotion and orientation. Pieces of street furniture also help people effectuate their everyday activities. Bus shelters, streetlights, and bicycle racks can be cited as crucial elements to support their common needs.

The function of stimulating the use of public spaces can be attributed to the urban elements. They are capable of providing these areas with a comfortable and attractive aspect. In this sense, they are able to aggregate people (Figure 1). Benches and tables in squares and parks fulfil this purpose. Contributing to the cities’ identity is another function that street furniture can assume. Urban elements lend a city its identity, making it recognizable to us (Creus, 1996, p. 6-7). This idea becomes very clear when considering cities such as London and Paris. Britain’s red telephone booths and Paris’ metro entrances have such a strong character that they have developed a symbolic function. If these elements were removed, these cities could have their identity compromised.

Figure 1 Example of pieces of street furniture that aggregate people

In the context of this investigation, the *user* of the urban elements assumes considerable importance. Identifying the specificities of this user-product relationship is, therefore, necessary. Creus (1996) highlights the fact that *users* do not choose urban furniture by noting that “unlike indoor furniture, *users* do not buy urban furniture and, therefore, maximum citizen comprehension of the elements has to be worked at" (p. 8). Malt (1970) also points out some aspects of the relationship between the public and the street furniture. He defends the idea that "the consumer, literally, the man in the street, never sees a variety of shelf goods" (p. 41). The *users* neither do comparison-shopping, nor are allowed to exercise the traditional veto of the market place.

At this point, it is important to understand who takes the decisions on public planning and how these decisions are made. Normally, city planners and politicians, also referred to in this paper as the *choosers*, are responsible for decisions regarding the public spaces. These decisions are often made without the knowledge and participation of the lay public. King, Ferrari, Conley, and Latimer (c1989) refer to the term urban alienation to define the lack of opportunity that the actual *users* have to participate in the design discussions. According to them, when people who are the most affected by the changes are not involved in the planning practices, they are more likely to be alienated. Alienated people do not feel that public spaces are part of their lives. In the same way, they do not feel related to the objects that occupy these areas. For this reason, acts of vandalism are closely related to urban alienation.

The solution to this situation might be public participation. King et al. (c1989) defend that "public participation reduces the vandalism and enriches the life of the community" (p. 163). In spite of the controversial response to the authors' claims, a shift in the contemporary design approaches suggests that the user involvement is highly important to longevity of product design solutions. As stated by Sanders (2005), "it has become increasingly evident that everyday people are no longer satisfied with simply being 'consumers'; they want to be 'creators' as well" (p. 5). This paper presents co-design as an interdisciplinary form of street furniture development in which designers, *users*, and *choosers* are involved.

Co-design in public spaces

The co-design process

Stappers & Sanders (2008) have identified a trend in the practice of design. "Designers have been moving increasingly closer to the future users of what they design" (p. 5). Furthermore, there has been a change in the focus of the emerging design practices. They centre on people's needs and societal needs. Co-design principles, stimulating the participation of the user in the development of design solutions for a group of people or the whole society, fit these tendencies perfectly.

Although practices such as co-design and co-creation seem to be relatively new, they have been used for nearly 40 years (Stappers & Sanders, 2008). Since the 1970s, research projects on participatory design have been developed in Europe, mainly in Norway, Sweden, and Denmark.

Stappers & Sanders (2008) define co-design as "the collective creativity of designers and people not trained in design working together in the design development process" (p. 6). They defend that co-design is a specific form of co-creation since the collective creativity is applied across the whole span of a design process. Kleinsmann (as cited in Kleinsmann & Valkenburg, 2008) developed a different definition, which emphasizes the interdisciplinary aspect of the process:

> Co-design is the process in which actors from different disciplines share their knowledge about both the design process and the design content. They do that in order to create shared understanding on both aspects, to be able to integrate and explore their knowledge and to achieve the larger common objective: the new product to be designed (p. 370-371).

In this paper, it is suggested a comprehension of co-design that results from the combination of the two definitions above. Co-design may be considered, for the purpose of this study, as an interdisciplinary process that involves designers and non-designers in the development of design solutions.

Co-design differs from user-centred design mainly in the role that the *user*, the researcher, and the designer play in the design process. According to the classical user-centred design process, the *user* is a passive object of study, the researcher brings knowledge from theories and complements this knowledge through observation and interviews, and the designer passively receives this knowledge, interprets it and uses it to generate ideas, concepts, etc. (Stappers & Sanders, 2008).

Stappers & Sanders (2008) explain that “in co-design, on the other hand, the roles get mixed up: the person who will eventually be served through the design process is given the position of ‘expert of his/her experience’” (p. 12). There is “a shift in attitude from designing for *users* to one of designing with *users*” (Sanders, 2002, p. 1). The researcher supports the *user*, providing tools for ideation and expression, and the designer develops tools for ideation in collaboration with the researcher and gives form to the ideas. Many times, the designer and the researcher are the same person.

Again, the interdisciplinary nature of co-design becomes evident. If interdisciplinarity is an “individual as much as a group affair, with team members allowing the perspectives and methods of others to interpenetrate and influence their thinking and understanding of a problem” (Sillitoe, 2004, p. 14), co-design is a perfect example of interdisciplinary work, where designer, researcher, and *user* work collaboratively in order to reach a common goal. The concept of interdisciplinarity, however, becomes broader in this context where it not only results from the union of different academic disciplines, but from the combination of different perspectives on a problem or topic.

Although the *users* do not represent a specific discipline in the co-design process, they contribute with their valuable knowledge about their experience to the process, and evolve as a key element. Sanders (2005) discusses the changes in the way designers think about people (Figure 2). If in the 1980’s they were referred as customers and consumers, in the 1990’s, they started to be seen as *users*, participants, and adapters. In the 2000’s, with the participatory approaches, people are considered co-creators and are invited to participate in the actual designing. In order for this to happen, the users’ knowledge has to be considered as important as the knowledge of the other professionals in the team, which can be an obstacle to the co-design practice.

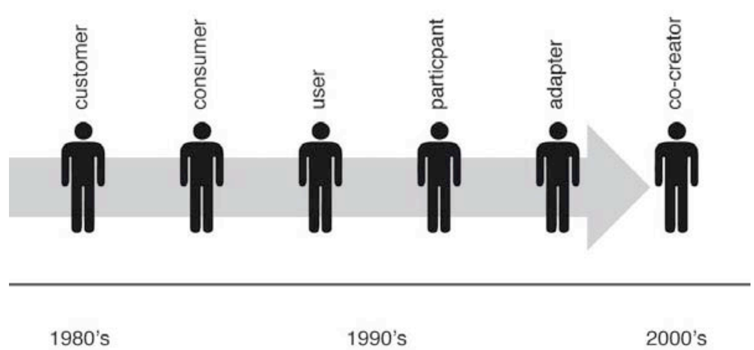

Figure 2 Changes in the way designers think about people (influenced by Sanders, 2005)

The co-design practice faces many other hurdles. As stated by Stappers & Sanders (2008), a premise for co-creativity is the idea that all people are creative. This idea is not commonly accepted, mainly by the business community. In addition, “co-designing threatens the existing power structures by requiring that control be relinquished and given to potential customers, consumers or end-users” (Stappers & Sanders, 2008, p. 9). Distributing and sharing the control is not easy for businesspeople who have been in control for a large period of time. Trained professionals are willing and eager to carry out their roles and are very often unwilling to accept input from lay people (Iacofano, Moore, & Goltsman, 1988, p. 78). Furthermore, “participatory thinking is antithetical to consumerism” (Stappers & Sanders, 2008, p. 9). Many companies base their sale strategies on convincing consumers that they will be happier buying their products and co-design does not interest them. Finally, co-creation is often seen “as [an] academic endeavor with little or no relevance for the competitive marketplace” (Stappers & Sanders, 2008, p. 10). This view on co-design is starting to change, in part because of the successful collaborative experiences between companies and universities. The groundswell of interest in ‘open source’ design has also contributed to a better acceptation of co-design, which becomes very clear in the Internet context. According to Sanders (1999), “new computer tools and applications have made self-expression through personal websites accessible to everyone with the time and desire to build one” (p.6). More recent studies reveal that “over half of all on-line American teenagers create their own content” (Sanders, 2006, p. 31).

Co-design experiences related in the literature have in many cases focused on healthcare environments and products. On some occasions, they had the purpose of improving the quality of life of people with certain diseases (Clemensen, Larsen, Kyng, & Kirkevold, 2007), or ameliorating nurses' workplaces (Stappers & Sanders, 2008) (Figure 3). In other cases, co-design principles were applied to contexts such as farms (Stappers & Sanders, 2008: 11), and learning environments (Druin, Stewart, Proft, Baderson, & Hollan, 1997).

Figure 3 Nurses co-creating a concept for ideal workflow on a patient floor (Stappers & Sanders, 2008)

King et al. (c1989) define co-design as "a combination of community, cooperative, and collaborative design" (p. 3) and affirm that architecture has been a community concern since the early days of our society. According to them, the exclusion of community from the creation of its architecture results in social alienation, and inhuman environments. Collective creativity, on the other hand, "causes neglected public buildings and open spaces to come alive and vandalism to cease" (King et al., c1989, p. 3).

As previously mentioned, this view was perceived as controversial. Nonetheless, it is possible to state that street furniture should be a community concern now. Urban elements support the community's activities, and should be designed according to the community's needs and values. It would be interesting to evaluate if co-creation in the development of these objects may also be a solution to alienation and vandalism.

The user, the chooser, and the designer

In the context of urban spaces, three actors assume crucial importance: the *user*, the *chooser*, and the *designer*. Stakeholders in the public spaces' issues, they are invited to participate in the development of street furniture, providing their distinct knowledge to the co-design process. The advantages of transforming an activity that was before practiced only by designers into an interdisciplinary collaborative process are related to a better comprehension of the *users*' needs, and the development of realistic solutions that can be more easily implemented.

The roles that lay people, city planners, politicians, and designers assume in the proposed co-design process are debated in next sections.

The public

The *users* of the urban elements assume the role of co-designers. They become a critical component of the process (Sanders, 2002), participating in "knowledge development, idea generation and concept development" (Stappers & Sanders, 2008, p. 12). Undertaking the position of 'experts of their experiences' (Stappers & Sanders, 2008), people contribute to the process with their knowledge about their way of life, the site values, history, and circulation (King et al., c1989). They are able to inform the functions that the urban elements must accommodate. They also better understand the activities that take place in specific public areas as well as the time of the day that these spaces are used. Finally, they know the local history in depth. This information is crucial to the development of urban elements that meet the community's needs.

In order to participate in the design process, the *users* must be given appropriate tools to express themselves (Stappers & Sanders, 2008). King et al. (c1989) suggest the use of an artist as a facilitator who draws the participants' ideas. More recent research, however, focuses on the development of other co-designing tools and techniques such as three-dimensional toolkits (Stappers & Sanders, 2008) (Figure 4) that allow common people to communicate their own ideas. In the case of Figure 4, the non-designer participants were primarily nurses whose experience with circulation and access to equipment, supplies, and patients was essential to the design.

Figure 4 Nurses co-designing the ideal future patient room using a three-dimensional toolkit for generative prototyping (Stappers & Sanders, 2008)

The city planners and politicians

These actors are not commonly cited in the co-design literature. Nevertheless, they should also take part in the co-design process in this context. As stakeholders in urban spaces' topics, they are capable of enhancing the interdisciplinary collaboration for the development of street furniture.

The inclusion of politicians in the process is important to "create a climate in which government action can realize community ideas" (King et al., c1989, p. 25). The planners can guarantee the continuity of the discussion on the strategies that follow the workshop (King et al., c1989). These actors provide knowledge on governmental policies, interests and restrictions, a subject that other participants are normally not familiar with.

The designers

The designers are responsible for developing the tools and methods for generative design thinking (Stappers & Sanders, 2008). These tools will support the *users* in the expression of their ideas. Designers also analyze and interpret the *users*' ideas and use them as a source of inspiration and innovation. They provide expert knowledge on existing and new technology, production processes and business context that the other stakeholders do not have (Stappers & Sanders, 2008). Taking into consideration the information and ideas provided by the other stakeholders, they design the final product that will meet the *users*' needs and the *choosers*' criteria of decision.

The outcomes of the association between co-design and street furniture development

The outcomes of the association between co-design and street furniture development promise to be very positive. The proximity between the lay public and the designer may result in a better comprehension of the *users*' needs, and can certainly improve design decisions about urban elements.

Since they are considered everybody's spaces, public areas are democratic by nature. They are, therefore, environments conducive to the acceptance of principles of idea sharing and to the democratization of the opportunity to create, which are important requirements to co-design. Furthermore, the distinct user-product relationship in these cases is not related to consumerism since pieces of street furniture are neither exposed in shelves nor participate in the exaggerated consumption dynamics. Again, urban spaces seem to be an ideal context for the development of these kinds of activities.

There are some examples in the literature that relate effective cases of use of co-design in public spaces. According to King et al. (c1989), public participation curtailed vandalism in Wessburn Park, Burnaby, British Columbia, 1977. By painting murals over the entire exterior of a community centre, children reduced the incidence of acts of vandalism in the proximities because they started to use the area intensely and care for it vigilantly. The same authors (c1989) affirm that community based design has improved community life in many cases. The collaborative experience encouraged people that had never talked to each other before to begin talking and listening. After workshops, community members interact more, which can also enrich community life.

The democratization of the innovation permits that *users* “develop what they want, rather than relying on manufacturers to act as their (often very imperfect) agents” (Von Hippel, 2005, p. 1). Likewise, the democratization of the development of street furniture pieces also allows the user to create what they want and need. It certainly guarantees a better comprehension of the product by the user. Furthermore, it enables the community to create their own identity. The products that the community members help create reflect the community's shared values (King et al., c1989), which strongly influences their attitude toward the public objects. As a result, they develop an affective relation with these objects and there could be a reduction of vandalism. The urban alienation also tends to disappear once all members of the community (young people and adults, poor and rich, powerless and powerful) are invited to enter into the design dialogue (King et al., c1989).

Discussion

The debate on co-design practices should incorporate questions about people's disposition to change and adapt to the new trends. Participatory experience is not simply a method or set of methodologies, it is a mindset and an attitude about people (Sanders, 2002, p. 1). Co-design implies a shift in the roles that the actors are used to play. The *user*, the *chooser*, and the designer represent three different views and are crucial to guarantee the interdisciplinary character of the process.

Whilst the public, who is the most affected by the decisions on urban planning, might be very interested in taking part in the process, the city planners and politicians might want to analyze the advantages and disadvantages of being involved in such kind of projects. Although the benefits of co-designing urban elements are clear, in order to participate in the discussion, the *choosers* need to share their power of decision with the other stakeholders in the project. As already mentioned, co-design threatens the power structures (Stappers & Sanders, 2008), and, in this situation, it becomes evident.

Most public involvement programmes fall in the consultation category (Iacofano et al., 1988, p. 78). It is important, then, to emphasize that co-design widely differs from this category of *user* participation (Table 1). Consultation or dialogue is based “on the concept of using *users'* knowledge as a source of information, and asking *users* to comment on the designers' proposal while the design is in progress” (Siu, 2003, p. 72). “Citizen surveys and questionnaires fall into this category” (Iacofano et al., 1988, p.78), which gives the designer the right to make the final decisions concerning the project (Siu, 2003), while the city planners and politicians make the decisions related to implementation. In co-design, the *user*, the *chooser*, and the designer are considered experts. For this reason, the *user* and the *chooser* participate in the design process since its early stages. The designer elaborates proposals with them, and shares the decision-making power with all the stakeholders. Differently from co-design, consultation does not jeopardize the established power structures, and this is probably one of the reasons why this category of *user* participation has been so largely implemented.

	CONSULTATION	CO-DESIGN
user	Source of information Comments on the designer's proposal while the design is in process Does not participate in the decision-making process	Expert of his/her experience Co-designer Participates in the design process since its early stages Participates in the decision-making process
chooser	Expert Makes the final decisions concerning the implementation	Expert Co-designer Participates in the design process since its early stages Participates in the decision-making process
designer	Expert Elaborates proposals Makes the final decisions concerning the project	Expert Elaborates proposals with the *user* and the *chooser* Participates in the decision-making process

Table 1 Differences between co-design and consultation

Another point regarding urban planning must be considered. Malt (1970) investigated the industry of street furniture fragmentation. Even today, many cities are not interested in producing an interrelated line of equipment. Given that the awareness of the importance of the urban elements is still in development, it might be difficult to convince some governments to invest in co-design projects with this purpose. Even though the advantages of involving the public in the process are obvious, changing past habits and thoughts is always a challenge.

Similarly, designers also face hurdles with the advent of co-design. To participate in this process, they have to work collaboratively with *users* and *choosers*. In the past, they used to rely on their individual creativity. Now, the acceptance of the idea that everyone can be creative too is demanded from them. It is just a matter of giving people the right tools to express themselves. In addition, designers are challenged to consider the knowledge that comes from the experience of the *users* as valuable as their own academic and experiential knowledge.

With the evolution of co-design, designers might experience the sensation of “losing [even more] control of the design process” (Sanders, 2006, p. 32). The *choosers* might feel less empowered as well. These reactions are expected when there are substantial changes in the traditional processes. However, the key to the success of co-design experiences in urban spaces is prioritizing the general well being. The stakeholders might need to compromise some power and authority. The benefits to the community and the urban environment, on the other hand, will be considerable.

Conclusion

Urban spaces are a perfect scenario for co-design. Engaging people in the development of urban elements they will use and with which they did not have any previous relationship, might be a solution for under-used and neglected areas with good potential. The co-design process almost guarantees that the final product will meet the public's needs according to their values, the history of the place and the time of the day it is used.

The outcomes of co-design exceed the features of the final product. Co-design workshops enrich the community life, promoting interaction between the community members. They claim a share in the success of the final product (King et al., c1989), and develop an affective relation with it. As a result, it might be possible to note the reduction of vandalism.

The success of the interdisciplinary process depends on the participation of all the stakeholders in the project. In this case, the *user*, the *chooser*, and the designer should be involved in the development of urban equipments. People become co-designers and contribute to the process with their expertise about their own experiences. Their creativity is explored through the use of appropriate tools. The *choosers* participate of the discussion and provide knowledge on governmental policies. They are able to discern viable from unviable solutions. Finally, the designers develop tools for the *users* to express their ideas. They also use these ideas in the conception of the final product.

It is clear that there is a shift in the roles that each actor traditionally plays. A compromise is, therefore, necessary. Instead of keeping their comfortable positions, the actors must share their power of decision, or creative process in order to reach a major goal, which is the benefit to the urban environment.

The changes that are being proposed are huge, but they are already in course. Co-design is being adopted in many contexts, and the idea that when people's creativity is amplified by co-design processes (Sanders, 2006), the results are advantageous to the society as a whole, is being increasingly accepted. Employing co-design practices to the development of street furniture might be a favourable opportunity to improve public spaces. If "all people have something to offer to the design process" (Sanders, 2002, p. 1), one can imagine how many good contributions can be made by common people, politicians, urban planners, and designers working collaboratively to ameliorate cities.

Author Biography

Maria Gabriela Sanches

Maria Gabriela is a Master of Design candidate at the School of Industrial Design, Carleton University, Ottawa, Canada. She obtained her bachelor's degree in industrial design in 2006 after having studied graphic and product design at the University of Brasilia, Brazil, for 5 years. In 2005, her graduation project was awarded the first prize in the Brazilian Contest of Social Design in the category of street furniture for historical municipalities. Her research interests include urban spaces, public spaces, street furniture, co-creation and co-design, design and emotion, and design for experience.

Lois Frankel

Lois is an Associate Professor and past Director at the School of Industrial Design at Carleton University, Ottawa, Canada. The primary focus of her work is simplifying the relationship between people and computer-enabled products.

A Study on Design Careers and the impact of Gender

Debra Satterfield, Iowa State University

Sunghyun R. Kang, Iowa State University

Nora Ladjahasan, Iowa State University

Andrea Quam, Iowa State University

Brytton Bjorngaard, Iowa State University

Abstract

Many of those entering the design workforce will at one point in time be affected by life choices. Some of these choices are welcomed, however, others are of necessity and are not reflective of personal preference. Life choices such as childcare, career advancement decisions, marriage, leaving the workforce, making a lateral career move, or becoming an attendant caregiver for an incapacitated family member are only a few examples of situations that can dramatically impact the course of a career in design fields. In addition, women and men may be affected differently by these choices.

The purpose of this research is to identify the impact of gender on design careers. The methodology for this research is an online survey of university alumni. The respondents represented a variety of design disciplines. This research found a statistically significant difference in perceived impact of gender on design careers.

Keywords

Design Careers, Gender, Culture, Diversity

This research analyzes and discusses the results of a survey developed to examine the perceived impact of gender by males and females on their design careers. The survey is a collaborative research effort by faculty in graphic design, interior design, integrated studio art, architecture, and the Institute of Design Research and Outreach. The survey will be used to measure the perceived impact of gender issues on design careers based on responses from alumni of these design programs and to analyze the actual impacts that were experienced by these respondents regarding issues such as leaving the workforce to raise children, care for elderly parents, or other life situations.

The results of the survey are analyzed and discussed with regard to how students in design programs could be better prepared for life situations through specific modifications to design curricula. Specifically, the data is discussed with regard to its ability to inform curriculum designs that can better address the life and career needs of men and women in design careers. The information will also be discussed with regard to how it can be used to increase awareness among students about life issues and their impact on design careers.

Literature Review

Existing literature with regard to design, gender and workforce issues was examined to determine what areas of study might improve curriculum in design programs. It was used to identify areas of concern both in design and the workforce in general. This literature review is used to identify ways of better preparing males and females for successful careers in design based on gender relevant information for curriculum design.

Gender Differences in the Workforce

Gender studies in design have shown distinct difference between how men and women are treated in school during the design jury process (Frederickson, 1993, p.38). In addition, Clegg, Mayfield, and Trayhurn say that men and women are differently attracted to various design careers. Perceptions of the dominant disciplinary discourse, they say, influences how men and women choose design careers and suggests how gender constraints define the design field. (Clegg, Mayfield, and Trauhurn, 1999, pp. 43-54).

Sex differentiation and sex stratification have been observed in the workforce. Cognitive psychologists indicate that there is an impulse to categorize people according to factors such as age and gender. This process of marking people by personal characteristics is called social differentiation. Social differentiation in turn leads to the unequal treatment for members of different categories, which is called social stratification. According to sociologists, Reskin and Bielby, all societies use sex as well as age to stratify members across virtually all domains. They also say that these disparities are indicated by more men that women participating in the workforce. And those men average more hours worked per year, hold different and more complex jobs, work in different industries, out earn women, are more likely to supervise workers of the opposite sex, and dominate the top positions in their organizations. (Reskin and Bielby, 2005, pp. 71-72).

These differences and disparities have also been noted in the design industry. Michael Bierut, in a post to the DesignObserver, notes a question that was raised at a panel discussion on book design. The question posed by an audience member questioned why all three panel members: Milton Glaser, Chip Kidd, and Dave Eggers; were men. Glaser offered the following reply:

> "…the reason there are so few female rock star graphic designers is that women get pregnant, have children, go home and take care of their children. And those essential years that men are building their careers and becoming visible are basically denied to women who choose to be at home…unless something very dramatic happens to the nature of the human experience then it's never going to change." [1]

According to Matlow, with regard to gender differences in graphic design education, it is apparent that women experience additional pressures when working in a typically male-oriented environment. They have to work harder than men, be more committed to their work, and become more involved in it. (2000, p.83).

Clegg and Mayfield note that women are under-represented in what they refer to as "hard design" areas such as product and furniture design and over-represented in "soft design" areas such as fashion and jewelry. They identify this dualism as a stereotypical association of women with the body and decorative fields and men with fields in the areas of technology and shaping nature. (1999, p.3).

Even in the realm of business ownership gender differences have been noted. Marlow, Henry and Carter examined the "female under-performance hypothesis" in small business ventures. However, when analyzed it was found that differences exist in how female owned start-up businesses are capitalized with women receiving more costly financing. When female-owned businesses are capitalized in the same way as male-owned businesses there were no differences in their levels of performance (Marlow, Henry, and Carter, 2009, pp.139-143).

In business, according to Lobel and St. Clair, research has been done to explain the differences in job performance and outcomes. The Human Capital Theory describes how voluntary life choices are made in allocating time and effort to tasks such as work or family. This theory has been used to suggest that because persons who are involved in labor-intensive tasks such as childcare and housework tend to select jobs that are comparatively less demanding. This theory thus predicts that because less effort and time is devoted to the job there are fewer positive performance outcomes such as pay or promotions. Another performance difference business theory is the Sex Discrimination Theory which focuses on the idea that men perceive women as a child rearer and as such it is appropriate to scale back their work duties and outcomes accordingly. Both of these approaches of describing the effects of family responsibility on job performance, say Lobel and St. Clair, suggest that family responsibility has an adverse effect on work effort, particularly for women. This limits women's opportunities for positive performance outcomes such as merit increases and promotions. (Lobel, S. and St. Clair,1992, pp. 1057-1058).

An in-depth interview with 48 highly successful women, conducted by psychologist Barbara White, indicated that there are several key commonalities to their success. White found the success of these women was predicated by a high centrality of their career to their lives, working continuously and full-time, fitting their family life around their work, and conforming to male standards of success. One common pattern of these women was to wait to contemplate a family until their careers were well established. If they decided to have children at all, the mean age of starting their families was 33 years old. They also chose to take a minimum amount of maternity leave. Of the women surveyed, 50% had children and reported that they did not see work and family to be mutually exclusive. In fact, they felt that their family was enriching and the time they spent on family was quality time. Other key issues for their success were to achieve promotions and positive evidence of their achievements at an early age. They also noted that they benefitted from a mentor. According to White, 38% of these women said that their abilities had been raised by the support and encouragement of a mentor. (White, B., 1995, pp. 4-15)

Research Methodology

The research methodology involved the development and pre-testing of a survey tool. The survey questions were based on a literature review of existing data about job satisfaction in design careers from research studies done on design and architecture.

Additional survey questions were developed based on research from focus groups with students and faculty groups in design. The survey questionnaires were carefully developed to measure the perceived impact of gender issues on design careers for alumni. The self-administered online survey was conducted through SurveyMonkey in December 2009. Eighty-eight alumni responded and participated in the survey. The survey collected participants' demographic information including gender, age, major, degree, internship experiences, ethnicity, and income ranger per month.

The respondents were all alumni from a Midwest land-grant university with approximately 28,000 students located in a town with a population of 50,000 people. The respondents were all from design disciplines in programs of Architecture, Community Regional Planning (CRP), Graphic Design, Interior Design, Landscape Architecture, Studio Art, Applied Art Education, or double majors in these programs.

Discussion and Findings

The data from this survey will be examined based on gender, age, and discipline with regard to their impact on design careers. The information will be analyzed with regard to those who stayed in design careers, those who left design careers for a period of time with the intention of returning, and those who permanently left their career either for another career, retirement, or unemployment. The information provided by the respondents will be used to identify the impact of gender, job satisfaction, life situations, and other issues on the decision to continue in a design career. Architecture (33%), Graphic Design (21.5%) and Interior Design (18.5%) were the three top survey respondents with a total of 73% of the total respondents.

The Interior Design respondents were all female, while both male and female were represented architecture and graphic design.

Retention in Design Careers

Out of the 88 total respondents, 61 (72.6%) are still working in design-related careers. Of these people still in design careers, 40%are male and 60% are female. However, of these people, 28% report that they left the workforce at some point in their career and 72% report that they have never left the workforce.

With regard to retention of females in their design careers, there were several distinguishing features between the disciplines. In architecture and landscape architecture, all of the female respondents remained in their design careers. However, in graphic design only 79% of the females who entered that career remained in their field and in interior design only 70% of the females remained in that career. By contrast, in CRP only 40% of females remained in their design careers and in studio arts 50% of females remained in their careers.

With regard to retention of males in their design careers, graphic design had 100% retention of males in the career compared to architecture with 87%, CRP with 67%, and landscape architecture with 71%. However, studio art did not have any retention of males in the career as reported by this survey.

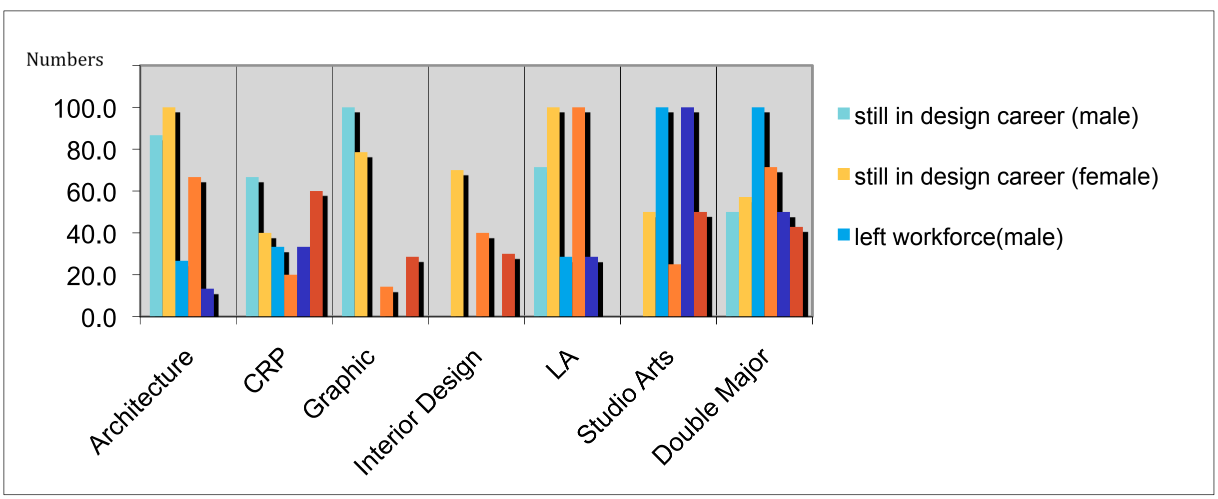

Figure 1. Gender Comparison of Numbers of Persons in Design Careers

Overall, the retention rate of all degrees in design careers was high. This may be related to the fact that 81.4% of respondents who are still in their careers report that they find their work rewarding. Figure 1 compares the percentages of total respondents in each discipline broken down by gender with those who stayed in design careers compared to those who left design careers.

Leaving Design Careers

Leaving a design career can be broken down into two basic categories. First, those who left design for what they perceived to be a temporary period of time and second, those who left design permanently. People who left design careers on a temporary basis did so for reasons such as going back to school, becoming an attendant caregiver, or maternity leave. Persons who left design careers permanently did so for reasons such as retirement, career changes, poor job markets, or unemployment. These reasons for leaving design careers were highly dependent on variables such as gender, age, and income levels.

Leaving Design Careers for a Period of Time

The survey asked respondents about whether they had ever left the workforce. Of males, 34% indicated that they had left the workforce for a period of time compared to 66% of females who indicated they had left for a period of time. Leaving the workforce for a period of time was also greater among those respondents who identified themselves as no longer in design-related careers. The primary reason given for leaving the workforce was returning to school (25%); however, 22% indicated becoming a primary caregiver was their reason for leaving the workforce for a period of time. An additional 12.5% indicated that they left the workforce for a period of time because of family issues.

According to the data in Figure 2, males only indicated leaving design careers for a change in career (29%), retirement (29%), and unemployment (14). None of the females indicated unemployment as a reason for leaving a design career. Women, on the other hand, listed change in career (14%) and retirement (14%) for reasons for leaving design careers. Females also indicated that they left design careers because of a poor job market (50%), limited or outdated job skills (29%), poor pay (21%), and children or family (14%). None of the male respondents indicated any of those four categories as reasons for leaving a design career.

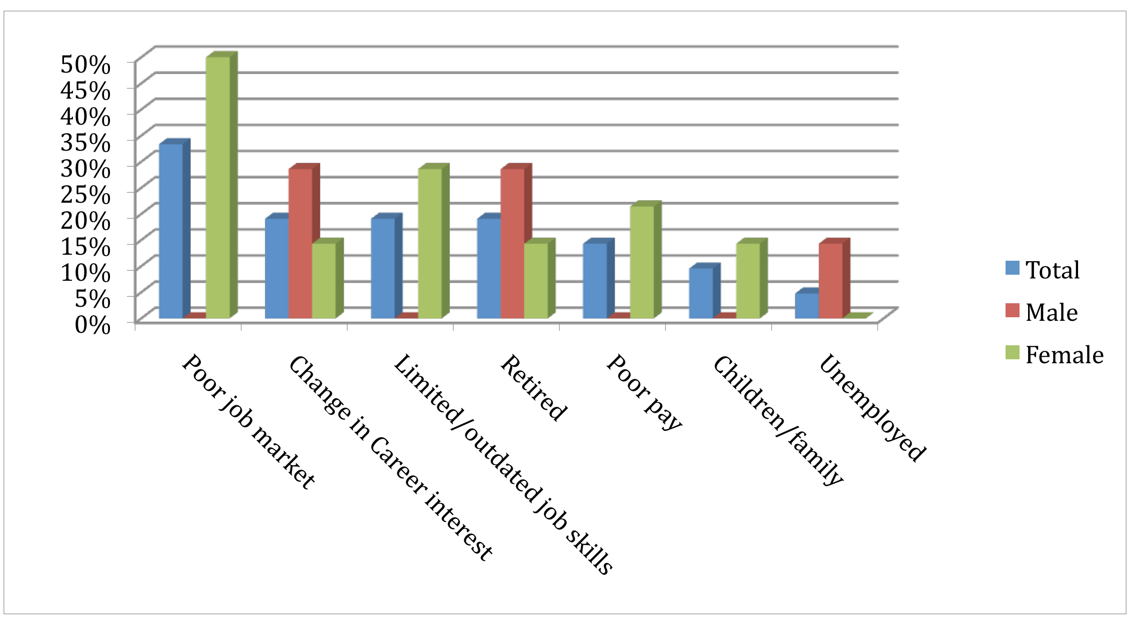

Figure 2. Reasons for Leaving Design Careers by Gender

Respondents No Longer in a Design Careers

The percentages of people who identified themselves as still working in their current field varied greatly by discipline. Architecture had the highest number of respondents who identified themselves as still in their career.

Gender, as seen in Figure 3, had a statistically significant difference between the responses of men and women. Men indicated that they never or were not affected by their gender in the school or work environment. Women, however, indicated that they were uncertain if their gender had affected their school or work environment.

Of the respondents, 27.4% indicated they were no longer in design careers. Males left design to change careers at 35%, females left design to change careers at 65%. The primary reason given for leaving design careers was a poor job market at 33%.

Table 1. Gender Significance for Those who Left Design Careers

	Gender	Number	Mean	Std. Deviation	Std. Error Mean	Sig. level
Gender	Male	8	1.88	0.83	0.30	.001
	Female	15	2.80	1.57	0.40	

Table 1 shows the statistical significance between males and females in how they perceived the impact of gender on their careers. Females significantly think they are more affected by the impact of gender than were their male counterparts.

Comparing respondents in design careers with those no longer in design careers, as seen in Figure 3-3, females are leaving design careers in higher percentages than their male counterparts. This is true when leaving both temporarily and permanently (figure 3-1 to 3-4).

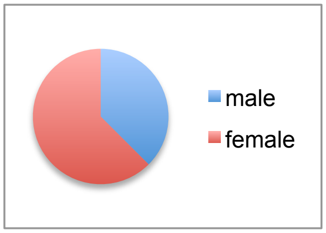

Figure 3-1 All Participants n=80

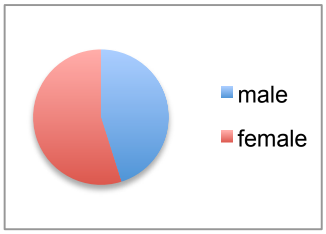

Figure 3-2 still in design career (n=61)

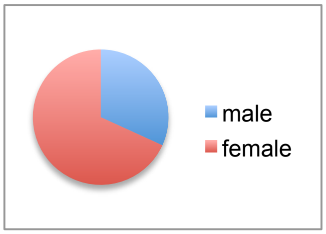

Figure 3-3 no longer in design career (n=22)

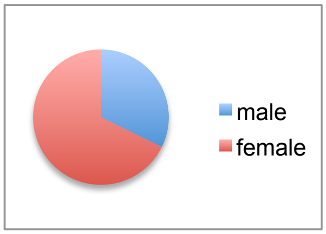

Figure 3-4 left workforce for a period of time (n=31)

Age, as seen in Figure 4, seems to affect the number of people who are in design careers according to a number of factors. The peak age for leaving design careers is between the ages of 36 and 45 (30%). This may be caused by factors such as career change or family issues.

Another peak time for leaving design is between the ages of 56 and 65. This is more likely attributable to retirement. However between the ages of 46 and 55 there is a resurgence of people returning to design careers.

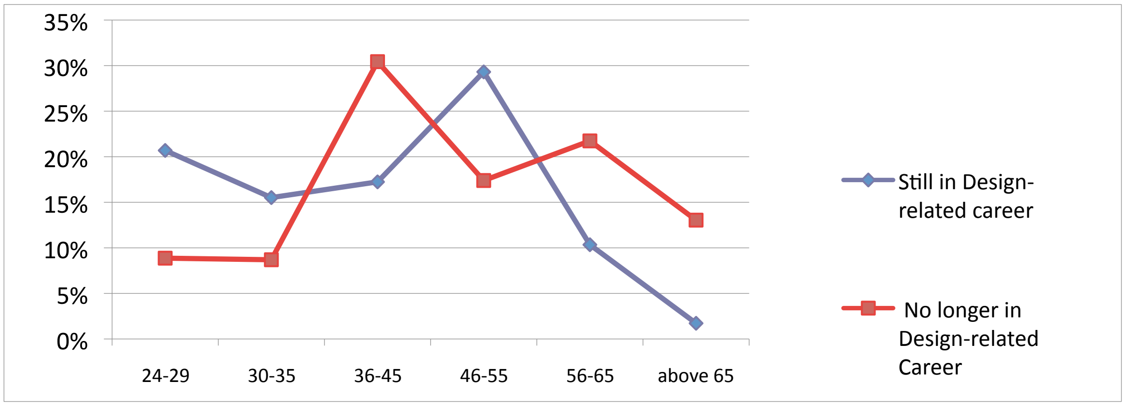

Figure 4. Age Comparison of Persons in Design Careers and No Longer in Design Careers

Respondents in higher income brackets, as seen in Figure 5, were more likely to stay in design careers. Those with lower income levels were more likely to leave design careers. Low income was indicated as a reason for leaving design in this survey.

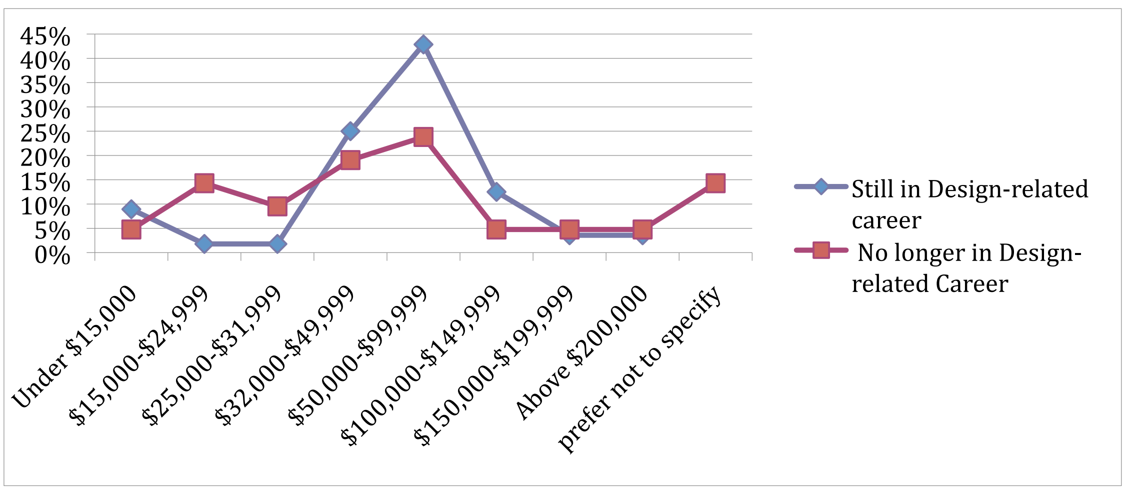

Figure 5. Income Comparison of Persons in Design Careers and No Longer in Design Careers

Conclusions

The analysis in this research is focused mainly on the respondents who left design careers on either a temporary or permanent basis. Leaving the workforce for a period of time, such as for returning to school (25%) or becoming a primary caregiver (22%), was greater among those respondents who identified themselves as no longer in design-related careers. Among those still in design careers, the vast majority indicated that they had not left the workforce even for short periods of time.

Of the respondents who left design careers, women indicated poor job markets, limited or outdated skills, poor pay, and children/family as the top four reasons for leaving design careers. It is possible that temporarily leaving the job market leaves women at a distinct disadvantage compared to their male counterparts in design careers.

Based on this research, design curriculum needs to address the different life situations experienced by men and women. Men tended to leave design careers based on changing careers, retirement, and unemployment. For men, there were fewer obstacles to their success. For this reason, design curriculum seems to be working well in the current business climate.

Because women are greatly affected by temporary leaves from design careers, it is important to equip them with education in areas such as business and entrepreneurial studies. This would allow them another career option other than simply returning to their previous positions. It is also important to provide women with role models and mentors in successful design careers and businesses.

Limitations

The study was limited by the number of respondents and the geographic area. This research was also restricted to the alumni of one university and should be expanded to see if similar outcomes are obtained from additional data collection sites. In addition, this study did not distinguish between part-time and full-time employment in design careers. This distinction may be significant with regard to the final outcomes.

Areas for Future Research

This study will be expanded to include a larger number of respondents from a wider geographic area. It will also include part-time and full-time data sets. From the current data, curriculum changes will be proposed and implemented for further testing with regard to their impact on retention in design careers.

Debra Satterfield

Debra Satterfield is associate professor of Art and Design at Iowa State University. She received a B.S. degree in computer science and art from Morningside College. She earned an M.F.A. degree in graphic communication from Iowa State University in 1991. She joined as a faculty of Department of Art and Design at Iowa State University in 2000. Her teaching and research is focused on graphic design, human interaction, and visual communication. Her research is in the areas of design for social inclusion, the design of educational experience for children with cognitive disabilities, and medical experience design. She has presented and published at numerous conferences including Interaction Design for Children Workshop on Creative Play for Disabilities, Asian Design Conference, the Design Research Society Conference, and America Institute of Graphic Arts (AIGA). During summer 2007, she conducted research with *Frito Lay* for Tostitos® Brand as a co-PI. Recently, she received the Bailey Research Career Development Award as a co-PI with Sunghyun Kang to conduct research on medical decision aids in collaboration with the Mayo Clinic.

Sunghyun R. Kang

Sunghyun Kang is an associate professor of Art and Design at Iowa State University. She received a B.F.A. degree in the field of applied art from Ewha Women's University in Korea. She earned an M.F.A. degree in graphic communication from the University of Houston and an M.A. degree in graphic design in 1999 from Iowa State University. She joined as faculty in the Department of Art and Design at Iowa State University in 2000. Her teaching and research are focused on graphic design, human interaction, web based design, and visual communication. She has over 20 years of experience in teaching, research, and consulting in these areas in Korea and the U.S. She has presented and published at numerous conferences including the Asian Design Conference, the Korean Society Design Conference, and the Japanese Society for Science Design conference, the Design Research Society Conference, and the America Institute of Graphic Arts (AIGA). During summer 2007, she conducted research with *Frito Lay* for Tostitos® Brand as a co-PI. Recently, she received the Bailey Research Career Development Award as a co-PI to conduct research in collaboration with the Mayo Clinic.

Nora Ladjahasan

Nora Ladjahasan is an Assistant Scientist II with the Institute of Design Research and Outreach in the College of Design at Iowa State University. She holds an MSC in Human Settlements Planning from the Asian Institute of Technology in Bangkok, Thailand, and a B.S. degree in Agriculture from the University of the Philippines. She teaches and coordinates the Geospatial Technology Training Program workshop, maintains and disseminates research data bases, assists faculty in developing research methodologies, advices students/staff on "human subject (IRB) " issues in relationship to design research. She is a member of the Design Information Research Group and has worked on projects in collaboration with the Mayo Clinic with regard to medical decision making. She is currently working on the data collection and analysis for the design of a medical decision aid for college women selecting birth control.

Andrea Quam

Andrea Quam is a lecturer in graphic design at Iowa State University's College of Design. She received a BFA in Graphic Design from Iowa State University in 1997. She has over 10 years experience practicing professionally as a multimedia and print designer. She has worked with a range of clients including: McGraw Hill, Ford, Conoco, AmerUs Group, Musco Lighting, Principal Financial Group, Elsevier Science, and Meredith Corporation. In May of 2008, she received her MFA in graphic design from Virginia Commonwealth University and joined the faculty of Iowa State University's College of Design in August of 2008. Her teaching and research interests include graphic design practice and education, design methodology and innovations in design pedagogy. She is a member of the Design Information Research Group and has worked on research on the impact of gender on design careers and on medical information design for birth control decision aids.

Brytton Bjorngaard

Brytton Bjorngaard is a Graphic Design graduate student at Iowa State University. Her thesis research is on the utilization of environmental graphic design and interior elements to protect patient privacy within healthcare, with respect to HIPAA regulations. Upon graduation with an M.F.A. in summer of 2010, she will begin a position at Whitworth University in Spokane, Washington as a Graphic Design Lecturer. She earned her B.A. in Graphic Design from Saint Mary's University of Minnesota in 2007. Her teaching and research focus is on graphic design, digital photography, and product design for children with Autism Spectrum Disorders. She has presented at the International Association of Society's for Design Research Conference in Korea and SIGCHI Computer Human Interaction Conference in Atlanta, competing in the SIGCHI Student Design Competition. For the past two years, she has worked as a research assistant at Iowa State University under the Bailey Research Career Development Award in conjunction with the Mayo Clinic.

Abstract

Designing is a highly collaborative and communicative process. To achieve good results effective teamwork is extremely important. Digital technology makes it possible for this process to be distributed across different spatial locations. Despite the potential of digital networks, commercial systems in the field of Computer Aided Architectural Design remain stuck in old patterns with strict role definitions and linear working processes. Open Architectural Design offers an alternative to this “sequential model” by providing an approach to distributed work oriented around "Open Strategies”. Open strategies facilitate an open exchange of ideas and artefacts with the aim of making better use of distributed resources and realising greater creative potential. The goal of our project is to apply open strategies to the architectural design process. The technical basis for our research is FREAC, a software framework developed in-house which provides a collaboration space for co-operation between different users and tools. This framework is designed not just for exchanging the outcome of the design process but also for opening up the design process itself and making it more transparent. Such highly open and distributed design processes, however, also present new problems and uncertainties which need to be taken into account in order to reach successful design outcomes. As a result proposals for the management of such processes need to be developed that facilitate collaborative work but do not unnecessarily constrain the inherent complexity of the design process. The focus therefore lies on the improvement of the negotiation process between users, tools and architectural design models. The actor-network theory, and other different management concepts, provides a theoretical underpinning for our approach. The project is a collaboration between the fields of computer science in architecture and media management.

Keywords

Collaborative Design; Open Design Processes; Actor-Network Theory; Media-Management.

Contemporary architectural design brings new challenges to the design process: internationalisation, digitisation, increased differentiation between disciplines as well as spatially and temporally distributed working methods. Effective coordination between different participants plays more than ever an important role in fulfilling the complex requirements of today’s building constructions and to achieve high quality results. Although the architectural design and planning process is now almost completely digital, computer-aided spatially distributed collaboration and the associated use of distributed expertise in the key phases of design have still be implemented successfully. While current developments in building information modelling (BIM) are centred around the integrative aspects of a common model, they focus primarily on effective data exchange and maintain a strict division of roles. Although the exchange of data is being conducted at a faster rate than ever before, the working process is still dominated by a linear and sequential pattern. According to the practice of designing, which typically deals with wicked problems (Rittel, 1973), such “a priori” hierarchically organised structures, hinder the emergence of creative processes and innovation.

The potential of digital technology lies not only in the acceleration of already established working methods, but also enables them to be restructured entirely. A good example of how structures are changing across many fields is the emergence of open development methods, e.g. open source initiatives in computer science (Raymond, 2001) or collective intelligence or swarm intelligence in economics (Levy, 1997). These make it possible to access and exploit decentralised skills more effectively. “Open” thereby designates the free exchange of information, licenses, ideas, data and artefacts. How this exchange is designed varies from

case to case. Initial approaches to applying such open strategies to the process of designing are evident, for example, in "Wikitecture" (Chase et al, 2008), the urban planning project "divercity" (Königs et al, 2000) as well as in product design (www.theoscarproject.org). All these projects, however, lack suitable management strategy approaches for successfully facilitating a genuinely open negotiation process. Typical problems include issues of quality assurance and motivation, the enabling of coherent action, the mapping and storage of information and knowledge, and effective communication between actors.

Our goal is the development of techniques and methods to enable spatially distributed design processes based on such open strategies in the field of architecture. A key challenge of the project is to avoid hindering the creative process of designing in digital environments, in other words to create “enabling spaces”. At the same time, it addresses approaches to coordinating processes occurring within these “spaces” without constraining their inherent complexity and unpredictability. In the following we introduce a technical and theoretical foundation that provides insights into how and with what mechanisms such open design processes can be controlled.

1. A technical framework for open architectural design in digital networks

In an open architectural design process the design object is constantly in developement. The negotiation process, in which this object is changed, manipulated, newly created or discarded, is therefore not innately suited to a sequential chain of fixed stages but is instead characterised by simultaneity, plurality and the mutual production of interconnected information (see for example the work of Rittel (1972), Lawson (2006), Schön (1983) and others). Everyone involved is a potential actor that informs the design object by contributing ideas and skills (fig.1).

To exploit such networked expertise as accessibly as possible, a space needs to be created on a technical level that facilitates the act of contributing. For several years we have been developing tools based on our in-house experimental programming platform FREAC (Framework for Enhancing Research in Architectural Design and Communication). This platform provides a flexible data structure for the integration and linking of digital tools. It allows an open exchange and transfer between different users and provides a flexible technical framework for different research projects. The main aspects of this framework are as follows:

Seamless coupling of heterogeneous tools

Almost all collaborative design projects face the problem of having to develop interfaces between different tools. As a result, many projects are limited to an asynchronous exchange of data over the net in the form of web platforms, etc. These “interruptions” reinforce a phase-oriented working method and thus interfere with the flow of the creative design process. To facilitate networking as an open process, it is vital that the barriers between tools are kept as low as possible. Rather than using one complicated universal program, it should be possible to create and use many small, easy-to-use tools that can be seamlessly interconnected and combined as required. The FREAC platform uses a TCP client-server principle to effect communication between these tools. When changes are made to the digital model all clients linked with the server are automatically informed and can synchronise their local models. The resulting seamless coupling of different tools means that every tool can immediately “see” how other tools have affected the model and can build directly on the changes made. It also allows different tools, methods and technologies to be brought into direct relationship with one another, for example to seamlessly integrate a freehand sketching module into a 3D Modeling environment (Schneider & Petzold, 2009). The resulting content is therefore always linked to each other in one or the other semantic form, creating networks of design tools and artefacts. (fig. 2)

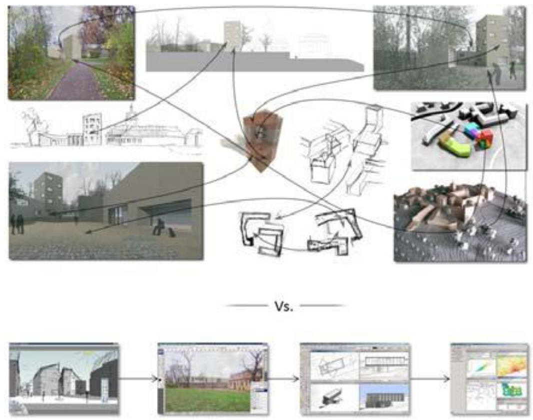

Figure 1 Different kinds of representation condition one another Vs. The Separation of these contents in traditional digital design applications

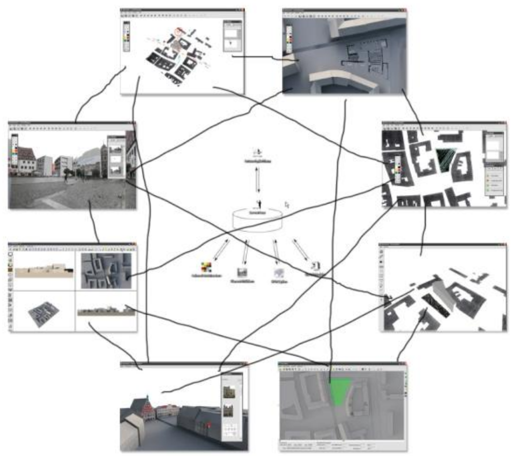

Figure 2 Via FREAC all (connected) tools are interlinked and form a complex network of heterogeneous data / content (video online at: http://vimeo.com/8591465)

Connecting users (seamlessly)

Negotiation processes within spatially distributed design actions is always mediated – by the digital tools as well as the design objects and artefacts created with them. These are stored on a server which all parties are able to access in real time using different tools. The seamless technical interlinking of digital tools and their users enables them to circulate freely and without barriers in the network. Modifications can occur both asynchronously and synchronously at any time creating a smooth transition between individual and group editing and facilitating the dynamic formation of networks (flexible group sizes) of human actors.

Storing processes (automatically)

The FREAC server can handle all kinds of data. Each item of data receives a reference detailing when it was created, with which client and by which user. Each reference can be called up, combined with others and interpreted selectively. To avoid unnecessary data load, the model only changes within the transactions, i.e. only the changes are saved, not the whole model. The aim is the emergence of an ordered structure that obviates the need to structure the data manually.

The technical framework is a basis for the creation and use of (design) tools and creates an open negotiation space for collaborative design projects. In the following, the theoretical foundation (from a management perspective) for capturing, analysing and evaluating designing in open networks is discussed.

2. The actor-network theory as a framework theory for an open architectural design model

The creation of technical networks is simultaneously the creation of social and organisational contexts and spaces of action and negotiation. To coordinate complex negotiation processes in such technical and social networks (different tools, content, users), it is crucial to make visible the processes taking place. The actor-network theory (ANT) is used to describe these multiple interactions between the actors in their necessary complexity. Decisive here is the acceptance of complexity, as a complex open design network is able to respond more innovatively and flexibly to changes and gives rise to creative synergies.

The actors play a key role in the ANT. They represent entities that freely interact within a network and behave in different ways. Their “capabilities lie in how they are able to affect other actors, how they change, transform or produce them” (Belliger/Krieger, 2006). A special aspect of the actors lies in the assumption that there is a coexistence or symmetry of human and non-human actors, who mutually ascribe one another actions (Belliger/ Krieger, 2006). As such, in the process of (computer-aided) architectural design, there are heterogeneous human and non-human actors that act differently within the network and influence one another mutually.

Besides the architect, expert planners and developers, one can also regard design objects, design tools, environmental conditions, laws, norms and institutions as contributing actors in the design process. In the ANT, so-called micro-actors such as individuals and single tools are treated equally alongside macro-actors such as institutions and organisations. While their differences are not denied, the construction of networks helps to uncover their differences and their available capacities and influence. Overall, the resulting design can no longer be seen as the work of a single actor, but as a net-work of all contributing actors, regardless of their importance or size. Although the network gradually stabilises over time, it can be understood as an open network: it is open to ongoing change produced by the participating actors, as well as any new actors that enter the process, and as such is in a state of permanent flux.

During the formation of networks it is assumed that the world is contingent, that is, that it does not have to be the way it is (Belliger / Krieger, 2006). Because they are able to bring about innumerable references and effects that emanate from something, selection processes are necessary to reduce complexity and create order. As each selection of “something” results in the introduction of a difference in the world, selection processes can be interpreted as actions. In the ANT these are generally referred to as translations and not attributed to humans or human-actors. “Translation is a complex process that consists of a number of different communicative acts, all of which are destined to construct a network.” (Belliger / Krieger, 2006). Actors become involved in a network “by ‘translating’ their interests and roles”, that is, by adapting their interests to one another to pursue a common direction. Translations in one or the other form therefore allow some form of cooperative action, since such joint action implies common objectives and interests (Belliger / Krieger, 2006).

Relationships between actors in open architectural design

The ANT extends our understanding of the design process as a matter of negotiation by considering not only human-to-human relations, but also actions that relate to objects. In the ANT, person-to-person relations are therefore complemented by object-to-person, person-to-object or even object-to-object relations, adding new dimensions to the notion of actions in the design process. In the Open Architectural Design process (using FREAC as a basis), the following relations have a significant influence on the digital design process and have therefore been considered in greater detail. Here we should note that the term “designer” refers to any human actor involved in the design process.

Data : tool relationship as an object-to-object relation:
The data : tool relationship describes how tools draw material from the data container and as such assume the role of an active actor in the network. The FREAC server provides an open data container, which can be filled with a variety of data that is then available to all other tools connected. This allows an exchange of heterogeneous information in real time.

Tool : tool relationship as an object-to-object relation:
This level of relationship examines the extent to which different tools interoperate with one another and how they are involved in network formation. The connection between different tools can occur, for example, by visually superimposing different tool contents. It can also occur by directly coupling or chaining the content or algorithms of different tools (e.g., building volume coupled with plan generator). Each new tool may therefore potentially change the structure of the relationships.

Tool : designer as a human-to-object or object-to-human relationship:
With tools, artefacts are created to articulate specific intentions and content, as well as to gain insight into the object to be designed. The designer as a human actor influences the design tool and likewise the design tools influence the actions of the designer. Crucial for designing in the digital space is therefore the ability to effortlessly switch between different tools and action spaces.

Designer : designer as a human-to-human relationship:
In distributed design processes, human to human communications are mediated by digital tools. As such, direct and indirect communication overlap in the interaction. The more "seamless" the connection between various actors within an action space is, the more direct and immediate their participation and their ability to form networks.

Designer : external constraints as a human-to-object relationship:
External factors such as environmental conditions, social-factors, laws, etc., are often difficult to transfer into the digital realm due to their specific context-dependency or their ambiguous form. To make them available to all the actors involved, they have to be translated into the digital model by the designers and the tools available to them.

At a technical (digital) level it is important that the different demands, ideas, constraints, rules, designers and tools can be integrated in a suitable manner to guarantee effective translation processes. The relationships between these actors influence the entire design process, and navigation, mediation and translation processes take place constantly between these heterogeneous components in the network. The more seamlessly they are integrated into the overall process, the more effective negotiation processes can occur and more easier networks can emerge.

3. Accepting and managing uncertainty and complexity in an open architectural design process

Open development methods, such as those suggested here for the creative design process, make it possible to effectively use and process decentralised skills and competencies. A complex network emerges with a high degree of variability (Malik, 1998). The more complex a network, the greater its behaviour spectrum and the more innovatively and variably it can respond to changes. At the same time, however, it is more difficult and challenging to keep it under control. Together with the emerging complexity, different sources of uncertainties appear, which raise questions about how to coordinate them effectively. Bruno Latour addresses, in conjunction with the actor-network theory, five sources of uncertainty in order to highlight the discrepancies between a sociology of the social and a sociology of associations (Latour, 2007). Below, four of these sources are used to address the most important uncertainties that have to be considered in an open design process in more detail.

The first uncertainty according to Latour lies in "the nature of groups". He describes the fact that within a network actors are constantly regrouping, leaving traces that can be analysed (Latour, 2007). Accordingly, a network is never pre-existent but must always be assembled anew through association. It is here that the design process manifests itself as an open network formed by many actors into which many ideas and skills can flow. It is a fluid and constantly evolving network which has no stable structure.

The second source of uncertainty is concerned with the nature of actions. Human activity is not transparent, but a conglomeration of many, often surprising sources which have to be unravelled to be able to make statements about who is in fact acting (Latour, 2007). Accordingly, one never knows who is actually acting. But if individual actions in the design process are difficult to identify, it is also difficult to coordinate and motivate these actors.

The third source of uncertainty – the nature of objects – describes that different threads of action intermingle arbitrarily, so that they rarely consist purely of human-to-human or object-to-object relations (Latour, 2007). Without objects / artefacts, architectural design processes would be unthinkable. Digital tools and the design object itsself have an impact on the perception and the actions of the designers and the entire design proces s, and should accordingly be taken into account for the purposes of effective management.

The fourth source of uncertainty – the nature of the facts – Latour stresses that an object of study should always be understood as a controversial and not as an indisputable fact. In architectural design processes, we are always dealing with unfinished, incomplete and vague constructions of reality. There is, therefore, a permanent need for interpretation, which in turn depends on the experience and knowledge of the actors involved.

The uncertainties discussed above, which occur in an open design process, raise questions about the coordination or management of the heterogeneous elements of a network. Unlike in traditional management approaches (e.g., principal-agent theory), it is not sufficient to search for moments of indeterminacy in only one other subject (Schreyögg, 2003). So how can one coordinate processes that take place in constantly evolving networks in which it is hard to draw conclusions about who is actually acting, where the influence of non-actors must be considered and where interactions occur with artefacts and design objects that are interpreted individually by each of the actors but must nevertheless be identifiable by their core characteristic?

4. Coordinating negotiation processes in open design networks

In our project, FREAC serves as a digital platform that provides the negotiation space for an open design process. For this to work, mechanisms and tools need to be developed to manage this process in its complexity. Based on the aforementioned uncertainties, we examine a series of possible solutions as to how these can be coordinated in a virtual design environment.

4.1. Uncertainty about the nature of the groups

An open design network is characterised by instability and constant change. The coherency of actions and the consistency of the results therefore appears vague because, unlike previous approaches, they do not take place within a fixed structure. The ongoing changes to networks with no predetermined structure are triggered by the free, creative and networked actions of different actors. Human and non-human actors contribute to each other, initiating translation and network-formation processes, changing them, expanding or limiting them. Through the seamless coupling of different tools and the temporally and spatially distributed constellation of designers made possible by FREAC, a high degree of openness and flexibility is created. This openness in the design network must be coordinated to facilitate consistency in action and consistency in results. Bruno Latour assumes that groups are not held together by existing commitments, but that the social network is created by mediators (Latour, 2007). Mediators complement the actors participating in a network. They circulate between the actors, modifying, translating and transforming the ideas of one actor into other ideas. Therefore the actions of the actors have to be mapped. With the help of FREAC these different stages of development are recorded in a process-oriented way. With the information collected, including the intermediate steps and links that were necessary for their creation, navigation techniques have to be developed that make permanent changes understandable and thus possible to coordinate. Individual actors cannot and need not understand all the complex processes of change nor integrate them into their local activities. They select only the relevant change processes and accordingly adapt them for their actions. Their changes are automatically stored and in turn available to other actors and their adjustment processes.

4.2. Uncertainty about the nature of actions

The scope for actors in an open design network is much larger than in a linear design process. However, assigning actions to actors is more difficult and may lead to motivation as well as quality problems. A decreased level of direct external regulation must therefore be compensated for by increased self-control. In addition to a policy of seeing and being seen, digital tools can be used for storing and reading evaluations and feedback. Beyond that, monitoring occurs not only directly but also, and more importantly, indirectly through networked action. As anyone is able to partner with another actor, actors need to react flexibly to one another, continually adjusting their actions and their designs to each other. Monitoring, control and by implication also feedback is therefore already an aspect of the open design process itself. Each actor stands in the centre of observation and is himself an observer of all the others involved. Observation is not limited solely to other human actors, but can also be undertaken by digital evaluation and simulation tools. Feedback from other actors allows the actor to adapt flexibly to the expectations of their environment. As in an open and complex network one is not able to immediately identify who does what at a particular moment in time, open design networks can potentially be seen as a permanent space and stimulus for self-reflection (Bröckling, 2007). Through the seamless linkage of actors and the permanent and automatic saving of changes in the design process, a technical basis is created for such self-reflection and self-optimisation processes. The seamless coupling of actors establishes a 360 degree field of vision, which makes it possible for actors to continuously monitor, evaluate and compare. By recording changes in the design process, it is possible to trace actions to a specific tool, user and point in time.

4.3. Uncertainty about the nature of objects

Digital tools, design objects and other non-human actors such as norms and laws have a significant impact on the overall process, as well as on human action and human perception. Here we need to consider the affect of individual tools and the impact of their limited functionality and action-space in the design process. The use of a tool of any kind sets up a temporary ‘world’, which is limited or defined by the scope of the respective tool (its functionality) and its compatibility with other ‘worlds’ (which in turn are the product of other tools). For example, while using a volumetric modelling tool, one can design volumetric models and is therefore restricted to this view. Since the process of designing occurs in parallel at many levels of abstraction and scale, one needs to be able to switch between tools and the functionality they provide according to the respective situation. In the case of digital tools, a crucial aspect is therefore the ease with which one can switch – the smoothness of transition – from one tool to the next. In FREAC heterogeneous tools (sketches, models, drawings, simulations) coexist within the same design space and one is not so tightly focused on one tool (and its scope), but can move freely between different ‘worlds’. The tools do, however, leave recognisable traces which can therefore be tracked and analysed.

4.4. Uncertainty about the nature of facts

When designing, constructs are constantly being negotiated and exchanged which need interpretation. This requires knowledge and competence on the part of human actors and means that design objects as boundary objects need to be robust and plastic so that they are able to constantly communicate meaning between different actors. "Boundary objects are objects which possess different meanings in different social worlds and yet are able to create a link between these worlds.” (Rossler, 2008). In this respect, we are concerned with the mapping, storage, transfer and use of knowledge and information. In digital design processes greater importance is therefore accorded to the transparency and stability of knowledge and information resources than in linear hierarchical design processes. Human actors must accordingly possess the competence to interpret the structures and develop this ability constantly. In addition, they must be able to work and learn independently without direct instruction. Non-human actors, such as digital design objects must constitute and maintain a connection between the different worlds of knowledge. Overall, it is difficult to coordinate a negotiation network of completely heterogeneous components, since the interpretation of the different content itself is problematic. This is due not least to the fact that their construction and interpretation depends on the specific knowledge of the respective individuals and is as a consequence highly subjective. Likewise, in many cases different tools are not directly comparable, and even artefacts created with the same tools can transport entirely different meanings, intentions, etc. Of course, ambiguity of meaning on the one hand and the specificity of the individual actors on the other can represent a creative potential that does not necessarily need conclusive clarification.

In the technical implementation, it is therefore necessary to establish connections between different virtual artefacts. These different pieces of information or artefacts must have some kind of semantic relationship to one another (e.g. a sketch belongs to a model from a particular viewpoint, authored by someone). Using this information, navigation structures can be derived which enable one to represent contextual links. Thus it becomes possible to browse between different states of artefacts, to derive and record intentions.

5. Conclusion and outlook

At the outset we discussed the concept of “open” as denoting the free exchange of ideas and artefacts, much in the same way that open source projects make their source data freely accessible. Using the technical framework FREAC presented in this paper, we extend this definition to open up the design process itself and understand it as a constant matter of negotiation. In this way, it is possible to facilitate the networking of actions by many different actors. However, open systems require efficient coordination mechanisms to keep the network under control, without – and this is the biggest challenge – limiting its degree of openness. The extent to which creative processes can actually be opened up, and whether this has added value for the quality of the results needs to be explored further. This paper has discussed a theoretical framework to assist in the conception of digital tools and design objects. In future work we will create coordination prototypes using FREAC, in order to extend “negotiation spaces” and manage them sensibly. Additional problems and issues relating to the management of these action-spaces can then be evaluated empirically.

A Case Study of an Andragogical Model in Design Education: *Experiments in interactive teaching and learning in graphic design pedagogy*

Sang-Duck Seo, University of Nevada Las Vegas (UNLV), sang-duck.seo@unlv.edu

Abstract
The purpose of this study is to seek an interactive pedagogical model in teaching graphic design in higher education. Malcolm Shepherd Knowles, an American adult educator, adopted the theory of 'Andragogy' which focused on self-directed learning theories. This author applied the 'Andragogical Model' to upper division design studios and addresses effective instructions and tips through case studies. In terms of the digital academic environment favored by Generation Y, educators in graphic design fields have been faced with difficulties balancing practical and theoretical disciplines for successful academic achievement. The challenge for educators caused by the digital culture is convincing students that professional jobs mostly require students to achieve multiple creative abilities. This phenomenon demonstrates the problems of giving students precise direction for academic achievement. Thus, this paper brings up questions about how we should structure design education in a digital environment, and how we define boundaries between pedagogical and andragogical models.

Keywords
Design Education, Pedagogy, Andragogy

What to teach, and how do we teach it?
For the past 10 years, mass communication has rapidly developed in various media both online and offline. As consumers demand more of a variety of mass media, new methods in visual communication have become more technical thus creating new challenges in graphic design education. (Samara, 2007) In comparison with earlier studio practices without computer aids, educators are currently confronted with enormous concerns regarding teaching strategies. Assignments need to be intensive with both practical application and theory. Also, due to lack of time and space in the educational environment, graphic design studios often require students/employees to expand their knowledge and skills outside classroom/studio as well. In addition, it often appears a difficult matter to deliver all disciplines of traditional design practices and add the challenge of new computer technology in computer graphics. Professional designer jobs require various qualifications, yet students strive to build their portfolio to show a number of computation skills instead of visual quality and uniqueness of design. "The challenge for educators today is to help designers become the masters, not the slaves, of technology." (Lupton, 2006) Students are looking for professional careers in their future, but students should be aware of important factors in professionalism relating to digital technologies. What is a good direction and strategy for educators? Should we instruct more in teaching computer techniques or advise students to build sophisticated portfolios in the way of traditional graphic design?

Teaching digital to Generation “Y”

Generation “Y”, also known as the Millennial Generation, Generation Next, or Net Generation defined by the age group between twenty (20) and twenty-six (26), has grown up with digital media from their earlier education. They are used to obtaining necessary or useful information through online and mobile applications. This digital environment refers to the new online culture such as “instant”, “virtual”, or “multi-media” and it often reflects their attitudes and manners which can appear as a lack of craftsmanship in studio practices. Because they have grown up relying on their parents for information, they are not independent in learning responsibility. (Alsop, 2008) The problem is perceived as a major detriment to achieving academic goals when following traditional pedagogical strategies. Their final submissions are often observed with mistakes and no attention is paid to detailed visual descriptions. This has caused Generation “Y” to misunderstand the definition of graphic design regarding computer simulation and its effects in design quality. They start and end creativity from “Google” to “Adobe” software and many educators view this matter as a main learning challenge. Computer technology has replaced traditional design tools such as rulers, pencils, colors, papers, etc., and students often mistake the magic of computer graphic tools as creativity. This phenomenon has many educators confused about academic goals, a lack of interaction between practical and theoretical disciplines in pedagogy and difficulties balancing the two. There are so many rules and various methods students should learn to achieve successful outcomes, but following traditional instructions is becoming an unproductive education problem. (Exley, 2008) It is important that graphic design educators understand Generation “Y” from different perspectives. Unless we seek solutions for this challenge, it will be difficult to educate this generation of students, let alone the generation that follows.

Andragogy in design disciplines

Pedagogy describes a traditional approach of teaching based on teacher-directed learning theories, but ‘andragogy’ is based upong self-directed learning theories. (Knowles, 1970) Malcolm Knowles addressed various andragogical models for helping adults learn. In contrast to andragogical methods, pedagogical methods usually appear in earlier foundation level courses, especially design fundamental studios. The structure of instruction is very strict and organized with various activities to gain basic knowledge and experience of required artistic capability. As a student moves into upper division levels, disciplines require more subjective and critical thinking in concept development. This means design outcomes should be more practical and of professional quality rather than how to create design. An andragogical model should be considered more in advanced levels, but it is necessary to apply it in all different levels for Generation “Y” in terms of lack of responsibility in their learning. As the main objectives of design education are to have diverse experiments and conduct research in many ways, an andragogical model can help them seek various methods in problem-solving. Applying these two different models in art and design education is also effective in terms of critical or conceptual tasks in each discipline. The reasons are: 1) Studio classes differ from other lecture classes in terms of both passive and active activities, working individually and in groups; learning design subjects requires more activities such as brainstorming, critique, communication, design management, etc.; 2) Students are isolated when using computers despite their perception that the computer is the whole structure of the learning process. The computer environment in graphic design field is accurate, but it is also a major problem in learning and teaching design education (Locker, 2008). In this case, many educators in art and design studio classes are often struggling to supervise or develop quality demanded at the higher educational level; and 3) Students are faced with difficulties with experimental approaches based on design fundamental theories in spite of their artistic talent or work experiences. For instance, some students in intermediate or advanced studio classes often have various problems due to aesthetic/functional knowledge in design fundamentals. These students need to pay more attention to teacher-directed learning in order to practice various design examples instead of continuing unproductive quality in their design before they follow andragogical direction. Thus, teaching methods should be distinguished by different diagnosis from each student and applying either one of them or both simultaneously.

Teaching strategies in a case study

In order to seek constructive teaching methods between pedagogical and andragogical model, this author has observed Generation "Y" applying different pedagogies in graphic design studios through two (2) semesters. In order to compare different responses from students between pedagogy and andragogy, this author applied either one of them or both properly in terms of lectures, assessments, assignments, design process, critique, individual work and group work, etc. Information from examined classes follows:

Table 1. A class information

Class	Assignments	Enrollment	
		Spring 2009	Fall 2009
Art 356 (Graphic Design II) Junior level	1. Sign and symbol 2. Sequential design 3. Information design 4. Advertising design	N/A	24
Art 358 (Typography) Junior level	1. Typographic expression (Static & Kinetic) 2. Typographic form and symbol 3. Typographic composition 4. Kinetic typography	20	22
Art 456 (Graphic Design III) Senior level	1. Corporate Identity 2. Stationery 3. Promotion Design 4. Signage and wayfinding system 5. System Manual	30	19

Table 2 introduces different pedagogical and andragogical models in terms of each task of the design process. The indicated symbols represent in which task each method has been applied and more effective in learning process. Instructions between students and teacher have been adjusted in terms of additional handouts per each assignment and process. The pedagogical method is defined by following instructor's guidelines, but self-direction is used in the andragogical model. Pedagogical model also refers to developing idea in a group, but andragogical method has been used for self-study in creative activities.

Table 2. Assumptions of proper teaching methods between pedagogy and andragogy

Task	Teaching methods

	Pedagogical	Andragogical
Project Introduction	O	X
Research	X	O
Brainstorming	X	O
Idea Sketches	X	O
Mid-Critique	O	O
Project Evaluation	O	O
Revisions	X	O
Final Presentation	O	O

Project Introduction
Project introduction is the first thing to define the each assignment's goal and it is composed of three different components including additional handouts: lectures, syllabus and checklist of design process (Appendix A). Because students are required to pay attention to understand problems and guidelines, the teaching method should be based on 100% pedagogical methods. Table 3 shows the main consideration, methods and strategies in the whole design process.

Table 3. Tips for the project introduction methods

Task	Teaching and learning methods	
	Pedagogical	Andragogical
Project Introduction	- Require full attention to the lecture and discussion - Analyze design examples - Clarify objectives and guidelines - Hand out repeating information - Explain evaluation criteria	N/A

Table 3 addresses tips for teaching methods in project introduction. It is necessary to push students into the subject-centered of the learning orientation. (Knowles, 1992) Turning off the computer and any mobile devices is mandatory during lectures. The lecture provides exact subject matter, objectives and design process requirements. It also brings out group discussions for understanding which design works or not. All design examples are from various student work related to concept development, design methodology and media exploration. This lecture is important to help students understand their role, and understand the importance of class participation. Clarifying objectives and analyzing examples of the successful designs demonstrates three things: 1) what they already know or do not know, 2) what they need to learn and achieve, and 3) what they can challenge and experiment with in new approaches. All instructions are handed out in the beginning of the new assignment, including evaluation criteria and the instructor should check their progress through individual meetings.

Design process
The design process is composed of four (4) different stages to develop design concepts and ideas: research, brainstorming/analysis, idea sketches, and mid-critique. There are two different models for each assignment. Figure 1 addresses distinctive methods

between academic and practical research type. The diamond method from the academic model indicates more time consumption than other stages, but the pyramid method follows the sequential problem-solving process to narrow down the final solution from the heavy amount in the research stage. Both are productive learning models to achieve the goal of successful outcomes in design process, but require a critical balance between pedagogy and andragogical teaching methods.

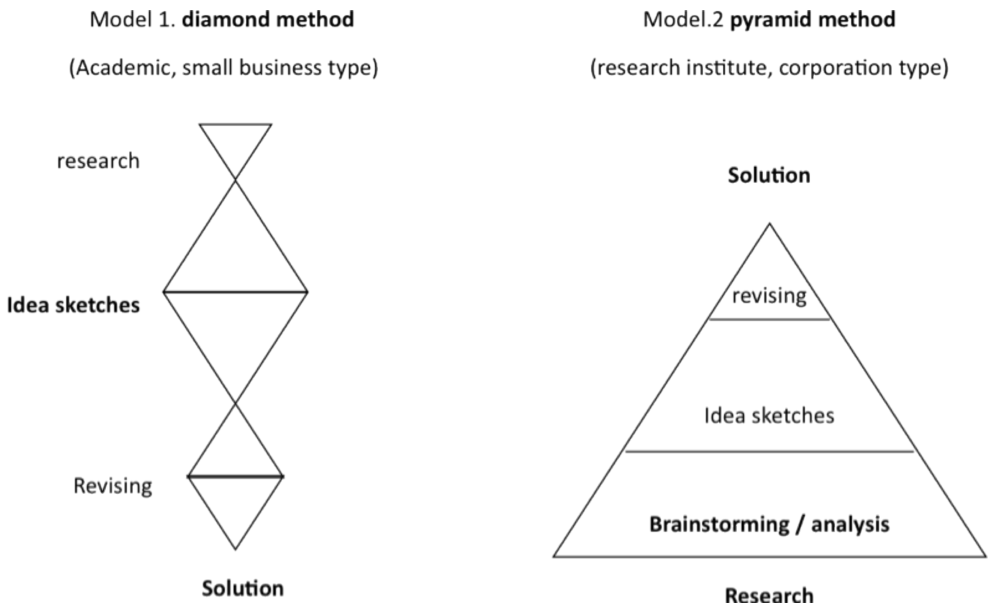

Figure 1. Structure of design process

Research & Brainstorming

In design research, andragogical direction should be 100%. This means students are responsible to seek the direction of study goals and design achievement. Research often requires unlimited resources and references to contribute a unique concept and creative ideas in visual communication.(Figure 2)

Figure 2. Research towards andragogical direction

Knowles (1977) wrote that the adult learner brings a greater volume and quality of experience and it becomes the source of self-identity. Therefore, enhanced and intensive research based on an andragogical model brings out good quality and successful outcomes in both aesthetical and functional aspects of design. In addition, research direction is determined by design methods. Students are always encouraged to invent their design method in order to contribute their concept and narratives in communication methods. This resolved the major problem when students begin with unproductive research with a few image collections from an online “Google” search. For example, in an upper level typography studio class, an andragogical model was used for a “typographic symbol” project. The goal of this project was to create a new typeface, but compose letters as type symbols. In order to lead students into self-centered thinking, each student submits a few keywords and then picks one randomly. We often observed students prefer to repeat same or similar concept and idea through different projects. In this research task, andragogical direction changes students’ learning methods for understanding self-direction in individual and group work instead of following the teacher’s direction.

Table 4. Tips for the research methods

Task	Teaching and learning methods	
	Pedagogical	Andragogical
Research	N/A	- Avoid “Google” research only - Apply research methods from design methods

Idea Development with Sketches

Many educators have discussed the problems with idea sketches. A major number of design schools emphasize the importance of idea sketches for the creative quality and uniqueness of idea in disciplines. Instructors address all guidelines and processes of idea development in syllabi but students consider it being satisfied with minimum work. For instance, this author observed the different responses from students between pedagogical and andragogical direction.

Table 5. The learners’ responses from pedagogy vs andragogy in idea development

	The Learners responses from Pedagogy vs Andragogy in idea development	
	Pedagogical	Andragogical
Quality	Considering only visual attractions in self-satisfaction	Going back and forth with visual research for audiences
Quantity	Following exact guidelines	Applying design methodology
Depth	Lack of Details	Profusion of ideas and solid finals

Table 5 shows the difference between pedagogy and andragogy on how students perceive the learning process in terms of different perspectives. In the task of conducting visual concept development, an andragogical model is more effective in achieving the goal of final design quality in both aesthetical and functional aspects. Therefore, students should not be limited to the number of sketches, but use any design method to expand their idea and creativity.

Critique & Project Evaluation

Critique and evaluation requires both pedagogy and andragogy in the various graphic design disciplines. Communication between teacher and student needs interactive methods: both written and verbal. Students are encouraged to participate on the final group critique. In order to have dynamic and productive criticism, there are pedagogical requirements in this process, but also andragogical encouragement by each student in class. Table 6 addresses an example of instruction for the teacher and students in terms of different directions between pedagogical and andragogical approaches. Andragogical direction should come after the pedagogical model. It gives students better direction to be motivated towards professionalism: perceiving lack of design ability and learning from comparisons, and achieving the goal of creativity to prove portfolio quality.

Table 6. Instructions for critique and evaluation

	Instructions for critique and evaluation	
	Pedagogical (Teacher-Directed)	Andragogical (Self-Directed)
Presentation methods	**Teacher**: Should provide guidelines and a list of design contents which students will follow.	**Students**: Use additional resources and references to explain their concept and idea clearly and interactively with others.
Participation	**Teacher:** Should ask each student questions to bring out their opinions because students are afraid of saying something wrong.	**Students**: Are motivated with sharing ideas and productive discussion for clients and designers to reach better solutions in self-direction.
Evaluation methods	**Teacher**: Should analyze design problems from each student's outcomes because students need to know exactly each problem in detail. (Figure 3) (Appendix B).	**Students**: Requires analyzing their own problems from the group critique and attempt to communicate with teachers to fully understand their directions.
Revising	**Teacher**: Give another chance to give an extra point and chances to see their improvement by teacher's instruction. In addition, it is effective if teacher provides them a demo and examples from a similar case study individually.	**Students**: Improve the final design following evaluations and experiments with problem-solving. Students should be aware of this process for building a quality portfolio.
Final feedback	**Teacher**: Should examine their final and provide the second comments to fix and change problems.	**Students**: Are willing to continue to revise their designs to achieve success and professionalism. (Figure 4)

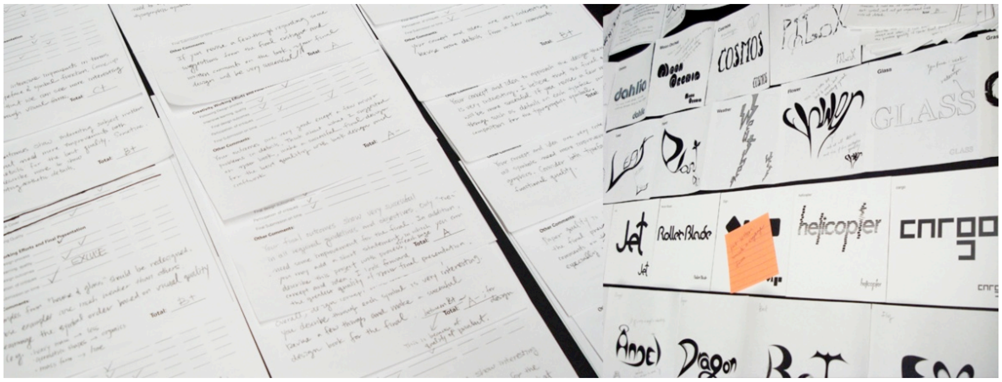

Figure 3. Research towards andragogical direction

Figure 4 is an example of students' works following an andragogical model. It shows great improvement after the final group critique and sequential revising process. Through advice and several comments from evaluations, students begin with revising and fixing major problems in their design. This method is critical in improving learning and teaching in design studios: especially in understanding objectives, perceiving all problems, and raising academic achievement.

Figure 4. Revising and fixing problems from the critique and evaluation.

Conclusion

Through this case study comparing pedagogical and andragogical models in graphic design studio instruction, this author observed that an andragogical model improved student outcomes over a pedagogical model. Students improved in intensive research, enhanced visual quality, and heighten their professionalism. In addition, applying an andragogical model appears effective in managing students as adult learners.

Another positive result is an increased interaction between students and the teacher which increases the number of student with successful outcomes. This approach also decreases the number of misunderstandings, increases motivation in self-direction, and also increases student-to-student feedback over traditional pedagogical approaches.

In conclusion, this case study will not only help educators improve student outcomes in design studio classrooms with members of Generation "Y", but also help frame future discussion regarding teaching and learning in graphic design education.

Contradictions, complexity and the 'conversational self' design research methodology: "Australian Citizens' Parliament" documentary

Kaye Shumack University of Western Sydney, Australia

Abstract

This paper addresses the role of the designer as actor/agency working within and across flows of knowledge, perception and information for filtering, negotiating and mediating design decision-making. The research methodology uses auto-ethnographic writing to construct and explore a series of deliberative conversations as (I /You/ Me / We). Each of these personas offers a distinctive mediatory stance for the designer/self to engage with relations to *other-ness* across personal and public social contexts. As a second order cybernetic approach, the designer/self is thus constructed as being simultaneously participant and observer in ongoing collaborative design conversations as synthesis. These fictive and auto/biographical personae provide access to a range of viewpoints and perspectives, which can be used to actively reflect, mirror and respond to stakeholder interests and investments, whilst effectively being considered in light of the designer's own reflections on, in, and through action (Schön).

Whilst the paper proposes this methodology as having general benefit for design research in any field, its application for a visual design narrative project is described. The case study is of the making of a video documentary about the 'Australian Citizens' Parliament' (2009), as 150 randomly selected citizen participants take part in a deliberation about ways to improve Australian democratic governance systems. The designer's process of decision-making and story telling is guided by using the personae methodology to engage with synthesis of multiple perspectives from the video capture process. Key stages of the script design process are described, where the designer uses the framing and mediating concepts of public/private; and individual/collective (I/ You/ Me/ We) to generate a revised form for the documentary as an essayistic work consisting of a series of ambient scenes. What emerges in this final video piece is an engaging narrative treatment and shared understanding about a uniquely Australian political context, titled 'Deliberation Nation'.

Keywords

designer as actor/agency, experiential narrative, ambient scene design methodology

For the designer as agency/actor, engaging with *social experiential knowledge* in complex negotiations and communication contexts involves working closely with multiple perspectives and approaches from 'problem' stages towards 'solution' stages. The kinds of decision-making that take place throughout these fluid processes are often difficult to make transparent due to the pragmatic and contingent nature of collective/individual mentalities, expertise and sensibilities which carry with them implicit and explicit values and normative assumptions. Kolko (2010) discusses the push towards synthesis in designing as a practice that can be described in terms of what is termed 'sense making'. He comments that synthesis is a means to apply abductive logic 'within the confines of a design problem' (2010,p 20). Kolko describes synthesis practice methods in design as 'reframing, concept mapping, and insight combination', which all emphasise 'prioritizing, judging, and forging connections'. (2010, p27). In this paper, I describe a particular approach for building about design synthesis by capturing project knowledge through auto-ethnographic writing from the designer 'self'. What this approach produces is a set of multiple personae (voices) through written form - as (I, You, Me, and We) personae insights and perspectives about the design problem context. The multiplicity that is generated by the usage of these perspectives provide a range of insights into possible solutions and sub problems which is similar to Kolko's description of abductive sense-making as 'judging, prioritizing and forging connections'.

Whilst initiated within the subjectivity of the designer's own thoughts and reflections, these personas gather momentum, and become ways to signify and represent a range of external stakeholder perspectives and project concerns. For design research generally, the use of fictive persona is already a well-established methodology shown to be useful and effective for establishing user characteristics and constraints for product designing (Carroll 2000; Pruitt& Adlin 2006). In this paper, I show how the synthesis work of design thinking can be made more concrete when written out using the (I/ You/ Me/ We) personae method. By writing and thinking about design practice using these subjective personae, both individual and collective viewpoints are kept in mind as dynamic spaces of private/public and individual/collective are mediated within and through the design process as it shifts across the space of problem to solution in design practice.

Methodology: Conversational learning and auto-ethnographic writing

Design and Conversation Theory

The cybernetic theory of conversation (Pask 1975) offers ways in which design communication can be explained and understood in terms of knowledge emergence, as new knowledge comes through the productive and generative interactions between conversationalists. The underlying ontology of conversation theory is the premise of an agreement, or, an agreement to dis-agree which is an interaction producing some kind of new knowledge as shared agreement about the particular context, as suggested by Glanville (2007). As key actor in the process, the designer brings 'expert' knowledge about how these communication scenarios may be nurtured and managed, towards innovation and successful outcomes. The designer is thus in a unique position to mediate, observe and oversight the influence and presence of all manner of experiential knowledge, events and actions which make up the project context as a real-life messy conglomerate. The fluidity of the design as 'problem' becomes clearer as norms and boundaries emerge, which provide frames for the further development of a design 'solution'. The random and contingent nature of such an understanding is similar to Latour's (1986) 'Actor Network Theory', where influences and active contingencies which are both human, and nonhuman (i.e. situational), are recognized and described as part of the social knowledge context – as a form of ‘assemblage’ (Latour) which the designer seeks to manage and explore. The designer thus leads from the knowledge space of the semi tacit, balancing the effects of concrete everyday experiences into a framing of social knowledge as abstractions as the design process unfolds over time. The designer as expert, understands knowledge complexity, and is also well able to both participate in as well as observe the design activity where they are actively and directly involved. I propose that these are significant features of how designers do design, but which are often so self-evident as to be not fully taken into account in the designing process.

Summary of theory behind the 'conversational self' writing methodology

The methodology for journal writing using these self-personae employs Baker, Jensen and Kolb's (2002) five dialectic frames for conversational learning. In using these frames the designer/author also employs two 'voices' of self, as 'subject' participant, and as 'object' observer, an approach adapted from the work of Margaret Archer (2003). This is show in Figure 1 below, as a form of what Maturana and Varela (1980) describe as an 'autopoetic' self-producing system for generating and exploring experiential knowledge.

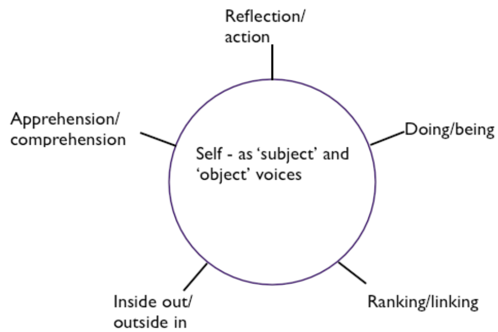

Fig 1: Conversational self as learning system: adapted from Archer (2003) and Baker, Jensen & Kolb (2002)

The configuration shown in Figure 1 provides a constructive means for developing written entries as layers of observation, reflection, and personal commentary. As a result stories within stories are recorded, as instances and episodes that take place in the designing. As a system for writing, these frames may be taken up at any point in the journal writing, they are not linear or prescriptive, but rather, suggestive of nuances of tonality and emphasis in writing styles and content. The first frame, 'Apprehension /Comprehension' provides a starting point to gather up and scope out a diversity of knowledge influences which may be of value for the design context, often linked to a sense of context and time passing. 'Reflection /Action' often takes place as longer forms of writing narrative which relate the history and background of the context. 'Doing /Being' offers a means to capture and note perceptions of the present time and place, as the doing action in a present time frame of human being-ness. 'Inside Out /Outside In' provides a means to evaluate what is emerging against a background of normative values and benchmarks around the design problem context. 'Ranking /Linking' provides a strategic approach for specifically assessing the value of the designing in relation to wider external social contexts. By continual use of the two 'voices' of self, an ambience is maintained across the writing, providing a kind of coherent narrative where idiosyncratic notations and codings come into play. The uses of the two voices of self (as 'subject' self and 'object' self) provide an opening up of the situation for engaging with experiential knowledge at many levels. In the process of writing in this way, the personae of (I/ You/ Me/ We) become personae as points of reference for views and commentary that address all manner of knowledge and knowing about the design problem and possible solutions.

Archer (2003) describes these states of self, as forms of self as agency, which emerge as a result of this self-conscious and deliberate positioning. Archer describes these states as the 'I', 'You', 'Me' and 'We' of the self-reviewing itself as social object. This is shown in Figure 2 as a process of self in review, shifting through different states of self as forms of agency showing how the identity of self is developed through a progressive working through of 'Self' ('I'), 'Primary agency' ('Me'), 'Corporate agency' ('We'), and 'Actor' ('You'). The conversations take place in a concrete way through writing as 'subject' self (SS) and 'Object self (OS) as shown in Figure 2. Thus, 'self' (I) begins the conversation, which progresses through the identifications of 'Me', and 'We', to reach a mature and considered status, as 'You' (Actor). In this way, the self converses with 'itself', as both observer and participant, across past, present and future. What results is a foregrounding of the dynamic interplays between what is 'individual/personal', and what is otherwise 'public/collective'. In effect, these states of self become metaphors for a variety of social communication scenarios. They exist as a unity of parts - they may be addressed and understood as separate approaches, yet they are also one to each other, as analogous components of human interactions within a design context. This sounds complicated, but when used as a process of self-capture, it provides a rich set of options for gathering and reflecting on the wide range of possibilities within a design situation. It is a way of capturing what one could and often is, thinking implicitly, and making these half-formed thoughts more explicit.

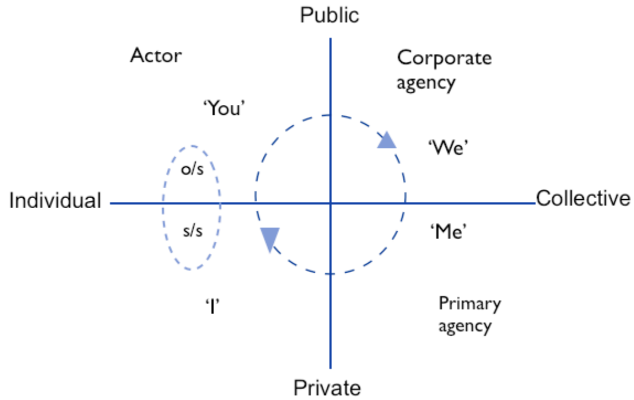

Figure 2: Adapted from Archer (2003: p 124): How the subject reviews itself as social object

As a result of the overall process of writing in this way for design research purposes, key themes emerge about place, time, characters, action, and tension relationships between story elements. The development of the 'what' is integrally bound up with the telling about 'how' and 'why' as the narrative evolves through contextually based references to time, place, actors, intentions, characters, objects, actions. The writing process evolves and configures the personae of self as characters, as voices within the narrative who participate and observe, who join forces at times, and or disagree as they work towards a shared or in-common understanding of some-thing about the situation at hand. What occurs is effectively a writing practice of mediation that takes place between the stances of observation/objectivity; and participation/ subjectivity (Shumack, 2009). As a design research method this is a particular style of abductive thinking for engaging with experiential knowledge and knowing. The method has value for design thinking practice, if and when it suits the designer's own interest and orientation. The process of writing out one's own thinking in this way is initially clumsy and can be fraught with self-doubt and a sense of being 'too personal' (Roth, 2005). However, over time and with practice, I have found the writing begins to flow more easily, and as part of my own designing I have been able to identify and engage with the object/subject voices of self to generate integral and meaningful insights. In effect, what is happening is that I am articulating what it is that I would be thinking, but doing so in a way that orders or structures, makes more self aware the depth of thoughts and influences which are occurring around the design problem. What also occurs is that the focus around being object/subject self creates a rich body of experiential project knowledge about what is collective/ what is individual; what is private/ and what is public. These knowledge strands can be seen as *dialogic framings* of the project that can be woven together towards the problem's solution.

I suggest that this approach to methodological framing using multiple points of view and narrative distance has a particular value for visual design story telling practices in communicating social knowledge, systems and contexts. In visual design, the designer is always present in some way, as a form of silent author, as explicit director, and always as a mediator of the context that is being explored and represented. By explicitly revealing the dialectics of object/subject relationships, the visual designer has much to gain from adapting and exploring the relational spaces of object/subject: participant/observer to encompass the designer's intentions and bias, alongside the capturing and understanding of stakeholders views. In the case study that follows I explain how this approach was explored in the design development of a documentary video that tells the story of an extraordinary national event, the Australian Citizens' Parliament. The final title given to this documentary is 'Deliberation Nation'.

Application: Design of 'Deliberation Nation' documentary

Background

The project involved a collaboration with researchers from the disciplines of political science, political theory and applied politics, and a partner not-for-profit organization (newDemocracy) on the video documentation of what is know as the Australian Citizens' Parliament (CP) research project. Our design team's brief was to produce video documentation of the project over several months. The mission of deliberative processes like the Australian Citizens' Parliament is to review the way the public discusses and engages with politics and political decision-making processes - the space of the 'commons'. The event took place as 150 randomly selected citizens deliberated, then delivered their recommendations at Old Parliament House, Canberra in February 2009.Their task was to answer the question: "How can Australia's political system be strengthened to serve us better?"

It is rare for such large-scale initiatives of deliberative democracy to occur. The success of the Australian CP event was largely due to the planning and coordination that took place prior to the actual three days of the event itself. As a government funded research project the CP had its own objectives, which were driven by research questions from the fields of applied politics, law, political theory and social policy. These involved the design of a system for conversational interactions to occur through deliberation processes, as a staged facilitation around generating new ideas and the process itself of conversation and engagement with the issues at hand using techniques such as the 'World café' and the '21st -century dialogue' with computer tabulated summaries of large scale conversations and suggestions.

The CP event provided a significant opportunity for the researchers and agencies involved to understand better the processes of deliberation and to be able to examine and trace the development of mass scale conversations as an experiment in deliberative democracy at work. As commented by Carson (2008) this large-scale public event can be characterised as an 'insisted space' for democratic participation as distinct to an 'invited space' which would be managed and promoted by governments and power brokers:

"The newDemocracy case study is an example of a nascent social movement of citizens-as-electoral reformers who insist on a place at the decision making table for a mini public because of the democratic deficit that has arisen as a consequence of a faulty system of governance. This site of activity can be described as an "insisted space". " (Carson, p7)

The CP event was momentous and extraordinary, in bringing together a large number of randomly selected citizens with academics, public figures, experts and researchers. Working with an experienced media team, my role was to direct the documentary of the event in its complexity, as a record of the event, but also to capture the essential qualities of deliberative philosophical thinking which underpinned the process. A challenging broad question was asked of the 150 randomly selected citizen participants. The video documentary aims to represent the findings in light of the event goals – to answer the initial research question.

Initial journal writing research

The initial journal writings assisted in framing the shooting script treatments, and approaches. Consideration was also given to how to encapsulate the 'conflict' or key question as a basis for the documentary work. The journal includes references to key protagonists, contingencies of production and resource constraints, and ideas about how to position and extend outward to the viewer. Figure 3 shows the baseline shooting script as a basic the narrative spine for the project. The initial story 'arc' was loosely aimed at showing the way the event played out based on linear time - the background, the event taking place, and reflections about what was learnt. Part of the design problem was the diversity of footage shot and the sheer amount of material with which to select from.

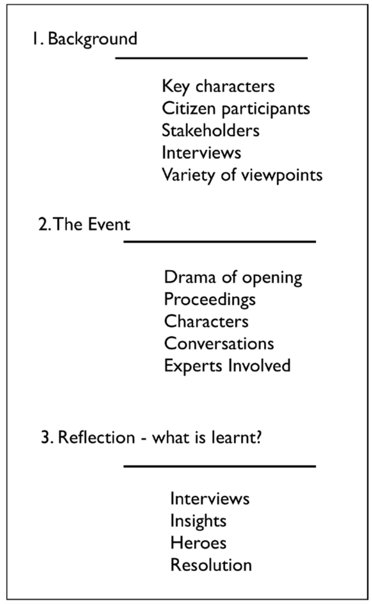

Figure 3: Baseline shooting script for documentary

Second stage script design concept

As the shooting progressed, key characters emerged, and the story lines became cluttered with possibilities and options for nuances and story 'hooks' on which to hang audience interest. The initial editing process followed the shooting script structure as a chronological unfolding of the event. Despite variety of video material that was included the tone or voice which came through in this first draft was authorial, factual, dry and often confusing. In order to develop a finer and more insightful story with greater human interest, the second draft focused on building a story around the theme of 'journey'. This was portrayed on several levels - as a journey being taken by a range of different stakeholder groups, and as a transformative process involving individuals, and groups. As shown in Figure 4 these themes were elders, teachers, hero characters, interaction, knowledge transfer, self-esteem and taking actions.

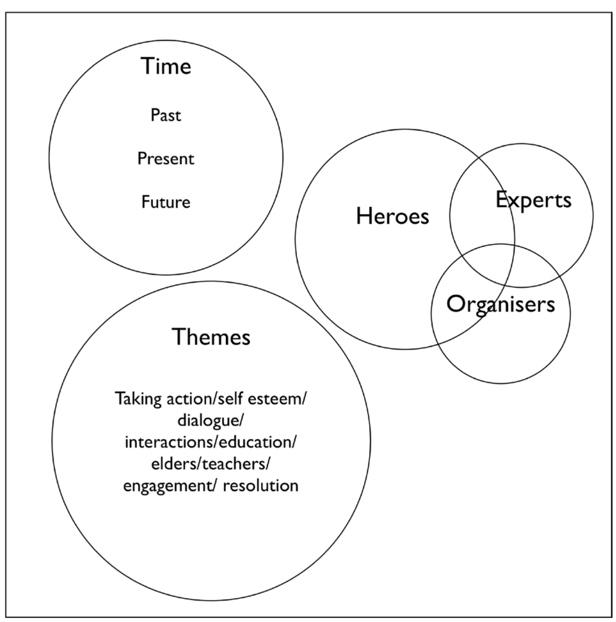

Figure 4: Second stage script as 'journey' thematic

Introducing the Personae of Self as Frames for the Script Design

Figure 4 shows the second phase of the documentary script development. It was thought that the story journey was still unclear, and lacked a sense of depth and cohesion in the script treatment and ambience. On reflection, it seemed that the first draft (Figure 1) of the shooting script presented a kind of authorial tone that was factual and highly distanced. The second draft (Figure 4) was overly personal, too close, a collection of many insights, thoughts and views which did not really tell a meaningful story about what had happened at this momentous event. Reflections led to a structural shift from an exposition about the actions of the event, to a more essayistic approach where a narrator asks a series of questions, and then these are answered through a layering process of different subject/object voices. The story telling needed a protagonist, a narrator figure to provide continuity and as an insight bridge for the imagined viewer, to balance views and perspectives, to moderate and mediate the range of views and tonalities being introduced. In order to begin to work with this dynamic, the four personae of self from the 'conversational self' research were overlaid onto the script map as a means of weaving the storylines together. One of the CP participants became the ‘everyman’ protagonist narrator as a focus for these new scripting directions. The journal writing process guided these reflections and decisions, resulting in a new approach where the personae of self were introduced to help frame the script's structure.

Figure 5 shows the way in which the four personae of subject/object self are now considered within the visual text. Each of these voices within the documentary represents a different mediatory presence and tone as a result of a sense of *rhetorical distance*. *‘I’* works primarily through self-expression and engagement with individual concrete experiences through curiosity and interest, providing an idiosyncratic and personal mediatory tone. *‘You’* self is the mature and resolved custodian of the emerging decisions about a particular design situation, the authorial factual voice. *‘Me’* engages with commitment to in-common histories and cultural and social identities, so is the often vague and imaginative mediatory tone. *‘We’* operates in the domain of current expert knowledge, and what is already part of a shared common public social context. This structure provides a scaffold upon which to begin re-shaping the script design around these concepts as ambient scenes.

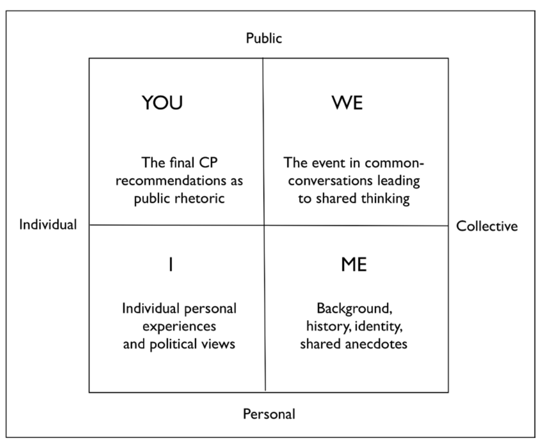

Figure 5: Alignment of personae as mediatory presences within the re-design for documentary script

The Process of Concept Development Using Self Personae – a series of ambient scenes

As a result of this new approach, the video material, which had been already selected from the first cut of video footage, was broken down into component parts, loosely framed around a series of narrator 'questions'. This initially took place using coloured index cards, resulting in a rich layered script treatment that highlighted the new role of a narrator in guiding the storytelling. The introduction of the 'narrator' creates an ambience around each section that is structured around a rhythm of the (I/ You/ Me/ We) perspectives within the visual script design. The key question or 'conflict' remains central, and the short essayistic vignettes each addresses aspects of complexity, contradiction and deliberations as the event unfolds. What is critical in adopting this ambient scenes approach is that the narrator's role is dialectic - presenting at least two perspectives relative to each other, not a single viewpoint to drive the overall story-telling forward. This takes place as a form of questioning which keeps the ambience of the themes open-ended and dynamic, but with a clear narrative idea. Figure 6 shows how the ambient scenes are constructed as a form of semantic architecture to underpin the script re-writing. Each of the fourteen vignettes is based around:

1/ A concept ideas for the development of the story

2/ The narrator evident before, during, or after the main action

3/ An ambient emphasis on each setting as a dialectic interaction between various combinations of these personae (as I/Me/We/You)

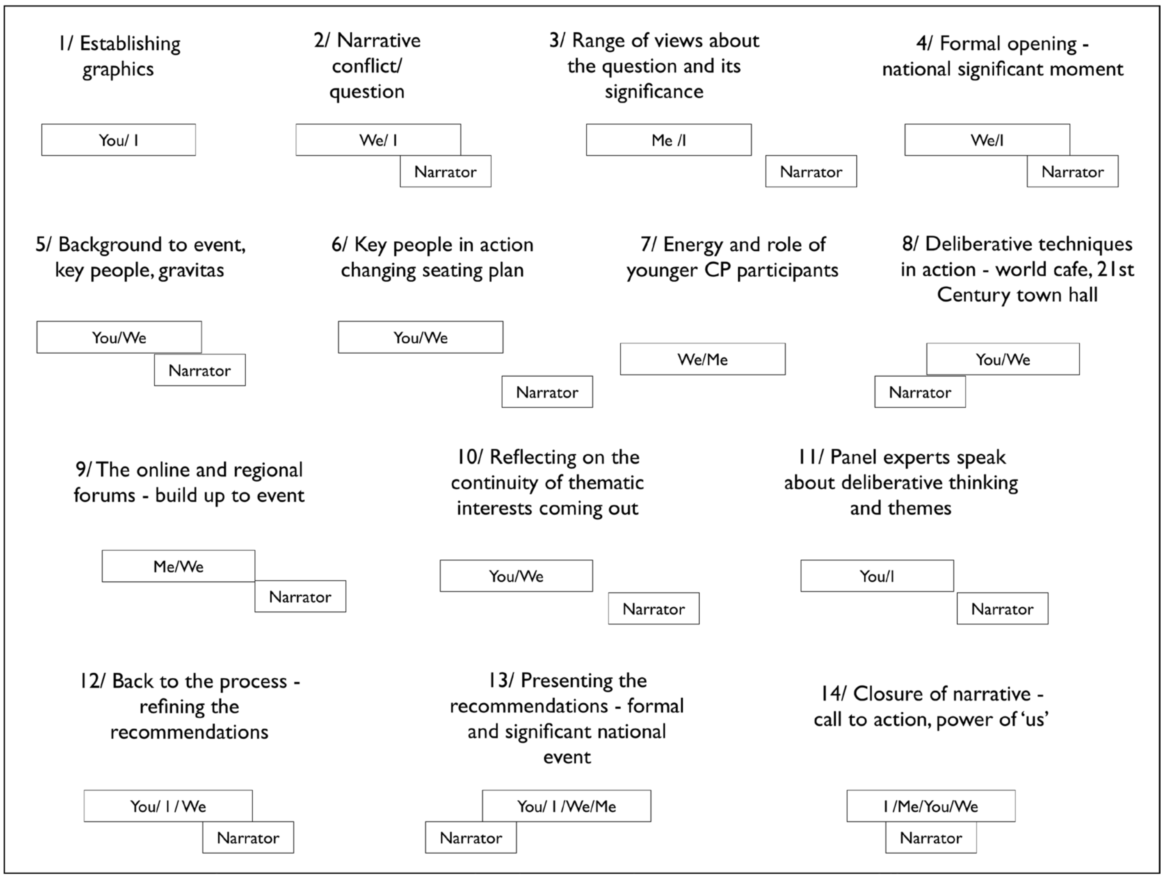

Figure 6: The script design as ambient scenes - a concept mapping of the narrator with the self-personae

As a result of configuring the script design using this approach, the story continued to become clearer, and key moments and characters emerged within the visual text. The narrator became a critical figure in the telling of the story, as a linking element across the hour-long documentary program. As the editing continued to shape and refine the work, further changes were integrated, but the semantic scaffolding that was established as a result of this approach continues to support and endure. On reflection, I believe that this approach was of particular benefit in the shaping of a rich documentary story where, as with documentary scripts in general, the actual ending is unknown in the initial planning stages. The application of a design methodology such as this one is, I propose, a valid and purposeful manner for the design of both documentary and factual narratives.

Conclusion

This paper has outlined an approach to design synthesis which engages with multiple subjectivities, as the designer self, is extended and negotiated through understandings of complexity, contradiction and negotiations with understanding other-ness and story-telling. The design process is shown as a movement towards solution, which takes place as a process that has its own momentum, critical pathways, and points of interest. What emerges from this design research approach is a focus on the development of a language around, and about, the dynamics of synthesis as a practice that involves transformative and creative thinking. The value of this approach has been shown in its application to a particular process of visual story-telling for managing complex knowledge and for how it can assist in crafting the 'raw material' of experience towards documentary design practices in a 'solid, useful and unique way' (Benjamin 1992).
