Interpretation as a method to be applied by the designer is based on the principle of building a new rationality: constructing material culture, holding as a reference the user, ultimate recipient for the projected product. Interpretation as a method further strengthens the specificity of 'designerly ways of thinking and designerly ways of knowing' (Nigel Cross). With this approach we aim to contribute towards the characterization of an innovative design: neither a singular problem solver nor solely solution-oriented devoid of dialogue with the question, but rather a semantic agent, a designium interpreter, a maker of meanings through the generated forms, a builder of new circumstances and contexts to contribute to human freedom. The methodological processes applied to an innovative design cannot be conceived as a sequential and linear process with no room for questioning or constraints. Interpretation as a method in design practice holds as a model the application of the hermeneutic cycle: a proposal of dynamic reasoning between an initial question (situation, problem) and a final solution. The development of the project takes place vis-à-vis with the context, culture, place, language, use, and these variables interfere with the initial proposal, reinstating and reformulating it. The choice of new and unexpected answers acknowledges the user as dynamic individual and key player in the interaction process between the proposed 'product' and its use. This research focuses specifically on the 'skin of buildings' as city's constituent component. To support that 'the skin of buildings' has a function-meaning we perform a comparative study on the use of interpretation as a method by the designer Daciano da Costa and the architect Carlo Scarpa. One of the outcomes of this approach is that postulating interpretation as a design method characterizes the designer as an interpreter. In our research we intend to address the designer as a role player in the city, intervention scenario, as an analyst of the cultural value of the context, coming upon a sustainable and innovative answer. This approach seeks to justify the use of a method that instead of designing an object aims at construing the object's meaning for the user, hence his relationship with the surrounding space.

Keywords

interpretation design, signification, pattern, material culture, equipment scenarios

Stemming from a hermeneutical perspective on the action and expansion of design we intend to reflect on interpretation design, qualifying the nature of the artifacts through their function-meaning instead of merely by their use-value. In such process, to reflect implies grasping a meaning for the referent. In other words, understanding (in this case the material or immaterial culture) through dialectics among and within all players (people, context, culture, complexity of factors, time) and abduction (logical inference, reasoning to evaluate and explain through the process of attribution of meaning). The first part of this text will present the advantages of interpretation as a method in design regarding other models, using a definition of the concept of design, to justify the hermeneutic circle as a model in the design process. In the second part of the text we apply interpretation design in searching for new solutions in the equipment scenarios, namely 'skin of buildings'. Design reasoning has several meanings, disclosing the abstract nature between conception and attribution of meaning ready for interpretation. Therefore, the exercise of design is competent to interfere with the function-meaning of space and disclose new connotations. Attribution of meaning as process of interpretation of the space may lead us to the understanding of semiotics applied to the design process. To support the function-meaning of the 'skin of buildings' we will analyze two cases of interpretation design, in Lisbon and Venice. To conclude, we will briefly approach the 'pattern language' rationale (Christopher Alexander, 1979) as autonomous units of thought installed in the membrane of the already existing buildings expressing onto the exterior what happens inside, an exterior skin connoting the status of the internal body organs.

Performing interpretation design

In 2008, the philosopher and anthropologist Bruno Latour presented the text ‘Prometeo cauto? Primi passi verso una filosofia del design’ at a Design History Society congress, calling upon reflection on the development of the term ‘design’, both in understanding and diffusion. In his text, the author argues that "più gli oggetti si trasformano in cose, cioè più le 'materie di fatto' si trasformano in 'materie in questione', più esse divengono sempre più profondamente oggetti di design"[1] (Latour, 2009:256). In his reflection Bruno Latour examines five benefits of the design concept: (1) modesty (2) attention to detail, (3) semiotic competence, (4) a process in which projecting is always re-projecting and (5) the ethical dimension, to conclude that today, design calls for precaution and attribution of meaning. Regarding the five benefits of design concept as autonomous 'patterns' of thought, we will commence by posing as a question one of the benefits that seems directly related to interpretation design: why is projecting always a re-projecting process?

Design action is displayed in the rapport with the context and in the ability to explore and evaluate emerging solutions. A path with no apparent right answer, but with truth, affected by the use and meaning we attribute to things resulting from our own creation. This allows understanding design in the second half of the twentieth century. As explained by Bernhard Bürdek regarding the influence of Leibniz's thought in German design: "se interesó igualmente por los procedimientos combinatorios e hijo aportaciones importantes para el perfeccionamiento de la lógica matemática. Precisamente estos aspectos fueron el fundamento del trabajo sobre a metodología del diseño en la Escuela Superior de Diseño de Ulm”[2] (Bürdek, 1994, p. 127). A process between finding and demonstrating (reflection, analysis, synthesis, rationale and selection of alternatives) and that although exported by his students as the ‘Ulm Model’, became one of the reasons for the shutting down of the school. During Maldonado’s administration, any project of industrial or craft nature was ignored, the attentions were entirely focused on the development of the concept for mass-communication with all other disciplines regarded as design supports. According to Bürdek, the Hochscule für Gestaltung in Ulm “no se mostró receptiva frente a lá entonces incipiente crítica al funcionalismo y al debate iniciado poco más tarde en torno a cuestiones ecológicas. Sobre todo en sus institutos reinó una comercialización tal, a través de proyectos industriales, que en el caso de algunos profesores ya no era posible hablar de independencia y distancia critica.”[3] (Bürdek, 1994, p. 42). The classic projectual method, science-based and product-oriented had revealed weaknesses by ignoring the external factors inherent to the process and to the impact of the final product on the user.

However, this model was not adopted in all contexts, as the English context or the Italian, in the sixties. In the former persisted a debate between craft and industry that endures to this day. In the later, the influence of the Renaissance and Futurism describes Italian culture as a broad context, once everything is presented in movement and ready for questioning and reinterpretation. This high propensity for debate will be decisive to the definition and development of projectual methodologies as a discipline.

---

[1] (Authors’ translation): the more the objects are transformed into things, also more the 'factual material' becomes the 'matter in question', as they increasingly become design objects.

[2] (Authors’ translation): also interested in combining procedures and made significant contributions to the development of mathematical logic. These aspects were precisely the foundation for design methodology studies in the Ulm School of Design.

[3] (Authors’ translation): was not receptive to the then emerging functionalism critique and to the debate started somewhat later regarding environmental issues. Especially in these institutes, commercialization was so dominant through industrial projects that in the case of some teachers, independence and fair criticism became impaired.

According to Nigel Cross (1981), if the scientific method controls the experiments, classifying and analyzing them, and the social sciences and humanities method employs an analogy, metaphor and evaluation method, the interpretation method employs an intellective and dialectical method which sets and analyzes hypotheses, followed by a phase of verification of errors and satisfactory solutions (Cross, 2007) as they arise. The prudent designer ponders the complexity of factors constituting the problem, grasping and therefore issuing a judgment before setting for action. But this method does not avert others, it is achieved through literary culture, scientific culture and technical culture, but by means of education, in the sense that, as argued by Peters (1965), if "an 'educated man' is distinguished not so much by what he does as by what he 'sees' or 'grasps'. If he does something very well, in which he has been trained, he must see this in perspective, as related to other things. It is difficult to conceive of a training that would result in an 'educated' man in which a modicum of instruction has no place. For being educated involves 'knowing that' as well as 'knowing how". (Peters cit in Cross, 2007, p. 4). This implies applying a method that assumes there is prior knowledge on the existence of things in the sense that there is a predisposition to know. There is always a set data, a projectual limit, therefore, in order to operate, the designer does not start from void but from a new problem, new questions, hypotheses: "I designer più intelligenti non partono mai da una tabula rasa."[4] (Latour, 2009, p. 257). The designer must depart from the already existing that longs for a new interpretation. The benefit of a process in which projecting is always re-projecting is relevant to design practice that is strongly process-oriented, engaged in a cognitive and prudent method related to the concept of comprehension. As explained by Nigel Cross: "An aspect of cognitive strategy that emerges from some studies is that, especially during creative periods of conceptual design, expert designers alternate rapidly in shifts of attention between different aspects of their task, or between different modes of activity." (Cross, 2007, p. 88). The designer, who draws advantage from the sense of time and plunges into different scopes to re-project, sets a path that summons the process of attributing meaning, summoning new interpretations. An ambiguous comprehension framework, in the sense that the onset referent apparently stable in other context or time, in a new scope – design, in this case – may become a new hypothesis, an intelligent question. A process that is close to the abstract nature of design but also to the practice of the hermeneutic cycle. This path of interpretation design is totally different from methodological analysis, for etymologically, design has more than one sense and manifests in different ways depending on the endless evaluation of the variants defining the context. Therefore, the practice of the hermeneutic cycle can be faced as the reading key for interpretation as a design method; "The operation of the hermeneutical circle is not the employment of a method. It is not something we can choose to use or not, in the manner of a tool. It is, rather, embedded in all thought and in all action." (Snodgrass-Coyne, 2006, p. 45). The two authors further argue that clarifying a project does not imply formulating a procedure as the alternative to any other, but devising what is operational in each stage of comprehension. The benefit of interpretation design lies in the possibility to always hold something as a reference, to question each stage of comprehension with satisfactory hypotheses, with examples and not merely with knowledge. Because they are sufficient, these hypotheses acquire the quality of rethinking all possible scenarios without prejudice, unlike absolute hypotheses which by nature consider one scenario only. Interpretation design meets the operation of the hermeneutic cycle that raises questions and that according to the use and meaning found (depending on time, context, etc.) may (or may not) shift, becoming a new question, an hypothesis, satisfactory solutions open to new questioning. The design that relates to the context, in the use and meaning of things, allows these variables to interfere with the onset proposal, constantly revisiting, reformulating and reprojecting it. The process is more important than the result, compelling the designer to operate at that present moment with complex and expansive factors. The designer transforms the initial question onto a new question, reevaluates it, considers all parties engaged along the evaluation path between the identification of the problem and the hypotheses found, with a particular type of knowing that may be classified as 'pensiero debole', weak thought (Vattimo, 1983), not in the deductive sense that for being weak it is frail or faint, but because the presented 'truth' is mobile and susceptible to an infinite number of interpretations.

[4] (Authors' translation): the more intelligent designer does not start from scratch anymore.

The semiotic competence in design

Interpretation design on the skin of buildings

In a conversation with Jean Baudrillard about the uniqueness of objects in architecture, Jean Nouvel (2002) raises the issue of architecture in the twenty-first century still being coupled to Vitruvius formulas, ignoring or avoiding new difficulties emerging in the second half of the twentieth century. According to the author, the demographic increase, the exodus towards the cities or the expansion of cities, but also the administrative inefficiency were new problems that architects were not prepared to deal with and whose answer lies essentially at the level of urban planning. Jean Nouvel denounces the gap and imprudence of architecture for ignoring this new scenario, “so in this sense, I’m against everything that is part of same order as Architecture. This means that from this point on, we must make use of another strategy, where we’re required to be slightly more intelligent – to the extent that we can be – required to constantly diagnose the situation, required to face the fact that architecture is no longer the invention of a world but that it exist simply with respect to a geological layer applied to all the cities…” (Nouvel, 2002, p. 18). Jean Nouvel even states he takes the side of whatever opposes this notion of culture. According to several authors such as Andrea Branzi (1975), the analysis of this complex and new city was the cause of architecture’s internal crisis. An investigation that for Branzi is never pondered by the architects, a project requesting orientation “verso i limiti oggettivi della città come strumento di vita, verso limiti ormai esplorabili di una disciplina che vive una propria contraddizione storica e intravede la propria possibile morte naturale all’interno di più ampi e profondi fenomeni di trasformazione culturale e sociale.”[5] We highlight two core issues from this reflection confirming the premises previously discussed regarding interpretation design: 1) It is essential to set conjectural answers oriented towards new solutions that meet the demands of the moment (time as truth). The project answer given by architects in the construction of buildings in the cities remains a sort of automatic procedure, an attention failure that urges resolution. It is important that the project’s designer recognizes in the complexity one opportunity to propose solutions. 2) The diagnosis to the complexity of factors is something that must be done continuously, not something that may or not be done. Projectual intervention in the city requires departing from architecture for historical and semiotic reasons, but architectural solutions are not necessarily the model for interpretation. Which architecture would be an interpretation model? Regarding the intervention in which the interpretation of the place is the style and/or the language of the project performer as response targeting a solution, architecture cannot be a reference for the interpretation of the city. Intervention is required specifically in the subproject of the ‘skin of buildings’, with a project tool from the twenty-first century and reflecting the volatile reality of the inhabitants, now more dynamic and ephemeral. An ambiguous reality, as is design’s nature, between conception and attribution of meaning. It is important to address the singularity of the ‘skin of buildings’ operating an inspiring model of interpretation originated from a fundamental concept, assessing and reassessing before delivering an answer. The interpretation design on the ‘skin of buildings’ is, for that reason, hermeneutical and dialectical. The skin is one of the components of the scenario interacting with man.

The singularity of the objects in the city as a space requesting interpretation may be understood as a premise for our research on interpretation design in the equipment scenarios, namely on the ‘skin of buildings’. Given that one of the roles of design is the connotative function and that semiotics[6], as theory of signs, deals with communication and connotation, we pursuit

[5] (Authors’ translation): towards the objective limits of the city as a way of life, towards limits now exploitable of a discipline that is undergoing an historical contradiction and assisting the own natural death as possible within a broader and deeper phenomenon of cultural and social transformation. BRANZI, Andrea 2003. Article from "L'architettura cronache e storia", n°234, April 1975. Andrea Branzi sulla linguistica architettonica di Andrea Branzi - Bruno Zevi. 13.2.2003. <http://www.antithesi.info/testi/testo_2_pdf.asp?ID=242>

[6] “Semiotics (Greek semeion ‘mark, sign’) older spelling of semiotics. This term was coined by Hippocrates (460-777 BC), the founder Western medical science, who established semeiotics as a branch of medicine for the study of symptoms – a symptom being, in effect, a semeion ‘mark, sign’ that stands for something other than itself. (...) American philosopher Charles S. Peirce as the basis for circumscribing an autonomous field of inquiry that de, like, Lock, defined as the doctrine of signs.’ The word doctrine was not used by Peirce in its religious sense, but rather in its basic meaning of ‘system of principles.” (DANESI, Marcel in Encyclopaedic Dictionary of Semiotics, Ed. Media and Communications, 2000: 203-204).

understanding how semiotics inform design, or as advocated by Bruno Latour (2009), understanding the benefits of semiotic competence to design. We are concerned with the space singularity referred by Jean Baudrillard (2002), the sense of location, expression, construction, attribution of meaning, and not the architectural meaning of buildings. The relationship established between the project performer and the citizen is a need to attribute and retrieve meaning, not merely an ability to communicate. Interpretation allows starting from a sign to travel a path leading to the understanding of the referent by means of other signs conveying connotation. According to Peirce “a sign, or ‘representamen’, is something which stands to somebody for something in some respect or capacity. It addresses somebody, that is, creates in the mind of that person an equivalent sign, or perhaps a more developed sign. That sign which it creates I call the ‘interpretant’ of the first sign. The sign stands for something, its ‘object’. It stands for that object, not in all respects, but in reference to a sort of idea (...)” (Peirce, 1955, p. 99). Peirce advocates a thought based on a theory of knowledge that asserts that the sign calls for sense, for meaning, emphasizing the importance of knowing what the sign means rather than what it represents, since the semiotic act regards understanding senses and meanings, instead of merely creating signs. With Charles Peirce the action takes place through signs, therefore it is crucial to grasp the definition of sign, analyzed according to each era. The meaning of the word ‘sign’ inserted in its context, the definition semiotics as a science has acquired and therefore interpretation as process of attributing meaning may lead us to the understanding of semiotics applied to interpretation design regarding the ‘skin of buildings’. Peirce called this pragmatic thinking ‘abduction'[7], as only logical operation which introduces any new idea. In the field of design, it can be translated into a process of suppositions, intuitions and not of certainties. In the present research on the action of interpretation design, this 'intuition' leads us to question and ponder about the ‘skin of buildings’, wanting to understand the difference regarding what might have been in its place, considering the characteristics that define the context. A path upon which the project’s hypotheses are autonomous cultural entities requesting permanent interpretation as in a narrative process whose characters (people, time, culture, context, ground, the skin of buildings, negative and/or positive factors) summon the narrator to provide them their speeches. An action exclusive to each actor, therefore qualified as identity of the space, but that will only be meaningful if there is a relationship between all characters. The façades request establishing dialogue with other 'patterns' so that reality may connote identity.

The logic intuition of new building skin solutions: the cases of Daciano da Costa and Carlo Scarpa

The interpretation of ‘genius loci’ (reason for the place) and the 'milieu' (environment) may be considered as an 'abduction' leading to the understanding of the function-meaning of the ‘skin of buildings’. Presenting innovative solutions, the designer can/should address the ‘skin of buildings’ as one of the city elements. To support this reasoning we will analyze two interpretation design cases, in Lisbon and in Venice.

In the first case, the atelier of Daciano da Costa started a proposal in 1999 for the reclassification of Praça da Figueira in downtown Lisbon. This intervention named by Daciano da Costa as ‘design as city fragment’ should reinforce the unity of the different façades in the square, simultaneously respecting their original diversity, given that this square belongs to the historic centre of the city, characterized by successive interventions over time. Through the ages, Praça da Figueira has been a meeting place for people, markets and communication, a public square, for public use, requesting a logical interpretation of signs requesting decoding. “O recurso a um leque restrito de cores e de motivos, tomados directamente da tradição de revestimento azulejares de fachada, a exploração sistemática das suas possibilidades de combinação, por forma a definir uma tipologia de padrões e a gradação das respectivas densidades, permitiu estabelecer uma série de critérios de aplicação (…)” (Costa Martins cit in Martins, 2001, p. 224). The result is the miscegenation of

[7] Abduction, from the Latin AB ‘away’ + DUCERE ‘to lead’ (see also *deduction, *induction). Term used by Charles Peirce to designate the kind of reasoning whereby a concept is formed on the basis of an existing concept or model; an abduction is essentially a ‘hunch’ as to what something entails or presupposes (DANESI, Marcel. Encyclopedic Dictionary of Semiotics, Media & Communications, 2000:3).

graphics elements connoting the experience of the square as if it were a scenic stage: the interpretation of immaterial culture, as the Lisbon city cries, the colors, and the trading feast at the square. Because it was process-oriented, the sub-project or the 'pattern' of the façade of the requalification project of Praça da Figueira in Lisbon has not ended yet. In terms of product and according to the City Hall, a total of about 150 thousand Portuguese ceramic tiles (azulejos) made the intervention 'too' expensive and therefore only partially executed, indefinitely postponing the façade intervention.

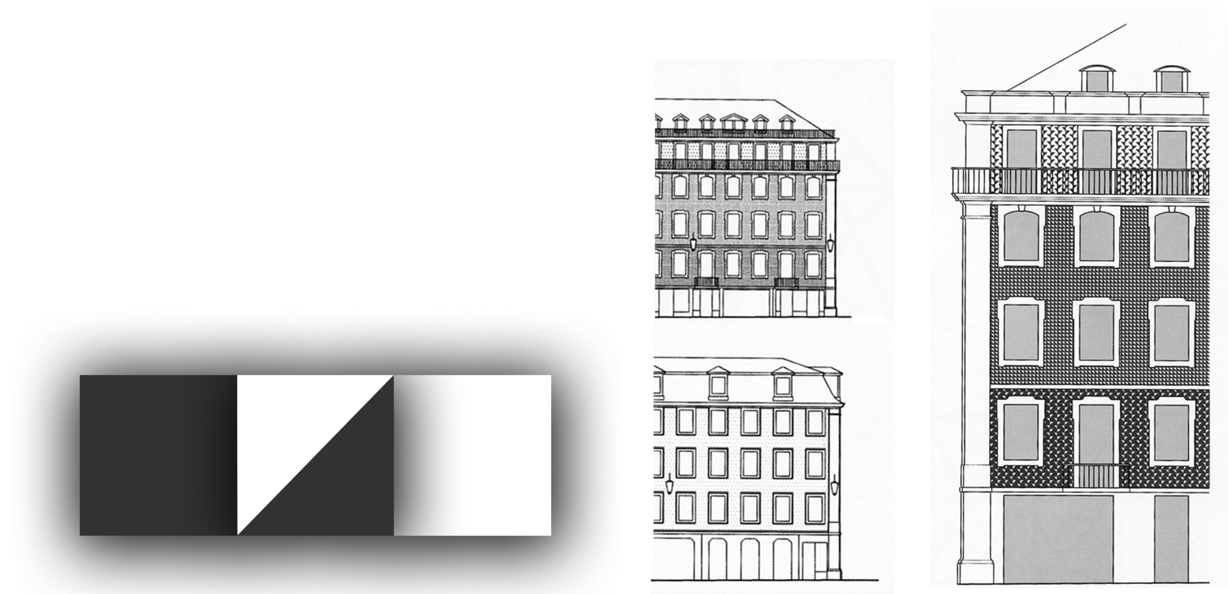

Figure 1 Project of the building skin by Daciano da Costa (1999 -). From left to right: Drawing of the 3 tiles (azulejos) used on the buildings skin at Praça da Figueira in Lisbon – Image by the authors. East Project and South Project. Vertical monochromatic sequence with variation of densities – Images adapted from the book 'Daciano da Costa, designer' (Martins, 2001, p. 225).

The second case regards Carlo Scarpa's interpretation on the restructuring of the Olivetti's shop in San Marco square in Venice, between 1957 and 1958, whereas the restoring of the Venetian shops began in 1950. As explained by Carlo Scarpa "Adesso ho per la testa un progetto per un negozio a Venezia, per un cliente molto danaroso. Poiché non posso toccare nulla, debbo fare una pelle, una fodera - ma quale è la più idonea in quel posto?..." (Scarpa cit in Dalco-Mazzariol, 1987, p. 287). After studying the problem, Scarpa intervenes in an emptied space, starting from a previously defined context, combining the tradition of the materials with the new technological developments available at the time: the Istrian marble, the Aurisina marble, tamped concrete, lapidated crystal in metallic structures, teak wood, ebony wood, pate de verre, stainless steel, stone, and opal glass. The process was performed by local artisans and fortunately, as stated by the author, limited by the client. The skin should be the outcome of the inside of the shop, therefore should reflect the luxury in materials and construction methods through handmade techniques. The complexity of elements that constitute the façade would infer the value of a client intending to connote the visit to one of the most luxurious squares in Europe. In this case, as argued by Carlo Scarpa, the intention was not to make one more shop. As he defined regarding the Venetian Olivetti store: "Chiesi al committente: "Cosa volete? Devo fare degli uffici?" -"No, no... un biglietto da visita..." (Scarpa cit in Dal Co-Mazzariol, 1987, p. 287).

Daciano da Costa and Carlo Scarpa, in different times and contexts perceived the need to apply a procedure based on a design project rationale that would call upon the complexity of signs that interpret the city. Through narrative proficiency, both creators called not only upon reflection but also upon the excellent opportunity to devise a system with the ability to define and relate the sub-projects in a dialogue between citizen and space. As advocated by Nigel Coates (2008), architect and head of Architecture at the Royal College of Art, nowadays it is important to think about the experience involving the body, not the body itself. "The city can reach a density of meaning because of the spirit in which it is put together rather than the sum of its individual parts. With today's means it is not only possible to explore architecture as an assembly of physical fragments, but as a ‘filmic’ continuum of events and experiences. In doing so it would ‘contain’ the interface between the individual and the place, and the various built bodies in it.” (Coates, 2008, p. 43). The sub-projects are 'patterns', autonomous units of thought installed in the ‘skin of buildings’ whose exterior means what happens inside.

Figure 2 Olivetti Store in Venice by Carlo Scarpa (1957 – 1958). Left to right: Main façade of the Olivetti store in Venice (Picture by Seier+Seier), stairs detail from the outside perspective (Archivio Fotografico della Fondazione La Triennale di Milano) and detail of the building skin (Picture by Seier+Seier).

Conclusion

We dare assuming that the project of the vertical surface of the city should take into consideration the design of the cultural experience. Among various satisfactory hypotheses we may consider Daciano da Costa and Carlo Scarpa, who made an intervention in a historical centre as a project’s answer with cultural implications. However, the designer (Daciano da Costa) gives an answer in a broader scale than the architect (Carlo Scarpa) who develops an intervention at the level of the detail. Da Costa is interested in the urban perspective and not in the building per se. It is important to refer that the clients of both of them are different: a town (Lisboa) and a brand (Olivetti). The first client is more generalist and asks for an inclusive project, for all people. The second asks for a luxurious project related with S.Marcos which cultural factor is the element of recognition of a town like Venice. Thus, the designer as an interpreter applies a combination of factors, such as existence, time and place, before pondering the city project. An action in distinctive parts, exhibiting the relationship established between fragments and man. To consider the ‘skin of buildings’ one of the components in this scenario indicates interpreting the city membrane as an 'intelligent skin' that relates to the citizen, to the building that historically already exists and to the other elements of the city. The project’s hypotheses are answers turned into questions, establishing a dialectic process with the initial question, and for that reason, with man. Fragments for which the designer lays out a language, an identity that connotes the citizen’s will for self-representation. Fragments interpreted like in movies, with core components as the Luchino Visconti’s draperies or Wim Wenders’ city. An intelligent skin that addresses all elements: people, culture, context, the (old and new) technological developments, the morphology of the materials, but also with the negative factors that persistently and relentlessly define the twenty-first century scenario. A skin that relates to the space and that for being interpreted through design action appears as a cognitive and dialectical skin: connoting meanings upon which the citizen is self-recognized in the outside, as a mirror reflecting various 'selves' in a building façade. As if by projecting outwards what takes place inside the skin would acquire a twenty-first century human body, a skin that mustn’t necessarily reveal the actual age of the body. Something happens, that other disciplines like cinema, fashion, literature or music have already explored, result of the evolutionary analysis of context and man. As if revisited, the skin of buildings yearns to be restored acquiring as many faces as the states of mind of the activity/ies taking place inside the building.

The experience of interpreting the city through design action already has a few decades, holding as chief reference the example of the experimental projects in the sixties by Peter Cook’s

Archigram or Andrea Branzi's Archizoom. The former based on an experimental utopia and the latter departing from the city as it was, not as it might be. We shall consider both cases as other satisfactory hypotheses to reflect on the operation of the hermeneutic cycle applied to design practice. An operation that is not intended to conceive new objects or new buildings, but rather product systems to qualify the objects singularity, in the present case: the peculiarity of the 'skin of buildings'. Operation for the designer to doubt, discuss and question with autonomy, with room for error and for certainty.

Author Biography

Liliana Soares

A Ph.D. student in Design at Aveiro University. This research was supported by the Portuguese Foundation for Science and Technology Grant SFRH/BD/46555/2008. She is also Guest Lecturer for Project Design Skill in the Product Design Course, at the Polytechnic Institute of Viana do Castelo, Portugal. She is graduate from the Architecture Faculty of Lisbon, Portugal and has a Master in Management, from the Euro-Arab Management School, Granada, Spain. Since 2002, she develops industrial design through collaboration with Portuguese and Spanish companies. She has published research articles in international academic journals and conference proceedings and has participated in fairs in Portugal and abroad.

Fátima Pombo

Associated Professor in the Department of Communication and Art, University of Aveiro, Portugal, where she has been Head of Design Course during four years. She is also Professor at Fakulteit Architectuur en Kunsten Sint-Lukas Brussels/affiliation K. U. Leuven, Belgium in the area of Graphic Design. She has lectured extensively on design and aesthetics at international and national conferences. She participates in several international and national research projects, reviews and anthologies. She also writes novels and children stories.

Retail Design and Sensory Experience: Design Inquiry of Complex Reality

Jihyun Song, Iowa State University, USA

Abstract
Understanding sensory stimulation of people in human environments is vital to designing an interior space. The senses play critical roles in human experience and the memories and emotions tied to it. In retail design brands associated to sensory experience attract customers and stimulate strong, positive, and distinctive impression across all five senses. In this case multiple sensory cues are found in a store interior including store and display layout, lighting, interior fixtures and furnishings, music, and air quality such as fragrance and temperature. All contribute and complement each other in orchestrating the complexity of interiors.

Malnar and Vodvarka provide sensory schematics to analyze the built environment. They devised a *sensory slider* to tap the clarity for a particular sense (Malnar & Vodvarka, 2004). Analysis of resulting sensory levels in interior environments provides expanded understanding of the interior's physical condition in relation to sensory perception of users. For retail, the sensory slider was simplified and adapted to analyze visual, acoustical, olfactory and tactile information in store "S". Key factors are found: (1) visual cues are most evident in retail interiors supporting previous research; (2) non-visual stimulations are evident in design narratives revealing emotional domains; (3) multi sensory experience supports literature on branding practices in retail; (4) interior detailing appear to impact all senses.

Using the tool contributes to creating a conceptual framework when evaluating physical environments and emotional factors concerning customers satisfaction. Implication on the application of the method to the design practice is noted. Interior designers as collaborators with retailers will find it useful for the branding and for new store design and services. Insights and directives from this work suggest added research possibilities and application in interior design, graphic design, as well as store marketing and retailing.

Introduction
Issue
In retail, storeowners and retail designers are concerned with success of market strategies driven by customers' desire, perception and satisfaction. As sensation-seekers, according to Floor (2006), consumers enjoy being inspired by a unique range of experiential shopping environments. These experiences and attractions include seeing, hearing, touching, smelling, and tasting products on display. Further, Healey relates customers' brand experience with what is memorable. He addresses customers' purchasing behavior as being driven by storytelling and emotions. A fact exploited by brands (2008). Other studies suggest that store location, atmosphere, emotional attributes, sensory stimulation, and visual presentation are contributing factors to customers' behavioral responses (Ahn, 2008; Andreu, 2006; Gobé, 2001; Lam, 2001; Park & Farr, 2007; Healy, 2008; Song, 2009). While studies show these factors influence visitors' perception of the store, the application and understanding of sensory stimulation and its

association in retail interiors remain limited. In what manner do people perceive memorable shopping experiences? How does the physical environment draw customers' attraction through human senses? How might we design a space to create positive memory and sensory appeal?

Sensory Branding in Retail Design

The effect of sensory stimulation on people and their environment is vital to designing an interior space. The senses play critical roles in memories and emotions attached to human experience. Lindstrom (2005) states that our emotions are linked to the information gathered through the senses. He introduced the concept of *sensory* branding that stimulates and enhances consumers' imagination and perception, creating emotional ties between the brand and consumer. Sensory stimuli can motivate consumers' purchasing behavior, spark their interest, and allow emotional responses to dominate their rational thinking (Lindstrom, 2005). Lindstrom gives an example of customers' personal interaction at Starbucks' coffee shop where the brand is associated with a sensory experience stimulating a strong, positive, and distinctive impression across all five senses. In this case multiple sensory cues are tapped; lighting, furniture, interior furnishings, music, coffee and aroma, which all contribute and complement each other as if a sensory orchestration. When the sensory experience is maximized, the store atmosphere creates a compelling experience that consumers will want to repeat through repeated visits.

According to Gobé "Understanding your customer well and catering to the taste and the aspiration of that customer is the key to building a long-lasting relationship" (Hellman, 2007, p.135). His philosophy of using the *senses* for a retail brand led to the success in redesigning the brand new style for Godiva. He emphasized that the connection between the sensuality of chocolate and the retail design creates an emotional dimension that customers could experience within the retail store (Hellman, 2007). At Godiva, the store experience is enhanced by a stylistic design of the interior, incorporating the brand's history and origins in Art Nouveau in Brussels (Figure 1). Visual sense is emphasized by adding interior details such as brass light fixtures, the wall mural, a large curved glass case, wire sign holders, white marble tabletops and cherry-wood counters, all contributing to European elegance and luxury. Sensory appeal is

Figure 1. The entrance to the Godiva store

doubled with the unpackaged individual pieces of chocolate that are displayed for the customers to taste and smell, bringing multi-sensory level and personal bond with the customers. Healy (2008) addressed the impact of using a brand history and states that most buying behavior is driven by storytelling, experience and emotion. "The experience of enjoying a great story is powerful one that pulls in all of our senses and immerses us so that we feel as if we are actually living the story" (Healy, 2008, p.28). His branding perspective reminds designers a fact that emotions drive our behavior including buying. Experience is the best way for consumer to appreciate things, whether the service or the product; experience is usually the most memorable aspect of each thing we buy (Healy, 2008).

Purpose

This study involved customers' sensory experience related to the overall store interior. The objectives have a two step design: (1) to develop an analysis tool to identify and describe sensory strengths, sensory limitations and their potentials in retail settings and (2) then using the tool examine existing sensory conditions from consumer and employee perspectives. Research questions include: (1) what kinds of sensory experiences currently occur in retail environments? (2) In what manner do the physical environmental features interface with these kinds of human senses? (3) What directives emerge for interior designers doing retail spaces? The answers to these questions will amplify the development of sensory design in the field.

Review of Literature

> *"The external senses have a double province; to make us feel, and to make us perceive. They furnish us with a variety of sensations, some pleasant, others painful, and others indifferent; at the same time they give us a conception, and an invincible belief of the existence of external objects…...The feeling which goes along with the perception, we call sensation. The perception and its corresponding sensation are produced at the same time. In our experience we never find them disjoined. Hence we are led to consider them as one thing, to give them one name, and to confound their different attributes…." (Reid, 1785)*

Sense, Sensation and Sensory Experience

Knowledge of sensation and perception, particularly their causes and processes, has been studied across fields such as philosophy, psychology, physiology, and psychophysics through cognitive theory. Researchers in scientific inquiry suggest how senses are detected, how it feels to perceive them and how they provide sensory information (Goldstein, 1996). Gibson (1966) defines the term *senses* as the systems for human perception that furnish us with a variety of sensations. He explains that the *senses* can obtain information about objects in the world without the intervention of an intellectual process (Gibson, 1966). When the senses are stimulated, each sound, taste, smell, touch, and image sends *sensory* information to our brain, where the sources and causes of stimulation are processed and perceived (Augustin, 2009).

The process of perceiving our built environment involves more than a sequence of steps resulting in experiences called *sensation*. Human experience is affected by cognitive processes such as thinking and memory that are obtained by organizing and integrating information and making inferences from it. Researchers accounted for the perceptual complexity of *sensation* that was converted into perception by past experience or memory (Helmholtz, 1925; Titchener, 1910). Human sensory experience involves more than a single sense (Augustin, 2009; Gibson, 1966; Goldstein, 1996). The ways in which humans respond by looking, listening, sniffing, tasting, and touching are not only achieved by the single input of sensation, but also by a combination of perceptual systems that overlap one another (Gibson, 1966). Goldstein (1996) describes the process of perception as an interaction between the information stimulating the receptors and information from our past experiences that already exists. Sensory inputs have direct influence on human behaviors and attitudes. Our emotional and cognitive responses are affected by our feelings from seeing, hearing, tasting, touching, and smelling (Augustin, 2009).

In retail environments, different levels of stimulation can add multiple dimensions to the sensory experience. A customers' experience is extended when exploring, orienting, and investigating different levels of sensory inputs that are available in the retail space. Thus sensory experiences are of particular importance to retailers because the store environment has a greater effect on a customers' emotional response to an object or place.

Visual Sense and Sensory Information

Sensory experience has origins from visual, auditory, tactile, and olfactory systems influencing humans' cognitive responses (Augustin, 2009; Gibson, 1996). Among the different sensory systems visual information primarily influences how we analyze things around us. Sight not only affects humans physically and psychologically, but also has strong association with other senses. When we touch something that we don't see, we try to determine what we are touching with the sound, smell, and taste of the object. Lindstrom (2005) mentioned that sight often overrules the other senses, and has the power to persuade us against all logic. Designers always consider physical visual stimulation, which is just one role of visual design. Furthermore, intricate details are used to prolong visitor's stay. According to Clark's study, people remember simple figures more easily than complex ones (Lawless, 1978). People are fascinated by ornament details, because those details cannot be remembered for along time. It is thus ever new and interesting, and people are willing to devote their information-seeking attention to it (Malnar & Vodvarka, 2004). Therefore, people linger longer time in a space where there are more details than in one with fewer details. This approach can be used by designers to control rate of movement. Far from concealing deficiency or redundancies, ornament delivers vital function. It precisely identifies a space, including its social and cultural function, and transmits that identity to the audience (Malnar & Vodvarka, 2004).

Through the visual sense, all the store elements in front of the customers' eyes will have a role in their perceived impact. Massara and Pelloso (2006) introduced the concept of the macro, the meso and the micro environment (Figure 2). The macro-environment concerns all the variable

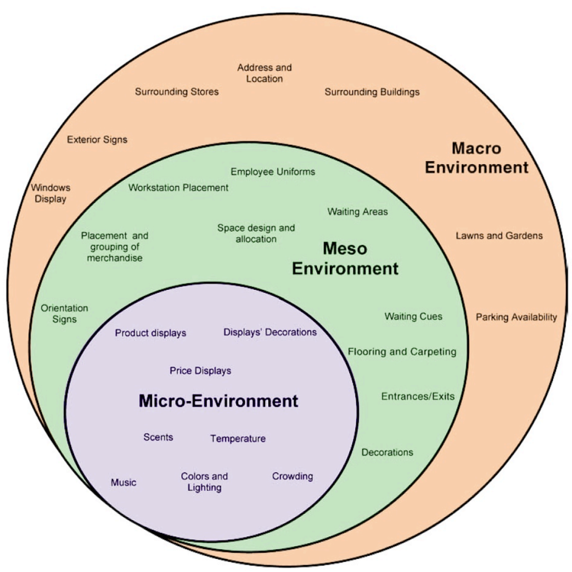

Figure 2. Scales of the store environment (Massara & Pelloso, 2006, p. 521)

on the exterior of the store whereas the meso-environment contains the variables that determine the structure of the interior. The micro-environment includes elements within close proximity to the customers such as shelves and tabletops. This impact on the customers' memorable experience starts from meso-environment elements, such as floors finish and ceiling materials, to micro-environment elements, such as product packaging and brand logo. The glare on the floor, the distraction from light fixture, and the hidden product in the package may affect the customers' experience and create a negative impact. Their judgment will be embedded in their mind with the brand. Therefore the sensory experience will be focused within the meso and the micro-environment.

Non-Visual Sense and Sensory Information

Even though vision is our primary sense, we use our other senses more often than we realize. Our other senses contribute a significant amount of extra information and experience to our everyday lives. Healy (2008) expressed the need for branding professionals to consider the other senses in designing every aspect of the brand experience: product, packaging, advertisement, and designing of retail environment.

In interior design practice, smell seldom receives attention. However, smell has a strong association with feeling and influences people's activities. Odor is a key motivational factor in human behavior, playing a critical role in behavior patterns. Smell affects areas of the brain that deal with emotions, feelings, and motivation, which can lead to a specific behavioral response. According to Malnar and Vodvarka, taste and smell usually function in concert and can be regarded as alternatives ways to experience similar phenomenon (Malnar &Vodvarka, 2004). Tuan suggested that odors lend character to objects and places, making them distinctive, easier to identify and remember (Tuan, 1977). Pleasant odor and fragrance provide a space with a favorable identity. Floor (2006) stated that coffee shops, candle stores, perfumeries, bakeries, and lots of other stores are characterized by the smell of their products as part of their meso and micro experience. Specific fragrances perform precise functions. For example, lemon and peppermint can reinforce alertness and energy; lavender and cedar can reduce tension (Iwahashi, 1992). This is why lavender fragrance is adopted in spas, and air fresheners mainly have a lemony smell. This theory has been put into use by interior designers. For example, several large companies introduce fragrance to heating and air condition systems to boost work efficiency and reduce stress. Fragrance makes a space more favorable to some; while if allergic to smells some could object. Knowing a range of responses has application in interior design practice.

"Without sounds, visual perception is different: less contrasting, less attention-demanding, and less informative" (Malnar & Vodvarka, 2004, p.138). When referring to the sense of sound, background music may be the first thing to come to mind. However, hearing as related to sensory design, is more complicated than that. Sound has strong association with human emotion. According to Floor (2006), older shoppers shop longer and purchase more when background music is playing, while younger shopper respond similarly to foreground music. Sound can be used to attract more attention to specific products or to reach specific target groups. Sound also plays an important role perceiving a space and enhances sight sensory perceptions. An example of applying sound in retail environment is found at Abercrombie & Fitch stores (Gobé, 2001). They have DJs in the store that carefully select music appealing to the shoppers that is consistent with the brand' personality and attitude. Sound may complement vision to perceive space in respect that it enlarges one's spatial awareness to include areas behinds the head that cannot be seen. Therefore, sound dramatizes spatial experience (Tuan, 1977).

Like sight, the haptic information plays a significant role in perceiving the world. According to Malnar and Vodvarka, the haptic system includes three branches: touch, temperature and humidity, and kinesthesia (Malnar & Vodvarka, 2004). Designers may pay more attention to surfaces which customers regularly touch, applying different textures to achieve sensory perceptions. Lindstrom (2007) states that the feel of a product is essential in forming the perception we have of the brand. Enquist (n.d) adds to it that the sense of touch establishes our existence because as we touch we feel ourselves touching: it confirms the presence of whatever it is we are touching. This is important for the designer, especially in complex reality where people's stress levels generally seem to be at a maximum, and where there is a deficiency of connection and exchanges. According to Lindstrom's study 35 percent of the interviewed consumers stated that the micro experience of how the phone felt was more important than the appearance. Further the study revealed that 46 percent of U.S consumers thought the weight of the phone was more important than the look in their purchasing decision. The Apple store demonstrates its new iPhone on a display table so that customers can touch, hold, and fell their new product, making full use of the sense of touch. Studies have shown that customers are more likely to touch a product in the process of evaluating it. Mainly because touching substitutes the absence of information at the meso level where shoppers use their senses to gain more information, whether it includes the product itself, the store fixture, the room temperature, or even the door's handle. The ability to touch the product increases the chance that the product will be bought. If customer can grasp or feel products, shopping can become more pleasurable.

Research Method

Overview

Malnar and Vodvarka's book on *Sensory Design* offers a sensory slider, a tool (Figure 3) for analyzing and measuring sensory existence and its intensity in existing buildings.

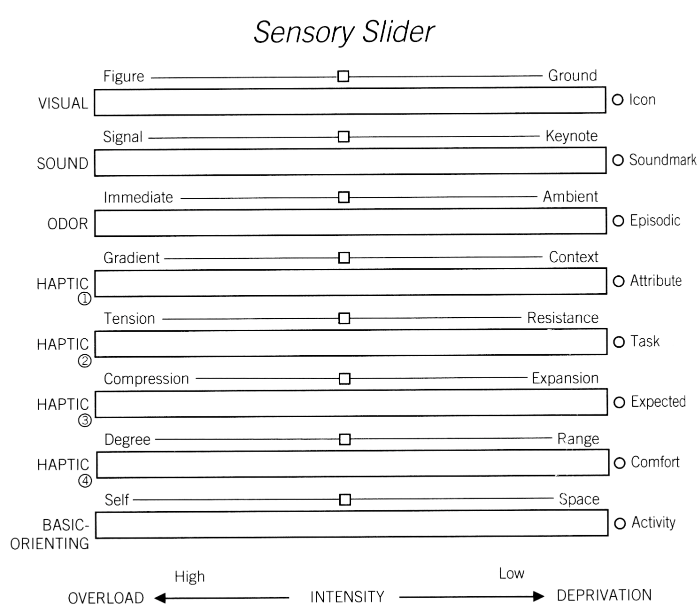

Figure 3. Sensory slider created by Malnar & Vodvarka (2004, p.248)

Analysis of sensory levels in interior environments requires observation of the interior's physical condition in relation to sensory perception of users. In order to study sensory stimulation and association in retail settings, a simplified version of the sensory slider was created (Figure 4). Using this adapted sensory tool, visual, sound, odor and haptic senses were analyzed to evaluate positive and negative values of existing sensory stimuli. The existing perception level, represented by a circle symbol (●) for each one of the four senses is shown in the slider while addressing the reasons that leads to that result. The expected value of sensory perception of the environment, represented by a square symbol (■), is shown as well while explaining what was supposed to be expected from that particular environment.

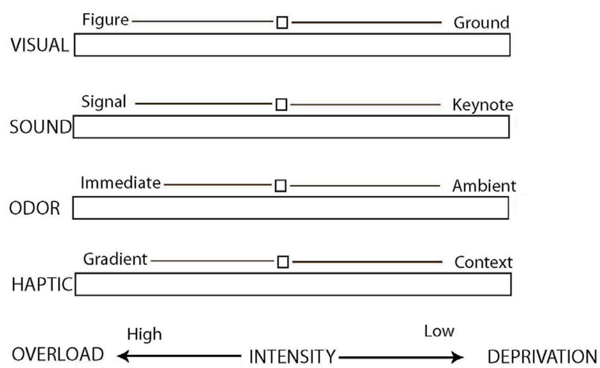

Figure 4. A simplified sensory slider

Site observations and sensory analysis followed three steps. (1) *Sensory diagnosis*: identifying common concepts to determine sensory strengths and sensory limitations, (2) *Sensory exploration*: testing the tool by analyzing consumer's sensory experience on the selected environment, (3) *Sensory treatment*: refining concepts and suggesting the sensory changes. Frequent on-site observation was conducted focusing consumers' use of space and their interaction within the store environment.

Site Analysis: "S" Retail Store

Analyzing the sensory level of an interior environment requires program information of the existing space in relation to sensory perception. The interior of "S" store is located within a two-story building with a total area of 1,992 square foot. The main entrance of the building faces Main Street of downtown providing visible access to the pedestrians. However, the display windows are not noticeable in terms of the store's identity, products, and service offered to attract customers from outside to inside. The interior space is divided into three distinctive zones: entry, point of sales and seating.

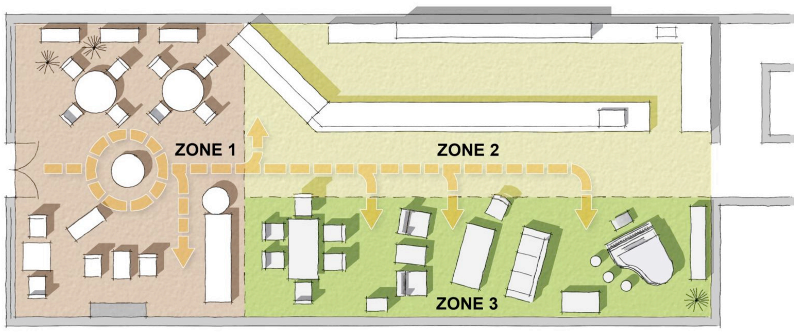

Figure 5. Circulation and zoning of existing store

Visitors enter the space through the entry door located at the front. Zone 1 is entry area that allows multiple seating, creating visitors' first impression. There is obvious flow of traffic along with distinct noise from the street, and other background sounds that are related to sales activity. This area exhibits a variety of items either for sale or for display only, creating distraction to a brand perception.

Major point of sales occurs in Zone 2 where gelato ice cream, fresh chocolate products and packaged items are displayed. Along the linear path traffic is congested by either groups or individuals due to the limited space facing the sales area. The majority of the visitors had their attention on the fresh product, although other visitors seemed interested in the products on display including pre-packed chocolate, coffee beans, gift items that are associated with a brand. Zone 3 has additional seating arrangement with a mixture of furniture types such as a dining table, a sofa and armchairs, a grand piano, and display cabinets.

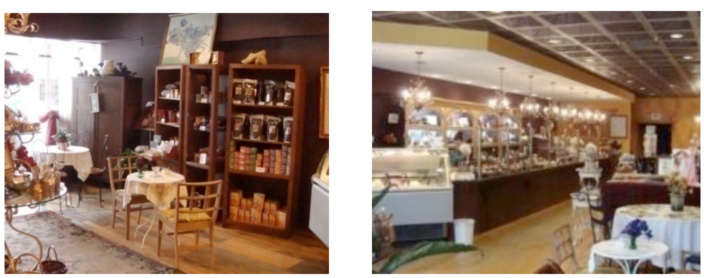

Figure 6. Interior view

Sensory Analysis

The layout of space gives an understanding of space flow relevant to human behavior and responses. Based on the site analysis problems are identified by analyzing consumer's sensory experience on the overall store environment.

Visual Information

The sensory level is overloaded for this main sensory perception. This result is derived from the following reasons:

- Visual clutter all over the space
- Over stimulation from quantity and type of furnishings, fabrics, and finishes
- Distraction of unintended illumination
- Reflection from the high glass barrier

- Over crowded with non-related products such as personal photos

Figure 7. Indirect lighting

Figure 8. Visual clutter

The expected level of visual information is higher than the current level. The unmatched expectation for this sensory perception is missing the following:

- Organized layout
- Clear pathways
- Quality fabrics and finishes
- Focused and non-distracting lighting
- Cohesive presentation of product

The sensory level is analyzed in the sensory slider (Figure 9). The slider for the visual bar is set at a high intensity. There is a strong figural content and high level of differentiation from ground. However, the visual quality of existing condition is misleading due to the excessive amount of light, reflection and glare from the surface materials, and type and furnishings and fabrics causing over stimulation. The circle symbol represents the existing level of visual information while the square symbol represents the expected sensory level.

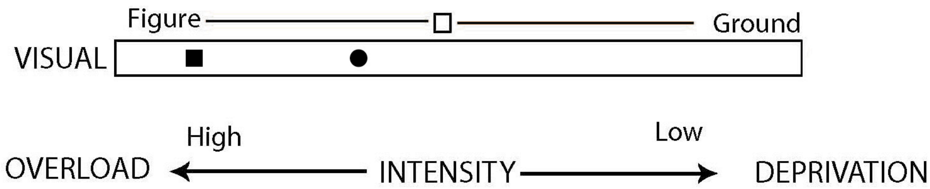

Figure 9. Visual rating on the sensory slider

Acoustical Information

The sensory level is set at a moderate level, providing a rich sound attribute. This result is derived from the following reasons:

- Sound system positioned at two ends of the store
- Diverse type of background music
- Musical performance on the weekend
- Customer's dialog, especially at the sales counter area
- Change in flooring material
- White noise, sounds from service area and mechanical sounds

Figure 10. Placement of grand piano

Figure 11. Speaker location

The expected level of acoustical information is higher than the current level. The unmatched expectation for this sensory perception is missing the following:

- Calm, controlled, and unified music
- Quiet environment for human interaction at the sales area

The sensory level is analyzed in the sensory slider (Figure 12). The slider for the sound bar is set at a high intensity. There is a low signal/keynote ratio, suggesting higher value to the expected level. The circle symbol represents the existing level of visual information while the square symbol represents the expected sensory level.

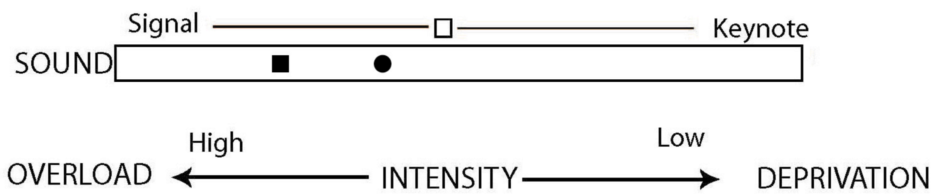

Figure 12. Sound rating on the sensory slider

Olfactory Information

The sensory stimulation is absent and the sensory level is at zero. This result is derived from the following reasons:

- No odor at all
- Temperature and atmosphere results in diminished smell
- Chocolate products are not made in-house

The expected level of olfactory information is significantly higher than the current level. The unmatched expectation for this sensory perception is missing the following:

- Given characteristics of the product and purpose of the space, the olfactory sense would be perceived to be high
- Low air circulation in certain areas
- Production of in-house chocolate products to have the freshly made chocolate smell

The sensory level is analyzed in the sensory slider (Figure 13). The odor information is very limited, however set at a central point. There is a high immediate/ambient ratio, suggesting higher value to the expected level. The circle symbol represents the existing level of visual information while the square symbol represents the expected sensory level.

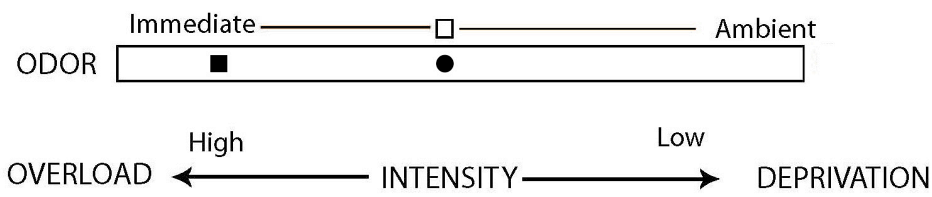

Figure 13. Odor rating on the sensory slider

Tactile Information

The sensory level is set at a moderate level, reflecting relatively low haptic rating. This result is derived from the following reasons:

- Tactile interaction is a secondary sense in the space
- Tactile stimulus comes from interaction with packaged products
- Coldness from the high glass barrier between customers and product at the sales counter
- Interference of multi-textured surfaces

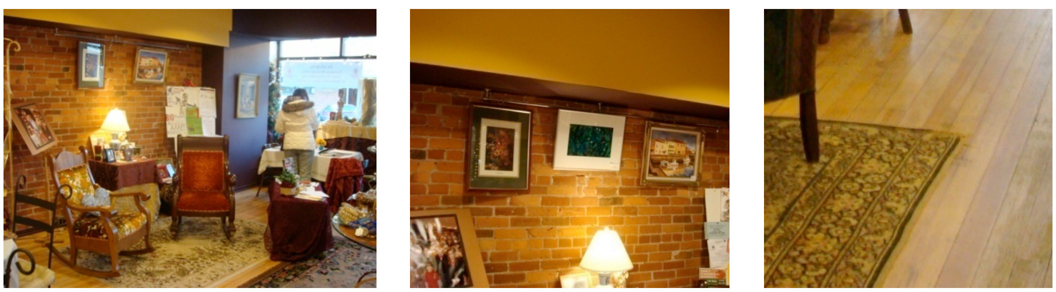

Figure 14. Interior furnishings

The expected level of olfactory information is significantly higher than the current level. The unmatched expectation for this sensory perception is missing the following:

- Main objective of a space to observe, sit, eat and have social interaction without tactile interference
- The main source of tactile stimulus should be the product

The sensory level is analyzed in the sensory slider (Figure 15). The haptic information is set lower level. The circle symbol represents the existing level of visual information while the square symbol represents the expected sensory level.

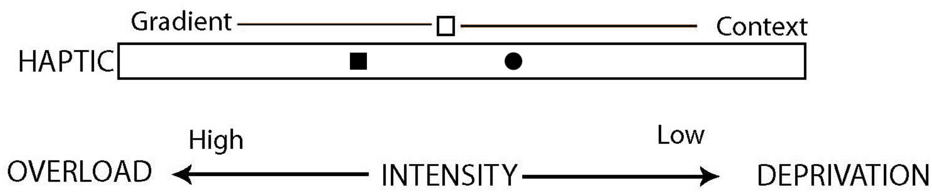

Figure 15. Haptic rating on the sensory slider

Conclusion

Relevance to Interior Design

The goal of sensory analysis of retail interiors is to determine problems and issues relevant to the customers' multi-sensory experience during the activity of sales, service, shopping, entertaining, and marketing. This study was exploratory given little research and writing on the relationship of human senses and retail interiors. The work does give direction for advancing the understanding of sensory perception as a key determinant of customers' attraction and satisfaction in retail. It clarifies for further study the hypothesis that a range and heightened sensory experience will induce stronger customers' shopping experience and thus sales and its meaning to design. Data can be further enhanced for maintaining or enhancing the existing condition and operational, aesthetic, expressive, and other qualities of retail design. Ultimately, the sensory tool may be applied to the creation of a unique retail experience as well as a range of other settings. Using the tool suggests the idea of creating a conceptual framework when evaluating the physical environment and creating emotional attributes toward customers' satisfaction. Interior designers as collaborators with retailers may find it useful for the branding of new store environments and related services. Insights and directions from this work suggest research possibilities and application in interior design, as well as store marketing and retail business.

Abstract

The world faces significant problems of high complexity. The potential of knowledge, methods and tools used in design education and practice are useful for the development of sustainable solutions. Sustainable design is regarded in this paper as the integration of multiple competencies in order to generate and implement creative interventions that trigger positive changes in complex socio-technical systems. In this paper, a multidisciplinary case study is created for experimentation on the way in which different student groups approach complex problems, the type and level of thinking used, and the evaluation of the adequateness of their proposals by experts. The groups analysed encompass eighty subjects enrolled in four different undergraduate and graduate programs. In the experimental groups, the lecturers integrated a number of methods and tools that target purposeful change in complex adaptative systems. In the control courses, the lecturers applied the more traditional methods and tools that are customary of their disciplines, without explicit linkage to complexity and systemic change. Students participated voluntarily in a team activity dealing with the pervasive and complex problem of garbage disposal and transportation in large urban settlements. The resulting proposals provide valuable insights, for example regarding the way in which students analyse the situation, the type and level of change that their proposals imply, and the scope and depth of their causal analysis. This study demonstrates that the set of methods and tools currently used in some of our courses are valuable tools for promoting systemic thinking in our students. Evidence is also provided to suggest that regarding systemic reasoning, the distinctions between disciplinary and multi-disciplinary teamwork may be weaker than what was expected. Furthermore, diagnosing systemic thinking in a team or a person would remain largely irrelevant if this type of reasoning failed to produce more creative and higher quality responses. Our study confirms the premise that teams with high-order systemic thinking consistently yield high-quality and original solutions.

Keywords

systemic thinking; design education; sustainable design; complex systems; creativity.

Rethinking systemic sustainability

The world faces a number of significant social, economic and environmental problems of high complexity, for example as a result of population growth and resource depletion. The potential of knowledge, methods and tools used in design education and practice are increasingly being recognised beyond the areas conventionally associated with the design disciplines, i.e., products, buildings, visual communication, and digital media. Strategies, services and experiences designed to address complex problems are being considered of key relevance for creatively conceiving and implementing sustainable solutions across the disciplines. The work presented in this paper emerges from the coincidence of a group of scholars from diverse disciplinary backgrounds who share a deep concern about the type of creative thinking that may be necessary to develop in our students if they are to face the complex problems in years ahead.

Sustainable design is here considered beyond currently limited interpretations such as the use of recyclable and certified materials, 'green' gadgets, or bioclimatic buildings. Sustainable design is regarded in this paper as the integration of multiple competencies in order to generate and implement creative interventions that trigger positive changes in complex socio-technical systems. Such a broad view of design is likely to demand a disruptive change in how we educate designers today. Moreover, it may demand a major review of education in general, for instance by integrating strategic design skills in all disciplines including engineering and business.

An implication of this paradigmatic change of view of design, is that the established design disciplines do not have the prerogative in the purposeful formulation of creative interventions in complex systems. Arguably, n-disciplinary teams (where multiple or n disciplines are integrated) are more likely to achieve creative collaborative interventions than teams from any separate discipline alone. Such teams may find design strategies, methods and techniques to be valuable in the generation of creative solutions to complex problems. Nonetheless, to our knowledge, there is insufficient evidence available to date regarding the contribution of design principles beyond ambiguous buzzwords like “design thinking”.

In this paper, a multidisciplinary case study is created for experimentation on the way in which different student groups approach complex problems, the type and level of thinking used, and the evaluation of the adequateness of their proposals by experts. The groups analysed include four undergraduate courses and two multidisciplinary graduate courses encompassing a population of eighty subjects enrolled in Industrial Design, Electronic Engineering, Manufacturing Systems and Business Administration.

In two experimental groups, the lecturers integrated a number of methods and tools throughout the semester that target purposeful change in complex adaptative systems. In the four control courses, the lecturers applied the more traditional methods and tools that are customary of their disciplines, without explicit linkage to complexity and systemic change. Students participated voluntarily at the end of the semester in a three-hour team activity dealing with the pervasive and complex problem of garbage disposal and transportation in large urban settlements. The resulting proposals provide valuable insights related to the impact of educational interventions, the composition of multidisciplinary teams, and the way in which students analyse complex situations.

The following section of this paper briefly introduces the theoretical underpinnings of systems thinking and introduces the concept of systemic thinking. Section 3 presents the context of our case study and our research hypotheses. Section 4 details the experimental details of our work. In section 5 the main results are analysed. Finally, section 6 presents a discussion of the significance of this work and concludes with a future research agenda to develop toolkits for systemic thinking.

Targeting sustainability through systemic thinking

Systems thinking has been defined as the type of problem-solving reasoning skills that deal with how causes and effects interact adopting a non-reductionism approach [3]. Existing frameworks distinguish basic/low-level, intermediate/mid-level and advanced/high-level systems thinking styles [6]. In other words, this range has also been defined as systematic or analytical thinking in the lower end, to systemic thinking in the higher end [7]. The term “systemic thinking” also corresponds to higher-order cognitive skills (HOCS) [11].

Systemic thinking describes the cognitive processes that “see relationships rather than things; cause-effect relations as reciprocal; multiple causes/multiple effects; and system structures that cause system behaviour” [2]. This level of reasoning is distinguished from basic or low-level reasoning, which is ascribed to subjects who “see things, not relationships; see cause-effect relations as one-way: one cause/one effect; and external events causing system reaction” [2]. Systemic thinking is valuable for sustainability because it “enables the dealing with complex systems with the appropriate scope, depth, versatility and insight to generate qualitative changes that increase the sustainability of products and systems” [1].

In order to characterise and diagnose systemic thinking, in this paper we adapt a three-tier framework based on [2, 9] where ideas generated by subjects are classified from low-level (SL), to mid-level (SM) and high-level (SH) systems thinking. At the base of this range, SL corresponds to systematic and analytical reasoning that is based on recognising variables, ascribing simple causal explanations, is aimed at system-wide solutions, and is focused on improvements and efficiency. SM integrates the linkages and relations between variables, identifies scales and stages in the system, generates strategies based on expected future effects including indirect consequences, and recognises stakeholders and information flows. At the top of the range, systemic thinking (SH) emerges when the person adopts a wider view of the system and shows evidence of reasoning about contextual and situational conditions, feedback cycles, second-order interactions, system trajectories, and exogenous trends and influences. SH includes reflection on the role of the problem solver in understanding, framing and approaching the problem. The SH person learns within the situation at hand and aims to develop new strategies, models, and policies that trigger sustainable paradigm changes.

We define “sustainable strategy proposal” here as a simple yet comprehensive approach to a complex problem that considers its economic, social and environmental dimensions. Such proposals are difficult to evaluate upon their generation, since their impact in transforming the system is fully understood only after their contingent implementation; but their potential can be estimated, particularly by experts [3]. Recent examples of sustainable strategy proposals include massive urban transportation systems, integrated energy and waste management systems, and other initiatives that address a large number of issues and stakeholders, anticipate first and second-order consequences, promote positive feedback cycles, deal with information flows and power structures, reveal hidden connections between system elements, seek emergent results, etc. Creative value is associated with SH, as there is wide consensus about its potential to transform paradigms and open new solution spaces [27].

Assessing systemic thinking across disciplines

This paper extends previous work where systems thinking was analysed in design and engineering students [1]. The goal here has been to extend our sample population, improve our experimental design, and to incorporate business students in our studies. In particular, the aim of the work presented here is to provide insights regarding the effectiveness of current teaching strategies and methodologies in achieving systemic thinking and creative responses in our students. The long-term objective of our work is to understand the role of creativity and innovation methods and group dynamics in promoting systemic thinking to empower n-disciplinary teams to achieve sustainable strategy proposals. Starting points for this inquiry include: to test the validity of these learning activities in the development of systemic thinking, to assess the relation between systemic thinking and multidisciplinary teamwork, and to understand the role of systemic thinking in the synthesis of valuable and creative solutions.

Hypotheses development

Being consistent with the theory developed in the literature discussed in section 2, we would expect that our teaching interventions designed to cope with complex problems will have an impact on the level of students’ systemic thinking when approaching with complex situations. Considering this, we propose the following hypothesis:

H1: "A combination of methods and activities geared towards the creative intervention of complex problems has a positive effect on the development of systemic thinking"

Considering that the level of heterogeneity in ideas among a group of people from different disciplines and backgrounds will be higher with respect to same-discipline groups, we expect that multidisciplinary teams will tend to provide a more systemic view of a problem due to the variety of ideas and information emerged from the team. Therefore, we propose the following hypothesis:

H2: "Students who work in n-disciplinary teams show increased systemic thinking compared against those in specialized or uni-disciplinary teams"

Finally, we expect that those teams with a higher systemic view when facing complex problems will be more likely to suggest more effective and creative solutions compared with teams with lower systemic view. Therefore, we propose the following hypothesis:

H3: "The level of systemic thinking of teams will be positively related to the quality of their strategy proposals"

Research methodology

We did an experiment using 28 different teams of students across three academic disciplines: design, engineering and business. For the first two hypotheses we created treatment and control groups – intervened vs non-intervened teams, and disciplinary vs non-disciplinary teams. We wrote a real-world case study in which we describe a complex situation. Each team had to work on the problem and propose a possible solution. In the following sections we describe in detail how we set up the experiment.

Educational settings

This section provides a brief description of each course and summarises the experimental conditions of our study. Six courses were selected from the Bachelor and Master programs at Tecnologico de Monterrey (Queretaro). The authors are lecturers of these courses, thus providing access to experimental activities throughout the semester. In two of these courses, the authors have been gradually incorporating teaching strategies, methods and tools related to sustainability and in particular, to the design of creative interventions in complex adaptive systems.

The first four groups selected for our study include three undergraduate courses from the Electronic Engineering, Industrial Design and Business Administration programs, and a graduate course from the MBA program. These cases are labelled as “non-intervened” because their emphasis is not on the generation of change initiatives in complex systems. Two of these cases are courses that do deal with innovation, entrepreneurship and sustainability principles, but do not incorporate the specific toolkits and their application in applied projects. The two remaining groups are an undegraduate course from the Industrial Design and a graduate seminar from the Master of Science in Manufacturing Systems. These courses are taught by different lecturers, and they are both based on team projects where the students apply methods and tools expressly aimed at triggering change processes in complex adaptive systems that include social, economic and environmental problems. The following coding is used to distinguish the groups:

a. Disciplinary (D) or Multidisciplinary (M)

b. Intervened (I) or Non-intervened (N)

c. Undergraduate (U) or Graduate (G)

Non-intervened (N) groups

- Course title: "Design of social-based wireless personal and body area networks" (DNU01) Last year of the Bachelor of Computer Systems and Computer Science. This is a project-based elective course on Wireless Personal and Body Area Networks (W-PAN/BAN). The course includes laboratory practices and the development of a project including the following stages: problem/need identification, idea generation, solution election, prototyping, and final presentation. The project incorporates a social-based framework for the design of technological systems to address social problems. The course also incorporates visits to industry, creativity sessions and principles of intellectual property. The final projects were submitted to the "Bluetooth Innovation World Cup 2009" [12].
- Course title: "Innovation by design" (DNU02). Final year seminar of the Bachelor of Industrial Design. The goal of this seminar is to introduce students to the reflexive practice of innovative design. At this stage, students have undertaken six design studio subjects in a wide range of themes and in an increasing degree of complexity. The design projects in those learning experiences had focused mainly on form, function, user and manufacturing issues, but they left unaddressed the complexities of innovative business strategies. This seminar challenges students' notions regarding the role of creativity, design and innovation, and provides concepts and techniques to incorporate strategic innovation into their design practice. The seminar includes a partial term on sustainable development, but the nature of this seminar is mainly theoretical and reflective, and does not include project development.
- Course title: "Information Technology Management" (DNU03). Second-year undergraduate course for Business majors. This course focuses on the operational and strategic role of information technology in the organization as well as on individual information-seeking skills. The main objective of the course is to learn how information technology can enhance organizational efficiency and even transform business strategy. The students practice their

abilities to search for, analyze and organize information using up-to-date information technology tools.

- Course title: "Innovation and Entrepreneurship" (MNG). First-year graduate course for the Master of Business Administration. This course focuses on the the challenges of entrepreneurial innovation and product/process design within a business model. More specifically, students acquire hands-on experience on identifying a social need, looking for business opportunities accordingly, and then the students have to come up with a sustainable business model to address those social needs and exploit the business opportunity. In addition, students are exposed to real-world entrepreneurship experienceses with local entrepreneurs, and also they receive lectures about innovation and business models. At the end of the course, students grouped in multidisciplinary teams present a business model as a final evaluation. They have to provide evidence for the social need, and also they have to show evidence of market, technical and financial feasibility.

Intervened (I) groups

- Course title: "Systems thinking design studio" (DIU). Eighth semester of the Bachelor of Industrial Design. This design studio addresses design interventions in complex social, economic and environmental systems. As is customary, students tend to think first in the design of consumer products. Through group debates around sustainability, ecological footprint, life-cycle assessment, consumerism, social wellbeing and biomimicry, students reinterpret their project goals in order to surpass the realm of objects. Concepts related to systems and services emerge, and the team proposals increasingly encompass a complex network of innovative decisions about people, economics, politics, markets, function, semiotics, production processes, nature, etc. The orientation of this design studio has yielded results with extraordinary potential for positive impact in our society, including the project "Waste Recovery System", a 2009 finalist in the prestigious Index Design Award [13].
- Course title: "Creativity and innovation graduate seminar" (MIG). Second-year seminar of the Master of Science (Manufacturing Systems). Students from multiple backgrounds converge in this course including Mechanical Engineering, Industrial Engineering, Industrial Design and the Master of Business Administration. This seminar seeks to promote reflection on the innovative potential of research projects and entrepreneurship initiatives. Teams of students develop a value proposal to an external client, addressing the clients' current problems and strategic planning. Students seek to introduce disruptive changes in their clients' practices rather than mere incremental improvements. The theoretical principles as well as their practical application deal with Systemic Complexity. Cases are analyzed and discussed in class, students write essays related to these themes, and the final project is evaluated by the client. As a result of this seminar in Fall 2009 one project was selected by the Business Incubator program and its business plan is currently under development.

The methods and tools used in design groups (DIU, MIG) are selected from the literature and from the authors' professional and teaching experience with the aim to enable and support systemic thinking. They include:

- Activity name: "The roots of the problem". Film screening of documentaries and movies dealing with social and economical complex problems as well as sustainable development. This material is selected thinking on the clear exposure of global problem roots. The objective is to move students from their comfort zone and trigger controversy for the debates following the screening. “Home” [14], “1984” [15], “Story of Stuff” [16], “An Inconvenient Truth” [17], "Hans Rosling TED talk" [18].
- Activity name: "Prosperity without growth". Class debates around the topics of how the current problems of social disintegration, lost of cultural heritage, economic gaps among social groups and nature depletion have reached their actual state. The relations between these problems are discussed, and the class identifies paradigms to be changed in order to achieve sustainability and social justice within global prosperity. Debates are open and the

objective is to help students reflect on these issues and their own personal and professional goals.

- Activity name: "Visualizing the system". System structure graphic visualization, this could be done physically or virtually in two-dimensional compositions, the objective is to visually understand the relation among the stakeholders and the exchanges they have, [19].
- Activity name: "User-centred Design". Surveys, interviews, behavioural mapping, camera journals and story telling; the main objective of using these tools is to understand as deep as possible the state of the system, develop stakeholder empathy, and elucidate their true needs, desires and expectations. Depending on the nature of the stakeholders (these could be any actor in the system with any type of exchange with others), students must select the apropiate tool and apply it to provide evidence of their understanding [10].
- Activity name: "Designing the change". Sketch, mind-mapping, and dirty prototypes are commonplace in all design studios, all these tools are implemented searching innovative ideas to be applied into the systems or to solve a particular aspect, like a specific product. The deliverables vary according to the project, from physical models, two-dimensional maps, photo-journals or drawings.
- Activity name: "Dancing with systems". This activity analyses the possible points of intervention in a system following a hierarchy of leverage points [3]. The objective is to create proposals of intervention in the semester project taking into consideration the consequences and the impacts throughout the system. Intervention proposals are analysed by an expert in each relevant area according to the project under development. Biologists, chemists, manufacturing engineers, biotechnologists, physicists, economists and lawyers are customarily consulted. The deliverable of this activity is a map of the system with the interventions and its new exchanges and expected consequences as advised by the experts.
- Activity name: "Complex problems may have simple, optional and unexpected solutions". This activity aims to introduce students to the idea that complex problems in large systems may be addressed by enabling counter-intuitive minimal changes that trigger positive effects. The three key issues in this approach are: to present the solution as an optional alternative in the system and not as a compulsory course of action, to focus on experimental evidence to select the smallest change (in cost, effort or time) with the largest returns, and to bet on counter-intuitive system dynamics. This activity is approached through the principle of "Nudge" by Cass Sunstein and Richard Thaler [20] where evidence from the literature and a range of methods are well documented. The deliverable of this activity is a one-week project where students design and document a 'nudge' that causes a behavioural change in their context. Pirnciples and examples of abductive reasoning are also useful for this activity.
- Activity name: "Identifying the growth and destruction of value in complex systems". The aim of this activity is to help students identify the values that the stakeholders of a complex system may perceive from its current state. Students realise that cycles of corruption and other negative behaviours often times respond to perceived values that reinforce negative outcomes. In design projects, this value-construction dimension of complex systems is best approached by learning the process of creative destruction in innovation [21], the dynamics of the Function-Behaviour-Structure framework [22], and the value of breakthrough products [23]. The deliverable of this activity is a team presentation where students seek and document examples of systems that yield undesired outcomes, and provide a value-based explanation of such outcomes.
- Activity name: "Life-Cycle Intelligence". This activity introduces students to decision-making processes based on a deep understanding of the life-cycle of a product or a service system, starting from the inputs, materials and supplies, throughout use and disposal. Simplified versions of LCA methods are used, such as the "Life Cycle Design tools" of the LeNS project [28]. Notions associated to "Ecological Intelligence" [24] provide an adequate starting point. The deliverable of this activity is to reveal, estimate and document the hidden costs of the team's main design project in the semester.

- Activity name: "Personal Sustainability Project". This activity provides students with first-person experience of changing deep-rooted habits in order to decrease their environmental footprint. Students use a number of online calculators to estimate their footprint and to identify the undesired consequences of their routine activities and everyday choices of transportation, food consumption, etc. The deliverable of this activity is a four-week journal where students record the challenges and milestones of their attempt to reduce their footprint. An essay is submitted by the end of this activity where students discuss the strategies that they would propose to help others implement this type of change.

	D/M disciplinary multi	I/N intervene non-interv	U/G undergrad graduate	Class size	Responses	Number of teams	Design (D)/ Engineering (E)/ Business (B)

MIG	M	I	G	13	13	3	D/E/B

Table 1 Summary of all 28 teams included in this case study. 16 control teams (N) and 12 experimental teams (I); 20 are disciplinary (D) and 8 multi-disciplinary (M).

The case study

In our experiment we wrote a case study that deals with the problem of waste disposal and recycling in urban and suburban residential areas. Then we asked our student teams to provide a solution for this case. We created this case study based on exhaustive information from a consultation project developed for the Miguel Hidalgo local government in Mexico City in 2007. The case was jointly developed by the authors considering its suitability and relevance across all disciplines. The case of waste disposal and recycling was chosen because it provides high complexity and presents a significant challenge for the development of local solutions that add value to the economy, society and environment [25]. The time allocated for this work is three hours during the last session of the semester, and participation is voluntary and independent from the course grades.

Student teams in control groups are formed, given a design brief about residential waste disposal and allocated a two-hour session to analyse and discuss the problem and to formulate a sustainable strategy proposal. At the end of this session, teams are required to formulate a plan to address the problem specifying the resources required, expected results, etc. Two types of control groups are studied here: uni-disciplinary and n-disciplinary groups, the first refers to specialized teams of only business, design or engineering members while the second refer to teams that integrate these disciplines.

Experimental groups are also presented the same design brief and allocated a two-hour session under equivalent conditions, except that a summary of the topics and projects covered throughout the semester is presented highlighting the methods and techniques aimed at triggering change in complex systems. In a one-hour preliminary activity, students of these groups are reminded of the several methods covered throughout the semester. A set of qualitative research methods is used to assess both the process and the product of this short activity: questionnaires are applied to the team members immediately after their participation, sessions are recorded in video for further analysis and interpretation, and a panel of (independent experts) evaluates the potential of the proposals from a sustainability and innovation viewpoint.

The assessment tool

The assessment tool is divided in two parts; firstly, a one-page scenario provides information about the current situation including the agents involved in the collection, transportation and sorting of garbage. Statistics and the general flow and interactions between agents are included. The main challenges and conflicts of the system are summarised. Students analyse and discuss the current situation in order to collaboratively develop a solution strategy proposal. Teams are required to submit the following information at the end of the two-hour session: a one paragraph summary of the team's analysis of the current situation, a one-paragraph summary of the strategy that the team proposes in order to approach the problem, and a three-paragraph explanation and justification of the team's consensual ideas highlighting the main objectives, expected outcomes, and the creative value of their ideas.

These teams' responses are reviewed by the researchers in a double-blind process, yielding a classification of the solution strategies in SL, SM or SH according to the three-tier framework presented above in section 2. As a result, the solution strategies developed by teams are independently categorised by 'systemicity' and quality criteria including its creative potential to trigger paradigm changes. The distance between the distributions of SL, SM and SH in N and I groups is the vehicle to validate H1. The distance between the distributions of SL, SM and SH in D and M groups is the criterion to evaluate H2. Lastly, the distribution of quality and SH across all groups is the means to evaluate H3.

The second part of the case consists of a questionnaire that students respond individually after submitting the team's strategy proposal. This questionnaire is based on the strategies proposed by Meadows to intervene systems [3] and is used to compare the level of systemic thinking in individuals and teams.

Results

We categorized team’s responses according to the level of systemic thiking and computed a standardized systemic thinking score. We tested H1 and H2 using a two-group-mean comparison t-test. For H2 we run a simple linear regression, and also run a two-sample-mean comparison t-test. Our data provides support for H1 and H3, but not for H2. Tables 2, 3 and 4 show the statistical results for these hypotheses.

Variable	Mean of Intervened teams (N=12)	Std error Intervened teams (N=12)	Mean Non-Intervened teams (N=16)	Std error of Non-Intervened teams (N=16)	t-statistic of the mean difference	Statistical significance of diff. between groups (p-value, 1-tailed)
Systemic thinking score	1.99	0.11	1.60	0.10	2.56**	0.0083**
Solution quality	2.34	0.17	1.74	0.13	2.80**	0.0048**

Table 2 Difference between systemic level score and solution quality between intervened vs non-intervened teams. Note: ** significant level at 0.01 level

Figure1 illustrates the information about systemic thinking levels:

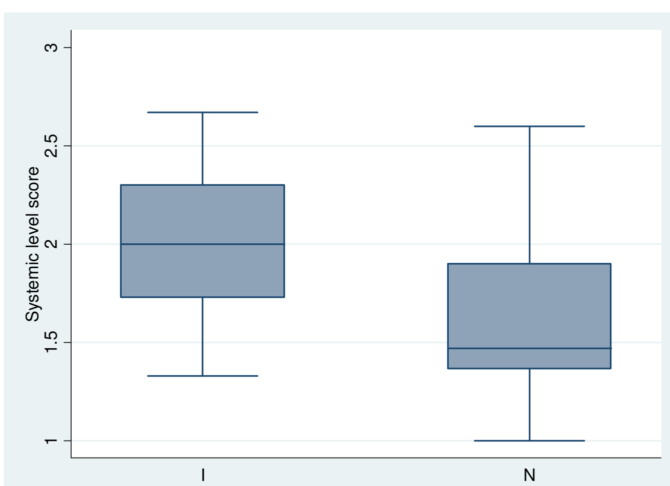

Figure 1 Box plot of the systemic level between Intervened (I) vs non-intervened (N) teams

As we can see from Table 2, there is significant difference between the level of systemic thinking between the intervened and the non-intervened teams. The intervened teams exhibit significantly higher level of systemic thinking compared with non-intervened teams (p-value=0.0083). If we can provide support to H3, then it would make sense to argue that intervened teams compared with non-intervened teams will experience a higher quality in their solution to the case. As we can see, we provide statistical evidence for this argument (p-value=0.0048). Therefore we provide strong statistical evidence for H1.

Variable	Mean of Multidisciplinary teams (N=8)	Std error of Multidisciplinary teams (N=8)	Mean of uni-disciplinary teams (N=20)	Std error of Non-Intervened teams (N=20)	t-statistic of the mean difference	Statistical significance of diff between groups (p-value, 1-tailed)
Systemic level score	1.71	0.13	1.79	0.13	0.42	0.33
Solution quality	2.00	0.21	2.00	0.14	0.00	0.50

Table 3 Difference between systemic level score and solution quality between intervened vs non-intervened teams.

There is not enough significant evidence to support H2. Multidisciplinary teams and uni-disciplinary teams do not show significant difference in their levels of systemic thiking. The difference between both groups' quality of solution is not statistically significant either. Therefore, H2 is not supported.

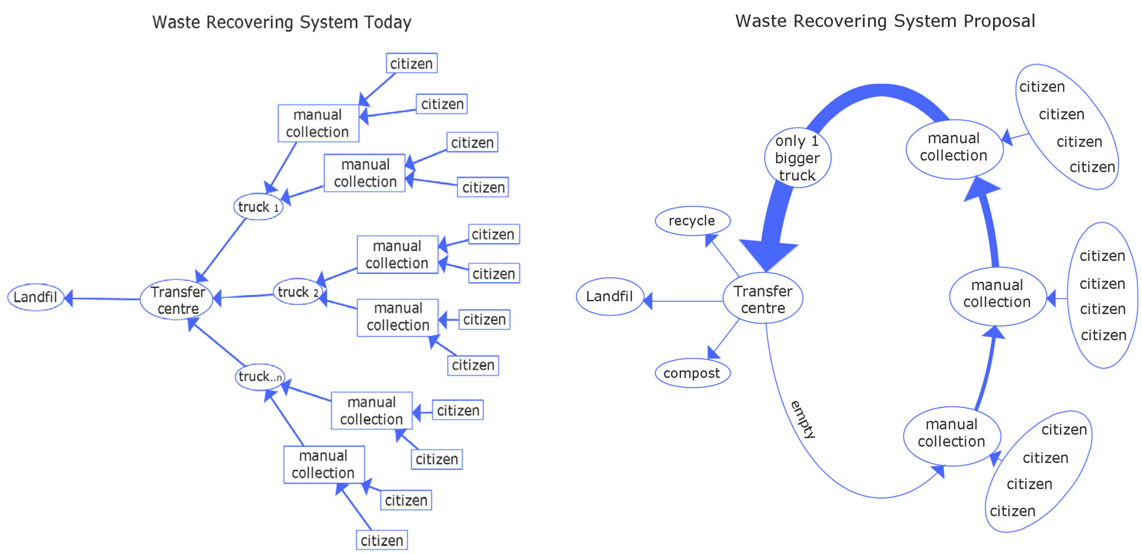
For H3, we run a simple linear regression using solution quality as dependent variable and the level of systemic thinking as independent variable. Regression results show that these two variables are positively correlated (correlation=0.31, and this correlation is marginally significant at the 0.055 level). We run an one-way ANOVA to see whether these three groups experience different levels of solution quality, finding significant difference between the groups (F=10.42, p-value=0.0005). After running Bonferroni comparisons, we found that SH teams receive a significant higher level of solution quality compared with SL teams (p-value=0.003). We also found significant difference in the level of solution quality between SL teams and SM teams (p-value=0.001). However, no significant difference between SM teams and SH teams was found. Considering these results we can say that H3 is supported.

To evaluate all three hypothesis at the same time, we run a multiple regression model with systemic thinking level as dependent variable and the dichotomous variables team type (Multi/ uni-disciplinary) and intervention variable (intervened/non-intervened) as independent variables (results are not shown in this paper due to space constraints). We also added as a control variable the academic level of the team (undergraduate/graduate). Interestingly, over and above all variables, the fact that the team is intervened was the only one significant in the model. We did a further analysis, regressing all these dichotomous variables and also the level of systemic thinking on the solution quality as dependent variable. For our surprise, the variable intervention explained most of the variance of the solution quality.

Besides these quantitative results, in the following section we present exemplary cases to illustrate the qualitative evaluations of the team’s proposals.

Exemplary systemic strategy proposals

Two strategy proposals developed by our students are documented in this paper as exemplary SL and SH responses. Team PLP of group DIU presented a majority of SM and SH responses, and received the highest quality score of all 28 teams. This team's main idea is to reorganise the network of garbage collection and waste recovery with the objective of minimising the number of trucks and optimising the manual collection process in the system. Rather than having half-empty trucks doing short trips from every existing small collection point to the transfer centre, PLP's strategy is to estimate the type of truck and route design that could traverse a number of larger collection points to deliver their contents in one longer trip into the transfer centre. Moreover, PLP's strategy includes a close monitoring program in every local collection point (citizen clusters) in order to capture information and learn the local patterns of waste disposal and separation, and customise the system accordingly. This paradigm change in the organisation of the network represents a creative breakthrough qualitatively different from the average strategy proposals; it is visually illustrated in Figure 2.



(a) (b)

Figure 2 A paradigm change from the system state today (a) to the new proposal (b) presented by team PLP in group DIU where the network of waste collection and recovery in the city is reorganised, transforming the values and dynamics of nodes, and enabling local customisation.s

In contrast, team LLJ of group DNU01 presented mostly SL ideas, and received a low quality score. This team's strategy includes the privatisation of the garbage collection process, salary raises for employees and subsidies for private companies with money from the recycling of materials. The strategy also incorporates an ambiguous system of garbage-management bonds that citizens earn as they comply with waste separation and disposal laws. While these ideas are not without good potential, they received SL tags because they address low-level leverage points of the system, and they earned low quality scores because they remain unconnected, ambiguous and lack details that demonstrate deep reasoning beyond trite stereotypes.

These two cases are exemplary of clear association of thinking style with quality of proposal, but in other cases this relation is not as straightforward, as discussed above.

Discussion

This study demonstrates that the set of methods and tools currently used in some of our courses are valuable tools for promoting systemic thinking in our students. These activities may vary in their objectives, scope, and implementation (as summarised in section 3.2.2), but they all address the deep understanding and purposeful intervention in highly complex systems. More precise studies are necessary to characterise the role of each activity type and their applicability in different disciplinary and teaching situations.

Evidence is also provided to suggest that regarding systemic reasoning, the distinctions between disciplinary and multi-disciplinary teamwork may be weaker than what was expected. No doubt, multi-disciplinary work has clear advantages and merits, but at least in the type of conditions and issues addressed here, its impact on high-order systemic thinking seems rather limited. This could mean that systemic thinking need not be constrained to multi-disciplinary settings, as intuitively assumed. An important implication of high-order systemic thinking as a cross-disciplinary skill, is that all disciplinary courses may be suitable for nurturing systemic thinking.

This somewhat unexpected outcome regarding multi-disciplinary teams may point towards other possible moderator variables at work. For instance, the creativeness and innovation of teamwork dynamics has been associated with the strength of social ties [26] and other variables related to culture [29, 30].

Furthermore, diagnosing systemic thinking in a team or a person would remain largely irrelevant if this type of reasoning failed to produce more creative and higher quality responses. Our study confirms the premise that teams with high-order systemic thinking consistently yield high-quality and original solutions. This is a promising outcome that validates this type of research initiatives, and motivates more specific questions for future work.

The research presented in this paper reinforces the claim that the design of sustainable products, services and systems could significantly benefit by the development and enactment of systemic thinking. This could be achieved by gearing teaching interventions across disciplines towards identifying, understanding and intervening complex systems. It is in this context that the buzzword 'design thinking' seems limited and inaccurate. What is necessary in design as in other disciplines, is 'to design our thinking' in a more systemic level.

Future steps

Further studies are required to characterise and develop 'systemic toolkits' to intervene courses across disciplines and at different scales: sessions, terms, semesters, etc. It is difficult to measure the potential of every learning intervention tool due to their varying nature, scope and time periods of applicability. However, such toolkits could provide cross-disciplinary teaching instruments to explore given the particular conditions at hand.

The assessment exercise presented here may require further exploration in terms of the topics covered, the length of activity, the team formation strategies used, and other potential moderator variables. The authors plan to replicate this study in future semesters in order to validate its predictive utility.

The analysis of the team responses could be revised and extended. The three-tier framework of systems thinking could be refined into more specific categories and responses could be contrasted against individual competencies before and after the test. The criteria of quality and originality could be validated against third-party evaluations by incorporating independent judging panels in the evaluation and categorisation of responses.

Finally, this work could lead to valuable input for curriculum design projects. Guidelines could be developed to incorporate teaching interventions throughout undergraduate and postgraduate programs across disciplines.

Author Biography

Ricardo Sosa

Industrial Designer, holds a PhD in Design Computing from The University of Sydney, Australia. He is the Head of the Industrial Design Department at Tec de Monterrey in Queretaro. He is currently developing an alternative Rapid Prototyping system for the creative stages of design. He supervises postgraduate research in the MSc in Manufacturing and MA in Multimedia Design. Since 2008 Ricardo is a member of the Sistema Nacional de Investigadores, CONACYT, Mexico.

Alberto Dorantes

Computer Systems Engineer holds a PhD in Information Technology from the University of Texas at San Antonio. He is currently a full-time researcher and professor at the Business School (EGADE) of Tecnologico de Monterrey in Queretaro. His interests include the study of IT industry clusters and modelling of entrepreneurship in the software industry. Since 2008 Alberto is a member of the Sistema Nacional de Investigadores, CONACYT, Mexico.

César Cárdenas

Professor of the Mechatronics Department at Tec de Monterrey Querétaro since 1996, he has been the academic program director of Electronics Engineering. He teaches captsone courses for electronics engineers and courses on telecommunications. He holds a BSEE, a MSc. in Satellite Communications from Telecom ParisTech and currently he is doing his PhD in Telecommunications at the same institution. His main interests are the optimal management and performance evaluation of complex systems, future of engineering education, social design, and future generation of manufacturing systems.

Victor Martínez

With more than 15 years of work experience in Mexico, USA and Italy, he has developed projects for first-class automotive companies around the world including Ford, Audi, Alfa Romeo, Fiat and Italdesign-Giugiaro. He has teaching experience at the Scuola Politecnica di Design (Milan, Italy) in the transportation design master and since 2004 he is a researcher and lecturer of Industrial Design. He is currently teaching a multidisciplinary workshop on Sustainable Mobility.

The Value of Stimulated Dissatisfaction

Nicholas Spencer, Northumbria University, UK

Kevin Hilton, Northumbria University, UK

Abstract

"I'm not saying it's a good quality to have, but my observation is that good designers are never happy, they're never satisfied, never content" (Adrian Stokes, quoted in Spencer, 2008, p. 145).

It seems self-evident that designers, whose raison d'être is to initiate change in man-made things (Jones, 1970), devising courses of action aimed at changing existing situations into preferred ones (Simon, 1969), will be dissatisfied, at some level, with the way they experience the material world. However, recent research (Spencer, 2008) suggests that expert designers deliberately enhance the pressure and stress of the design situation – stimulating dissatisfaction. By stimulating the experience of dissatisfaction their imaginative and investigative action is given urgency, focus and purpose as they pursue excellence and attempt to unfold from their own view of the world to empathise with a broad project community.

This discursive paper highlights the need for a developed understanding of the reflective practitioner model to inform the post-rationalist generation of design methods. This paper: reviews critical literature about the experience of designing; discusses the role of dissatisfaction within the practise of design; and presents a research project that aims to evaluate the value of stimulated dissatisfaction for the purpose of supporting practitioners' empathic appreciation in early design direction generation. This paper argues that the reflective practitioner model of the designer must address the stimulation of dissatisfaction as a condition of creative and explorative design practice.

Keywords

Design Practice; Reflective Practice; Experience; Dissatisfaction.

Understanding design activity is an extremely complex task; particularly, if we accept that designers are intimate aspects of the very context dependent problems they aim to resolve (Schön, 1983; Lawson, 2006; and English, 2006) where bounded action encompasses all the various parts comprising human existence (Bousbaci, 2008). This paper aims to contribute to our understanding of design activity, specifically contributing to Design Epistemology (Cross, 2006), by focusing upon design practitioners' experience of practise (Spencer, 2008), reflecting upon the role of dissatisfaction, and presenting research that evaluates the benefit of stimulated dissatisfaction for supporting empathic appreciation in early design direction generation.

Theoretical Context

Based upon the 'generation game' (Cross, 1981), found within Design Methods, Bousbaci (2008), argues that each shift in the evolution of Design Thinking has been accompanied by a major shift in the implicit 'Model of Man', and, as a consequence, the implicit model of the designer (refer to Figure 1). Bousbaci states that, "each design theory, unless it puts forward its philosophical assumptions, assumes as well a particular view (i.e., a model of the designer)" (ibid, p. 39). Bousbaci describes Design Thinking's changing theoretical landscape:

- First-generation design methods shifted from the romantic, intuitive, and artistic model of the designer to embrace a very logical and rationalist view. The logical and rationalist model of the designer, which Alexander (1964) described well, has its philosophical roots in Descartes' (1637) mechanical world and investigative method.
- Second and Third-generation Design Methods – which delivered intellectual tools widely used in contemporary design discourses: wicked problems (Rittel, 1972); solution focused strategy (Lawson, 1980); design conjectures (Hillier, Musgrove & O'Sullivan, 1972); primary generator (Drake, 1979); ill-structured problems (Simon, 1969); and problem space and generative processes (Newell & Simon, 1972) – rested on the premise that design was a problem solving process and the model of the designer supporting these views was conceptualised by Simon as Bounded Rationality (1945).
- The reflective practitioner is a post-rationalist model of the designer and the 'reflective turn' that Schön's work provoked is the last paradigmatic shift in support of Design Thinking.

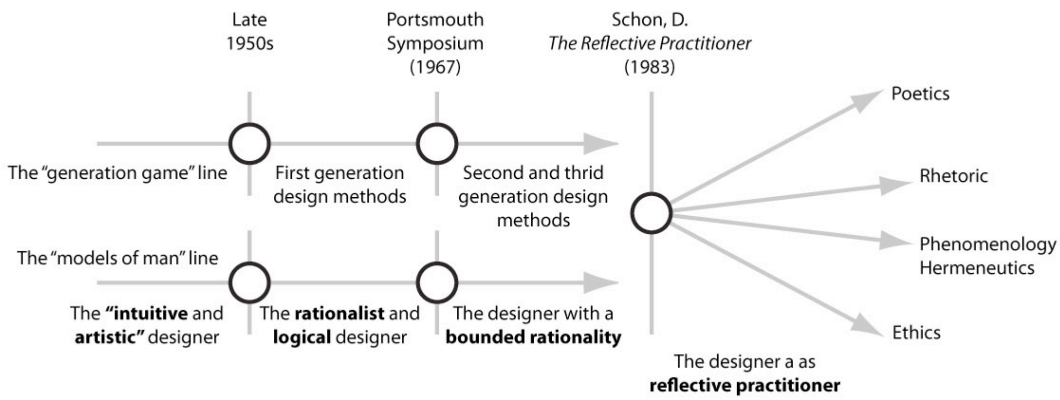

Figure 1 – 'Some landmarks in the evolution of design thinking', taken from Bousbaci (2008)

According to Bousbaci, Schön's reflective practitioner is:

> A post-rationalist model of the designer [that leads design theorists] to gradually abandon the very rationalist and logical concept of 'problem' (and the entire instrumental view of design as a 'problem-solving process') in order to adopt the more pragmatic and phenomenological concept of 'situation' (2008, p. 40).

The differences between the instrumental view of design, seminally illustrated by Simon (1969), and the constructionist view of design, as Schön described it, have been well discussed and dissected (Schön, 1983; Dorst, 1997; Spencer, 2008 & 2009). This paper is not concerned with debating the merits, contradictions, or paradoxes of these paradigms of design; it is concerned with examining the reflective practitioner model of the designer. If, as Bousbaci proposes, there is a causal relationship between Design Methods and models of a designer, then improving our understanding of the reflective practitioner model, furthering its detail and accuracy, should provide an improved theoretical foundation for developing fourth generation design methods.

In Schön's reflective practitioner model, designers are makers in the broader constructionist sense; using professionally and personally determined practices and competencies to impose coherence and order complex situations, converting indeterminate situations into determinate ones, bringing new things into being through their actions and inquiries. The reflective practitioner model describes the role and interaction of three different knowing modes: knowing-in-action, reflection-in-action and reflection-on-action. The knowing modes, knowing-in-action and reflection-in-action, are differentiated by the practitioner's ability to progress a task situation through action, and, reflection-in-action and reflection-on-action are differentiated by their relation, in time, to the task situation. The reflective practitioner model defines the pattern of inquiry (reflection-in-action) used when knowing-in-action is insufficient to proceed or when the situation falls outside the boundaries of 'normal' where knowing-in-action cannot be brought to bear. The pattern of inquiry, reflection-in-action, employed within an action present, is a process of: simplifying a situation's complexity (consciously or unconsciously naming the elements to be attended to); arriving at a standpoint about the situation, its problems and issues (framing); exploring the standpoint through action, experimentation and solution propositions (making moves); and considering implications and consequences in two directions, 1) forwards, to consider the value and consequences of the propositions and the barriers to successful implementation, and 2) backwards, to consider the restrictions and relevance of naming and framing and the appropriateness of the investigative actions (reflection).

For the reflective practitioner model of a designer there appear to be a number of factors that influence the effectiveness of an inquiry, they are:

a) The designer's ability to understand the design situation – the methods, tools, skills and cognitive capacity to identify issues and their consequences – i.e., appropriate naming.

b) The designer's ability to empathise with the project community – the creative capacity and knowledge to frame and reframe the design situation including personal empathy, commercial empathy and discipline empathy – i.e., appropriate framing.

c) The designer's ability to explore frames – the discipline skills and knowledge necessary to explore frames and solution opportunities, expose them to internal and external audiences for feedback and complete projects within specific design domains – i.e., appropriate move making.

d) The designer's ability to critically reflect – the sensitivity to recognise feedback from propositional explorations, the ability to recognise limitations with naming and framing actions, the ability to discover and see the implications of propositions – i.e., appropriate reflection.

e) The designer's ability to engage uncertainty and manage mental and emotional states – the confidence to feel the discomfort of uncertainty; and the willingness to repeatedly explore alternative frames and solutions and expose the coherence of the thinking structure to criticism (Spencer, 2009), time allowing, or to commit – i.e., appropriate application of the practitioner's mental and emotional resources.

Schön describes the good reflective practitioner as being willing to enter into new confusions and uncertainties, but does not provide a good account of states of confusion or the experience of uncertainty and how these affect reflective inquiries. The conversations that Schön presents (1983 & 1987), focus upon illustrating how naming, framing, making moves toward solutions and evaluating through reflection develop through dialogue, focusing upon design content and action (descriptions of solutions and frames; and explanations of moves and reflective behaviour). Schön does not highlight what it is like, experientially, to be in a reflection-in-action moment. Nor does Schön focus upon the affect a practitioner's mental and emotional state has upon their ability to have effective conversations. The role of a designer's mental and emotional conditions is a potentially fruitful area of investigation for informing the reflective practitioner model of the designer. In order to inform the reflective practitioner model of the designer, this paper: discuss findings about expert design practitioners' experience of practise; reflects upon the role of dissatisfaction within the practise of design; and presents preliminary research that aimed to test the value of using a Dissatisfaction Matrix to stimulate early stage design direction generation.

Investigating the Experience of Designing

Spencer (2008) conducted an investigation into the experience of designing. The research examined experiences of expert design practitioners' practise of reflective practice. His study was an embedded multiple-case study with multiple units of analysis, where qualitative data about the experience of designing were obtained from eight semi-structured interviews with expert designers.

Spencer's work suggested that design practitioners explore their design situations, through the propositional experimentation process suggested by reflective practice, intuiting the value of frames and solution propositions as a felt experience. It appears that dissatisfaction plays an important role as practitioner's continually strive for better personal and professional performance through their design inquiries, avoiding the extremes of conceit or stress induced inertia and avoiding habitualisation in preference to reflection-in-action. It is also suggested that in addition to developing self awareness of the personal and professional performance dissatisfactions, which can bring about changes in identity and expertise, there are also dissatisfactions with things beyond the person and the business, including: products, processes, services, communications, policies and politics. Each of these anticipated or experienced dissatisfactions become part of the context around which, and within which, the designers design. Dissatisfaction is therefore argued to be an integral part of motivation for change and motivation to design. Nevertheless, this does not mean that it is possible to use all dissatisfactions positively in a given context, for example dissatisfaction over price, when reducing price makes it ethically unacceptable; or dissatisfaction about diversity of choice, when the breadth of product range is already unsustainable in the marketplace. There is also a question as to whether the positive prompting of dissatisfactions can provide the same benefits throughout a design process; dissatisfactions at the ideation and brief development stage are anticipated to support in a different way, to dissatisfaction identification at design specification.

To illustrate the role of dissatisfaction that Spencer identified in the expert designers' experience, it is useful to present some of his research findings – descriptive statements about the experience of designing. Sample transcript excerpts, taken from his thesis's discourse analysis, follow the findings and a brief commentary is provided.

> Finding 1
>
> Expert designers are optimistic about their ability to resolve design problems, see problems as opportunities and begin their task with positive excitement (Spencer, 2008, p. 286).
>
> There's a sort of optimism that designers have to have, you have to be optimistic that you can solve the problem (Tim Brown, quoted in Spencer, 2008, p. 205).
>
> As a designer you need to be quite passionate about solving things and I think that most designers want to do things well, they want to create a better world, they

> want to do better things, they want stuff to be better (Mark Delany, quoted in Spencer, 2008, p. 206).

Cross (2006) stated that “the uncertainty of design is both the frustration and the joy that designers get from their activity” (2006, p. 54). Spencer refutes that claim: “it is not the uncertainty of design that expert designers enjoy, rather it is the potential and pregnant opportunity that uncertainty represents, it is the fear that is generated as the designer experiences uncertainty that is enjoyed” (Spencer, 2008, p. 242).

The excitement a designer feels at the start of a project appears to be a consequence of the opportunities they see in the design challenge. Spencer’s data suggests that the uncertainty, inherent in the design situation, provides perceived opportunities to make positive contributions to society through the activities of design and to achieve positive re-enforcement of the designer’s professional identity. The dissatisfactions implicit in Finding 1 are: a) the belief that society and material culture is not as satisfactory as it could be and can be improved by deliberate and organised action (design); and b) that one’s own practice can be further improved and refined and hence has not yet fully met self-imposed standards.

> Finding 2
>
> As expert designers engage with a professional context that is uncertain, ill structured and ambiguous they personally experience uncertainty. As the uncertainty of the challenge is grasped, fear develops about their ability to resolve the design problem’s issues and exploit its opportunities (Spencer, 2008, p. 285).
>
> Often the first month or so you’re kind of stabbing away and it’s all a bit hazy and you’re a bit worried you’re going in the wrong direction, […] there’s always that uncertainty at the start of a project ‘*Are we going to be able to pull it out of the bag this time*’ (Kevin McCullagh, quoted in Spencer, 2008, p. 208).
>
> Even now, after God knows how long that you’re doing it, whenever you get a project in there’s still a little bit of panic at the start of it, ‘*Shit, I don’t know what I am going to do, I don’t know what the answer is*’, and that fear is quite enjoyable. I think the moment I lose that fear is the time that it’s like time to give up! (Mark Delany, quoted in Spencer, 2008, p. 208).

The situation, and phenomenological state, that Finding 2 describes, is presented as central to practitioners’ reflective inquiry. The design situation in itself is dissatisfactory and it is the designer’s role to produce solution propositions for satisfying the issues, contradictions and conflicting commercial demands. As described by reflective practice theory and by the design expertise literature (Lawson, 1994, 2003 & 2004; Dorst, 2003; and Lawson & Dorst, 2009), the form of inquiry dominant in design practice requires practitioners’ intimate engagement and personal investment. The initial engagement with an ill-structured design situation is complex. In addition to external ambiguous conditions and criteria there is the designer’s experience of this situation, as Spencer highlighted:

> Expert designers, in addition to imposing order upon their situation of practice and developing solution propositions, must cope with their personal response to the experience of uncertainty and its discomfort and their personal doubts and insecurities that are given focus as they engage with challenging design problems (Spencer, 2008, p. 242).

Spencer’s data illustrates that designers experience the situation’s uncertainty without necessarily being immediately able to unpick and cognize the strands of doubt that create it. This phenomenological state seems crucial, and Spencer suggests that designed outputs can be viewed as a result of coping with, and attempting to resolve, this state of uncertainty and stress; therefore, reflective practice is a series of attempts to escape from the unsatisfactory experience of uncertainty, creating conceptual certainty and coherence by employing imaginative and investigative action.

Finding 3

Iterative attempts to develop solutions can lead to frustration as the expert designer assesses his/her propositions as inadequate for resolving the design challenge. Over time, if solution propositions continue to be assessed as inadequate, dread is experienced as the expert designer questions his/her ability to resolve the design challenge. Mental paralysis can occur after this stage where the expert designer is unable to further explore the design situation (Spencer, 2008, p. 285).

Coming up with ideas is pretty easy; making them reach the other end of the net is not easy. Ideas are two a penny at one level, even though people say, '*How do you have ideas*', ideas is not the problem, making them the right ideas, better ideas is a problem and you can only do that if you have reference points to judge better-ness against and then successful exploit them (Steven Kyffin, quoted in Spencer, 2008, p. 210).

There is a huge amount of worry to turn that [creative] moment into a finished product. Without that moment there would be no successful products and without that worry there would be no successful products. There are all these opportunities to ruin that moment (Adrian Stokes, quoted in Spencer, 2008, p. 210).

I think designers are inspired by quite negative emotions, you know you're really frustrated with something and you want to design it better, or you're just frustrated with the way things are going and you need to solve it, you cannot let it go until you solve it, you know I think any creative act involves a bit of pain, you've got to give a bit (Mark Delany, quoted in Spencer, 2008, p. 211).

I think there's something about the creative process that requires your brain to work pretty hard and it has to be open to certain things and so you can't be scared and frightened. If you're scared and frightened you can't design, you can't be in too much of a hurry all of the time or you can't design and you need to be fit, mentally fit and physically fit […]. So there is something in being in a good state of mind and state of body that does help you be creative. I mean you see it in people who have been working too hard for too long they just stop having good ideas (Tim Brown, quoted in Spencer, 2008, p. 212).

It's amazing how confidence can desert you; emotions are very fickle, lifting your mood sky high or just shutting you down. At those moments you never look at the bigger picture, 30 years of achievement for example, you always just think, '*Oh God, I'm in trouble*' (Adrian Stokes, quoted in Spencer, 2008, p. 214).

Finding 3 describes ongoing proposition experimentation and the emotional states that can occur if solution propositions are assessed as inadequate. This finding highlights an interesting area for further research: what influence does the experience of stress and uncertainty have upon a designer's assessment of their solution propositions. An ideal-type designer would be one that has developed tactics and gambits to help manage the effect that strong and/or sustained levels of anxiety have upon their practise of design while maximising their motivational benefits positively – they would be effective in the appropriate application of their mental and emotional resources.

Discussing the Experience of Designing

Spencer's research explores the application of practitioners' mental and emotional resources as they practise design. His investigation, however, is not intended to be, nor claimed to be, a complete picture. The methodology and cases studied shape the scope of the research and its limitations provide avenues for further inquiries. However, Spencer's thesis is useful in developing our understanding of the reflective practitioner model of the designer; it highlights that reflective practice has a significant phenomenological dimension to it beyond the action-orientated theory of Schön. Spencer's (2008) findings deal with aspects of experiencing dissatisfaction, but do not address the role of dissatisfaction and relate it with stages of the design process, nor does his work address the significance that dissatisfaction has upon a practitioner's practice over time. The Dissatisfaction Matrix project described in this paper outlines an experiment that is an attempt towards evaluating the role of dissatisfaction in Opportunity Identification (Hilton, 2002).

The generation of the experience of uncertainty and its discomfort is evident in Cross and Clayburn Cross's (1996) study of Gordon Murray. In a description of his situation of practice Murray is quoted as saying, "the pressure then to come up with something new becomes intense, and the responsibility is all yours, and you get sort of panicky" (op. cit.). Cross and Clayburn Cross suggest that innovative designers frame or reframe the design situation in a way that creates significant challenge. Davies and Talbot (1987) stated that although ideas can occur at any time they seem "most likely to occur when the person has to cope with significant life events, and/or a particularly knotty design problem" (1987, p. 23). Spencer suggested that, expert designers stimulate their experience of uncertainty and inquisitive discontent: "engaging with design problems of increasing complexity appears to ensure that expert designers' experience of their design challenge is at the edge of what they are able to cope with" (2008, p. 282). Perhaps, taking on problems of increasing complexity and framing a problem so that it is seemingly impossible are tactics designers use to enhance the pressure and stress of the design situation, creating the unsatisfactory experience of uncertainty and discomfort from which they attempt to escape through their professional activities. If this is the case, it appears that the reflective practitioner model of the designer must address the stimulation of dissatisfaction as a condition of creative and explorative design practice. Also, if this is the case, then designers may manipulate their awareness, and perception of project progress, in order to improve creative engagement and performance. This control of stimulation may in part relate to the balance of Boredom and Anxiety for Flow experiences (Csikszentmihalyi, 1975 & 1992).

There appear to be sets of interesting relationships between the balance of dissatisfaction/satisfaction and ambiguity/clarity for our understanding of Design Expertise and designers' personal development. The point at which an individual design practitioner experiences enough satisfaction with their approach to designing to be uncritical about the way they design is interesting. It perhaps signifies the point where competency and confidence has allowed a practitioner to deploy their critical attention to a different area or set of concerns regarding their profession. However, it may also signify the point where a practitioner believes that they no longer need to deploy the extra effort to critique their practices, as they are sufficient to do the job. It may also be the case that a practitioner may not know how to do things differently without potentially sacrificing quality. Spencer's (2008) data highlights that a lack of curiosity, or the early satisfaction of curiosity, is an issue that becomes a point of friction between designers:

> This is a bit of a personal bug bear; when people just want to slip into a pattern that they're familiar with, '*So we did this with the last project let's do that*', rather than go, '*Well what's actually the right thing to do on this project*' (McCullagh, K., quoted in Spencer, 2008, p. 223).

> I think that there are some designers, quite a lot of designers that are insufficiently curious or critical about what they are doing on the other hand they have job and a mortgage and have to pay off their credit card bills, like along with many other people they don't make life complicated they just do their job (Thackara, J., quoted in Spencer, 2008, p. 223).

In Spencer (2008) Stokes, A., suggests with astonishment, that the majority of designers that he has trained or known do not develop because they are too easily pleased with themselves and too smug (ibid, p. 145), he states: "they became complacent, lazy designers and lazy people who took things for granted and were more interested in going out to the pub at 5.30 than they were about their work and the world around them" (Stokes, A., quoted in Spencer, 2008, p. 149). As a designer develops solutions that provide greater clarity of a concept, they become more satisfied with the concept's development and so continue to move towards the specification phase. However, it has proposed that ambiguity is a resource for design (Gaver, Beaver, and Benford, 2003), in that it allows for more open association and intuitive leaps to take place, and therefore the feelings, if satisfaction is arrived at too early in the process, could reduce beneficial engagement with creative thinking, and the project may therefore conclude with less value added.

Dissatisfaction Matrix

Inspired by the research into the value of stimulated dissatisfaction, and in an attempt to further understanding of this area of research, a Dissatisfaction Matrix was developed by the authors as a tool to test if dissatisfaction could be prompted to support creative engagement with ambiguities. The Dissatisfaction Matrix was intended to offer designers a multi-perspective association approach to inspiring Opportunity Identification (Hilton, 2002) at the ideation and brief development stage. This proposition was a further development of work using 'personas' for design critiquing (Hilton and Henderson, 2008), where here, the matrix was to prompt using characteristics, a selection of which might make up a full persona's concerns. Using the Dissatisfaction Matrix requires that the designer/design team imagine and consider dissatisfactions for specific characteristics in specific contexts, providing a structure to empathic appreciation, and informing their understanding of the project community's design challenge. The characteristics of dissatisfaction, which populated the prototype matrix, were identified through a session that involved naming product and service related dissatisfactions and later categorising them. This list was not exhaustive or intended to be in any way definitive, it served to create a reasonable test framework. Lists should always be viewed as 'live' not 'set', able to be questioned and added to, or made more specific, to be appropriate to the design task.

The research method required that the design-teams, each made up of three 2nd year industrial design undergraduate students, imagine and list on post-it notes either dissatisfactions or ideas for each of the characteristics against each context. In each case, the 5 teams of 3 students were briefed and given two hours to generate as many responses as possible. In addition to the verbal briefing session, each team was provided with written details of the task and efforts were made to ensure that each design team carried out the two hours task in separated workspaces free from distractions.

This project involved an iron and a kettle, in two separate sessions, so that participants had opportunity to compare experiences of using the Dissatisfaction Matrix, to list dissatisfactions, against traditional brainstorming (Dominguez, 2008) or the Dissatisfaction Matrix used to list ideas. This enabled the investigation of differences in dissatisfaction/idea-fluency between a traditional brainstorming format, and two applications of the matrix, one for dissatisfactions the other for idea generation.

The results showed a greater fluency of responses where ideas were required. When ideas were required it was noted that 1-5% of the post-its listed dissatisfactions, whereas when dissatisfactions were required it was noted that 20-85% of the post-it notes listed ideas. There was an obvious slew towards the habitualised ideation process, possibly in part due to lack of practice with the dissatisfaction matrix, possibly in the way responses were framed as ideas even if they originated as feelings of dissatisfaction.

The participants found the Dissatisfaction Matrix to be engaging and proved to be a good way of ensuring that a large number of associations were considered. The Matrix therefore functions in a more prescriptive fashion than the theme prompting of idea flow experienced in a traditional Brainstorm.

The nature of the matrix approach, requiring a fast response in order to complete within a two-hour period, was reported to be exhausting. This reported exhaustion, is believed, by the authors, to be because there were a greater number of matrix associations, than there were brainstorm themes, making the experience much more one of thinking against the clock. Although it was reported to be more challenging to list dissatisfactions, a number of participants did describe feeling that the dissatisfactions would provide more concrete direction for concept development than many of the ideas. This conjecture would have to be investigated with future research using listed dissatisfaction for concept development and design, as a comparative study with concept development and design using listed ideas. It would also be of value for future research to investigate the design practices of critically reviewing and selecting noted dissatisfactions to progress, in comparison to what would occur with noted ideas, and then seeing how the selections influenced the quality of design process and creative output. It is expected that experienced practitioners may generally have become more critical, more dissatisfied, though some may have become somewhat apathetic. This leads to further research and raises the question of Design Apathy and whether there is any evidence of it.

Conclusions

It has been argued that expert designers stimulate their experience of dissatisfaction to create the phenomenological conditions for their imaginative and investigative actions to be given urgency, focus and purpose as they pursue excellence and attempt to unfold from their own view of the world to empathise with a broad project community. As such the reflective practitioner model of the designer must address the stimulation of dissatisfaction as a condition of creative and explorative design practice. Further research could explore designers' variety of responses to design-situation induced anxiety and discomfort and how this influences design decision-making and reflection.

The value of stimulated dissatisfaction within design practice and to the practise of the design practitioner, as an alternative approach to idea generation, would appear to be the heightened awareness of needs for improvement, as opposed to wants or hopes. This would make it more useful in certain cases where a more critically developed brief is required for example, possibly prior to a more divergent traditional brainstorm session being run. Choosing dissatisfaction assessment appears to bring a more critical view of needs, helping to address any possible over-optimism or motivational bias to reflecting upon, and working with, what works well.

The value of stimulated dissatisfaction, for the design practitioner, appears twofold: 1) it helps form phenomenological conditions that a designer attempts to resolve through the use of their creative cognitive capacities, i.e., it helps to keep a designer designing; and 2) it helps to keep the design situation at the boundaries of a designer's capacities; it ensures reflection-in-action, i.e., it helps to keep a designer designing. The descriptions, in this paper, have illustrated the use of stimulated dissatisfaction as a positive resource for creativity and design. How defined the balance is between healthy and positive usage of stimulated dissatisfaction and unhealthy and destructive usage is unknown and a source of further research.

Abstract

Designing digital artifacts for a culturally diverse market implies the thorough understanding of the psychological mechanisms derived from the social and environmental context. The next article introduces a research that investigates the relevance of cognitive and identity diversity (Page, 2007) in the working groups that have as a task the design of interactive services for digital environments. The argument of the article does not focus on the positive aspects of the heterogeneous quality of the group, but simply aims to understand how the diversity of the design group could help improve the nature of the interactive services designed for a multicultural market. Considering the craft of a virtual environment in terms of interaction metaphors that have to be understood by the end users, the step prior to the design of the above-mentioned environment is to be taken into consideration. Two pedagogical experiments placed in two different cultural contexts, Italy and China will be presented in order to exemplify the prior findings of the research inquiry. First the common ground creation in the context of multicultural workgroups will be analyzed, and second how the internal dynamic of the group reflects in the creation of the digital working model will be shown. Taking into account all the above, the question asked is: what methods and tools can be used to support an internal communication language of the working team and how the developed skills could then be applied to the process of designing digital interactive artifacts.

Keywords
Communication design, work group dynamics, collaborative projects, cultural diversity, interactive digital media.

What connections could be made between two different groups of students placed in different cultural contexts? In the next chapters it will be shown how apparent cultural differences in the design teams could be mitigated through a constructed disciplinary language, and how eventually this experience could bring more insight to the overall quality of the project. Although the final outcome of the experiments to be presented concretized into a digital artifact, the study of the diverse group dynamics could inform other disciplines of design as well.

1.Concept design for mobile communication

The above-mentioned experiments have involved two groups of students in Italy and China and have been organized to share the same brief. The brief asked the students to generate collaborative service ideas for mobile communication that will help social aggregation and promote a sustainable lifestyle.

More specifically the Chinese project came as an iteration of the Italian one and was intended to test and refine a previously defined teaching structure. Both groups had a similar no. of master degree level students (22-27) with an industrial design background and were asked to design digital intangible artifacts using a methodology specific to service design (Gong et al., 2008). It is interesting to note the same type of first view reluctance in dealing with service. The correct appropriateness of words such as interaction, service, system, scenario, prototype and simulation had to be stressed out and supported with comparisons between industrial and interaction design. In other words the input lectures given by the professors and technological partners had to be explained in the group revisions and "translated" almost into a vocabulary of concepts already used by the students in their previous learning experiences. In the same time the students had a much better ability to use the digital technology, being part of the digital native generation (Prensky, 2001). Both courses underlined the need for two ways of learning to design for mobile communication: one by using the physical and digital interfaces actively, and another by applying an awareness strategy to the acquired knowledge. From pedagogical point of view the role of the professor has to be seen not as an authoritarian presence that imposes a set of methods and tools, but as an active participant in qualifying the tacit knowledge (Polany,1966) gained through the shared experience.

1.1 Laboratorio di sintesi finale, Italy

The course followed a predetermined sequence such as case study collection, concept generation, concept development – which included service and interaction design, followed by the financial analysis of the project, service simulation and communication design. After the projects' completion the students had to prepare a presentation for the sponsoring partners in a public venue and for an extended audience. The activities that took place during the course were of three types and involved three distinct groups. An organizing group of tutors and professors from the university, an external group of experts and the group of second year masters degree students. The input lectures, and revisions given by the teachers and expert teams were followed by progress presentation offered by the students.

The team of professors had to adjust from the beginning with each other's disciplinary language even before proceeding to develop the content of the course. The definition of notions and terms, which have a different understanding for the different disciplines, were subject of an ongoing negotiation process. Even more when the area of application dealt with the new and continuously evolving mobile communication systems, the above mentioned process had to be acknowledged and purposefully evaluated. The common ground creation effort was consequently reflected in the course material.

1.2 Workshop, China

Following the experience in Italy, the Chinese course was organized as an iteration of the Italian one and shared the same brief. The intention of the workshop was to test the same didactical structure following the same logical steps, but evaluate and review the methods used in the first place. This is in part due to the analysis of the students' response embodied in the projects that have been developed and the working flow observed in the class activities. Other important factors were the different geographical location as well as the ethno-cultural differences. In the same time the lecturer team was aware that given the circumstances the students' behavior and most of all their understanding of apparently obvious content, could not be fully anticipated this is why the pace of the lectures had to be tuned according to the reaction of the students. From this point of view the pre-established sequence that worked well in the first case had to be reviewed and adjusted to meet the students' needs and bridge a common ground between the two groups. In the next chapter it will be discussed how the above-mentioned differences could be mitigated and channeled into a creative environment that leads to effective problem solving.

2.Cognitive and ethnic diversity

2.1 Personal relationships and student-professor interaction

After having seen how the cultural differences could modify the structure of a pre-defined teaching structure, we will now discuss the distinction between the cognitive or disciplinary differences and the ethnic ones. The Italian example offered a lesson on how teachers from the same university, therefore sharing the cultural base for a fruitful discussion, had to acquire certain awareness and construct an interdisciplinary bridge of understanding. The engagement in a conversational relationship had to balance the inner mental representations of possible outer circumstances (Shotter 2000) of four academics and professionals coming from service design, interaction design, architecture and management in one coherent chorus capable of developing a specific educational content. The difficulty in that situation was to correlate the construction of the particular representations. In this case the apriori explanation of the commonly shared terms and notions was necessary in order to avoid subsequent misunderstandings. Analyzing the initial phase of the content development, it is important to underline that this kind of negotiation has to occur at the beginning of the conversation otherwise the consequences will cost the participants a loss of time and an increased level of frustration. Good communication within the group could maintain open the flow channels (Csikszentmihalyi…) therefore be enriching, because all the participants have gained a new understanding of there own perspectives, beneficial because the collaboration had an optimal result, and rewarding because the overall experience was positive and not frustratingly tiresome.

The result of the conversational effort being, in this specific case the content of the course dealing with digital services for mobile communication the next important step to be discussed is how the students reacted to the content. Here it is important to stress out the presence of the generational gap. In his seminal work *Digital Natives Digital Immigrants* (Prensky 2001), Mark Prensky shows the ways in which the younger generation that grew up with the digital technologies thinks and learns in alternative ways and how this contradicts the traditional methodology of teaching. In fact he argues that the role of the professor is shifting from the authoritarian status to a peer status (Prensky 2007). Although the course at the Italian university had an ex-cathedra setting and an hierarchical organization, the information was exchanged in a peer to peer situation not only from the professors to the students but also from the students to the professors.

The experience and knowledge gathered from teaching the course was then reviewed and adjusted for the Chinese workshop. Here the already consolidated group of lecturers had to deal with the ethnic differences. Aside from the language barriers, the way in which the Chinese group of students assigned meaning and importance to the taught content made the lecturer group to change the way in which the lessons were taught. In this sense the theoretical lectures had to be supported by intensive mentoring sessions with the students in which the appropriation of the concepts took place from both sides. The conversation in this case had to be supported by hand drawn visual representation and the use of commonly shared metaphoric comparisons. If in the beginning there were two distinct groups foreign to each other, the common effort in developing a mutually accepted communication language helped establishing a cohesive collaboration group.

2.2 Interacting with the mobile technology

If the previous chapters have explained the cultural context in which the two courses were placed and the pedagogical structure they followed, in the next part it will be explained how the students interpreted the brief and in particular in which way they have chosen to use the mobile technology.

As mentioned before both groups worked on how the mobile communication could help the social cohesion and lead towards a more sustainable lifestyle. In the Italian case having as a partner a major communication company, the group has received a very strong technological input on how the avant-garde technologies work. Perhaps this is one of the reasons for which the outcomes tackled the requirements of the brief from a technological point of view, suggesting rather futuristic solutions. In the same time the students successfully identified the critical moments in which the mobile technology could be successfully be employed without being intrusive (Ling 2004; Fortunati 2003). In this respect a good example is the project La Maglia -The Patchwork (fig.1), in which the service proposed acted upon the underused or “wasted” moments (Perry et al., 2001) imbedding them with a new meaningful activity. More specifically the project analyzed the behavior of a very specific group, a women’s community center on the outskirts of Milan, in the time span of a working day. The delay moments, such as the waiting time at a bus stop, at the dentist or the hairdresser were qualified by getting in touch with a friend which happen to be nearby. The technology proposed the use of GPRS - general packet radio service, SMS –short message service, pc server, and smart phones.

fig.1

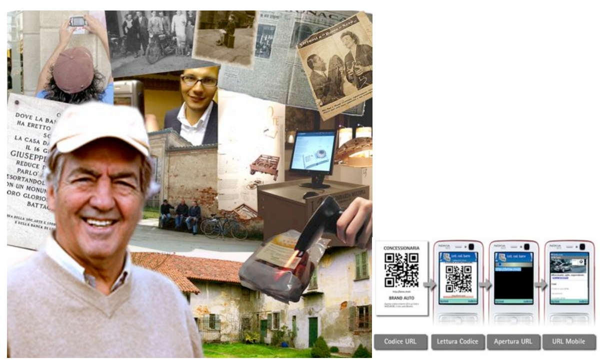

fig.2

The re-interpretation of public/and private space it is another issue that emerged in the usage of mobile telephony. In this sense the awkward situations are encountered every day insofar that they became an embarrassing but inevitable reality. The loud voiced conversation of a neighbor sharing the public transportation could irritate if not even annoy the others. The misuse of public space is in the eye of the beholder. If one party asserts his rights too boldly, the other side will feel that his or her status is being affronted (Ling 2004, pg.127).

Acknowledging this critical point in the user behavior the Cantastorie- Storyteller (fig.2) project proposes an alternative perspective raising the awareness and eventually re-

defining the public realm. Using the semantic code technology the lost story of the place is being remembered. Placed in the Comune di Opera, the service aims to preserve the memory of the different sites. Even if most of the physical traces of the history of the place have disappeared the stories told by the older generation create an alternative topology made out of pieces of memories, waiting to be shared with the younger.
The workshop in China offered the opportunity to test not only the revised teaching methodology but also the different perspectives on the same brief. Presented with a similar structure and input lectures the Chinese students have chosen to base their concepts in the ethnographic insights provided by the field trips. More important almost all projects presented strong reactions to the changes in the social structure, and the events experienced through personal involvement. In this sense a good example is the Pride House (fig.3) concept, which focused on the migrant workers issues and their insecure status with respect to the local communities in the locations they are employed. The project proposed the use of GPRS and MMS technologies.

fig. 3

A particularly interesting example is Yesterday Once More (fig.4), because the target and starting idea of the concept are somehow similar to the Cantastorie project developed in the service design course in Italy. The initial idea is based on the same critical observation of the continuous change of the public space; only in this case the landscape is modified literally over night. Although the message is supposed to be positive the project conceals certain nostalgia for the traditional landscape and the traditions imbedded in it. The ethnographic research reveals stunning images of the demolition process in a low-income environment in contrast with the hi-rise concrete buildings that will replace the houses. With the help of MMS and SMS technology the memories of the community could be shared and the richness of the personal relationships revived.

fig.4

The examples shown above provided a thorough inside on the complexity of factors to be considered when approaching the same design brief requirements in two different cultural contexts. Moreover the understanding of the mobile technology and the project concepts developed by the students, expressed the richness of applications for which the mobile technology could be used. It is a matter of conscious choice to employ the digital tools in a meaningful way, addressing the social and environmental issues relevant for each culture.

3.Research Methodology: analyzing the iteration process using action research methods

The complexity of the subject matter in the design teaching activities, calls for an ongoing appropriation of the research methods from other scientific disciplines; moreover when, most of the times, the person carrying on the pedagogical tasks is also a practicing designer. This is why the engagement in collaborative conversations (Feldman 1999) qualifies as a valuable inquiry tool belonging to the action research methodology. Action Research is a way of learning from and through one's practice by working through a set of reflective stages that helps a person develop a form of "adaptive" expertise (Riel, 2007). In fact in the passage from the first iteration to the second one the lecturer team engaged in several sessions of reflective conversations, which led to the evaluation of the accomplished experience and the craft of the following iteration. The conversations were synchronous or asynchronous and involved the different group members either as a full group or in separates sessions. The main subjects of the discussion were:

-what the team will do and the expected outcome, the evidence to be collected – in this case related in some respect to the kind of material the students had to prepare in their deliverables.

-the evaluation of our collective action that in the specific case of the design workshop involved not only the team but also external advisors.

-finally reflecting on the action taken and understanding the critical points, the knowledge created and outlining next possible directions of action.

The level of complexity in the second case presented shifted from the interdisciplinary lecturer team that had to achieve a level of common understanding of the emergent issues to the cross-cultural lecturer-student relation that had to be constructed through shared perspectives on the subject matter of the brief.

In the examples described before the outcome of the conversations was not only the improvement of the course structure and teaching practice but also an introspective journey into the creation of common ground in a interdisciplinary and multicultural situation. The iterative process provided a reflective inquiry into the professional action of the group and the initiation of an ongoing process of adjustments. The result was the acknowledgement of the need of change in the role of the academic from teacher-researcher to teacher-learner (Noffke, 1997)

Conclusion and future work

The qualities of a digital artifact conceal the laborious effort of multicultural teams and a fair amount of negotiation within the group. Having to face a fast pace in the changes that occur in the social context and in the technological field, the question is what kind of formation could prepare the next generation of designers to face increasingly complexity of the design projects. The paper presented intended to offer a view on the educational process and the complex issues that emerge in the development and teaching of the didactical content. Using the example of the two concept design experiments situated in two different geographic locations, the paper analyzed the multiple facets of the cultural differences. If the understanding of the notion of “culture” is commonly assimilated with ethnicity at a closer look the fine layers in cultural differences include discipline, age as well as gender or religion. In the case studies presented we tackled the intricacies of the interdisciplinary conversations and the need for a mutually agreed vocabulary. It was shown how the experience gathered in the process helped the professors deal with the generational gap and the different perspectives brought by the young students that grew up in the digital era. It was shown how the learning paradigm changes from an hierarchical structure to a peer to peer one, and how the classroom becomes a physical space for exchanging ideas. Moving to the second iteration of the same brief part of the lecturer team had to confront the complexity of multiethnic communication and face the radical view change brought by the social context. The results of the both courses have shown how the above-mentioned differences reflected in the final outcome.

To draw a conclusion, it stays in the teacher's ability to properly articulate the requirements of the didactical content and to encourage the students' progress in a collaborative manner. This is particularly important when the young generation has to be prepared to do the same under the pressure in a work environment. Especially in the specialized area of digital services, in order to achieve this goal the teacher has to be ready to adopt the alternative ways of transmitting the knowledge and be prepared to adjust these methods according to the cultural component of the student group.

Insofar the experiments presented have dealt with internally homogeneous student groups coming from different ethnic contexts but sharing the same disciplinary language. For a thorough understanding of the multicultural issues, the future work should employ a similar teaching structure involving this time both ethnically and disciplinary diverse students and teachers.

Implications of Spatial Abilities on Design Thinking

Ken Sutton, University of Newcastle, Australia, ken.sutton@newcastle.edu.au

Anthony Williams, University of Newcastle, Australia

Abstract
The relationships between various cognitive characteristics and design creativity provide the necessity for consideration for design education. It can be argued that constructive perception ability that combines perception and conception and basic ability in visual reasoning composed of visual analysis, synthesis and representation in iterative nature are equally related with creative design ability. This paper reports findings of the application of a Spatial Ability measurement tool to first year design students and considers the results across three parameters, gender, University entrance Score and students' achievement in a first year Graphics course.

Keywords
Cognition, cross/trans/inter,multi, disciplinarity, Architecture, Learning

This paper reports on the application of a Spatial Ability test to first year design students in the School of Architecture and Built Environment at the University of Newcastle. The evaluation of the results gained from the 170 students provided some interesting considerations where the students' performance relative to their University Entrance Score, their performance in a Graphics based course and the performance based on gender. Firstly the paper will consider the role of spatial ability in the design activity as document in current literature.

The Relationship of Spatial Ability and Design

Design is a natural human activity present in many professions (such as engineering, industrial design and architecture). The design activity when utilised by the design professions provides a significant force for innovation and change in our societies. Despite the fact that the activity of design and the activity of science are tightly linked, design can be contrasted to science in that it is considered to be about imagining and synthesising new realities, rather than analysing and describing existing ones. Design can also be contrasted to art as it is essentially guided by human purposes and is directed towards the fulfillment of intended functions (Alexioua, et al. 2009). The distinctive nature of the design activity as illustrated by this emphasis on novelty and usefulness makes design fundamental to modern society.

Although design is customarily taken to be a high level cognitive ability, and many empirical and computational studies are focused on design cognition (Alexioua, Zamenopoulosa et al. 2009), there is to date very little research that touches on the biological or neurological basis of design (e.g. Cross, 1984, 1990; Goel and Grafman, 2000; Vartanian and Goel, 2005). On the other hand, there are many neurological studies that focus on creativity and aesthetics in art (e.g. Zeki, 1999; Martindale et al., 2007).Lloyd *et al.* (2007) argues that a major problem with a lot of research in this field is the poorly defined relationship between theory and empirical evidence. There is a sense of disconnect between the world of what design researchers talk about and the world of design activity itself. In addition, studies often come from a wide range of analytical approaches, including psychology, sociology, anthropology, grounded theory, and management studies. This diversity enriches the empirical-based study of designing but at the same time points to the absence of an agreed research methodology for design studies.

Definitions of design usually refer to the importance of "constructive forethought", or as Gregory (1987) states: "Design generally implies the action of intentional intelligence." A few common themes have emerged around the ways in which designers work and what designers do. Designers are said to (1) produce novel and unexpected solutions; (2) tolerate uncertainty and work with incomplete information; (3) apply imagination and constructive forethought to practical problems; and, (4) use drawings and other modeling media as a means of problem solving.

These themes provide us with an understanding of what designers do, however they do not inform us about the *Design Thinking* which underpins such design practice. Cross (1995, 2006) suggests that design aptitude consist of several key components including the ability to resolve ill-defined problems, adopt solution-focused strategies, employ abductive, productive and appositionial thinking, and use nonverbal, graphic/spatial modeling media.

This definition of design cognition acknowledges the particular ways that designers think, work and know. It separates designers' behavioral and cognitive processes from scientific and artistic forms of knowledge, both of which have tended to engulf design within their own epistemological and pedagogical frameworks. The unique nature of design processes suggest that there is a need to establish a distinct language and research of design, though care needs to be taken so that design is not reduced to static cognitive and behavioral categories for the sake of it (Allison 2008; see also Snodgrass and Coyne 1992).

Considering the crucial components of the design process, Kim and Maher (2008) defined the process of designing as a cognitive activity that involves the production of sequential representations of an artifact, both mental and external. Although further research is required on this matter, it can be argued that viewing design as a form of intelligence is productive; it focuses attention on design as a cognitive activity, it helps to identify and clarify features of design ability, and it offers a framework for developing further knowledge of the case for 'designerly' ways of knowing, thinking and acting.

Defining spatial ability

One of the more important cognitive components for designers is spatial ability. The concept of spatial ability refers to a complex process that designers utilize extensively in their design activity. Spatial ability has been defined as:

- the performance on tasks that require mental rotation of objects, the ability to understand how objects appear at different angles, and the ability to understand how objects relate to each other in space (Sutton & Williams 2007);
- "… the ability to mentally manipulate, rotate, twist, or invert pictorially presented stimulus objects" (McGee, 1979, p. 893);
- "… visual skills, spatial manipulation, recognizing the similarity of visual images, and imagining how visuals might appear in other orientations'' (Jonassen & Grabowski, 1993, p. 64);
- "… the ability to generate, retain, and manipulate abstract visual images (Lohman, 1979, p 188)";
- the ability to conceptualise links between reality and abstract; and
- the aptitude needed to mentally process three-dimensional images of objects (Fleisig *et al.* 2004).

Considered in their most basic form, spatial abilities form part of the visual thinking used in everyday life. Common activities, such as maneuvering a car along an unfamiliar road or rearranging furniture, require visual thinking. Spatial ability requirements escalate when higher order skills are needed as, for example, in the interpretation of technical drawings such as in building plans and in the process of translating these plans into buildings (McKim, 1980; Lajoie 2003). High spatial ability is therefore a requirement for design related activities where it is related to successful performance in real-world occupations such as architecture and engineering (Cronbach, 1970; Smith, 1964).

Spatial Ability and Design Learning

Spatial ability in the domain of design is essential for both learning and problem-solving, even when a problem is not specifically spatial (Alias et al. 2002; Roberts et al. 1997). From this it can be easily deduced that spatial ability plays an important role in design education and for the learning experiences of design students. There is a body of research (Sutton & Williams 2007; Sorby 2005; Potter & van de Merwe 2001) that indicates the importance of spatial ability in graphics-based courses and the implication of poor skills on success rates and career choices. However, despite there being a vast amount of research on spatial ability, there is very little known about the effects of spatial ability on design thinking and how it is developed through appropriate education programs. Furthermore, previous research on spatial ability tends to focus on one or two test types and neglects test types that specifically target spatial cognition relevant to disciplines such as design (Allahyar & Hunt, 2003).

Spatial ability has in the past been considered an innate ability. Recent research conducted at the University of Newcastle (Sutton & Williams, 2007) has, however, started to increase our understanding of spatial ability as well as of the effect it can have on students' performance in design related courses. A substantial part of spatial ability is 3D understanding; that is, the ability to extract information about 3D properties from two-dimensional (2D) representations (Sutton, Heathcote, & Bore, 2005). For the purpose of interpreting 2D drawings that are based on a notational system, design students require the ability to think and reason in 3D. By adopting the 3D Ability Test (3DAT), the projects reported here aimed to measure the spatial ability of students.

The studies on which this paper reports were conducted under laboratory conditions and in accordance with established psychological methodology protocols. Data were analysed using standard and appropriate statistical procedures. The underlying hypothesis was that no one spatial task is ideal when measuring the spatial performance of designers but that multiple subtests are required in order to gain a measure spatial performance. The studies used a range of paper ability tests that measures accuracy on a set of test items within a set time frame, and they assessed the validity and reliability of the 3DAT by comparing performance of the unskilled and skilled groups on both the 3DAT and the paper ability tests. This paper only reports the results of the 3DAT. In what follows, we present the approach used to investigate students' spatial ability and report on the results of statistical procedures.

Testing Spatial Ability

3DAT is a computer-based instrument that measures choice accuracy and response time. In its present form, the 3DAT consists of 12 subtests. Each subtest aims to measure separate factors of spatial ability, often referred to as elements or spatial skills. There is disagreement in the literature about the number of spatial skills that make up spatial ability.

The 3DAT is delivered on a computer using psychological experimental research software (SuperLab Pro). It consists of 72 items that are divided into the 12 subtests mentioned above. The items are all made up of straight lines and flat planes, but they vary in form and are novel in design. They were created using a CAD package (AutoCAD) and saved in bitmap format to suit the experimental software. Below is a description of the broad areas that make up the subtests:

- 2D3D Recognition: Objects are presented as orthographic and isometric projections. Participants select which type of two alternatives match a standard of the other type (Cooper 1990; Bertoline & Miller 1990). Subtests use either (A) an orthographic standard or (B) an isometric standard.
- Correct Fold: Objects are presented as an isometric projection or as an unfolded view. Participants select which type of two alternatives match a standard of the other type (cf. Blasko et al. 2004). Subtests use either (A) an isometric standard or (B) an unfolded standard.
- True Length Recognition: Objects are presented as isometric and orthographic projections (Sutton et al. in press). In one subtest, participants decide which view in a set of orthographic projections shows the true length of a labelled edge in an isometric projection (True Length Recognition A). In a second subtest, participants decide which of three isometric projections shows the true length of a labelled edge in a set of orthographic projections (True length Recognition B).
- Mental Rotation: Participants decide if a rotated isometric projection of an object matches the isometric projection of a standard or its mirror image (Metzler & Shepard 1988). The object on the left is always in the same position and is the referent. The object

on the right can be the same or the mirror image of the referent and its orientation in the XY plane can be different.

- Object Decision: Participants decide if an isometric projection can represent a 3D object (Schacter & Cooper 1990). The objects can be one of two types: the first (possible) is one where the projection can reasonably represent a true object. The second (impossible) displays some visual feature that cannot reasonably represent an aspect of a true object.
- Dot Coordinate: Participants are shown an isometric projection of a 3D Cartesian coordinate system and a text description of the position of a point in that system (Bore & Munro 2002). From four orthogonal projections, participants choose the projection that corresponds to the description.
- The tests cover a comprehensive range of different components of spatial ability and provide a detailed understanding of the spatial ability of the participants. A range of the examples of these can be seen in Appendix 1.

Results

The study, of design students spatial ability attributes has yielded a range of interesting and, in some cases significant, results. There are three areas aspects of the results that stand out, namely:

- the disparity between gender when considering spatial abilities;
- the relationship between high university entry scores and spatial ability; and
- the relationship between spatial ability and success in university design courses.

Gender

The test results show a significant difference in the performance of male and female students in relation to different aspects of spatial ability. As illustrated in Figure 1, which shows the level of performance by gender, female students did not perform to the same level as their male peers.

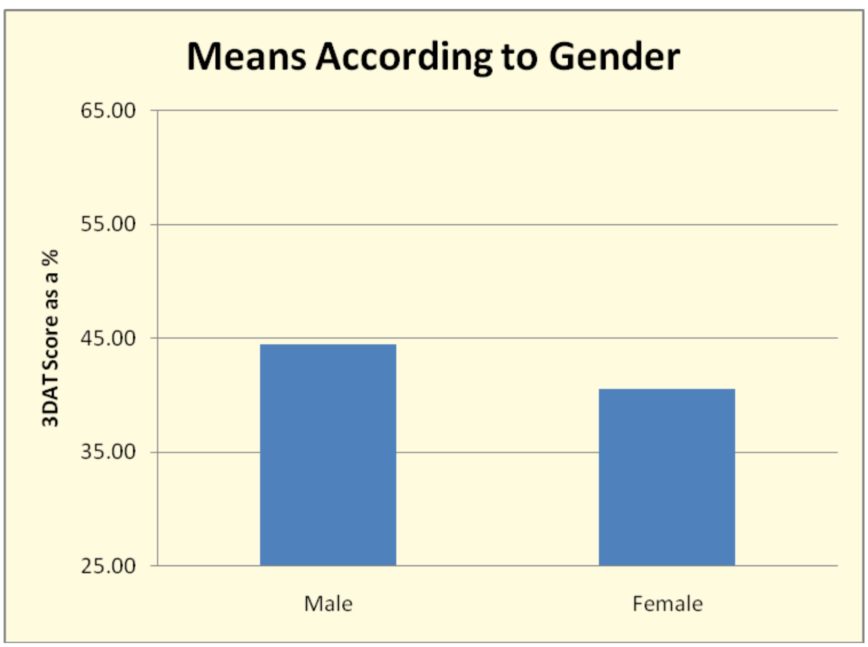

Figure 1 : Outcomes for Gender

The 12 subtests combined attained an overall mean score of 42.5%, with the males having a mean of 44.5% and females a mean of 40.5%. The female design students did not perform as well as their male counterparts on any of the singular subtests. Figure 2 illustrates the significant difference between male and female students on the 12 different subtests. This breakdown of the results makes the impact of gender even more apparent.

The performance of females across these fields is significantly lower than the males showing that females would find concepts that require such cognitive processes would not be able to function at the same level.

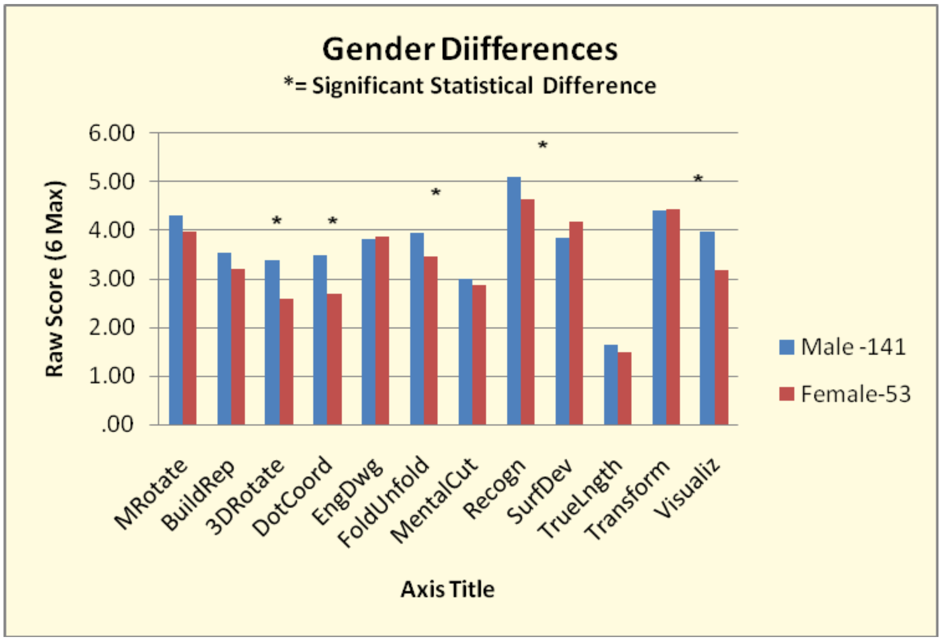

Figure 2: Performance of genders across the range of subtests

More research on this matter is required, and studies that will include other design discipline and other institutions are in planning. The results indicate that females experience more difficulty than their male peers when dealing with spatial problems and female students are likely to face greater difficulties with subjects that involve spatial ability aspects. The significant difference between male and female students across all the 12 tests raises a range of issues. It highlights the importance of preparing females for work in areas that require spatial abilities and consideration for educators as to how this divergence can best be addressed. The desire for increased female participation in the range of design disciplines at universities and in the work force accentuates the need to address this issue.

The preparation of students for university courses that require and utilise spatial ability needs to be a consideration of the secondary and perhaps even the primary school sector. Indications are that if exposed to appropriate experiences already at an early age, females are able to improve their abilities in this area.

Universities need to consider the abilities of female students when they enter design based courses or courses which would require application of spatial abilities. Curricula need to include experiences for females to that they are able to participate fully in subjects involving design or drawing and problem solving that requires spatial abilities.

The Relationship of Spatial Ability to UAI

One of the long held beliefs of universities is that high entry scores will ensure the quality of the students. Accordingly, it may be anticipated that there is a correlation between the novice designers' scores in spatial ability and their university entrance score. This assumption has a historical link with the inclusion of spatial ability type problems in traditional IQ tests. It is, however, evident from the results presented in Figure 3 that there is negligible correlation between university entry scores and spatial ability.

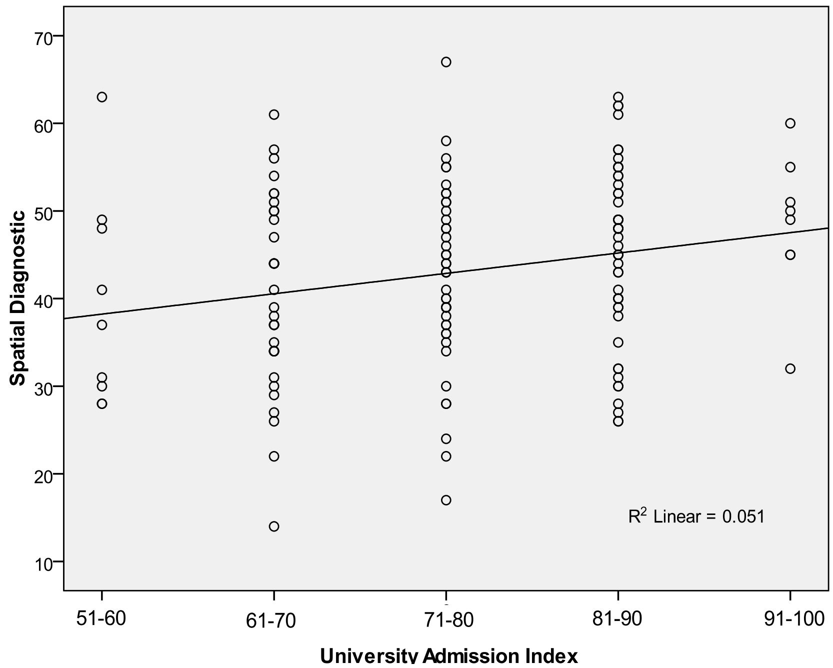

Figure 3: The relationship of the Course Score to the Student UAI

What is evidenced is that the students with higher UAI scores did score higher in the 3DAT when it is looked upon as a mean or average. But what this does not indicate is the range of the results in each grouping. This is evident where the spread of the results show that there is just as significant range of results in each university entry score deciles.

The relationship of UAI to performance in spatial ability provided some interesting outcomes. The project team expected a high positive relationship between the UAI performance and the spatial ability results. This was not confirmed by the results, which instead showed a low to medium positive relationship between these variables. This result suggests the need to consider the potential problems that students who enter university with a high UAI might have in subjects utilizing spatial abilities. Drawing and CAD courses are often part of the early curriculum structure of design programmes, requiring pre-existing spatial ability skills. Such skills are, however, not necessarily reflected in the UAI of the students. Obviously further study is required in this domain but, with such consistent results, the question must be asked about preparedness for study in some types of subjects. One factor that may impact on this situation is the experience level of the students undertaking the tests.

The material reported here suggests that students with high UAI do not perform as well as could be expected across the range of spatial ability tests. This implies that, firstly these students may not relate well to subjects that utilise spatial ability, and, secondly, that it is not possible to consider UAI as an indicator of expected performance when dealing with spatial ability problems.

The Relationship between Spatial Ability and Results in a University Course

This study investigated the relationship between course marks attained in a university undergraduate first year graphical communication course and the 3DAT to determine if the 3DAT could be used as a reasonable predictor of success in certain graphics based courses. Deno (1995) points to a deficiency in visualization skills as a reason for many design students withdrawing from graphics courses very early in their careers and considers addressing shortcomings would improve retention rates. In one detailed study (Blasko, Holliday-Darr, Mace, & Blasko-Drabik, 2004), a number of variables such as academic background, motivation, parental persuasion, verbal skills and spatial ability were tested to determine what might impact on student retention rates the most. The researchers found that scores on basic tests of spatial ability (e.g., mental rotation) were the best predictors of retention.

	BuildRep	DotCoord	EngDwg	FoldUnfold	Recogn	SurfDev	Visualiz	3DAT
Course Mark	.18*	.17*	.34**	.21**	.24**	.29**	.23**	.3**

*p is significant at the .05 level. **p is significant at the .01 level. Sample (n = 179).

Table 1: Correlation Between Arbe1100 Marks and the 3DAT and Subtests Scores

Correlation coefficients (r) for the Graphics course marks and the 3DAT and selected subtests are shown in Table 1. Correlations were statistically significant for 7 out of the 12 subtests and these are the subtests listed in Table 1. For effect size, r = .10 is considered to be low, r = .30 is considered to be medium and r = .50 is considered to be high (Cohen, 1992). Effect size is also termed practical significance and it is a measure of the extent of a relationship between two variables (e.g., Arbe versus 3DAT). Using this scale, the relationship between course marks and the 3DAT and each of its subtests shown in Table XX is in the low to medium range. Although the correlations are significant, the correlations are not strong. Using the 3DAT in its existing format at the time provides a modest predictor of success in a graphical communication course such as Arbe1100. However, the 3DAT has undergone a number of reviews and modifications in accordance with psychometric standards for test development since the testing with the participants reported in this study. These standards include item analysis, validity assessment and measures of internal consistency (reliability) of the test items in each subtest. We have confidence that the 3DAT is a more effective instrument in its current form and further testing is planned in 2010.

Conclusion

The 3DAT test for Spatial ability has now been evaluated and refined over a four year period and the statistical results gained from its use across a range of disciplines and levels in both Design disciplines and non-design disciplines has proved fruitful data but also a validation of the test. The result of the First Year Design Students doing a course in the School of Architecture and Built Environment School showed a range of interesting results across the three areas reported in this paper. Results indicate a statistically significant difference between male and female spatial performance, favouring males, and overall spatial performance showed only a marginal correlation with university entrance scores but the range of scores at any level was very broad with students at the top end of the UAI scoring very low results in the 3DAT test, inferring that the higher UAI students may not have high Spatial Skills and visa versa. Spatial performances were also compared with course results and indicate that spatial ability can be used as a moderate predictor of success in graphics based courses.

Further refinement will be undertaken of the test but more importantly the project now moves into a phase of resource development to develop online resource packages aimed at enhancing students' spatial ability and using the 3DAT as a self diagnostic stool.

Abstract

In this research we used inductive reasoning through design to understand how stakeholders in the Waterfall Way (New South Wales, Australia) perceive the relationships between themselves and the place they live in. This paper describes a collaborative design methodology used to release information about local identities, which guided the regional brand exercise. The methodology is explicit about the uncertainties and complexities of the design process and of its reception system. As such, it aims to engage with local stakeholders and experts in order to help elicit tacit knowledge and identify system patterns and trends that would possibly not be visible if a top-down expert-based process was used. Through collective design, local people were drawn together in search for a symbol to represent the meaning attached to their places/region in relation to sustainable tourism activity.

Keywords

Collaboration; complexity; identity; place branding; tourism; design and society

This paper describes how collaborative design can be used as a tool to acknowledge and engage the complexities of place branding for tourism destinations. In this research, we used inductive reasoning through a collaborative design methodology to help release information about local identities, perceptions and expectations of stakeholders in relation to tourism and how it should be promoted. In the approach we describe below we are explicit about the uncertainties included in the design process (e.g. uncertainty about a client's cognitive model to successfully brand a product) and also about the complexities of the design process and of its reception system, i.e. conflicting interests about what should tourism should bring to the places as well as the numerous relationships between the branding process and how potential visitors perceive it and choose a destination based on it. It seems to us that a methodology that aims to engage graphic designers with stakeholders and experts involved in branding destinations, hosting tourists and tourist activities can provide advances in design research. We argue that our methodology provides results that would possibly not be visible if a top-down expert-based process was used.

The main challenge of creating a brand for the Waterfall Way lied in harnessing an identity to represent a destination that does not naturally sees itself as one. The sole creation of a symbol would not necessarily help bring this identity to surface, hence the need to engage locals in thinking about their places, perceptions and expectations, and about how their lives are connected to the others (peoples and localities) along the region. We believe that the active involvement of locals into the brand design process allowed the elicitation of a regional identity that is grounded into actions and interactions, rather than simply dependant on an isolated symbol to represent them to the outside world, as suggested by Anholt (2008).

Thus, the objective of this paper is to describe a collaborative methodology that is focused on active stakeholder engagement in the design process. We also discuss the methodology in terms of the local knowledge and the conceptual regional identity it helped release. To do this we first sketch the geographical and historical conditions of the Waterfall Way in order to contextualise prospects on how the collaborative design approach was applied. Then we present the theoretical background, followed by the description of the design process, the results it produced, and a reflection about the advantages and limits of our methodology. It is outside the scope of this study to analyse the design outcomes in relation to the efficiency of their application. Further research is needed in order to survey and evaluate the current situation of the tourism activity in the Waterfall Way region, and how it is related to the collaborative brand design work.

Geographical and Historical Setting

The Waterfall Way is located between the New England Tablelands and the Mid-North Coast of New South Wales, Australia (Figure 1). It is known for its variety of landscapes set in a relatively short distance (approximately 250 km), showcasing significant diversity in climate, wildlife and culture. In addition, the region is privileged with rich stories concerning indigenous culture and pioneering history, as well as collections and festivals of art and music reflecting the painters, poets and scientists who have frequented the region over almost two centuries (Atkinson, Ryan, & Davidson, 2006; Hassall, 2008; Haworth, 2006; Kane, 2007; O'Loughlin, van der Lee, & Gill, 2003a, 2003b; Pigram & King, 1977).

The area is called “Waterfall Way” due to the pre-existing name of the road that links the Bellinger Hinterland, up the mountain through to the University town of Armidale, administrative capital of the Tablelands. Numerous waterfalls pour over the escarpment and run down the deep gorges through which the rivers reach the sea creating the so-called ‘falls country’ which has long been a scenic tourist attraction. While tourism activity exists in the area, it has always been scattered and disparate, with the places along the corridor usually competing for visitors and business (O'Loughlin, et al., 2003a, 2003b; Pigram & King, 1977).

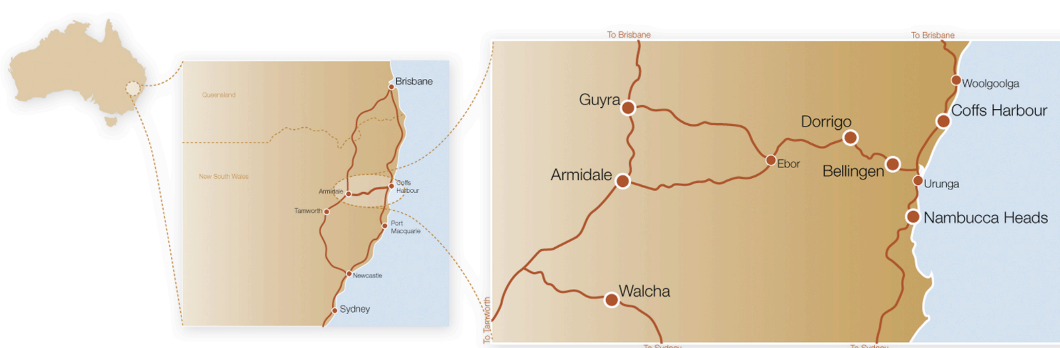

Figure 1 – Location map of the Waterfall Way, NSW, Australia (Taboada, 2009).

Local initiatives have emerged along the years envisioning an increase in tourism activity that could bring new economic possibilities to the communities in the area. In 2002 an initiative to build a long distance walking track along the Waterfall Way was identified as a way of unleashing the tourism potential of the region. In response to this initiative, a Concept Plan and Feasibility Study were developed at the time in a partnership between the New England Ecotourism Society and the University of New England. Among other strategic recommendations, these studies pointed out the need to create a shared regional destination brand to represent and promote the whole region as one, instead of promoting parts of it as it has been traditionally done (O'Loughlin, et al., 2003a, 2003b; O'Loughlin, van der Lee, & Gill, 2004).

Branding a destination is more than simply creating an image for a product (Anholt, 2008; Anholt & Hildreth, 2005; Marzano, 2006; Morgan, Pritchard, & Piggott, 2002, 2003; Pike, 2005). It involves a process of creating meaning for the place/places being branded; meaning that will impinge on the place not only through the new tourist activity that it may bring, but also on the way local people act and see themselves and their places (Hough, 1990; Taboada, 2009; Taboada, Haworth, & Spence, 2008). A new symbol alone for the Waterfall Way is not able to change its reputation. It requires, proper institutions, policies and collective actions to create a new place image in the minds of the outsiders (Anholt, 2008).

Therefore, in accordance with Morgan (2002, 2003), Pike (2005) and Marzano (2006), destination brands should start from inside out, rather than the opposite. Local people should be the drivers and owners of the strategic solutions created during the process so that the new “brand” can be in line with and support their actions and ways of living, resulting in collective will to change actions and ways of living in order to support the newly created brand.

Theoretical Background

What Morgan et al. (2002) describe as the challenges of branding places (multiple stakeholders, little management control and destinations being normally under-developed identities) can, in fact, be seen as points of advantage if we understand places/destinations as complex emergent systems with flow-on effects on the governance systems of the region. Through this perspective, the multiplicity and diversity of stakeholders can enhance the capacity of interpretation and understanding about the place; “little management control” may open doors for self-organising actions to emerge, and “underdeveloped identities” can be a good blank canvas to bring people together around catalysing a latent regional identity.

The background theories we use in this research are complex emergence (Holland, 1998; Johnson, 2004; Nova Science Now, 2007) and systems thinking (Ackoff, 1960; Angyal, 1941; Capra, 1982; Checkland, 1999; Jackson, 2003; Senge, 1990; Stacey, 1993) where a “system” is defined as a complex whole that emerges from interactions between its parts through networks of relationships.

The theory of complex emergent systems can be used to explore the dynamics of place and to describe the growth, development and change cycles of towns, cities, or regions. Systems tools can be applied to develop planning/designing methodologies that consider the local identity system as a whole, reflect this identity, and draw upon the self-organising characteristics of the place to implement small changes that can have broad, long-term positive impacts (Innes & Booher, 1999; Johnson, 2004; O'Loughlin, Taboada, & Gill, 2006).

Complex emergence and systems thinking approaches emphasise that actions within a system are not necessarily coordinated by a leader or leadership group (transformational leaders may be key factors in catalysing emergence). Rather, they unfold from the actions of individuals who follow certain system embedded rules of behaviour, normally defined by survival / instinctive needs (physical or social). “Individuals and like communities observe, inform each other and develop adaptive responses; they swarm, re-think and cluster”, to form their own individual identities (O'Loughlin, et al., 2006). These identities will reflect on the system behaviour as a whole and will determine the kind of interactions the system will attract as well as its evolutionary pathway.

Additionally, complexity theory is concerned with uncertainties rather than certainties in the systems’ behaviour. These views engage with our postmodernist approach where we acknowledge that there are multiple interpretations of the world and that not much can be predicted in the long-term (Capra, 2002; Castells, 1997; Crotty, 1998; Gadamer, 2004; Healey, 1997; Searle, 2005).

Designers create and deliver their designs into this complex setting. Destination branding, the focus of this paper, has specific demands and challenges that differ from branding other kinds of products, and that reinforces its complex character. (Anholt, 2008; Morgan, et al., 2002, 2003; Taboada, 2009). It deals directly with the systems’ physical and social structures, and with the interactions within the place being branded. Efforts have been made to accommodate the complexities of places into destination brand design (Marzano, 2006; Morgan, et al., 2002, 2003; O'Loughlin, et al., 2006; Pigram & King, 1977; Taboada, 2007; Taboada, et al., 2008). Most of which involve broadening the participation of local stakeholders into the branding process.

This study understands places and tourism as complex systems that involve a broad range of agents and meanings attached to them, deeply interacting with each other to create tourism experiences (Bosselman, Peterson, & McCarthy, 1999; Burns & Novelli, 2007; Jafari, 2000; Pigram & King, 1977; Robinson, 1999; Shaw & Williams, 2004). Thus, the process for developing a promotional image for a destination should take into consideration these critical interactions. Figure 2 depicts the dynamics of destination branding, showing the interactions between the hosts (who live at the place and deal with the positive and negative impacts of tourism, and build the reputation of the place) and the visitors (who are attracted by what the place communicates, and create images of their own about what it really is).

It is important to acknowledge the multiple interactions of tourism destination and the impacts its communication system has upon the host communities. These dynamics will determine if the messages released from the place genuinely reflect local values, vision, and parts of the place identity that the locals wish to reveal to visitors. At the same time, through acknowledging the complexities of place it is more likely that the actions of hosts will support and reinforce the brand messages, helping to construct a reputation for the place, rather than having businesses just applying (sometimes struggling to apply) an “empty” new symbol (Anholt, 2008, Pike, 2005 #308).

Figure 2 – The dynamics of destination branding. From (Taboada, et al., 2008).

The role of inductive reasoning in our methodology

The methodology described in this paper used design as a tool to stimulate inductive reasoning to conjecture how stakeholders perceive their place system individually and collectively. Inductive reasoning means that when we, humans, face complex problems, rather than looking for solutions that thoroughly consider all the possibilities in the system, we deal with these overwhelming amounts of information by intuitively simplifying the problem. We naturally search for patterns and “we simplify the problem by using these to construct temporary internal models or hypotheses or schemata [that are simple enough] to work with” (Arthur, 1994). We then use these internal conjectures to “fill in the gaps” of knowledge we don’t have or things we don’t understand about the problem. Subsequently, we try to find a solution based on the information we can recognise or induce from what we can observe.

In other words, instead of creating and thoroughly testing all possible variable of a hypothesis, and then generalising the answers, through inductive reasoning we unconsciously observe the world and consider what patterns emerge from those observed situations, and how can specific solutions be found. Therefore, inductive reasoning is highly context dependant and considers the fact that we never understand each and every aspect of a certain problem, but what we can do is deal with the parts, interactions and patterns we are able to reason.

This may seem contradictory to the systems approach that suggest that problems should be tackled holistically rather than through dividing it into parts. However, the individual maps we collected from participants enabled us to create a broader (and more holistic) map that can provide a better representation of the system (Özesmi & Özesmi, 2004). Mapping individual perceptions of patterns and interactions can help us deal with the overwhelming feeling of the whole at the same time as it makes us acknowledge the unknown.

In our methodology the design process was used as an instrument to help find patterns that are easier to identify and tackle strategically. In other words, the action of designing the strategy and the visual communication material for the Waterfall Way brand helped simplify the broader complex problem of understanding the region's identity. It worked as a "translation" tool that helped stakeholders make sense of their thoughts and feelings about the place system.

In the next session we briefly explain the methodology, show some of the achieved results and interpretations of patterns and interactions in relation to the places identities and to the final brand and visual communication concepts.

The collaborative design process

The branding of the Waterfall Way involved seven local shires and consisted of public workshops, one-to-one interviews, and collaborative design workshops where participants were invited to share local stories, personal views and opinions as well as to actively contribute to the brand design itself. The process can be explained in three stages: the elicitation of the local identities, the conceptualisation of the regional brand, and the delivery / implementation of the created strategies.

Eliciting local identities

This phase consisted of public workshops and one-to-one interviews. The workshops aimed to collect market information in relation to the local tourism opportunities, existing businesses and gaps. Approximately one hundred and fifty people attended the workshops and all of them were invited to take part in the branding process through the one-to-one interviews. A total of fifty-nine people from across the area were interviewed.

The interviews were unstructured (and we refer to them as 'conversations' in the remainder of the manuscript) and the starting point was the open question: 'What is special about your place?'. This question led the conversations into other reflections and considerations about the places, especially in relation to tourism activity and the positive and negative impacts it may bring to the region.

The conversations were conceptually mapped in a way that themes, ideas, opinions and the links between them were registered as they were mentioned. For each locality, the conversation maps were conflated according to common key ideas and themes and a new map was created that represented elements of the identity of each place according to the conversations. Figure 3 depicts one of these place identity maps.

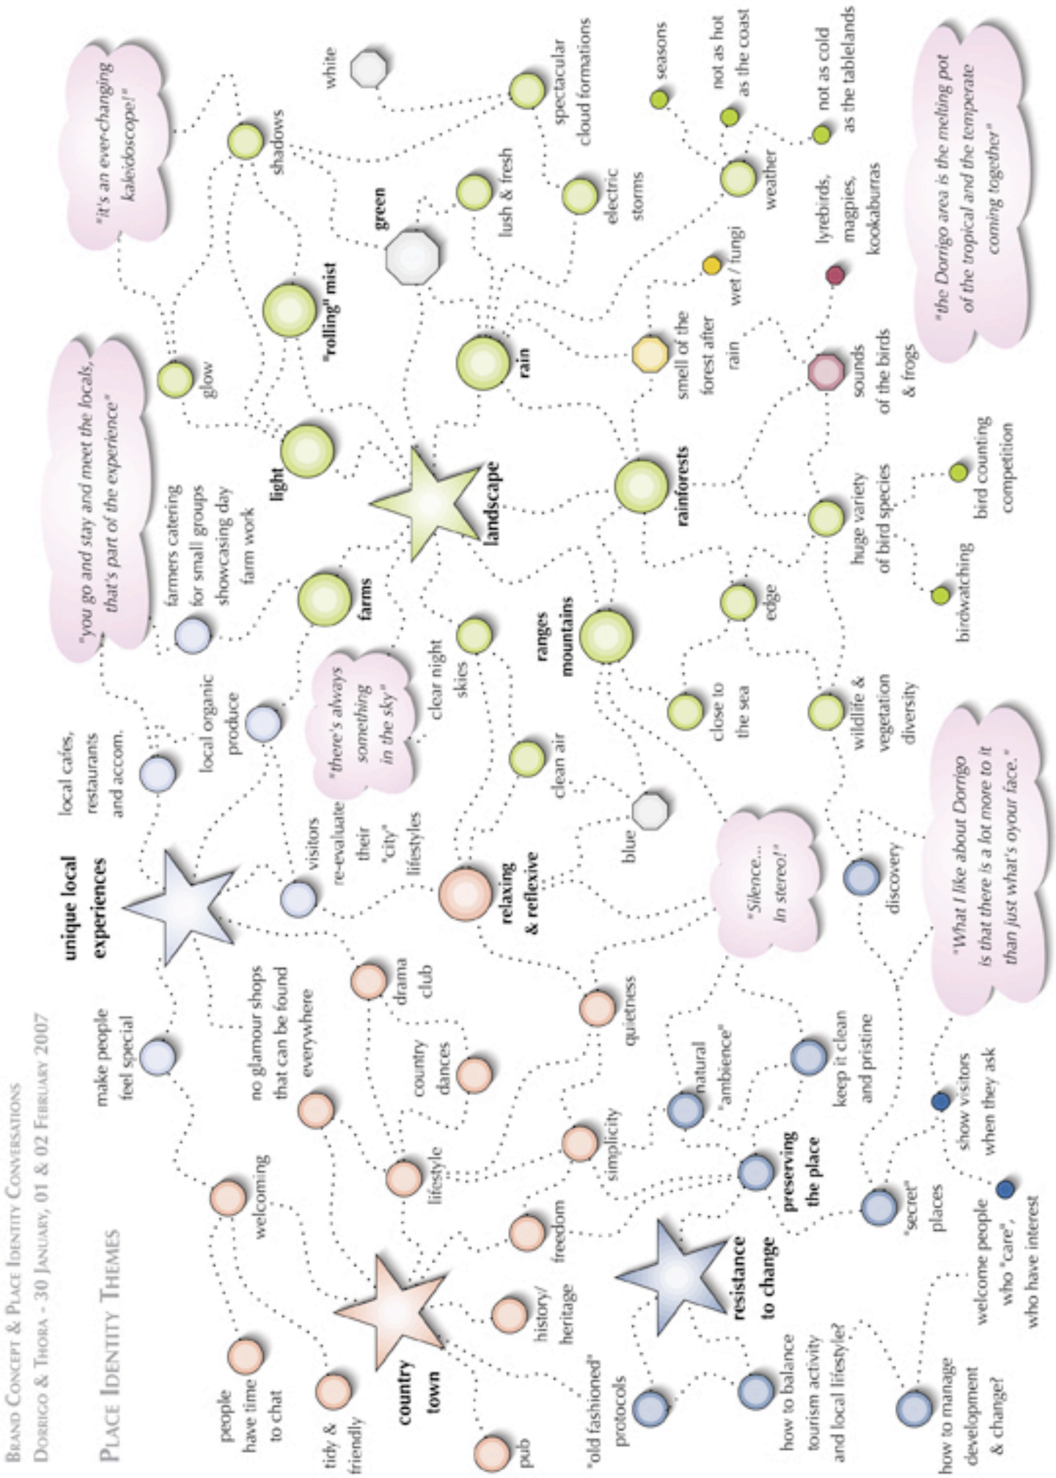

Figure 3 – Place Identity concept map created for Dorrigo, based on eleven one-to-one conversations with local farmers, dwellers and business owners.

Concept mapping was used to reason the information collected during the conversations. The maps were used as a model for tackling the complexities of local identities by representing ideas on the same ‘plan’ (a board or piece of paper). As such the insights from different people are seen equally and the interconnections between them become clear. Additionally, through visually mapping the conversations using a phenomenological approach, the feelings and impressions expressed during the interview were captured in a richer systems map, showing the interactions between concepts and the emergence of certain key themes.

At the end of the one-to-one interviews, Place Identity Reports based on the concept maps were produced and sent back to stakeholders for feedback.

Identifying a Regional Brand Concept

Nineteen people from the broader group of stakeholders were selected to participate in a two-day workshop for the consolidation of the regional identity concept. Participants were community members, tourism business owners, government representatives, academics, as well as design and marketing experts. The aim of the workshop was to collaboratively design the brand concept for the region, to create the visual communication tools for the brand (name, slogan, logo, etc.), and to outline the brand principles, ethos, and management strategies.

Despite the strong presence and informative collaboration of the experts in the workshop, their opinions concerning the creation of the brand had the same weight as the ones from all other participants. Experts and lay participants had to express their opinions in a way that all could understand, thus promoting clear and open discussions. Along with brainstorming and group concept mapping, the following approach was used to elicit information in regards to how the region looks and feels like:

A broad collection of existing publications and promotional materials of different styles, formats and colours was presented to the group in order to engage them in thinking visually about the message that needed to be conveyed for the region. They were asked to choose the items they believed would be most suitable to represent the Waterfall Way. One by one, the participants presented and justified their choices. In so doing they were indirectly telling the team which elements – type, colours, style, texture, imagery – they thought would be appropriate to carry the message of the Waterfall Way as an eco- and nature-based tourism destination. Each idea was discussed and registered on the white board, so the group could visualise the full picture of the message they were collectively designing through the exercise.

This exercise helped participants visualise and express abstract ideas and concepts that they were not used to verbalise. It allowed for them to use different channels to communicate their ideas, which were compared to inputs brought in by the broader group of stakeholders through the previous interactions with the researchers.

Later, the group engaged on the discussions around the brand principles, the regional charter that would inform the management of the brand, and some rules of behaviour for local tourism operators and visitors. The same group involved in the creation of the shared brand concept designed the brand principles and management strategies. During this part of the work the participants drafted a document describing the shared agreement on brand principles, a proposed governance structure and some management strategies.

The one-to-one conversations and workshops made it possible to collect information about people's perception of the area. At the same time, it stimulated reflection upon what is special about the places, thus reinforcing a sense of belonging. Feedback and communications between the smaller working team and the broader stakeholder group were constant and remained an essential element of trust among the participants (Figure 4). The collective process helped elicit tacit knowledge (similarly to findings from (Dray, Perez, LePage, d'Aquino, & White, 2006; Polanyi, 1967; Rust, 2004a, 2004b; Senker, 1995)), in relation to communication design and promotional strategies, from people who would not normally be involved in these practices.

Figure 4 – Scheme of public participation and communication flow during the Waterfall Way collaborative brand design process.

The collective work undertaken during the workshop helped reinforce the identity concepts initiated during the conversations by locking into a communication strategy that intends to synthesise the essence of the destination system as a whole. Table 1 outlines a summary of concepts and ideas, and how they developed from the initial conversations to the final brand concept and visual apparatus. This demonstrates the inductive reasoning in relation to the elicitation of the regional identity.

Key ideas from conversations (identity concepts)	Brand concepts from co-design workshop (image / promise)	Translation into "tangible" aesthetic elements (communication)
Diversity	**Connection**	
Diversity of landscapes	Connection with changing landscapes and environments	Contrasting combination of colours and type
Distinctive local cultures	Connection with local people,	Welcoming, familiar tone

	cultures and arts Receiving visitors as friends	Stories and quotes from locals Poetic language
The “small town” atmosphere and natural beauty of the region works as an antidote to everyday city life	Connection with nature and self, through the journey	‘Hand made’ tracing style Recycled paper, matt, soft, natural feel Use of white space
	Travelling slowly, journeying	
	“Waterfall Way: a new journey, a new story”	

Table 1 – A synthesis of the collective reasoning process: from broad identity concepts to tangible communication elements.

Implementing the brand strategies

After the strategies and visual elements of the brand were finalised, the Waterfall Way brand was presented to the public on 8 February 2008, in a specially organised event in Dorrigo. After the launch, public workshops were organised across the region in order to present the brand and all the prepared material to the local people, tourism operators and business owners who would be interested in joining the Waterfall Way sustainable tourism network. At the workshops the brand was presented and explained in detail, including its features, possibilities and rules of use. A promotional pack was given to the attendees, which contained promotional material and the Waterfall Way Sustainable Tourism Toolbox (consisting of three booklets with support information about business development, marketing, communication activities, and the specifications of use of the Waterfall Way brand. Toolkits can be accessed via the Waterfall Way Operators Website: http://www.waterfallwaytourism.com).

Discussion

This study shows that a focus shift in brand development from an external perspective to an internal perspective is possible, and that, consequently, it requires not only the traditional market knowledge regarding consumers niche markets and what goes on the minds and hearts of potential visitors, but also the knowledge of the destination itself, its attractions and sensibilities, and its peoples’ cultures, hopes and expectations in relation to tourism activity and to the visitors that are coming to their places.

The impact of the collaborative methodology in the construction of a new region and in the decision-making process

The collaborative design methodology helped initiate thinking, among locals, of how multiple places along the Waterfall Way area can be understood as one. Through acknowledging the complexities of the task, the collaborative approach encouraged the shared construction of meaning in relation to the places and stimulated the rise of one potential single identity for the region. The use of our methodology enabled the creation of opportunities for stakeholders to reconcile information, expectations and place identity issues among themselves, confirming that place identity is socially created through conversation (Dixon & Durrheim, 2000).

Engaging multiple stakeholders in the creation of knowledge – the actual development of the visual and strategic components of the brand – with sometimes divergent points of view enriches and consolidates a regional identity that becomes more coherent in relation to expectations from hosts as well as tourists. Our research was effective to better understand people's perceptions about their places, about the possible unified tourist destination, and about the role of tourism in the region. Therefore, we opine that the act of collectively designing worked well as a tool to engage the complexities of place branding and of combining diverse people, backgrounds and expectations into one potential regional vision. An applied outcome of our research was the regional brand itself.

This kind of process can be a good alternative for planning in rather complex transdisciplinary areas, such as tourism, as it allows for different views to be acknowledged, perceived and taken into consideration. Our research also reinforced the fact that not all information can be known, and that, as humans, we naturally simplify, organise and recognise patterns of behaviour. In the end decisions are made based on what we know about the system as well as on the regional social networks where information flows. Through engaging multiple stakeholders from diverse backgrounds, we increase the chances knowing more about the system, building more interactions and creative connections, and therefore, being able to make better informed decisions. Including interested parties also promotes ownership and helps spread the information around the region. This is probably a useful way to catalyse emergence about solutions to issues related to tourism and regional planning.

On another perspective, the search for a symbol naturally engages one in reflection about self, or about what that symbol is to represent. Collectively searching for a symbol to represent their social group induces people into reflective conversations about who they are, what matters, what they want to communicate about themselves, and what are their roles in building the identity of the group they are in. These reflections are an expression of inductive reasoning in relation to your own “complex” self, or, place, as is the focus of our study.

During the work, participants learned by doing. Learning happened at a reflective and reflexive level. Reflection means that participants learned from each other, acquiring information and experience from outside. Being reflexive means that they learned from themselves by becoming conscious of knowledge they did not realise they had, while trying to express and explain them to the others. Experts and researchers learned about the places and the participants during the workshops and interviews. This dynamics helped create a level of tolerance that allowed for informed decisions to be made based on agreement and shared understanding, rather than consensus.

The collaborative design process also originated some challenges such as the change of roles of the designers, and the dealing with multiple mental models involved in the decision-making process. The role of the brand specialist and graphic designers changed significantly as most of the decisions were to be made by the group instead of an expert (e.g. graphic designers, planners). Consequently, leaders and experts became catalysers, interpreters and/or facilitators, rather than making the final decisions as is usually expected from them. This turned out to be one of the main challenges in applying the collaborative design methodology, as the graphic design team was disempowered to a certain degree.

If on the one hand some power was taken from the designers, on the other hand the close interactions with stakeholders gave another dimension to their work. Instead of designing the brand for the locals, the team designed the brand with them. As expressed by Rust (2004a), this kind of direct hands-on research allows users to “feed directly into designers' thinking and feed their tacit understanding of the people they are designing for". The change of roles helped the designers explore a more holistic view of the effects of their work on the region and its people.

Another challenge encountered during the application of the methodology was the fact that, in order for the collaborative approach to flow genuinely, the management of the design process needed to rely less on control, and more on facilitating the emergence of multiple local leaders. As a consequence, the process of making decisions changed: instead of having a single person or expert group deciding on design solutions, there was a large group of empowered stakeholders making decisions.

Our methodology was effective in understanding how participants perceived the Waterfall Way as a regional tourist destination at the same time as showing what the important links are to make it work according to tourist hosts' expectations. The design of the regional brand was a consequence of this understanding and an applied outcome of our research. The openness and flexibility of our approach comes at the expense of long periods of training to draw the concept maps during the conversations and subjective interpretations of the interviewer about how the interviewee's cognitions are perceived. Other approaches, such as the use of multi-step fuzzy cognitive mapping (Özesmi & Özesmi, 2004), qualitative modelling (Dambacher, Luh, HW, & Rossignol, 2003; Levins, 1974, 1988; Puccia & Levins, 1985) may be used along with our approach, in future research where they can all be combined and compared.

Conclusions

The main conclusions of our research are summarised as follows:

Collaborative design proved to be efficient and to facilitate real solutions in terms of the brand concept design. It is an example of inductive reasoning being used through design to tackle the issues of planning for sustainable tourism. Furthermore, by understanding destinations as complex emergent systems, we acknowledge that there are uncertainties in the "picture" provided by the conceptual identity design, and that decisions need to be made based on what we know and are able to understand about the system under a certain context.

Involving stakeholders in the design processes is not an easy task. It is time-consuming, hard to manage and highly context dependent. However, the power of this kind of collaborative process applied to brand design is the collaboration between lay people and experts in the design and decision-making processes. This collaboration led to reflections upon their own roles in the process of creating and marketing a tourist destination. The impact from this kind of collective work can be perceived on the final product as well as on the realities of people involved in the process.

Future work is needed to evaluate the brand in terms of its acceptance, recognition and usage by all concerned. The methodology can be further refined and may be applied in other areas of social research, in order to continue testing the efficacy of collaborative design as a tool to help engage complexity in constructing social identity and meaning.

Author Biography

Dr Manuela Taboada

Manuela is currently a lecturer in graphic design at Queesland University of Technology, in Australia. She completed her PhD at the University of New England in 2009. Originally from Brazil, she graduated in Computer Sciences at Salvador University in 1998, and in Visual Communication and Industrial Design at Federal University of Bahia, in 2004. Manuela has worked with a variety of graphic design and branding projects in Brazil and in Australia. Her research focus is on the social role of design on fostering change and reinforcing local identities and sense of place.

Dr Leo Dutra

Dr Leo Dutra is a marine scientist with experience on biology and ecology of tropical marine invertebrates, marine geology (sedimentology), and ecosystem modelling for multiple-use management. He has worked extensively in Brazil, East-Timor and Australia on issues related to coral reef ecology and geology, tourism planning and coastal zone management to assist in the design of management strategies to improve the health of waterways and the coastal zone. Leo is also the convener of the CSIRO catchment-to-coast community-of-practice, a group composed of scientists working on catchments, estuaries and the coast who are willing to share experiences and learn from each other in this complex domain.

Dr Robert Haworth

Robert Haworth is Adjunct Fellow of Geography and Planning in the School of Cognitive and Social Sciences at the University of New England, Armidale, New South Wales. He has researched and written extensively about the geomorphology, archaeology, and environmental and cultural history of the New England and adjacent regions. He has also worked in both advertising and other communication media in Australia and Britain.

Dr Rebecca Spence

Rebecca is currently the Director of Peaceworks and a parttime Senior Lecturer in Peace Studies at the University of New England.   She has an international reputation as a peace/conflict specialist. She has particular expertise in the following areas: Conflict sensitisation of development programming, Gender and peacebuilding, Peacebuilding after armed conflict and Community reconstruction processes.

The Design and Development of Microcab

Michael Tovey, CEPAD, Coventry University, UK

Abstract

The combination of the global economic crisis and the issues associated with reducing our carbon consumption has made the Microcab project both timely and relevant. The company is essentially a spin-out from Coventry University's design expertise. The project has been to design, develop and test a sequence of vehicles for urban transport using low carbon hydrogen fuel cell technology. The key process issue is whether a relatively straight forward and familiar design process can be followed up successfully by a design product evolution and testing programme which is complex. Its complexity is in its dependence on various funding sources, in its engagement with a changing array of development partners, and in its relationship to a number of public sector programmes.

Keywords

Industrial design, Eco-design, Sustainable design

The Microcab project is led by John Jostins who is located in the Centre of Excellence for Product and Automotive (CEPAD) at Coventry University. Established as the result of a successful bid to HEFCE's Centres of Excellence for Teaching and Learning initiative in 2005, CEPAD now has an expanded remit. It encompasses both pedagogic development and applied research, seeing these activities as mutually reinforcing. The author, as Director of CEPAD, has taken a direct role in managing and ensuring an appropriate context for the Microcab project.

The Microcab Project

The intention in the Microcab project has evolved during its development. When it was initiated in 1996 the vehicle concept was considerably further from the mainstream than it is now (in 2010). It can be summarised for the current phase of work as:

- To design and develop a vehicle for urban transport using low carbon, hydrogen fuel cell technology.
- To manufacture and test a number of vehicles

The design concept is a vehicle with good environmental characteristics. It incorporates a powertrain architecture which is modular and full optimisation of systems and components has not been attempted. Technology and component choices have been dominated by considerations of availability, practicality, robustness, affordability, and avoidance of the risks associated with emerging exotic technologies. The original inspiration for this extended piece of work came about as a response to urban congestion problems, particularly in large cities. The intention has been to design and prototype vehicles employing lightweight structures powered by means other than the internal combustion engine. A range of electric drive systems has been adopted for propulsion, initially using battery and solar power, but subsequently adopting hydrogen fuel cells.

Whole vehicle design has always been at the heart of the project, with specific purposes and users in mind (eg. taxis). This has allowed all aspects of the vehicle to be re-evaluated including developing a more sustainable drivetrain. There are two aspects to the current approach:

1) Low carbon footprint designs for vehicles can be different from those currently in use. Patterns of usage will probably change and this is an ideal time to offer up alternatives.

2) New drive systems offer new ways of packaging components in and around vehicles and therefore offer potential for better use of the space.

The project has grown steadily in scale allowing a range of experiments with alternative vehicles, fuels and drive systems. As global environmental concerns are being taken extremely seriously by governments and industry leaders, the future of individualised transport products is likely to be in the integration of engineering and design innovation. From that, new products could emerge for mass use.

Approach Used

As the Microcab project has developed, numerous partnerships with academic institutions, companies and other organisations have been formed to create a network of support structures to test particular concepts. Throughout its development the project has been led by John Jostins, who divides his time between running the Microcab company and as a professor at Coventry University. He has a background in motorsport and special effects for film and television. His original motivation to develop what became microcab was a very personal response to the frustration of experiencing the difficulties of urban travel.

John Jostin's role throughout, has been as:

- Project Owner
- Concept Designer
- Project Manager

For the intial design work John was joined by Mark Dickins (a Transport Design graduate) who did the concept design styling drawings. He produced design sketches under John's direction, acted as a sounding board, visualiser and then model-maker. This core staffing of two produced a 1/4 scale chassis model, followed by a full size automotive clay model, from which a grp shell was taken.

The earliest physical model (1/4 scale) on show at the Oxo Tower, South Bank, London. It was intended to be a pedal/electric hybrid.

The original concept was of a pedicab type trike. This was a pedal-electric hybrid which weighed 150 kilograms. Jostins was able to secure private investment of £20k which was sufficient to pay for the construction of a prototype. By August 1999 a full sized working vehicle which was half pedal-powered and half electric had been produced. To do this Jostins used industry contacts and called in favours from the cycling industry and others. Honda for example provided the electric motors. The prototype design was exhibited at Interlaken in Switzerland.

Interlaken, Switzerland for the European Velomobile Symposium - the first full size working prototype. Battery electric with pedal assist.

Experiments were carried out with three different drive trains and eventually single motor system was chosen. The tiny battery pack weighing 28kg was not very effective and hydrogen fuel cells were examined as an alternative as they are lighter and better for re-fuelling.

In order to be able to apply for public sector funding to develop the vehicle a project team was created. Zytech had worked in Coventry with LTI and added necessary fuel cell expertise. John Piper was a former colleague of John Jostins from the Williams F1 team, who brought chassis design expertise. The team was thus expanded to:

- Microcab
- Zytech Power
- Piper Design

This enabled an approach to be made to the UK Government for funding. The basis was a claim that at a weight of 180kg for the revised design the vehicle had an extremely light chassis which provided the appropriate framework for developing hydrogen fuel cell hybrid propulsion. The application to the DTI (Department of Trade and Industry) in 2002 for a SMART innovation award was successful.

The first prototype was reworked with a new, lighter, moulded carbon sub-frame, and a single motor geared up and driven through a differential shaft.

Development was still a little precarious and uncertain as Zytech went bankrupt and had to be replaced by Intelligent Energy to sustain the fuel cell expertise within the team. In order to provide greater stability Coventry University became an equity partner in the company, and provided development and funding support.

2003, working in the new Bugatti building facilities at Coventry University, a styling exercise, led by Geoff Matthews, looked at a possible new four wheeled Microcab design.

This stage in the development of Mircocab was based on 4 core partners:

Microcab Industries Ltd.,

Coventry University,

Piper Design,

Intelligent Energy

In 2004 this partnership provided the basis for an application to the DTI for a Research and Development grant. £145,000 was awarded to develop the principles of the previous prototype. Now numbered H4 the project commenced in April, 2004 lasting for 15 months, completed in July 2005. As with the preceding design, the H4 was an urban, ultralight, city speed, 'short hop' taxi or freight vehicle. One important consideration in the design was that vehicle should be able to carry a wheelchair-bound occupant.

Context for the development

Since the initial idea for Microcab the context for its development has been one in which it has moved closer to mainstream concerns. This has included the developing body of published advice and opinion which was considering alternative energy sources for vehicles, and various configurations and drive trains. Samples of such developments give an indication of the direction they have taken.

In 2002 Jeong et al proposed that the most promising vehicle engine that could overcome the problem of present internal combustion is the hydrogen fuel cell. Fuel Cells are devices that change chemical energy into electrical energy without combustion. Pure fuel cell vehicles and fuel cell hybrid vehicles (Fuel cell + battery) studies indicate that hybrids which can capture regenerative braking energy look most promising. Hybrid vehicles are superior to their non-hybrid counterparts (Jeong, K.S., and Oh, B.S. 2002). Hybridizing a fuel cell system with an energy storage system offers an opportunity to improve the fuel economy of the vehicle through regenerative braking and possibly to increase the specific power, and decrease the cost of combined energy conversion and storage systems (Ahluwalia, R. K. and Wang, X., 2005).

Fuel Cell vehicles will be quieter and will have lower non-GHG tailpipe emissions, but will be more expensive and will require new infrastructure for vehicle manufacturing and maintenance, and for producing and distributing hydrogen fuel- thus making rapid acceptance and market penetration more difficult (Weiss, M.A., et al 2003). Automotive manufacturers and suppliers are investing heavily in the development of fuel cell systems as potential power sources for light duty vehicles. At this point fuel cell vehicles promise to be far more efficient, clean and truly zero emission with the only by-product being water (Lee, H. S., et al 2003). Reports on trials with Scania Hybrid PEM Fuel Cell Concept Bus, using hydrogen stored in cylinders on the roof concluded that such vehicles have big potential, but that there are issue to be considered, relating to durability, lifetime, costs, vehicle and system optimisation and subsystem design (Folkesson, A., et al 2003).

Battery and hybrid vehicles are seen as today's sustainable mobility solutions, preparing a future shared with a hydrogen economy. The summary report of the EU High Level Group for Hydrogen and Fuel Cells, presented in June 2003, developed a vision of the contribution that hydrogen and fuel cells could make to the realization of sustainable energy systems in the future. However as a long term vision (2000-2050), there is a need to take a strong action in the short and medium term to address current environmental and energy concerns (Mierlo, J. V., Maggetto, G 2005). Because of their high efficiency and low emission potential, fuel cell vehicles are undergoing extensive research and development. However several major barriers need to be overcome to enable a hydrogen economy. Because fuel cell vehicles remain expensive, very few fuelling stations are being built. To try to accelerate the development of a hydrogen economy, the auto manufacturers are developing a hydrogen fuelled internal combustion engine as an intermediate step (Kwon, J., et al 2006).

The hydrogen era is foreseen following the European research programme in a time horizon of 2020-2040. There will clearly be a choice between the electron economy using directly produced electricity, and the so-called hydrogen economy, which leads to the introduction of intermediate hydrogen production, transport and distribution. For passenger transport/ delivery vans there is a big time gap between the looming oil shortage and 2020-2040 for the hydrogen economy. Hybrids and electrics are needed to fill the gap and the better they perform the more questions there are over hydrogen fuel cell vehicles (Mierlo, J. V., et al 2006).

Fuel cells are projected to have energy efficiency twice that of internal combustion engines. They can start in freezing conditions without significant deterioration. Hydrogen storage systems for vehicles are inadequate to meet customer driving range expectations without being intrusive. The transition to hydrogen-powered fuel cell vehicle is projected to occur over the next 10-15 years. In the interim fossil fuel consumption will be reduced by increased use of battery gasoline hybrids (Chalk, S. G., and Miller, J. F., 2006).

Various fuel cell vehicles have been designed and prototyped by a number of companies - according to one source some 40 vehicles by 16 companies (TUV SUD). These vehicles have not become available for evaluative scrutiny and are not available at an affordable cost for public sector testing.

In this context the argument for the design, development and testing of vehicles employing fuel cell technology, and available for public sector scrutiny in universities and government agencies, becomes fairly compelling. There was a need to respond to this requirement, which the Microcab group endeavoured to meet.

Design Development of Microcab

For the current version of Microcab the overall vehicle design was developed under John Jostin's leadership. For the vehicle re-design Jostins engaged Automotive

Design graduates Adam Fairless and Alan Barrett as concept design/stylists. They were responsible for:

- Design: styling sketches
- CAD
- Ergonomics rig
- Full size styling buck

The full size styling model was sculpted and milled in Coventry University's Bugatti automotive design studio. It was used to facilitate design approval sign-off.

This new vehicle design was exhibited at the Grove Fuel Cell Symposium in London in October 2005 (Jostins J., 2007)

The next stage in the development of Microcab was concerned with addressing the engineering and operational requirements of the design. The need was to move from a concept design with a good external appearance and sound spatial ergonomics which was functioning as a rolling prototype, to a vehicle design with proven technical capability. This required considerable development. The UK National Engineering Laboratory in East Kilbride needed a test vehicle to sustain their programme in 2006, and Microcab was able to fill the gap. Their test results confirmed the viability of the design, and clarified the direction for future technical development.

However depending on the serendipity which had made available the East Kilbride facility was not a very secure strategy. There was a need for a greater focus on making the company viable, and on collaborative arrangements to sustain intellectual and financial investment. At this point Mike Wade joined as an equity partner bringing expertise in small manufacturing company start-ups, and investments.

The necessity for this was made apparent with the loss of Piper Design from the group due to bankruptcy. As a number of Piper's engineers then moved to Delta Motorsport Ltd, it was appropriate for Delta to replace Piper in the core consortium. This meant that individual contacts could be maintained.

The key to the next stage in Microcab's development was Wade's bringing a second University into the programme. His approach was to the Chemical Engineering Department of the University of Birmingham. In a programme of research led by Professor Kevin Kendall the department was already investigating CHP (combined heat and power) and canal boat propulsion using hydrogen fuel cells. They were quite amenable to extending their activities to encompass Microcab. However for this to be feasible a further funding source was necessary.

Design: technical details

What was needed for Microcab was that its technical details be developed and tested through running protypes. Its technical package consisted of its powertrain and the vehicle structure.

The powertrain is a fuel cell series hybrid, with a relatively small battery pack to deal with power transients and provide for short periods of operation on stored energy. (Tovey, M. 2009). This enables adequate performance with minimal fuel cell power output, giving benefits in cost and simplicity. If fuelled with hydrogen generated from renewable sources, this gives a truly zero-emissions fuel cycle. Current vehicles, designed for limited low-speed operations only, use the following components:

- Dynetek carbon-composite cylinder storing 0.63 kg hydrogen at 350 Bar
- Ballard Nexa fuel cell system, producing ca 1.5 kW at 24 V, with DC/DC converter
- Sealed lead-acid batteries 48V, approximately 35 Ah

- GE motor (wound, 48V DC, brushed, separately excited) rated at 4 kW continuous, 11 kW peak
- GE electronic drive, including simple regenerative braking (rear wheels only)

The vehicle structure has been designed with a frame holding lightweight GRP panels and vacuum formed plastic parts. The intention is to minimize weight with a target of 450kg. The current test vehicles have steel chassis components partly in order to allow modifications as required, and as a consequence are heavier. It has been necessary to use standard parts from production vehicles for reasons of availability and cost. The chassis has a sandwich structure with the steel frame assembled around it to contain the fuel cell, motor and hydrogen tank.

The original intention to use regenerative braking has not been retained in the current prototypes. The intention was to recover power from deceleration but this proved to be unsatisfactory in practice. This was because short pulses of high current generated on deceleration could not be absorbed by the batteries.

As anticipated, issues related to hydrogen safety required considerable attention to design details. There is a requirement for leak testing and monitoring, for avoidance of any accumulation of gas, and for other measures to comply with the draft European safety standard for hydrogen vehicles.

Fuel economy and range of existing vehicles are compromised by low efficiency of the mature, off-the-shelf fuel cell, the extra power converters, and the motor. However general performance has been fully satisfactory for trial purposes.

The limited budget, requiring maximum use of standard components and the prohibitive costs of carbon fibre, engineering and tooling have required major compromise on weight, with vehicles weighing approximately 650 kg against the original design target of 450 kg. The effort required for electrical integration of the fuel cell and other vehicle systems was underestimated and a wide range of electrical system revisions has taken place. Overall packaging was relatively straightforward, because the vehicle design is spacious, the all-electric powertrain facilitates a modular approach, and the low energy requirement results in small sizes of fuel cell and batteries (Tovey, M., 2009).

Birmingham University Project

The Birmingham Science City Project is part of the UK Government's Hydrogen, Fuel Cells and Carbon Abatement Technologies (HFCCAT) Demonstration Scheme. The scheme is designed to address key energy priorities of cost competitive carbon emission reductions and increased security of supply. A number of projects are being funded throughout the country. The Birmingham scheme is also supported by the regional development agency, Advantage West Midlands (AWM).

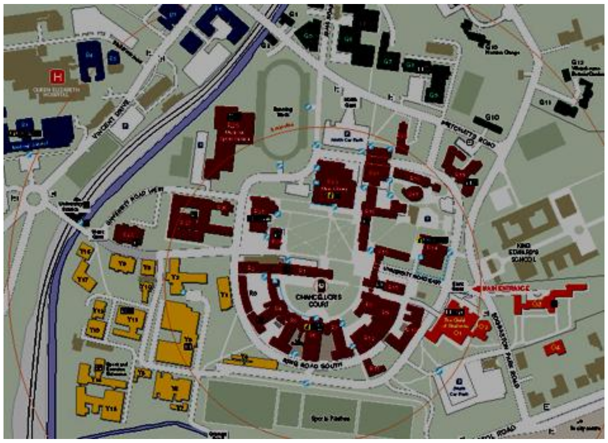
HFCAT project proposal created with funding support from three sources;

Science City (pays for vehicles)

AWM: hydrogen fuel station.

DTI: project funding.

The Birmingham project includes commissioning Microcab to supply and operate 5 of its vehicles on the Birmingham University Campus. It provides a good test arena for evaluating the vehicles on real roads where there is mixed use, but off the public highway. Part of the facility is a dedicated hydrogen fuel station



the fleet of five vehicles at the University of Birmingham

The project began in November 2007. The plan has been to investigate the use of the vehicles through various cycles of operation. A number of tasks have been trialled including postal and food deliveries, taxi services for visitors and estate duties. The intention has been to produce results which would allow comparison with the types of standard diesel vehicles currently used for such operations.

The filling station which has been installed contains hydrogen at 400bar. The filling operation was planned to take 4 minutes to pump 0.6kg of hydrogen into the carbon fibre/aluminum core composite storage tank at 350bar. The hydrogen is fed to the 1.2kWe Ballard Nexa PEMFC system which provides current direct to the motor and/or recharges the batteries to give a predicted 100 mile range. On campus that should be sufficient for 5 days of operation, making refuelling a weekly task.

The project which is now 50% completed involves 23 separate work packages, delivered by 8 separate organisations:

1. Microcab Industries Ltd
2. RDM Ltd — microcab consortium.
3. Delta Motorsport Ltd
4. The University of Birmingham – demonstration site.

5. Coventry University
6. Westfield Sportscars Ltd
7. Potenza Technology Ltd
8. Tempus Developments Ltd

The early work was reported on by Kendall, Pollet and Jostins (Kendall, K., et al 2008). They identified the basis in the development of hybrid fuel cells in previous work (Kim, M. J., and Peng, H., 2007), (Schell, A., et al 2005), (Lin, C., et al 2006), (Vahidi, A., et al, 2006).

In a recent technical paper Kendall et al described the Microcab test fleet test as the largest such trial in England to date. Their conclusion was that the hydrogen filling of the vehicles with green hydrogen could operate successfully on the university campus. Vehicle performance was good in terms of acceleration, cruise speed and range, satisfying the campus drive cycles. However the regenerative braking system was not adequate and needed improvement. Further optimization in terms of efficiency and reliability was required and a more powerful hybrid drive train would be needed for the ECE15 urban drive cycle (Kendall, K., et al 2010) and (Kendall, K., 2009).

Further Projects

There is regional support for further development work on the vehicle design through the regional development agency Advantage West Midlands. It is funding a research and development programme for small companies who are involved in the development and manufacture of vehicles and members of its Niche Vehicles Partnership. Microcab is a member. It is managed and led by CENEX, the Centre of Excellence for LowCarbon and Fuel Cell Technology, and supported by Coventry University, which both hosts the project and delivers the programme.

The Niche Vehicle Network consists of some 37 organizations. Microcab's development programme involves 3 of them in collaboration, along similar lines to the Birmingham project.

Microcab

RDM Automotive

Delta Motorsport

Further, through the Technology Strategy Board, the UK Government has announced that it is supporting CABLED (Coventry and Birmingham Low Emissions Demonstrators), as part of its Low Carbon Vehicle Demonstrator Programme. This will be delivered as 8 projects nationwide featuring 340 vehicles showcasing a range of technologies. About a third of these will demonstrated in CABLED and Microcab has been asked to provide 10 fuel cell vehicles for the trial, the only hydrogen vehicles in the scheme. This builds directly on the Hydrogen Fuel Cell and Carbon Abatement Technologies (HFCCAT) project at UB and extends the reach of it to Coventry.

Conclusions

The initial design process for Microcab has been successful. The complex design development programme has clearly had some success. However it is incomplete and there is a difference between the successful completion of its various programmes, and the overall achievement of a successful and proven product.

A key characteristic of the project has been its dependence on public sector funding. Its being timely and contributing to longer term future rather than short term economic returns has been an important component in arguing for such support.

The organizational components which have been crucial to its survival are probably twofold:

- The role of John Jostins as the project manager has been essential.
- Maintaining a small core of collaborating companies to design and make the vehicles has ensured a manageable approach.

The medium term future for Microcab will depend these elements being maintained.

Author Biography

Professor Michael Tovey

A graduate of the RCA, Professor Mike Tovey was in industrial design practice prior to entering education. In 1973 he joined the institution which was to become Coventry University, as a lecturer in industrial design. He was appointed to Head of Industrial Design in 1985 and in 1989 was made Dean of the Coventry School of Art and Design. In 2007, he changed position to take on the University-wide post of Director for Design. Professor Tovey is responsible for developing courses and applied research in design across the University and is Director of the Centre of Excellence in Product and Automotive Design (CEPAD).

Developing a Pedagogic Framework for Product and Automotive Design

Michael Tovey, Director, CEPAD[1], Coventry University, UK

Karen Bull, Deputy Director CEPAD, Coventry University, UK

Jane Osmond, Senior Research Assistant, CEPAD, Coventry University, UK

Abstract

An approach to industrial design education based on 'transformative practice', which has the ambition of equipping students with a passport to enter the community of professional design practice, is described. This is mapped onto a version of the designerly way knowing which is illustrated as an analysis-synthesis model involving a conversation between the two cognitive modes, which are emphasised in various teaching activities. The uncertainty threshold, which is inherent in this, is both essential and routine, but can present problems for some students. The development of a re-designed course programme devised with a more flexible project delivery arrangement to accommodate these issues is briefly described. Its effectiveness is assessed through focus groups and feedback from early results is giving a broadly positive response to the new scheme.

Keywords

Project-grounded research, design process, industrial design, creativity, design practice, learning, reflective practices, pedagogy.

This paper outlines a particular strand of pedagogic research undertaken by the Centre of Excellence for Product and Automotive Design (CEPAD) at Coventry University. Established as the result of a successful bid to HEFCE's Centres of Excellence for Teaching and Learning initiative in 2005, CEPAD initiated several strands of pedagogic research, all of which are underpinned by Wenger's community of practice theory. Specifically the research focused on the journey of industrial design students towards successful entry to their professional community of practice. From this starting point, research was undertaken into identifying threshold concepts in design – those crucial transformations that turn students into designers equipped to engage with their professional community. This identification was then used to develop a pedagogic framework for product and automotive design. Also linked to the research are issues concerning how to foster students' visual creativity and these are discussed in a separate paper to be presented at this conference (see Tovey & Bull, 2010).

Community of practice theory

The CEPAD research is underpinned by community of practice theory (Lave and Wenger 1991). A community of practice typically comprises a group of professionally qualified people in the same discipline, all of whom negotiates with and participate in a mutually understood discourse. This discourse is both explicit and, very often, tacit and the signs of membership are usually unmistakable. (Osmond, 2010)

Lave and Wenger also highlight a theory of learning as being our 'lived experience of participation in the world' (Lave and Wenger 1991, Wenger 2007): that is, our learning takes place through a

[1] Centre of Excellence for Product and Automotive Design

deepening process of participation within a community of practice, and even our identities are formed from this participation. Wenger defines the major principles of a community of practice in three separate, but related quotes:

> *Communities of practice are groups of people who share a concern or a passion for something they do and who interact regularly to learn how to do it better.*

> *A community of practice is not merely a community of interest – people who like certain kinds of movies, for instance. Members of a community of practice are practitioners. They develop a shared repertoire of resources: experiences, stories, tools, ways of addressing recurring problems – in short, a shared practice.*

> *In pursuing their interest in their domain, members engage in joint activities and discussions, help each other, and share information. They build relationships that enable them to learn from each other.*

Thus within a community of practice learning can be seen as an experience of identity formation: it is not just an accumulation of skills and information, but also a process of becoming – in this case a certain kind of creative and critically minded design practitioner. (Osmond, et al 2007) It is through this “transformative practice”, as Wenger calls it, within a professional community of creative design practitioners that learning can become a source of motivation, meaningfulness and personal and social energy.

Design Communities

Designers come in many types, for example architects, industrial designers, design engineers, graphic designers, interaction designers, fashion designers, interior designers, craft designers, furniture designers and jewellery designers. Each of these represents a significant group of practitioners and each one can be regarded as a community of practice. Some of the categories are sufficiently large that they subdivide into groups of more specialist designers, for example graphic designers might distinguish between those concentrating on corporate identity, media graphics, or information design. Similarly industrial design contains the large sub-categories of product design and automotive design, and smaller groups such as boat designers.

For key groups there are formal bodies to which entry is by examination – for example, in relation to architects there is the Royal Institute of British Architects in the UK, and the Society of American Architects and the American Institute of Architects in the USA. For a wide range of design professions in the UK there is the Chartered Society of Designers and in the USA the Industrial Design Society of America. Most such societies are national and tend to have national membership, but less formal groupings can be international in scope and a powerful example of this is the community of practice of automotive designers.

The International Community of Practice of Automotive Designers

There are car design studios in all of the major industrial countries of the world, and in most of the world's continents. The designers who work in these studios typically share their passion for automobiles and each time a new vehicle concept is revealed by one studio it causes interest and excitement in others. Although during the development of a new design there is usually great secrecy in the company concerned, a great deal of information is shared throughout the industry, and companies often move in similar directions, responding to common pressures from the market and governments (Tovey and Owen, 2006).

For an international community to function it is important that there is communication between its members. For automotive designers this is supplemented by online resources such as the Car Design News (CDN) website. This was created by three car designers from both the USA and the UK and contains news from a designer's perspective of developments in car design, with in-depth reviews and an extensive on-line gallery from all of the major car shows. CDN also features student exhibitions and competitions, discussion forums, resources and job listings, a large on-line collection of car designer portfolios, (paid for) members editorial and a car design taxonomy. With over a million hits a year CDN is a highly effective device for facilitating the community of practice.

Designerly ways of knowing

A working assumption in CEPAD is that - within the design community of practice - designing ability can be described in terms of both generic capabilities and specialist capabilities. The generic capabilities are those that are shared by designers across a wide range of specialisms and the specialist are those areas of domain-related knowledge that distinguish designers in particular areas.

In the practice-based approach to design education we suggest that the intention could be seen as one of combining the generic capability with domain related specialised knowledge, to produce a level of capability sufficient to gain entry to the relevant community of design practice. The portfolio of work could then be characterised as the passport to enter that community (figure 1).

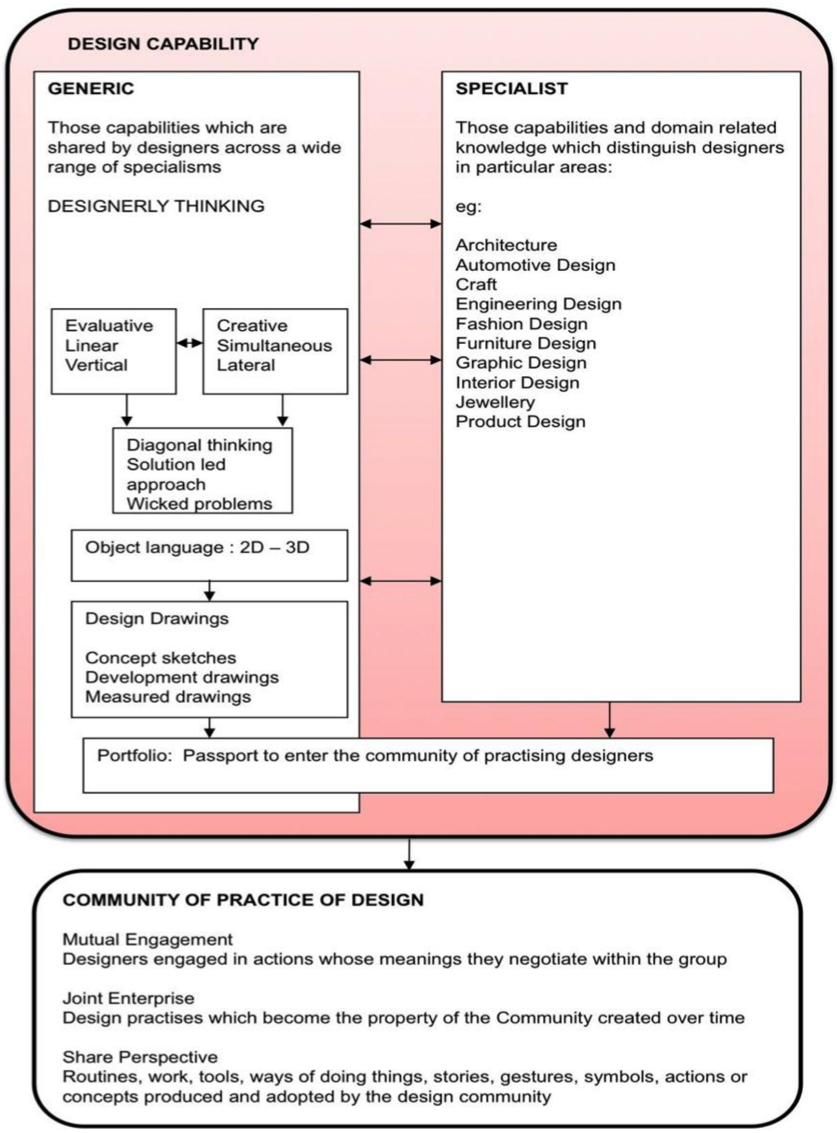

Figure 1 Design Capability Model

In order to develop this 'passport' there is a long tradition of teaching design through 'transformative practice' in which students' educational experience is centred on tackling design problems that become progressively complex. This practice-focused education is reinforced by real world design experience and CEPAD's engagement with this community has been developed and evaluated through industry involvement in course work, placements and internships and university-based consultancy. From this professional engagement comes the picture of designing ability described in terms of both generic and specialist capabilities.

However, although there are specific skills and areas of specialist information that mark out product design, graphic design or architecture for example, there are also important commonalities. One of the most important – generic design thinking capability – has been labelled by Cross (2006) as 'The Designerly Way of Knowing'.

Cross describes this capability has containing five aspects:

- Designers tackle ill-defined problems
- Their mode of problem solving is solution focused.
- Their mode of thinking is constructive
- They use codes that translate abstract requirements into concrete objects.
- They use these codes to both read and write in the object languages.

It is in the character of design problems that they tend to be ill-defined, ill-structured, or 'wicked' (Buchanan 1992) and designers may not have all the information necessary to solve them. To cope with this lack of information, experience indicates that the quick production of a draft solution will allow a definition of the limits of the problem and the provision of a basis for developing an idea or ideas further. To quote Cross (2006)

> *In order to cope with ill-defined problems, the designer has to learn to have the self confidence to define, redefine and change the problem-as-given in the light of the problem that emerges from his mind and hand. People who seek the certainty of externally structured, well defined problems will never appreciate the delight of being a designer…*

The production of a solution conjecture at an early stage in the process could be said to facilitate the re-examination of the problem by providing the spectacles through which to look at it. The designer is able to tell where she or he needs more data because without it the design cannot move forward. In some areas of design this solution-focussed strategy is fully formalised in the way in which the design activity is managed, for example at an early stage in the process there will be a requirement for a 'Concept Design' which is the designers' attempt to provide a sketchy representation of what the finished design might be, or might look like. If the designer or design manager sees the concept as providing a basis for proceeding then the structure of the rest of the process falls into place. This is the solution-led approach, which has, at its core, the process of moving from an abstract statement to a visual object. The designer learns to think in a sketch-like form, in which the abstract patterns of user requirements are turned into the concrete patterns of an actual object. Thus the designer uses a code to effect this translation from individual, organisational and social needs to physical artefacts. This is the use of the visual language of designing, employing its translation codes, and is the match of the analytical (left hemisphere) statement to the holistic (right hemisphere) solution. The manifestation of this outcome will be a visual representation, a drawing, a 3D or virtual model.

Developing a Pedagogic Framework

The Analysis-Synthesis Model

This picture of the thinking processes involved in designing corresponds with the classic analysis-synthesis description of the design process. Such a dualistic characterisation corresponds with the view of brain function which orders cognitive activity to align it with the different characteristics of the two halves of the brain, or cerebral laterality. In the substantial work on this many researchers in this field have characterised the two parts of the brain as separate information processors and encoders. There is strong evidence for the view that underlying the left hemisphere's dominance for expressive speech and the right hemisphere's dominance for manipulospatial activities are different processing modes. Typically the modes are characterised as analytic-synthetic, linear-holistic, serial-parallel or focal-diffuse for the left and right halves of the brain, respectively. This dichotomy is attractive as it seems to correspond with the different types of cognitive style identified by psychologists in problem-solving procedures.

It is clear that for anything other than very simple mental operations, both halves of the brain are involved, as has been shown in EEG maps of cerebral activity during experimental tasks. It would seem that the two processing modes are typically employed at the same time and interactively, and that a more complete understanding of any particular problem arises from the matching of initially separate simultaneous mental operations.

It is possible that design thinking may be organised in a similar way, with two simultaneous interacting cognitive styles being employed. Thus it would be expected that an analytic, linear strategy would be at work in the process of data generation and organisation to yield a design specification, and also in the evaluation of design proposals. In parallel with this a synthetic-holistic strategy, used in the generation of solution conjectures, would be the integration of visual relationships and the physical representation of the design as drawings or 3D models.

These two interacting lateralised mental operations can be used to map out design thinking and help understand it. Tovey (1984) has called this the dual processing model of the design process. In it there is the assumption that the two halves of the brain will both be involved in solving the design problem, each half working in its own preferred information processing mode, each tending towards its favoured modelling language, the left in words and symbols, the right in drawings and 3D models.

In order to offer a way of characterising some of the key areas identified in our investigations into design pedagogic process Figure 2 maps the industrial design programme activities onto the dual processing model.

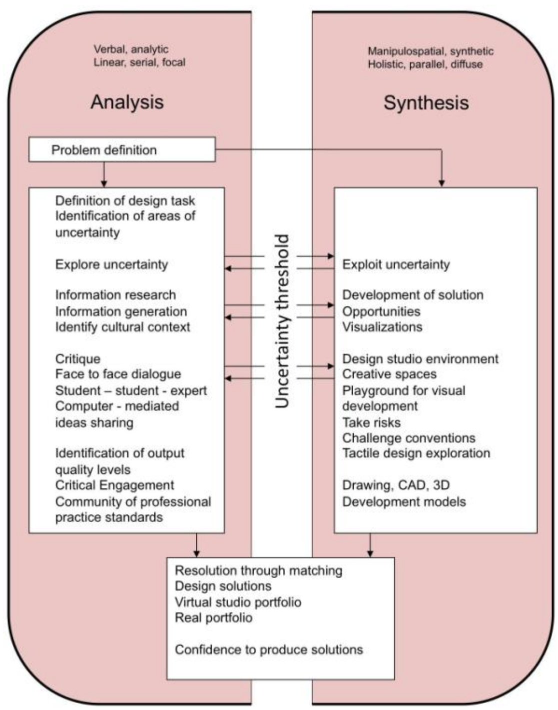

Figure 2 Analyses – Synthesis Modes

Identifying threshold concepts in design

As outlined above, this ‘dual processing’ strategy is routinely employed by designers, involving a ‘conversation’ taking place between the left-brain (convergent, reflective, field dependent, serialistic) and the right-brain (divergent, impulsive, field independent, holistic). The result of this 'conversation', in what Tovey describes as an 'incubation period', enables a designer to arrive at a 'solution':

It is possible that the incubation periods, that time of apparent inactivity during which the designer's brain furiously grapples with the problem, is simply the period during which the two halves of the brain are out of touch or unable to agree. But contrast the moment when they do suddenly come into alignment would be the classic 'eureka' point.' (1984: 226)

However, qualitative data from the CEPAD longitudinal study into identifying threshold concepts in design with a cohort of industrial design students from entry (2005) to graduation (2009) showed that some students, presented with typical 'wicked' design problems may get stuck in this 'conversation'. Often students are trying to satisfy what they think tutors want rather than trusting their creative abilities and those who do not get beyond this lack of trust can remain in what Meyer and Land describe as a 'liminal state'. In this context a liminal state relates to the notion of a threshold concept, which Meyer and Land define as:

> *… akin to a portal, opening up a new and previously inaccessible way of thinking about something. It represents a transformed way of understanding, or interpreting, or viewing something without which the learner cannot progress. (2003:1)*

As such then students can be stranded within a liminal space while they struggle for understanding and this struggle can involve identity shifts and 'troublesome, unsafe journeys' (Cousin 2006:5); in other words they will experience a period of intense uncertainty. As reported in Osmond et al, 2010, a threshold concept also features other characteristics: it is *transformative* in that it involves a personal and a conceptual change; *irreversible* in that it will not be easily forgotten; *integrative* in that it allows hitherto unrelated knowledge to 'slot into place', and *troublesome* in that it appears 'appears counter-intuitive, alien…or seemingly incoherent' (Perkins 1999 in Meyer and Land 2003:7).

In order for students who are 'stuck' to move beyond a liminal state they need to experience a unforgettable, integrative and troublesome transformation - almost a leap of faith - to navigate this uncertainty, and if they do not, they are unlikely to possess the confidence to challenge design conventions, produce solutions and thus innovative designs. However it looks as if once students accept that each time they approach a design brief they will experience this uncertainty they can then use the tools and methods inculcated within their programme to harness their thoughts and ideas and begin designing. In essence, the research identified a threshold concept, which CEPAD has labelled as 'the toleration of design uncertainty', defined as:

> *…the moment when a student recognises that the uncertainty present when approaching a design brief is an <u>essential</u>, but at the same time <u>routine</u>, part of the design process.*

From this analysis the notion of providing a safe 'creative space' in which the students could experiment and experience intense uncertainty within a supportive environment emerged. Indeed it was considered that this represented a key change for the curriculum and that the design programme should be revised to incorporate both scheduled time and physical space to allow it to happen.

The revised design programme

In 2009 the creative space idea was incorporated into a course review process for the industrial design programme, which resulted in the introduction of a new and fundamentally revised curriculum design for the academic year 2009-2010. This new scheme also capitalised on the analysis of data gathered from student course consultative committee meetings, special focus groups with external examiners, leaders in the School, and designers in professional design studios.

In particular, major changes were introduced that addressed the modular structure of year 1 and year 2 of the course in that the existing eight-module provision was replaced with an arrangement incorporating one quadruple practice module, which spanned the whole year. In keeping with this, the assessment requirements for the new module now take the form of staged gateways, attached to a number of briefs associated with a range of key 'drivers of design' such as branding, sustainability, historical context, user needs, technical advances and cultural differences. Some briefs have been designed to be 'tight' and others to be 'open'; the latter designed to encourage and develop students' creative abilities. To this end, the weightings given for marks in each assessment have also been staged and graduated to encourage a 'creative' journey, with the first assessment attracting only 10% of the mark for the year, the second only 15% and the final 75%. The aim is to allow the students space to experiment with their designs and then put forward their 'best' work for the final 75% assessment. In addition year 1 and year 2 students are given a specific studio space to work within and colonise as their own.

Student feedback

In December 2009, a series of focus groups and one-to-one qualitative interviews were carried out with eight year 1 and six year 2 students in order to capture their experiences of the new curriculum design. Open-ended questions were used around the themes of assessment, feedback and the new 'creative space'.

The findings showed that the first year students were, on the whole, enjoying the creative space and freedom they had been given:

> *I have to say I do like it – I like the relaxed style of teaching it makes you feel more comfortable and it feels like you can express yourself a lot more and the course is designed around you instead of a specific standard that is supposed to fit every kind of ideal person.*

At the point at which the focus group took place, the students had yet to receive a summative assessment mark (although they had received two instances of formative assessment), which was in contrast to some of the students' previous educational experiences, which could be characterised as very structured:

> *In the beginning [of the BTEC] we got a list – and the criteria of what gets merit, what gets distinction and if you do all of them, you get the grade basically*

This change was reflected in their current experience, which is very far from 'trying to tick boxes':

> *It is not a case of just trying to tick the boxes - which they keep drumming into us - you are not going to tick the box you are going to develop your own ideas.*

The students were asked if they found the increased independence they were experiencing caused uncertainty in tackling design briefs, and one did feel that this could be problematic as 'you don't know where you stand', but another, whilst acknowledging this, felt 'it was good because it drives you on.' Another pointed out that their tutor had gone to great lengths to make sure not only that they understood the brief, but also to make sure that they related to the brief in terms of their own ideas and thus gained 'ownership' of their designs.

The second focus group, which took place much closer to the first formative assessment gateway, did result in some anxiety being evidenced by the students about the vagueness of the briefs, although some students thought that the briefs were 'deliberately vague':

> *I think also that the way they have structured it with the freedom, because if they drilled it into us you have got to do this, this and this, I don't think it would give us the chance to develop our own style as much, so with the freedom we can have a chance to work on that a lot more*

Again, some of the students put the ability to embrace the freedom down to previous educational background, with some having experienced the same kind of freedom in 6th form college, and others working to a tick box system:

> *There are a couple of people that I have heard that do want to be spoon fed and have come straight out and said tell me what to do and I will meet the criteria if you tell me what to do, but from day one I know that it has been drilled into us that they are not going to tell us what to do, they are expecting us to get pro-active with it*

One student did recognise that the transition from student to designer took place when ‘you have got past that bit where you want to just fill in tick-boxes’ but again another pointed out that, depending on previous experiences, some students might need more help:

> *I think you have to appreciate at the same time, everyone has different levels of stages where they can just go and do that, some people who do need that support more than others*

Overall though, despite some anxiety being expressed about the freedom of the new style curriculum, the first year students appeared to be enjoying the creative space they had been given. However, as the focus groups took place at the end of the first term of the new curriculum and before the first summative assessment we can only speculate that this would continue. Having said this, the comparison with the responses of the 2005 cohort during their first interview is quite striking. Most of those responses concerned meeting deadlines, and as their first year progressed, a particular task entitled the ‘thought receptacle’ proved troublesome for the students. As reported in Osmond (2007) the task was designed to foster creativity and encourage the students to experiment with ideas. However, several students failed this task and comments in relation to staff feedback included: ‘I really thought I had understood [the thought receptacle] – but from the feedback I hadn’t. Apparently it was too planned’. Another reflected that: ‘[the thought receptacle] should reflect your personality and music I liked and sometimes poems and wrote down a lot of … but it wasn’t much so then later on [the lecturer] said relate to design as well…the creative thing wasn’t really set in.’. This was echoed by staff comments in relation to this assessment, which identified a ‘limited sense of personal point of view, …distance from being a designer, lack of confidence.’ and ‘not much personal stuff coming through.’

For the year 2 students interviewed, it appeared that the new curriculum had already made an impact in that they had just completed their first piece work and that attracted a summative mark of only 10% of the total for the year. Firstly, several of the students had experimented with designing different vehicles in order to improve the variety of their portfolios, with one stating that ‘if it had been a higher percentage I would have thought of sticking to what I know.’ Another found that because the mark was such a small percentage that he could spend time on sketching, which allowed him to ‘get better at the design process’:

> *I had a sketch book and I was constantly sketching, sketching and I noticed that my sketching did improve from the beginning to the… at the very beginning I was quite scared and drawing very neatly oh no i don’t want to make a mistake but later on got more free and didn’t really care and that is when I got my best bits when I was – there was a point where I was really angry I just couldn’t get a design and really angry and scribbled and oh actually that’s quite good…*

Secondly, for another student who felt he had performed poorly at this task, the 10% mark was a relief because he could use the feedback he received in a constructive manner for his next assignment.

> *In a way I am glad because I don’t think I did very well…I think if I ever did something like that again, I would probably have a better stab at it…*

In addition to this marking system, a new ‘buddy’ assessment method was introduced where students who were not presenting their work were asked to write down feedback given to the student presenter; this would allow the tutors to enter into a conversation with the students about their work without also having to write down every comment. Also, the summative mark for the assessment was not given until a week after the presentations.

The students felt that this system was excellent as they not only received good quality feedback, they also had a record of it and got to see feedback given to other students which allowed them to ‘see where you are at and where your peers are at and whether you are doing good or not so good – and if they are doing better, you want to do better’.

This is in contrast to the 2005 cohort responses during their first interview during their second year where some students had problems with understanding the brief that was set:

> *My main problem - especially the ones that I only just passed they said I didn’t understand the brief - I had obviously read it and gone out and done my own thing and*

completely forgotten about it and not stuck to the brief at all - that was the main problem

Finally, some of the students could not see the 'join' where all the modules intersected within the previous curriculum design and thus found it difficult to design 'holistically':

I don't really like the idea of splitting things up…I don't really like the way some of the modules are done this year…because they are splitting up disparate parts of the design process and they are not bringing them together at the moment.

In summary, the qualitative research with the first and second year students showed that they were enjoying the new creative space afforded by the newly designed curriculum evidenced by the lack of 'deadline panic' that was apparent in previous years and by a willingness to experiment when faced with a design brief. However there are indications that some students are finding the provision of such an 'open' space difficult and this may well be linked to previous educational background. However the study sample was a small percentage of the total number of students, and the data gathering took place at the end of the first term, so cannot be seen to be representative of the experience of all Year 1 and Year 2 students or representative of a complete study year experience. To address this, more data is to be gathered at the end of Term 2 and Term 3.

Conclusion

It seems that part of the mutually understood discourse of the professional design community of practice is what Cross aptly calls 'The Designerly Way of Knowing': the recognition that design problems will always be 'wicked' and therefore problematic, and possession of this knowledge is a passport to the professional design community of practice. In more detail, Tovey posits that the thinking process that underpins this 'knowing' involves 'dual processing', where two parts of the brain have a 'conversation' with each other, which then produces a quick solution that can be built upon and expanded.

However, the CEPAD research found that some students get stuck in the 'conversation' between the cognitive modes associated with the two halves of the brain and consequently cannot move quickly towards a draft solution. This may be because they are trying to divine what the tutors want or because they do not trust their creative abilities enough to recognise that the conversation and draft solution is an essential part of the design process. From this the identification of the 'toleration of design uncertainty' as a threshold concept was made in order to provide a benchmarked portal for students to pass through on their journey towards becoming a designer. In other words, once the students recognise that the conversation and the process of drafting a solution involves experiencing design uncertainty and that this is an essential but routine part of the design process, they then can move on towards experimenting, innovating and playing around with design conventions. In recognition of this a new design programme was introduced for the students, which was designed to encourage creativity, and early indications are that the new 'creative space' is indeed fostering the students' creativity. However, there are also some indications that students from a 'rigid' or 'tick-box' educational background may experience difficulty with such a creative space and more research is needed in this area.

Overall the CEPAD research has enabled an essential threshold concept to be identified and explicitly surfaced within the curriculum and a pedagogic framework developed in order to support student designers on their journey to assuming the identity of professional designers. The ability to work with the toleration of design uncertainty is a quality exhibited by established designers, and is part of what is shared within the community of practice. The intention is to research further the utility and impact of the new programme design on students' creative confidence and on the extent to which it develops capabilities which are in line with the aspiration to achieve entry to the community of professional practice. It is anticipated that this will involve a process of adjustment and fine-tuning.

Author Biographies

Professor Michael Tovey

A graduate of the RCA, Professor Mike Tovey was in industrial design practice prior to entering education. In 1973 he joined the institution which was to become Coventry University, as a lecturer in industrial design. He was appointed to Head of Industrial Design in 1985 and in 1989 was made Dean of the Coventry School of Art and Design. In 2007, he changed position to take on the University-wide post of Director for Design. Professor Tovey is responsible for developing courses and applied research in design across the University and is Director of the Centre of Excellence in Product and Automotive Design (CEPAD).

Dr Karen Bull

Dr Karen Bull is Deputy Director, Centre of Excellence in Product and Automotive Design at Coventry University. This centre focuses on evaluating spatial design understanding and identifying the transformative threshold concepts associated with students entering the Global community of practice for industrial design. Her expertise is in industrial design theory, design analysis and design context. Her background is in product design and her PhD is titled Advanced Personal Telecommunications Products and Industrial Design'. She has continued to research pedagogy in relation Art and Design and is especially interested in the area of critical and reflective learning, e-teaching and learning and e-portfolio.

Jane Osmond

Jane Osmond is Senior Research Assistant for the Centre of Excellence for Product and Automotive Design (CEPAD), Coventry University and is researching students' spatial awareness skills, threshold concepts in design and internationalisation of the curriculum. Jane is undertaking a PhD by research in this area, and has published several papers on threshold concepts including: Osmond, J., et al (2009) 'The Threshold Concept Journey: from identification to application'. *From theory to practice*. Sense Publishers. Rotterdam [in publication]; Osmond, J. et al (2008) 'Measuring the creative baseline in transport design education.' In Rust., C. (ed) *Improving Student Learning – For What?* OCSLD. Oxford; Osmond, J. et al (2007) 'Threshold Concepts and Spatial Awareness in Automotive Design.' Land, R., & Meyer, JHF. (eds) *Threshold Concepts within the Disciplines*. Sense Publishers. Rotterdam. Previous projects include: 'Improving Retention, Supporting Students'; 'Mapping Equality & Diversity Initiatives in HE' and 'Meeting the Challenge: Managing Equality & Diversity in HE.

Craft as a Form of Mindful Inquiry

Louise Valentine, University of Dundee, UK, l.valentine@dundee.ac.uk

Georgina Follett, University of Dundee, UK

Abstract

In this research project 'Communication of Craft Practice' is the subject and the problem is one of transparency of the intellectual act and accessibility to the embodied knowledge. Why? The skill of coherently expressing the intellectual and personal voice within the development of craft practice is usually missing. There is a gap in our knowledge.

The methodological framework is *Mindful Inquiry* which is a synthesis of critical social science, hermeneutics, phenomenology and Buddhism (Bentz and Shapiro, 1998).The research involves working directly with professional practitioners to embark on a series of creative journeys from which craft as an experience, process, product and service could be observed and evaluated. The practitioners included a 3-D metal designer, curator, interactive jeweller, product artist and woven textile designer.

The aim is to reassess the term craft practice as a means of understanding the impact of social, political and technological change by documenting the practitioner's thinking processes throughout a period of practice. It is to consider combining visual and written outputs as means of supporting the identification of the new knowledge gained through practice, and how this knowledge is used cumulatively to develop craft. The objective is to nurture a dialogue with practice and to document the process of thinking and making associated with craft.

This paper provides the context and framework for research as well as presenting the findings from it. It exposes the methods and the accompanying rational for using them in relation to mindful inquiry, and it presents a new perspective from which to view and discuss craft practice. The argument is concerned with articulating the relevance of mindful inquiry as a methodology for critiquing and supporting the development of craft thereby supporting the contextual understanding and meaning of the research findings and procedures when they are presented. It is also to offer new craft knowledge in terms of the phrase 'practice'.

Keywords

craft practice, mindful inquiry, visual language, communication, methodology

Introduction

Mindful Inquiry is a synthesis of critical social science, hermeneutics, phenomenology and Buddhism. At the heart of this methodology is the concept of 'change' where perpetual activity is its inherent characteristic, both within the research context and of the subject under consideration, because the human condition is at the centre of investigation (Bentz and Shapiro, 1998).

Buddhism permeates *Mindful Inquiry* through the philosophy of mindfulness which is an awareness and understanding of one's own mind and how it influences one's perceptions and actions. The process and product of the discipline of mindfulness is inextricably interwoven: it is both a means and an end – a philosophy and a method (Valentine, 2003; Valentine and Ivey, 2009). The concept of 'postmodern chaos' and its presence in our everyday existence is a key reason for selecting *Mindful Inquiry* as an appropriate methodological framework to investigate contemporary notions of craft practice. The consequences of interdisciplinarity to the field of craft or the implications of modern high technology to methods and their associated aesthetics, for example, gives rise to a situation whereby traditional static frameworks for analysing and evaluating the applied arts can provide a distorted view of the realities of being a creative practitioner.

The person is placed at the centre of the process of inquiry in both a psychological sense (for example, my personality style can shape my research method) and a philosophical sense (in that research is viewed as an embodied programme of activity, a way in which I engage with the world). The premise of Bentz and Shapiro's concept of *Mindful Inquiry* is the idea that research is intimately linked with the researcher's awareness of his/her life and his/her lifeworld.[1] They advocate that 'awareness and reflection on your world and the intellectual awareness and reflection that are woven into your research affect – or should affect – one another' (Bentz and Shapiro, 1998:5). *Mindful Inquiry* is a reciprocal system: quality research contributes to personal development as a mindful practitioner and personal development, in terms of awareness and reflection, embodies the research. It sits within the realm of 'reflective practitioners' where the researchers do not adopt a detached and impersonal approach rather they have direct engagement and involvement. In this investigation 'Communication of Craft Practice' is the research subject and the problem is one of transparency of the intellectual act and accessibility to the embodied knowledge. Why? The skill of coherently expressing the intellectual and personal voice within the development of craft practice is usually missing. There is a gap in our knowledge.[2]

On reflection of the intellectual and social meanings of craft practice, craft is often misunderstood as skilful making. The notion of craft as a concern for innovation, individual vision and future cultural concerns: a fusion of art, science, engineering, and technology, is uncommon. The misconception of 'craft as skilful making' fails to address the maker's capacity to synthesise and integrate information. While recent texts (for example the work of Glenn Adamson, Howard Risatti and Richard Sennett [3,4,5]) have gone some way to redress the imbalance in understanding the intellectual value of craft, the plethora of literature which services crafts as a hobbyist pursuit remains uppermost in the minds of popular culture.

In *Mindful Inquiry,* the researcher's ways of engaging with ideas, data, methodologies and decisions are a critical consideration and as such, it is pertinent to pause and present what they are to this study. My environment for learning is design and I[6] understand design as a dialogue,

> an activity that requires a freedom to explore, to allow imagination and creativity to range widely and bring knowledge and expertise alive in a

> wild uninhibited dance. It is a process that involves looking, listening and thinking, allowing collective thoughts to levitate: to sit suspended in the mind and to be given space, through time, to develop as the process of creation unfolds (Valentine, 2004:15).

This suspension of thought allows a pattern to evolve, providing an individual with a picture, which depicts the interrelationship(s) between different and often contrasting elements of an idea. Subsequently, the lens with which I view *Mindful Inquiry* is design and the context for developing design is *Mindful Inquiry*.

Adopting *Mindful Inquiry* for this investigation is used as a means of generating and contributing to social knowledge of craft practice, thereby complementing the existing cultural, material, product and technical knowledge. *Mindful Inquiry* was used to embark upon a journey into the context and culture of contemporary practice. The journey asks questions of how the mind's eye synthesises visual, oral, sensory and written information, and the process by which ideas are transposed into an individual's personal philosophy.

Mindful Learning

The cognitive aspects of mindfulness, as adopted by Hanh (1991), Kabat-Zinn (1994), Langer (1989, 1997) and, Bentz and Shapiro (1998) are that it is a way of seeing which causes and maintains inter-connections. It is an approach to inquiry that draws a person's attention and awareness to the impermanence and uncertainty surrounding a problem. Much of the learning associated with Mindful Inquiry is social learning; learning about language and social convention rather than methods, and it is a requirement of the inquirer to become socialised into a community. The inquirer's remit includes learning where the action is and becoming an active member of the community (Bentz and Shapiro, 1998).

This process of socialisation and familiarisation for this study of craft took place throughout the research but was intensively invested in within the first two years (of the five year project), attending national exhibitions, museums and trade fairs, meetings with national agencies and champions of craft within Scotland, England and Ireland[7,8,9]. In-depth conversations about craft as a practice and methodology were held at regular intervals with the jeweller Georgina Follett.[10] The process also took the form of an international conference and exhibition entitled 'New Craft: Future Voices'[11] and 'Future Voices: Celebrating Diversity' organised by the authors.

The process and output of these events were a fundamental aspect of the social learning perspective. Taking place over an 18-month period (including pre and post event responsibilities), it offered the researcher deep insight into the intellectual dialogues that go with craft practice; the multiple forms of craft; the range of traditional and digital methods currently being employed; awareness of the material, technological and cultural aesthetics of craft practice; the alternative ways of approaching collaborative and interdisciplinary frameworks; the various ways people discuss and emphasise craft and, the visual impact of craft research as a new form of craft practice.

The ‘Future Voices: Celebrating Diversity’ exhibition provided the opportunity to view a broad range of craft practice from different cultures (in terms of academic cultures of inquiry or research frameworks and, cultures associated with native or societal heritage *eg* Australasian, Canadian, Nordic). The exhibition also offered the opportunity to view craft practice across a bandwidth of material specialisms (*eg* ceramics, jewellery, interactive jewellery, metalwork, printed textiles, woven textiles). It presented a visual discourse and offered a way of distinguishing between traditional and non-traditional forms and, historical and contemporary aesthetics. For example, the work of Carol Epp (Figure 1) exposed a traditional perspective in terms of the form and aesthetic, while the work of Sarah Kettley (Figure 2) presented a non-traditional example of form and aesthetic. Epp’s work is concerned with refining the form and function through subtle shifts in technique and, the concept underpinning the work (*ie* that of a vessel) is in the tradition of ceramics. Kettley’s work on the other hand, is a non-traditional form of jewellery and as such, challenges the traditional concept of jewellery. While the conceptual underpinning of her work is very good (*ie* wearable computing infused with soundscapes), the relation between final form and concept is oblique.

Figure 1: The ceramic work of Canadian craft practitioner Carol Epp

Figure 2: The interactive jewellery of Scottish craft practitioner researcher Sarah Kettley

The collection of exhibits facilitated understanding of a subtle but important delineation, in that a traditional form (for example, a ring or neckpiece in the context of jewellery) does not indicate a lack of innovation in terms of concept and aesthetic. And, that a historical or cultural aesthetic within a traditional form does not indicate there is no radical thinking underpinning the craft. For example, in the work of Barbara Jardine (Figure 3) whose jewellery exposes a strong Trinidadian cultural aesthetic through a traditional form, the intellect is found through the interrelation between the material elements of metal, stones, amber, black coral, ivory, beetle carapaces and tortoise shell. The visual experimentation and high level of craftsmanship used to bring the array of materials together is where the intellect is embedded and, where the level of risk and innovation can be measured. The value of this observation of practice was that great care must be taken when evaluating craft in terms of the aesthetic (where aesthetic is the intellect). It also indirectly raised an issue with the use of language when looking at craft as an intellectual inquiry, specifically in the application of familiar terms or categories of form such as ‘traditional’ and ‘non-traditional’. If innovation and radical thinking can be found in traditional forms employing a historical aesthetic, then mindfulness must be adopted when observing craft that employs contemporary materials and new, advanced technologies to achieve unusual forms: one cannot assume innovation exists within craft because it exposes an unusual form or applies new techniques and/or technologies to create an aesthetic.

Figure 3: ‘Heigh Ho’ is an example of the intellectual and visual voice of Trinidadian jeweller Barbara Jardine.

‘Future Voices: Celebrating Diversity’ evidenced (amongst other issues) differentiation of craft aesthetic specifically in terms of technological, material and cultural-led aesthetics and, the myriad forms of craft that result from the interplay between technology, material and culture. It indicated that craft research is having a positive impact on contemporary developments, influencing thinking and the quality of product in terms of a new aesthetic of ‘captured time’, for example the work of Gillian Bunce, Drummond Masterton and Hazel White. It was observed that technological pathways also act as a progenerator of works, achieving aesthetic qualities previously unattainable through traditional skills, materials and techniques (see for example, the works of J R Campbell and Tara Carrigy in Figures 4 and 5). These works embrace the human body as part of their aesthetic with interaction as the aesthetic, moving the tradition of the automaton[12] further forward. The exhibition raised a number of questions, including: when craft knowledge is used in the production of a visual object, can the object be framed as craft? Are historical frames of reference appropriate when evaluating the aesthetic impact of modern technologies on postmodern craft? Is twenty-first-century craft an ethos embedded in the maker rather than being embodied in an end product of making? How can we evaluate the aesthetic of postmodern craft?

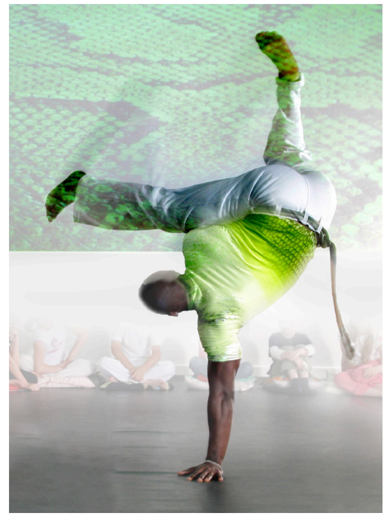

Figure 4 (left): J R Campbell's 'Wearing this Distorted Image' and Figure 5 (right): Tara Carrigy's 'Adaptive Craft'. The aesthetic lies in level, form and sophistication of interactivity between object, viewer and environment, which has been facilitated by advanced technologies and, in the case of Carrigy within an interdisciplinary context involving scientists, musicians, dancers and engineers.

The exhibition and its associated international peer review process of selection provided the platform for identifying and commissioning five practitioners to engage formally with the '*Past, Present and Future Craft Practice*' project and create new works. The following practitioners were selected: Hazel White (Figure 6), interactive jeweller and conceptual thinker; Tim Parry-Williams (Figure 7), a textile designer working from a depth of understanding of the nature of textile material; Geoffrey Mann (Figure 8) whose work is concerned with capturing the transient through the use of new technologies; Sally Moir (Figure 9), curator with the ability to conceptualise space and, Drummond Masterton (Figure 10), silversmith using a reductionist approach to product development. They are all mid-career and have an acknowledged reputation for their work in the UK. Selection was made on the basis that the work demonstrated a strong visual aesthetic or indexical mark, had clarity of purpose and was articulate in discussing and revealing conceptual thinking.

Figure 8 (bottom left) ‘Flight’ by Geoffrey Mann, Figure 9 (bottom middle): Sally Moir, section of her New Craft Future Voices curatorial strategy. Figure 10 (bottom left): An example of Drummond Masterton’s craft.

Removing the ‘Blinkers’[13]: a phenomenological study of craft practice

> Phenomenology is a school of philosophy that focuses on the description of consciousness and of objects and the world as perceived by consciousness … [It attempts to take seriously the fact] that we know we are conscious beings and that everything we know is something we know only in and through consciousness … A primary focus of phenomenology has been to get ourselves out of everything we take for granted about the world and about ourselves through ‘bracketing’… [a process] that sets aside aspects of a situation in order to focus full attention on other aspects of it (Bentz and Shapiro, 1998, p.40-41).

In terms of this research, the culture of inquiry helped me to look at the phenomenon that is craft practice by ‘bracketing’ the everyday definition of ‘craft practice’. It was the means with which to *reconsider* it as a final product or object, in order to focus fully on the experience, process, product, and service aspects. I looked at craft practice from this collective perspective by creating a ten-year map of an individual’s ‘lifeworld’ (Figure 11), rather than drawing a chronological portfolio of the production of single objects (Figure 12). This perspective is of craft as a lifework, an ethos developed through time where technique, attitude and behaviour evolve through, and emerge within, a mixture of life experiences, for example, behavioural tendencies, educational background and cultural engagement activities. I also created a series of creative, critical writings as a means of familiarising myself with the different modes of craft practice and as a vehicle for evaluating the extended conversations with the practitioners.

This notion of ‘lifeworld’ in the context of craft is referred to as a ‘cultural enrichment cycle’ (by the lead researcher) whereby craft practice is understood to be a constantly moving and continually growing process, with embedded layers of meaning and experience. It is considered in terms of layers of activities, running concurrently through the everyday life of an individual craft maker, rather than a solid ‘block’ of unrelated events or projects. This viewpoint is understood to be one way in which this work contributes to craft knowledge as many existing historical and theoretical contributions favour interpretation of craft practice as a finished object(s) disassociated from the deep personal tendencies and individual values of the maker.

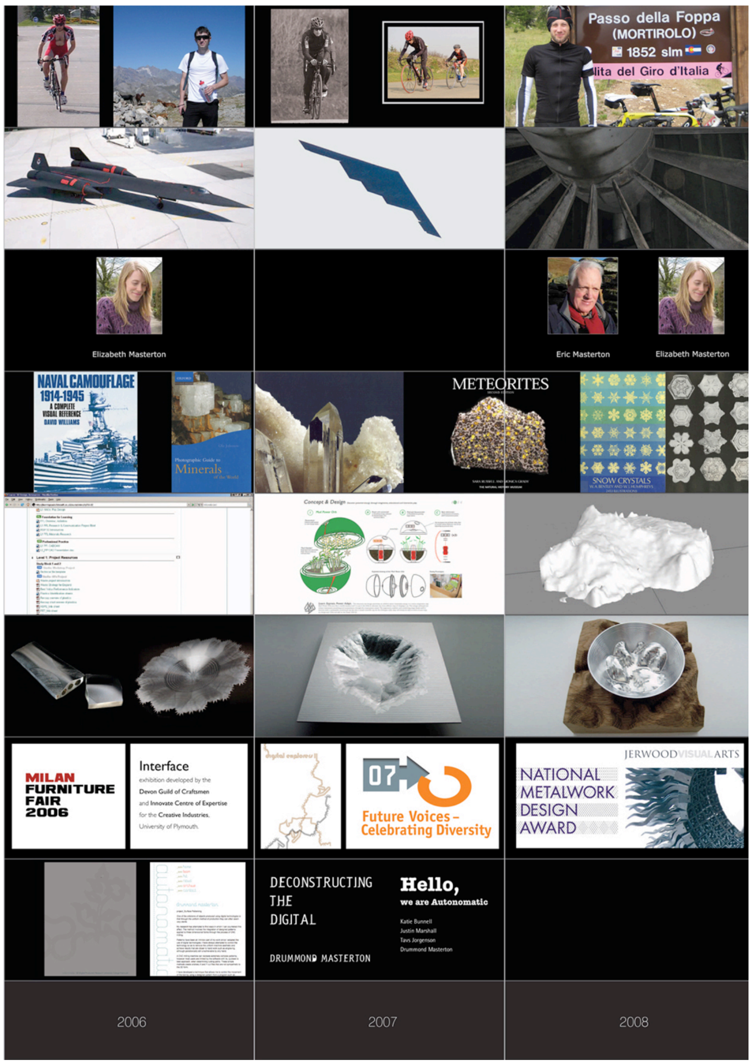

Figure 11: A snapshot of (three years out of the ten year) visualisation map or ‘cultural enrichment cycle’ for Drummond Masterton, created by the lead author, offering an alternative viewpoint from which to understand the term ‘craft practice’. From top to bottom, the concurrent layers of activity that constitute ‘craft practice’ for Drummond are cycle racing, developing knowledge of military modes of transport, (specifically aeroplanes and submarines – their form and nature), people who influence his thinking, reading of books concerned with mathematical structures and visual forms such as crystals and meteorites, teaching 3D design, crafting objects, exhibition participation and academic writing.

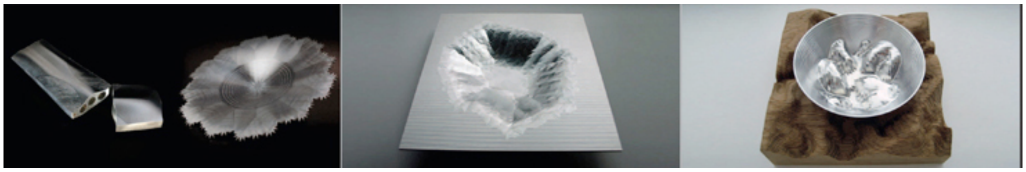

Figure 12: A snapshot of objects from the 'cultural enrichment cycle' for Drummond Masterton, representing three out of ten years of craft practice.

Phenomenology is very useful for noticing what things we take for granted and it encourages us to see things in a new way, to step outside of our culture and question our habitual ways of describing and defining things. In this respect it is part of mindfulness. In a world where the concept of 'change' is a given and technological progress pervades our everyday existence, this viewpoint was deemed appropriate as it supports the need for questioning basic assumptions about the concept of 'making' craft, and a reappraisal of the question, 'What is craft practice?'

The 'cultural enrichment cycle' as craft practice was questioned directly and indirectly via extended conversations with the practitioners. I paid attention to the phenomena being investigated by writing a deep phenomenological description of my own experience of craft practice: my experience of the craft of five practitioners and extended conversation with them about their practice. What was their way of experiencing craft practice? As human phenomena, what does craft practice mean from the perspective of an individual maker?

In this study, I am the instrument of articulation and to become this I developed deep empathy with the concept and practice of craft through observation and extended conversation with contemporary practitioners. As Bentz and Shapiro (1998:97) note, '[t]he primary tool of the phenomenologist is the inquirer's own consciousness'.

I am not the subject. In my preparation for working with the research participants, I immersed myself in experience that matches the participants. I continued nurturing my lifeworld and reflecting on the development of my 'cultural enrichment cycle'. I engaged in the creation of new work (which in my practice is visualisation through interactive media) and I taught design and practice-led research to a range of undergraduate and postgraduate art and design students. I daily discussed the business of design and the practice of creativity with my partner (a design consultant). I wrote and I nurtured my network by engaging in a series of new activities (such as novel research projects) and conversation about craft, design and the future of education for the creative industries. In doing so, I created in-dwelling awareness.

What is important to note about this phenomenological study of craft practice is that the process brought into awareness and made use of my 'Grasshopper' tendencies. What do I mean by 'Grasshopper? I mean my propensity to see opportunities all day, everyday and to pursue the subconscious idea that shines brightest or speaks loudest.

The rhythm of my hopping and jumping does not always make sense, sometimes it can appear that too much is going on at one time and at other times, it can look as if I have gone off at a tangent for no apparent reason! The important aspect *is* the random movement; this movement is a way of evaluating, it provides necessary time and space to test new ideas and talk to different people. It creates an intellectual freedom to look at work from different points of view and, perhaps most importantly, it keeps my mind active. The other thing that my 'grasshopper' strategy helps to manage is a tendency to want everything to be perfect. This characteristic is with me in all that I undertake, but through this study I realise that it is balanced by the inherent *inability* to give full attention to one study or project – a mixture of small and large, complex and complicated. It is also distinctly possible that it is the perfectionist in me that brings out the 'grasshopper' rather than the other way round!

In this research, the implications of 'grasshopper' were that my engagement with the 3D metalworker, curator, jeweller, product artist and woven textile designer were mixed together as one collective process, where conversations, interviews, observations, workshops, writing and visualisation activities flowed in and out of awareness. Attention was given to all of them and none of them and reflection on small pieces of information was made in parallel with reflection on the entire *Mindful Inquiry* framework.

It is important to highlight that while I present this work by writing in first person rather than third person (which is the convention for much scientific research), it does not devalue it, or imply that it is detached from the real world. A critical attribute of phenomenology is the ability to provide rich descriptions of the phenomena and the ability *not* to approach discourse analysis through a mechanistic manner of interview, transcribe and thematic identification. As Bentz and Shapiro (1998:104) note:

> [T]o believe that phenomenology is focused primarily on the personal experience of the researcher and her subjects or on subjective experience cut off from the real world is a mistake. Although phenomenology may focus on personal experience, one of its primary goals is to understand the real world. It simply recognises that the real world is given to us in consciousness.

The Hermeneutic Dimension: interpretation of and for craft practice

The interpretation of texts or the theory of interpretation and understanding is the basic premise of hermeneutics. This view, note Bentz and Shapiro (1998: 40) was extended by Martin Heidegger,

> into a general approach to our understanding of our existence and Being in general….[Indeed, h]ermeneutics emphasises that all our understanding and interpretation are bound to, and shaped by, our existing in a particular historical and cultural context, because we use the concepts, language, symbols and meanings of our time to interpret everything. Therefore hermeneutics involves us in perpetual asking, of anything meaningful that we study as well as ourselves, 'Where are you coming from?'

Interpretation has a divergent nature; it is methodologically open-ended and ambiguous. In this sense, it can be directly linked with theories of design where indeterminacy is a key tenet and the activity of rhetoric (as both a language and a metalanguage) is a core element in a designer's thinking (Buchanan, 1995; Cross, 1999; Valentine, 2001 and 2004). Subsequently, there are two contradictory elements to the hermeneutic analysis for this study which must be acknowledged – one is that a heightened level of ability and understanding of ambiguity has been achieved by the lead author through her 17 years of design studies, yet, this interpretive ability and viewpoint may cloud her judgement when analysing the texts gained through extended conversation and observation with the five contemporary craft practitioners. However, this realisation of a potential prejudice is one of the values of hermeneutic analysis as Bentz and Shapiro (1998: 114) note, 'The hermeneutic encounter is one that, when done mindfully, prompts the interpreter to reflect on her prejudices, understand them, attempt to justify them as rationally as possible, and go beyond them through what is encountered.'

In this study, hermeneutics is blended with phenomenology to provide contextual awareness and perspective, where narrative, specifically the method of storytelling, is used to identify the theoretical underpinning of an individual's craft practice by analysing his/her craft practice through visualisation and extended conversation. It is also used to nurture understanding of the meaning of craft practice in modern society. The stories are the rich descriptive texts created as part of the phenomenological perspective of this *Mindful Inquiry*. The texts are both an outcome of interpretation and a basis for further interpretation. They denote a level of understanding about craft practice when read as individual pieces and as a collective body, and they also form the basis for further interpretation.

The stories exposed craft practice as a meditative act requiring mental and physical distance during the decision-making process, yet a constant, intimate relationship with the idea. They revealed craft practice as a pursuit of personal and professional 'identity': a means of realising and recognising the concept of 'self'. It was unveiled as a social activity, a dynamic network of conversations with people, places, memories, ideas, objects, fact and fiction – both *in* time and *through* time *ie* conversation(s) with people in real time, mixed with conversation(s) with the self about past experiences and knowledge. Craft practice was understood to be a fascination, indeed an obsession with developing their own visual language or indexical mark, where experimentation and risk taking were central tenets and the essence of the term 'making'.

The stories offered insight into the personal need to achieve excellence and seek approval – sometimes from the external world and sometimes from themselves, sometimes only from themselves. There was an intuitive need to clarify the value of their ideas in the context of culture through exhibition(s), awards, lecture(s) and workshop(s). There was also a business need to secure financial investment through these same aforementioned activities.

They provided insight into how individuals create the questions with which to challenge the idea. They revealed that the practitioners all looked for rhythmic activities, and constructed meditative spaces in different ways to suit their lifestyles in order to internally resolve issues within their making practice. The interactive jeweller's rhythm was found in the way she engaged people within her thinking process; her craft is a social product. She carried the most recent prototype with her at all times and used the interstitial moments in her day to unwittingly inform colleagues of her new work and seek their immediate reaction, using this to inform her questioning and decision-making. The silversmith's rhythm was found through the solitary pursuit and physical challenge of cycling/cycle racing which was used as a means of resolving 'tension' in his craft practice, often riding for hours at a time to understand the intellectual conflict hindering progress; his craft is a meditative product. The woven textile designer's intimate relationship with material (fibres, structures and finishes) coupled with his audacious and poetic personality was the home for his rhythm; his craft is also a social product. His affinity with the cultural ethos of Japan significantly influenced his thought process, especially his efforts to achieve a holistic approach and a balance between tradition and modernity. The curator's social relation with object (be it art, craft or design) and the insatiable need to take the object to new audiences is where we found her rhythm; her craft is also a social product. The speed with which she conceives and transposes her visions from two-dimensional abstract forms to three-dimensional tangible environments and, the manner in which she communicates with her team and artists is where we find the intellect and decision-making. In a similar way, the ceramic and glass artist is also audience driven, and the rhythm of his practice was tied to the pursuit of identity through international acknowledgement, which stimulates his new product cycle; his craft is both a social and political product.

The stories revealed physical making *ie* the application of techniques and hand skills, as a small proportion of the craft practice process as they exposed a large repertoire of activities, personal traits and personal histories that impact on their craft. The stories described the rhetorical act of craft practice by exposing the myriad of interrelated activities that exist within the process, irrespective of the material or technology employed to physically expose the idea and transpose it into a tangible object. In doing so, they exposed craft practice as a personal journey conducted through life, where a heightened, proficient and eloquent use of the visual language is developed and used to question and resolve a concept.

It is important to draw attention to the fact that hermeneutic inquiry is not a free-reign approach to analysing text but a mindful quest for objective understanding through interpretation. It is founded in the belief that the researcher cannot escape from being involved in the context of explaining which naturally encroaches on the context of the data. This is the 'nub' or the heart of the challenge for the researcher, in that close proximity,

> is both the problem of validation and the basis for validation. The researcher's job is to bring to bear on the data all he knows about his present context in order to understand the context of the data. For in the long run the validation is the ability to make sense of the relations between the two contexts. (Bentz and Shapiro, 1998:112)

Craft Practice

In this investigation, a dialogue with practice was nurtured. The involvement of craft practitioners was seen as a fundamental tenet of the research project, in that the voice of practice is missing in large part from literature on crafts. The assumption underpinning this was that viewing contemporary craft practice from the practitioner perspective would enable primary knowledge and give clarity to the way in which craft was advancing and evolving within contemporary visual culture.

The research sought to understand the development of a craft practitioner's personal journey, of how they gain inspiration and what drives them to develop their work, whether it is developed on the visual, conceptual, material or technical basis. In order to understand an individual's development the research looked at recent practice to understand whether the journey is linear, moving in a forward direction, laterally or backwards. To facilitate this understanding visual timelines were constructed from final product/objects and personal influences including literature, travel, teaching, sport and related creative practices, such as writing and exhibiting. This visual mapping allowed for an evaluation of patterns of productivity, from which an individual's development can be extrapolated and compared in order to understand whether craft practice operates a universal model, or whether it is idiosyncratic in form and dependent on many variables.

Given the rationale for selection it may be possible to understand that different individual imperatives require specific circumstances for craft to operate within, and to develop an understanding of which particular environments allow for the greatest progress to be made, collectively and individually.

The visual timelines and stories encapsulate the working life and environmental constructs used by the practitioners in the formation of their work. The model has the potential to act as a developmental tool for ongoing use by practitioners to enable them to understand the generative circumstances under which they operate most effectively, and how they operate within certain patterns, and what effect apparent disparate and unconnected elements have on their practice.

Outcomes of 'Mindful Inquiry' were constructed through stories and ten-year visualisation maps of each practitioner's journey of practice. The assumption of craft as a lifetime journey means the ten-year snapshot was the shortest timeframe possible to give coherence to the practice of the practitioner, and allow an understanding of the patterns of an individual's progress and the constituent parts of their practice. Mindful Inquiry of Craft Practice through the work of the four practitioners all showed different patterns and the visualisation maps identified rhythms within practice revealing progress. However, ten years was too short a timeframe to gain a full sense of these; a timeframe of 15 years would allow for verification of the working processes and practices. The maps identified the progress of skill, intellect, content and knowledge; understanding progress within practice, not through singular objects, but as a holistic journey. The maps or pictograms evidenced that intellectual skill developed in the work of all the practitioners, as did knowledge of material and technique, people and culture. And, the ability of the practitioners to develop self-knowledge directly impacted on the levels of innovation within their practice.

Craft research has a value to craft practitioners, demonstrated through taking a research methodology and applying it to support understanding of both practice and research.

On reviewing the research process and outcomes, it is acknowledged that they offer a basis to undertake a SWOT analysis of the individual's practice to understand the different layers of activity that makes up their practice. The visualisation will allow for an individual evaluation of the impact of the different elements of their life journey on their work; providing an insight into different aspects and their direct effects on practice, through research, intensive engagement, volume of work and their management within it. Potentially the practitioner could alter these relationships within their portfolio, rebalancing and influencing potential impact thus perhaps driving innovation at a faster pace than their current practices.

The model offers an understanding of craft practice as layers of a journey of the self, which influence how an individual moves forward; it is the self that requires understanding as a practitioner/researcher with layers of activity rather than through an outcome or output.

The ten-year snapshot is the shortest timeframe possible to give coherence. The authors believe a 15-year timeframe would allow for verification of the progress of skill, intellect, and understanding progress within practice as a journey. This further research will need to be undertaken through revisiting the practitioners within a five-year window.

The 'Mindful Inquiry' model revealed that all the practitioners developed their intellectual skill, knowledge of material and technique, people and culture: they also enhanced their ability to develop their self-knowledge to increase the level of innovation within their practice.

In order to make this model universal Valentine will develop a series of self-reflective questions along with a pro forma for practitioners to place the essential elements that make up their journey, which embodies the elements of practice. This will offer individuals an understanding of craft practice as layers of a self-directed journey.

Endnotes

[1] A 'lifeworld' is essentially 'the world of everyday life'. In this research, the lead author's life is situated within the field of design, having trained as a printed textiles designer and developed her visual thinking through interactive media over the past decade. Richard Buchanan's philosophy of design has shaped her knowledge of design and her understanding of its role within contemporary society and culture. Buchanan's work emphasises the rhetorical dimension of design thinking and is discussed in the context of the liberal arts. He articulates design as both a language and a metalanguage.

[2] The ideas underpinning this study were initially articulated by the authors in the original Arts and Humanities Research Council (UK) grant application proposal, 'Past, Present and Future Craft Practice: an investigation into the relation between skill, intent and culture'. For further information, visit www.futurecraft.dundee.ac.uk. [Accessed May 2010]

[3] Glenn Adamson's *Thinking Through Craft* (published by Berg in 2007) explores historical and contemporary ideas surrounding 'craft'. His examination offers a range of historical, critical and cultural perspectives, giving insight into the instrumental space that craft occupies in contemporary art. In his book Adamson discusses, for example, craft as an altered currency in today's visual lexicon, he examines attitude between art and craft, provides a forum for 'thinking though craft' and what such thinking might entail and he considers the finished work (be it art, craft or design) as supplemental to the underlying concept. He does not seek or provide definitive answers. This in itself is a useful and much needed contribution to the field.

[4] *A Theory of Craft: Function and Aesthetic Expression* (published by The University of North Carolina Press, 2007 and written) by Howard Risatti addresses one of the most persistent issues in craft; that of craft's relationship to fine art. As discussed in the introduction, the process of 'intellectualising' art – from the Renaissance humanists to the present day – has no parallel to date in the craft field. This lack of an equal theoretical framework has cast craft in a negative light and it is this imbalance that Risatti addresses by providing a new formal theory of craft. The abiding theme of the text is the notion of craft and the crafted object: what distinguishes a 'craft' object from a 'fine art' object? Can craft objects be considered 'art' objects at all? What is the difference between functional objects and 'art' objects and does craft's symbiosis with making, use and function preclude the label of 'art' at all? Rather than seeing craft as a traditional practice which is unconcerned with the challenges posed by modern industrial production or an area of practice, which should be allowed to dissipate into 'fine art', Risatti argues for a theory grounded in craft's own distinguishing features; not a theory imported from elsewhere and adapted to fit.

[5] Richard Sennett's *The Craftsman* (published by Allen Lane in 2008) examines the articulation of technique, and is viewed from the social context of material culture rather than a visual arts perspective. In this first volume (of a potential three) the author addresses the theme of craftsmanship and the portfolio of mental and physical skills required to do something well, for its own sake. Sennett draws upon diverse facets of society to illustrate this, citing examples ranging from parenting to computer programming. By using an eclectic range of illustrations, he broadens the parameters of what constitutes craft thus introducing a new concept, which one might describe as 'social craft'. Sennett's earlier career was that of a cellist and his understanding of the sensitivity and craft of music greatly informs his writing. *The Craftsman* is split into three parts (Craftsmen, Craft and Craftsmanship), and each section addresses elements that constitute the mix of skills required for the dialogue that exists between mind, body and materials.

[6] 'I' denotes the lead author

[7] Examples of the trade fair events include 'Collect' (2006 and 2007 at the Victoria and Albert Museum [V&A], London) and 'Showcase' (2006, Crafts Council of Ireland, Dublin). Exhibitions included 'International Arts & Craft' (2005, V&A Museum, London); 'Black Mountain College' (2006, Oxford); 'Beauty & Japan', (2006, British Museum), 'Out of the Ordinary: Spectacular Craft' (2007, V&A Museum, London), 'Cutting Edge Craft' (2007, National Museums Scotland, Edinburgh); 'Memory and Touch' Symposium (2008, Royal Institute of Architects, London).

[8] National agency meetings included one with Dr Helen Bennett, (the then Director of the Crafts Division), the Scottish Arts Council; Professor Stuart MacDonald, (the then Director of) The Lighthouse, Glasgow; Ms Rosy Greenlees, Director of the Crafts Council, London; Mr Leslie Reed, (the then Chief Executive of), Crafts Council of Ireland (1994–2006) and Ms Rose Watban, Senior Curator of Applied Arts Collections, National Museums Scotland, Edinburgh.

[9] The lead author organised a series of talks, inviting craft champions to visit Dundee and discuss their work with the research team and their colleagues. Examples include: the silversmith Michael Lloyd; the Scottish craft historian, Elizabeth Cumming; interactive jeweller Jayne Wallace and curator Amanda Game. Author Biography

Louise Valentine

Dr Louise Valentine is a researcher leading the major Arts and Humanities Research Council project 'Past, Present and Future Craft Practice' with Professor Georgina Follett. She is a lecturer at Duncan of Jordanstone College of Art and Design, a fellow of the Royal Society of the Arts and an Executive Member of the European Academy of Design.

Georgina Follett

Professor Georgina Follett is a Deputy Principal of the University of Dundee and Dean of Duncan of Jordanstone College of Art and Design, Dundee. She is also Principal Investigator of the 'Past, Present and Future Craft Practice', Arts and Humanities Research Council funded project. Georgina is a contemporary visual craft practitioner of 40 years, specialising in plique-à-jour enamelling. Her work is held in many private collections as well as the permanent and Roy Strong collections in the Victoria and Albert Museum, London.

A Didactical Framework to Experiment the Potential of Visual Languages in Engaging Social Complexity.

1 - Introduction

Development models often apply expert knowledge to social needs using a top-down approach, thus rendering these models insufficient in coping with the issues of a complex world. Effective changes in social systems arise from iterative and dialogic processes in which information and knowledge are exchanged between heterogeneous actors, building a common background that enables a shared hypothesis.

The design approach involves the ability to select results from various disciplinary fields, activating a trans-disciplinary circulation of concepts. Designers should use their skills to facilitate the emergence of a system, rather than concentrating on finding solutions to specific and well-identified problems. The focus should be on developing tools that can be self-adaptive, continuously modifiable and improvable by utilizing the ongoing process of wicked problem transformation. Social complexity requires new processes fundamentally attuned to the social and conversational nature of decision-making and design work; these processes should enable an increasingly valuable interaction level and dialogue among the actors of a social system.
And considering the Design discipline in respect to language, Communication Design could allow for the creation of visual and interactive languages relevant to the representations of Complex systems, thus creating shared visions within multi-actor contexts. In this sense, communication design can facilitate dialogues within participatory actions, and verify the potential of communication artifacts in supporting and externalizing sustainable and self-adaptive learning processes.

Therefore, the possibility of consciously facing social issues and orienting the behavior of complex social systems could benefit from the use of communicative tools and methodologies, thus supporting collective learning processes and building a common vision, shared by various stakeholders. Engaging complexity calls for visual languages.

2 – The role of Communication Design within the Complexity Framework

The centrality of communication and learning processes in dealing with complex systems - especially social ones - has been explored and criticized in several domains in different disciplines: from the theory of social systems (Luhmann 1984) to knowledge management (McElroy 2000). How these processes should be handled and shaped in order to be able, effectively and collectively, to drive and orient the evolution of a complex social system is a subject that is less explored and less clear.

We believe that communication design capabilities go beyond the general approach of taking into account complexity and developing a systemic perspective, and then examining the limits and opportunities of such a system. The type of communication design we are advocating includes the skills to concretely and actively insert, in every kind of process that aims to confront complexity, an intervention that enables a system change. In its evolution, the design field has defined itself as a cross-field discipline with different competences, addressing interdisciplinary issues, and often developing, by the creative recombination of knowledge units, the ability to create connections and new ties, thus giving shape to innovation. The design discipline creates innovation by pursuing relationships and combining the usual elements in a new way. Design has the capability to foresee, represent, and potentially visualize a complex of elements and relationships. Zurlo (2007) summarizes design capabilities as, *see* (understanding the context), *show* (visualizing the information) and *foresee* (making critical predictions), thus communication design is able to make complexity visible, understandable, accessible, and more easily practicable.

The importance of the concept of shape grounds the systemic thought that moves the focus from single parts to the whole, and sustains the need to understand the specific configuration of relationships (*pattern)*[1]. Understanding and intervening in a complex system requires the perception of the system as an integrated structure, and understanding which properties characterize the whole system, rather than belonging to any one specific component…those properties that emerge from the relationships and the interactions between single elements.

In our research, and in students activities, we assume the idea that the distinctive pattern of a complex system belongs to the visual domain of networks: it's the common organizational structure that belongs to all living systems, as Capra (2001) recalls: "Anytime we observe a form of life, we observe a network pattern […] the life pattern, we can say, is a network pattern that is able to self-organize".

To make the complexity of a system visible means to show what is latent; a fundamental step to enable access and intervention to the system itself. Both design disciplines and complexity theories refer to the domain of possibility and the hypothetical, and the specific contribution of design bases on the ability to both make a pattern visible and to assume the point of view of users: a user centered approach that produces prototypes as cognitive tools, for testing activities and reflective learning (Cottam and Leadbeater 2004):

> *Designers make problems and ideas visible, creating frameworks to make visual sense of complex information, and quickly sketching ideas to share work-in-progress with others. Making even intangible concepts visual creates a common platform for discussion, avoids misinterpretation and helps build a shared vision.*

The teaching and research program we propose explores and develops the visualization of networks, their features and dynamics, with the aim of educating designers in the exploitation of visual languages in dealing with social complexity. We intend to amplify the peculiar competences of designers to perceive and make visible those complex structures and concepts.

3 – The DensityDesign Laboratory: complexity, density and communication design

DensityDesign Lab was born in 2004 as a didactic initiative with the aim of developing experimental visual representation languages, to facilitate the sharing and the development of knowledge within groups of heterogeneous actors engaged in a complex system.
Let's imagine a decision-making table around which different stakeholders sit together: students are asked to define the concept and the design of communication artifacts intended to visualize the system as a complex whole, to create a common knowledge base for different actors.

The resulting communication artifacts cannot be considered as the solution to a wicked problem: mostly they are cognitive tools that are supposed to contribute both to better understanding and better acting, taking into account - through the visualization - both uncertainty and unpredictability.

3.1 – Density method: from graphs to diagrams

The communication artifacts designed by students during the laboratory are conceived as negotiation and decision-making tools. Communication design builds, through a visual language, the dialogical tools that allow the depiction of a common and shared understanding, and the emergence of common interests and goals in multi-actor contexts. From the beginning we

1 Capra says: "In the study of structure we misure things. But schema cannot be weighed: they need a visual representation. To understand a schema, we need to draw a configuration of links and relations. In other words, structure entwines quantity, and schema is more related to quality" Capra, 2001.

designated these artifacts with the generic term of *maps*, which evolved through the support of doctoral research[2] into the concept of *diagrams*. The etymology from the Greek διαγραμμα, DIÀ (through) GRÀMMA (sign), is open to the widest visual opportunities, and includes those communication artifacts that have a revealing ability - such as maps, scenarios, schemas, storyboards etc. - and represent the *visions* behind visualizations.

In our meaning, diagrams provide the system with an understandable and sharable shape that can overcome the constraints related to technical and disciplinary languages. Diagrams can visualize not just quantitative data, but also ideas, concepts, point of views and perspectives, as well as qualitative and value assets of complex systems observers. Beginning with a review and interpretation of insight into diagrams emerging from architectural research, we underline four important characteristics of diagrams (Corbellini 2007):

Condensation: diagrams can manage huge amount of data and information, and can demonstrate connections between elements that otherwise would be difficult to understand.

Connection: diagrams are able to express relationships between non-homogeneous data and information, encouraging unexpected interpretations and perspectives.

Proliferation: diagrams enable dialogue and inspire different ways to approach the problem setting and the understanding of systems; they are also fertile narrative devices.

Inexactitude: the construction of diagrams always displays a partial and non-comprehensive description of the system. Acting within complexity requires considering the impossibility of reaching an exhaustive knowledge of the system in which one operates. This difficulty could be overcome by developing strategic stances that allow for the ability to face system changes and their evolution, and are also the opportunity to visualize complex information referring, not solely to the communication of quantitative information, but also to intangible values and qualitative data. In this sense, it's necessary to emphasize that for designers, diagrams always represent a process of choice between the representation of certain things, and the renunciation of others. It's a political action, intentional, and arbitrary, and an aspect that clarifies and pinpoints the designers' responsibility when constructing visual representations.

The diagram takes the Deleuzian meaning of *conceptual device, abstract machine and proliferating machine, enabling method*, and *discursive instrument*. Through diagrams, the visual language demonstrates the shift from product to process, the movement "from the sensible to conceptual, from symbolic to syntactical" (Corbellini 2006), and from visualizations as a result, to visualizations as a process (attitude).

The methodology through which we approach the representations of complex systems is based on the visualization of (a) actors (people and organizations), (b) the relations between those actors and (c) the pattern of flows that involve those actors, defining also information *graining*, the boundaries of the system (*framing*), and the size and perspective of observation (*scaling*) (Scagnetti et al. 2007, Authors et al. 2008).

This is the approach that grounds our practice; the ability to reconstruct the schema, the shape of the system, and the entwining of connections and influences, even if the full potential of diagrams has not yet been fully exploited. Barabasi (2005) states, "networks are just the schema of complexity, the basic mechanisms. In order to describe the society we have to hold the links of the social network with the actual dynamic relations between people".

2 Gaia Scagnetti, 2009, The design practice of complexity. Communication atlas for sustainable social system integration. Author3, 2010 expected, Seeing what they are saying: diagrams for socio-technical controversies

3.2 DensityDesign tools: diagrams as a cooperative visual device

The interest in diagrams is less about the result itself, but rather as a visual/discursive tool and the generator of dialogical actions. Diagrams are not a final solution, but are instruments for better framing an issue. An apparatus in the hands of the visual designer, diagrams enhance not only the designers' own ability to see, but also enhances the vision of others by creating a collective vision of a form that binds the different elements of an issue or complex system; a precious skill when addressing contemporary problems that require a more participative and collaborative approach:

> *To speak of a problem and to engage with solving it is to engage in a conversation among stakeholders (people who care about the outcome). In my thinking about wicked problems, I like to introduce the notion of 'social complexity' as inseparable from problem wickedness. There are no single stakeholder wicked problems. (Conklin, Basadur, VanPatter, 2002)*

To make visible the relational structure of a complex system, and to describe the dynamics that animate this structure, by combining various tools and visual patterns, is what communication design can add in order to facilitate the exchange between stakeholders, enable negotiations and mediations and enlighten common visions and intents. It's a relevant contribution, acknowledged by Burkhard (2004):

> *You don't so much "solve" a wicked problem as you help stakeholders negotiate shared understanding and shared meaning about the problem and its possible solutions. The objective of the work is coherent action, not final solution. Thus, Rittel and Webber's contribution was well ahead of its time, and is now finally helping us understand why communication and collaboration, more even than creativity, keep emerging as critical to success on large projects.*

The design of diagrams, and a diagrammatic approach, are primarily useful for the design process itself, especially when faced with complexity: "The emerging horizon of the designer depends mainly on the capacity of building and improving the perception of the complex reality, even before building and improving the skills to address it" (Pizzocaro 2004). Some of the proposals that drive the continuous redefinition of the design discipline, bestow the field with the duty of diffusing and making more accessible the design method itself: the development of "open" languages enabling the participation of non-expert users in producing diagrammatic visualizations, is tangible evidence of the enlargement of the communication design domain.

4 – The structure of the Density framework

Since 2004, we have defined and improved the processes of building and structuring visual languages. The methods and procedures of visual analysis, and representations of complex systems have undergone continual improvement over the last five years, and with the development of specific conceptual and operative tools, the initiative has recently reached a more ripened stage (2009). The following section briefly describes the process utilized during the laboratory's activities, and includes the presentation of some artifacts along with descriptions of sample results.

4.1 – Visualized data, information and knowledge

The potentialities of visualization are experimented in two complementary domains: 1) the visualization of Data, Information and Knowledge (DIK), 2) the visualization of the structure of complex social phenomenon (structural visualization).

In the first domain, the students work to improve the cognitive processes that transform data into information, and information into knowledge. Within these processes, any visualization acts as a translator: it identifies and visually represents relationships between data and information, in order to communicate it and leverage knowledge. In the second domain, the focus is on the form of social phenomenon, assuming that understanding a system means understanding its form, and understanding form means to see and visualize a pattern. In this domain, visualization aims to amplify the *pattern finding* human capability (Ware, 2004), connecting the actors and/or the forces that drive the complex system or the dynamics of social phenomenon.

In general, the perspective of complex systems is recognized as the best occasion in which *"to observe the social world and its' making of. […] According to this approach, nothing can attain a collective existence without being the result of a collective work and controversies are the settings where this work is more visible"* (Venturini 2009). With this feature, any actor within a complex system is continuously involved in data production, information gathering, and knowledge exploitation, in order to support and nurture his own position and interest within the collective undertaking. Data, information and knowledge are the structural and basic elements of representation theories, and in a general way, of the communication and cognitive disciplines. The connection among these elements and visualizations is a key issue in the communication design field.

Any kind of discussion and research that tries to better redefine the role of visualization within the evolution of complexity cannot avoid a clear reflection about the role of design in the process of transformation from, and to, data, information and knowledge. The distinction between these three elements still remains commonly confused. Data and information are sometimes intended as synonymous, and information generally converges with the concept of knowledge. Timetables, for example, are basically lists of data. These raw — and thus disordered — data about train numbers, departure times, arrival times, and routes, etc., become information when they are structured, passing from a state of high entropy to a state of low entropy.

The timetable example illustrates the role of communication design as a tool for sensing, retrieving and using data. In fact, once data has been organized the second step is represented by the user's assimilation and interpretation. Thus, it emerges that information and knowledge do not represent the same notion. Only thanks to previous knowledge, an internalization or interpretation process, are we able to contextually comprehend a message by transforming the information into further knowledge, thus allowing for action. In this way we can define the second difference between information and knowledge (i.e. knowledge as action).

A Pyramidal hierarchy is often used to represent the relationship between data, information and knowledge (Awad and Ghaziri 2004; Bellinger, Castro, and Mills 2004; Chaffey 2005), yet a flow representation better depicts the relationship between these elements (Cooley 1987; Choo 1996; Jacobson 2000; Bellinger, Castro, and Mills 2004). For this reason, understanding the transformation from data to information is a fundamental matter: the way data and information are presented is of crucial importance in enhancing, understanding and facilitating effective action. Knowledge can be externalized in books or documents (thus turning into information) but can be represented only by experience: *"knowledge is a fluid mix of framed experiences, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers"* (Davenport and Prusak 2000).

Knowledge can be seen as an interpreter in the transformation of data to information; information can be extracted from data only through knowledge. Even though it's not hard to imagine a designer visually representing data and information about controversies, the problem arises when trying to visualize the knowledge produced by the actors of a complex social system.

We have to come to terms with the impossibility of visualizing knowledge, per se, or of considering it an instrumental, operative and reproducible object as it is defined by some knowledge management research lines. Still, we can represent it. However, visualization can only be given by representing knowledge in action, tracking back to the last step of the flow, the one that leads from information to knowledge (i.e. from knowledge to information).

Visualizing, communicating and sharing knowledge means to engage in a process opposite to that of natural acquisition, taking in a contrary direction the data, information, and knowledge continuum. Knowledge has to be converted into information so that it can be transferred and transformed into a physical and visual artifact. Thus signifying that every graphical representation is a visualization of information.

4.2 – DensityDesign experiments and outcomes

Over the years, the number and typology of the didactical modules have been refined, along with the range of disciplines that have been involved and integrated. The choices have been made primarily according to the results of two activities: a) internal discussions with professors of other disciplines (i.e. Statistics and Semiotics) about the outcomes produced by students and, b) the collective discussion sessions organized at ENEA (the National Agency for Energy and Sustainable Development) during the development of Alessio Romeo's Master thesis, "Sistema Energia Italia: Progettazione di un dispositivo comunicativo per i processi decisionali inclusivi" *(Italian Energy System: Designing a communicative system to support inclusive decision-making processes)*. During these sessions, stakeholders from the Italian energy system were asked to depict possible scenarios through the collective discussion of the system maps produced within the thesis work (see fig. 5a, b, c).

In the first stage of the Density Design didactical framework, students were asked to identify a social system, about which they were passionate, and to then gather data and draw a description of that system. The students designed the diagrams, providing a visual representation intended to provide a comprehensive description of the system, in order to better depict its current configuration and dynamics. These kind of maps supported the next design action: using their maps the students would articulate a communication design strategy relevant and useful to the system dynamics, and then return to the diagrams to depict the impact and the new configuration of the system after the interventions. At that stage, the basic intention was to reflect on the selective processes that give shape to a map, and to refine the visual language and empower the ability of representing these different views by the exploitation of details.

A more reflective capability has been explored over the years, and the framework evolved towards a more articulated definition of the visualization modules, according to the communication goals. The current structure of the framework is composed by four modules that drive students from the use of the standard techniques in information visualization, to the development of motion graphics artifacts, depending on the communicative goals. Two modules – *information visualization* and *motion graphics* - belong to the first visualization domain previously mentioned (DIK visualization); the others - *causal diagrams* and *system maps* - are expressions of the structural visualization domain, based on the need to understand the social system/phenomenon as a whole. Similarly, the impact of visual rhetoric has been introduced, in order to evaluate the potential role of visual metaphors and analogies. This distinction between the diagrammatic modules and the Infovis modules refers to the different intentions of the visualization process: diagrams exploit the system's analysis and display, while Infovis explores the narrative techniques, and the conversation between form and meaning.

Information visualization

The challenge of the information visualization module is to nurture and clarify the process of translation from data to information to knowledge. In this module, complex data sets are explored and transformed in visual representations that aim to clarify the meaning of data and make them useful to knowledge enhancement.

Our recent experiments have explored the socio-economic phenomena that present both representational and visual problems. Economic statistics involve understanding complex, multidimensional, ambiguous and dynamic phenomena, and building formal representations (models) based on statistical data. Communication Design addresses complex phenomena in order to interact with them, building multi-dimensional visual representations based (in some cases) on statistical data. The goal is to contribute to the construction of representation and visualization models, while respecting and preserving the inner structure of the analyzed phenomena, allowing users to know (or see) them as a whole.

We used official data (provided by the ISTAT) about poverty and social exclusion conditions in Italy (2007), with each of the students asked to provide a visualization about poverty in Italy, using the data as their primary, though not exclusive, source.

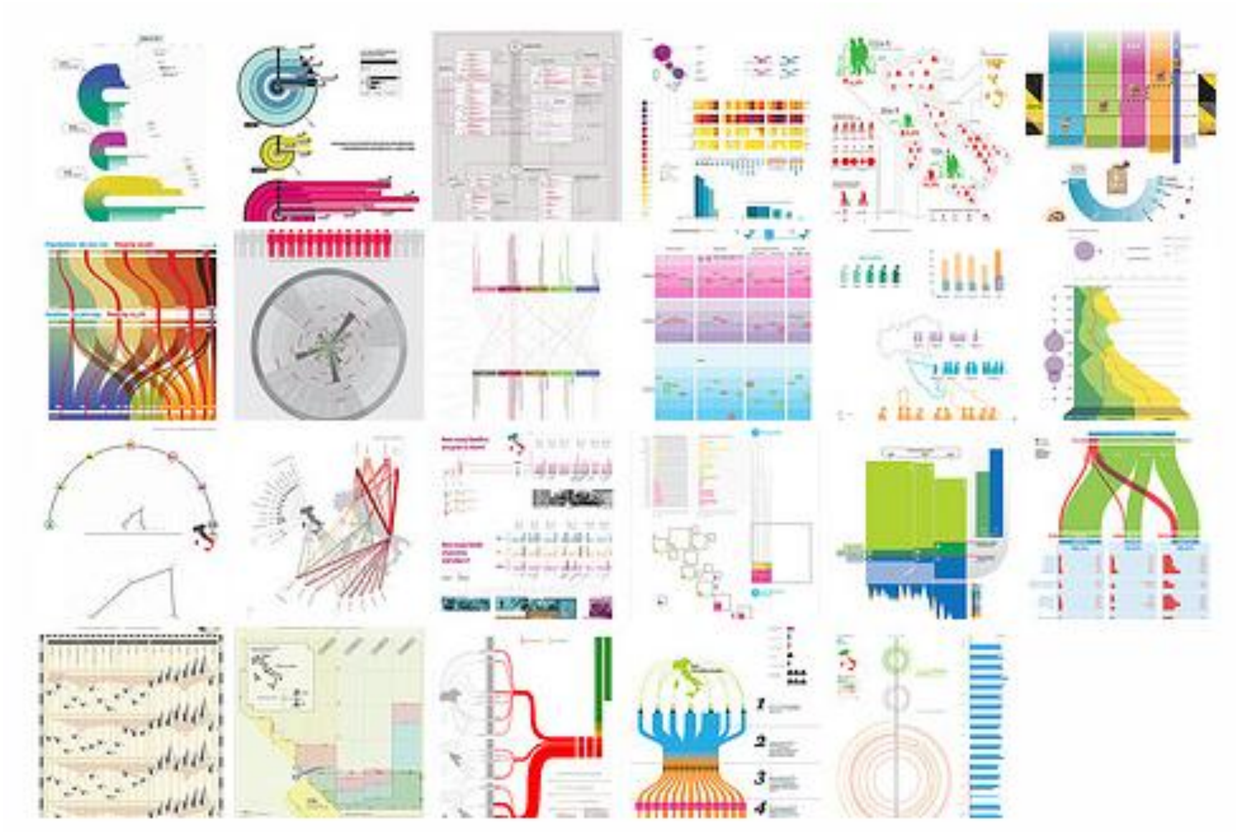

Figure 1 –from data to information: an overview of the different maps designed with the ISTAT italian national report about poverty

Exclusion is a socio-economic status that refers to people located at the margins of society, because of their economic, psychological, physical, and/or cultural conditions. To evaluate the forms and intensity of exclusion requires models that consider a multitude of dimensions, for the determination of poverty status cannot be reduced to a simple and single indicator. The representation of socio-economic problems is not reducible to a single problem or purely algorithmic technology, not because of lack of quantity of data, but rather because complexity, multi-dimensionality and ambiguity are difficult to reduce into algorithmic computations.

This module requires the development of new visual grammars and communication tools that do not superimpose artistic elements, over the representation of the phenomena, but rather build narratives deeply consistent with its inner structure. Visualization artifacts, diagram and maps, have to *respect* the robustness of the scientific approach to phenomena, while remaining *consistent* with the structure of the cognitive and logic capabilities of the observer.

Causal diagrams

The module of casual diagrams is a structural visualization tool that aims to fully describe the actors and variables of a system, and to exploit their influence and directions. It is a kind of representation that better describes the structural part of the system, pointing out the elements as single and detailed, as well as the main structure and influences. At this stage, students were required to split into groups, and select one specific topic from within the wider poverty framework, and to further develop their visualization. Casual maps are necessary to fix the mechanism of the system, and they are the primary schemas in the understanding of system behavior.

A causal loop model has been developed in order to help understand the complex systemic structure of poverty in all of its dimensions. System diagramming is here a loose term used to describe the activity of conceptually representing and visualizing a system in its constitutive elements: the elements, the relationships and the system boundaries distinguishing what does, and does not, belong to the set. The system has been visualized in a particular format: a causal loop model (or diagram). In a causal loop model, boxes represent the system's elements (factors, variables), while arrows represent the causal relationships between the two variables. The variable at the tail of the arrow has a causal effect on the variable at the point. In addition, a distinction can be made between positive and negative causal relationships. A positive causal relationship implies that both variables will change in the same direction: if variable *a* (at the tail) increases, then variable *b* (at the point) will also increase (and if *a* decreases, then *b* decreases). A negative relationship, on the other hand, implies that variables change in opposite directions. The causalities discussed so far are linear causalities (from *a* to *b*). Circular causalities (e.g. from *a* to *b* and from *b* to *a*) in systems maps are called feedback loops. They are an important feature of causal loop models because they help to explain the dynamic behavior of the system.

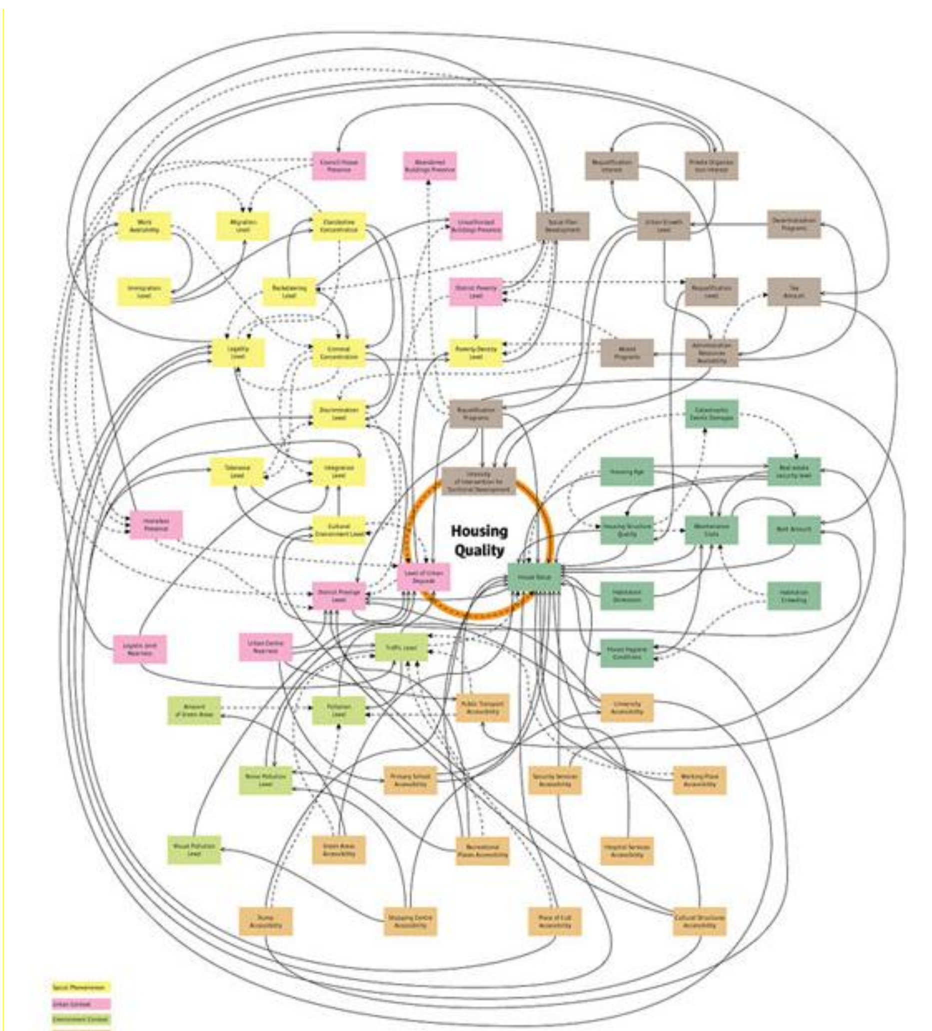

Fig. 3 –a casual diagram about the poverty system

Motion graphics

The motion graphics module mostly explores the narrative power of information visualization. In this case data become information, and then knowledge, and the visual languages are devoted to defining a relevant narrative. Motion graphic techniques are used not for the systemic representations of complexity, but rather serve as thick descriptive tools, able to reduce the distance between data, patterns and meanings within a narrow perspective of the system. Information visualization, in this case, provides a thick description of a single perspective, and visually clarifies the way in which the specific point of view is related and interconnected with the wider configuration.

Fig 2 – from information to knowledge: screenshot from the video Choice, motion graphics about the Poverty System and Food, http://www.vimeo.com/4002528

System maps

The final artifact discussed is the system map, which can be considered as an overall perspective of the system, a sort of bigger picture that describes the components, dynamics and contextual characteristics of a system. System maps emerge from a hybridization of the previous diagrammatic artifacts and a deep visual description of all the content; they aim to suggest the form of the system by the visualization of the found pattern. System maps don't emerge just from data analysis, but are connected to some previous knowledge that is itself depicted within the maps. They are composed of raw data and structured information and are able to finally provide a wide scale representation.

Maps are intended for an audience that is within, or related to, the system, and for those actors who operate from within the system. The maps exploit the knowledge layer related to experience, and should be able to activate dialogues and discourses about the system itself. Maps represent the final step in the cycle between data and knowledge, and transform and elaborate the previous contents in order to enrich a collaborative and shared knowledge.

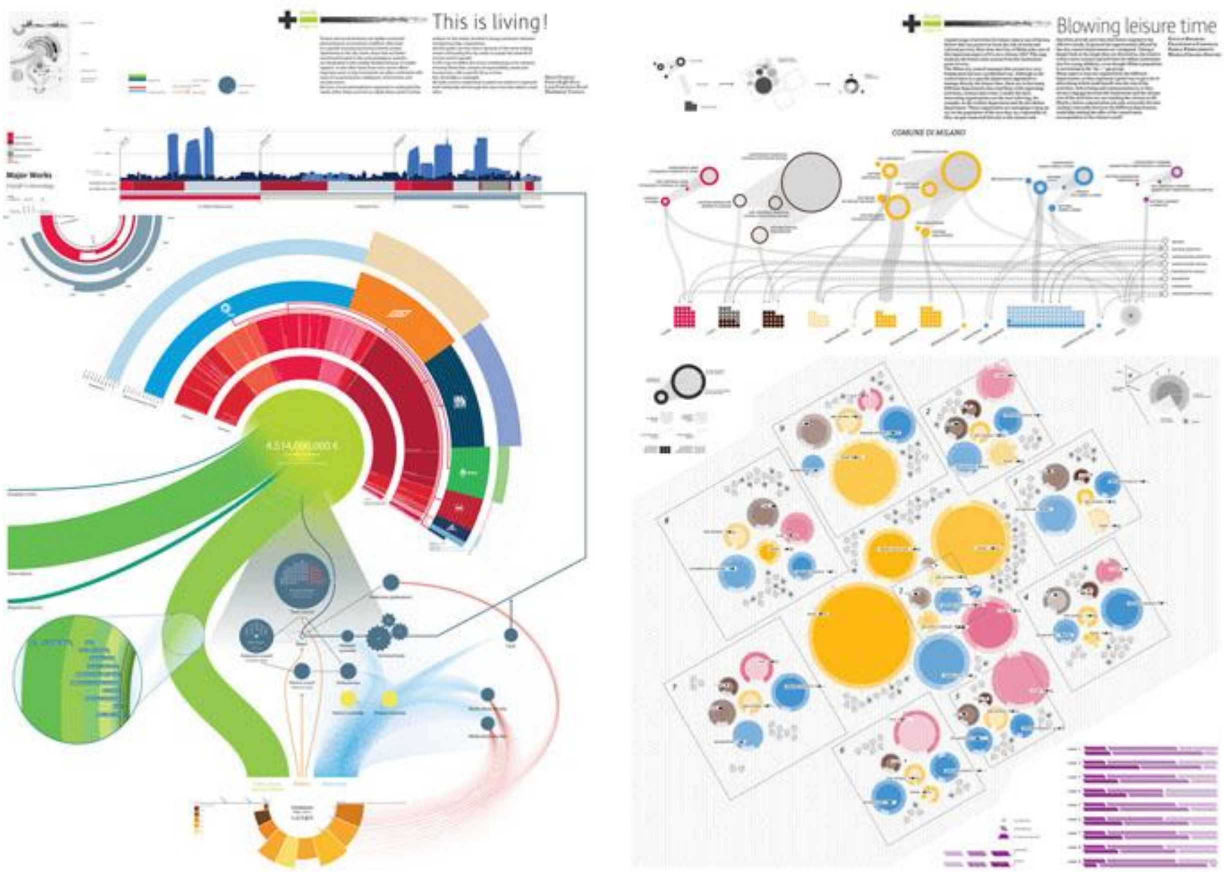

Fig. 4a,b –the system map, Poverty&Housing, Poverty&Leisure

In this module the possibility of evaluating the projects in real contexts is more relevant; finding an evaluation context for projects always means interfacing with institutions, organizations, and identitary structures, and represents a concrete example of negotiating and decision-making that is supported by visual languages. In many cases the process has been successful, and the students were able to verify the effectiveness of their own design, thereby making improvements.

Alessio Romeo, MA thesis “Sistema Energia Italia. Progettazione di un dispositivo comunicativo per i processi decisionali inclusivi” (Italian Energy System. Designing a communicative system to support inclusive decision-making processes).

Conclusions

In these pages we have tried to systematize both the theoretical and the artifact outcomes that we have experienced in the development of the DensityDesign Lab. The theory and the results are ongoing tensions that we continuously consider in our research and teaching practices, and that we mainly try to get across at concrete evaluation stages by prototyping (in case of interactive

artifacts), as well as in the participation of decision-making tables. In fact, an extension of the practice of evaluation in real contexts is needed, and the trend also in publications and conferences indicates a fertile horizon in this direction. The challenges shaped by global change require a collective disciplinary engagement, and design is called, and strongly aspires, to participate in finding the solutions to these challenges.
Through the DensityDesign approach, we hope to provide those facing global challenges with a cognitive and practical set of visual tools, a generative machine that allows for a discourse about a changing system, and that facilitates a more conscious approach to complexity. These visual tools aim to originate from common objectives, and consequently develop shared perspectives.

The approach requires a continuous refinement of the nature of the team, and an open and interested attitude toward future projects. The didactical framework proposed here is intended as a multidisciplinary platform, where visual design is the core and leading discipline, complemented with the integration of semiotics, statistics and network science. In order to nurture an intersection between the disciplines, the development of the framework will follow two main directions. First, more research is needed into understanding the cognitive issues of information visualization, and the language of visual narratives. This will involve the efforts of communication design using both representation skills, and interaction and cooperative capabilities. A more unexplored, second direction, introduced through a real data set, is more technical, and involves the power of computational and semantical processing of data. A structural robustness in the framework can be achieved by consolidating the approach to quantitative data, along with the effectiveness and variety of the transformation process into visual information. This step represents a marked evolution, for the integration of other disciplines will certainly lead to experimentation with the field of computer science, to theories of network semantics, as well as social system theory, and will challenge communication design skills to constantly cross languages, from bi-dimensional illustration to interactive processing.

The more refined the process of visualization becomes; the more articulate becomes the strategy of data gathering. These are the basic tensions that we tie to the concept of visual languages as a multidisciplinary cognitive device.

Is systemic design the next big thing for the design profession?

Design is increasingly used for tackling large and complex problems and this new systemic design thinking is often interlinked with large societal issues. This paper will give the historic background and context to this development; it will show how the overall economic situation affects the design profession as well as exemplify recent development of the design practice. In order to do this it will describe three case examples of recent design usage in large societal issues: the birth of a new university, the municipal commitment of using design to improve society and the national approach of Finland in pushing systemic changes through design.

Keywords: Design and society, Design Practice, Systemic design

Authors: Anna Valtonen, Umeå Institute of Design, Umeå University, Sweden

Economic downturn has tended to bring forth the moral aspects of the design profession in Europe (Author, 2006, article). In a shattered post-war Europe, belief in a new world and modern liberal democracy was largely expressed through consumerism and not many moral considerations of what was designed were raised. During the late 60s and the oil crisis of the 70s, designers sought for moral and ethical stances, and the ethical justification of capitalism was frequently questioned. Victor Papanek turned the ethical blowtorch on the industrial design profession (Papanek 1972, Lewis & Gertsakis 2001,19; Whiteley 1993, vii; Heislinger & Marcus 1993, 249) and many others followed. With the economical upswing in the 1980s, ethics were suddenly again of lesser interest for the designers. Designers no longer aimed to find one ideal product solution or to defend those with disabilities, but to do good business. The postmodernist ideals of the 80s saw the meaning of a product to be the primary criterion in its conception and use, rather than the uses to which it was to be put (Heskett, 2002, 57; Julier 2000, 31). The arrival of the 90s saw an economic downturn in many European countries, and the importance of brands grew for companies. The main focus was no longer purely on the product portfolio, but also on the end-user experience of the corporate and its brand (see Press 2003; Mitchell 1993; Kuniavsky 2003; Shedroff 2001; McDonagh 2004). There was a paradigm shift from the utilitarian, rationalistic-individualistic, neoclassical paradigm, to a new paradigm where people were considered to be able to act individually and rationally but with a very strong moral and emotional underpinning.

In Finland crisis has always been a good cause of change for the design profession. The industrial design profession was born in the aftermath of the Second World War, where the national reconstruction also included rebuilding much of the national identity through design. Many Finnish designers gained great international fame during this era and a vivid discussion on design education with an industry approach flourished. This debate resulted in founding the industrial design education and the first educated industrial designers graduated in 1965. (Korvenmaa 2009; Sotamaa (ed.) 1999)

During the late sixties, seventies and eighties the professional practice of design developed steadily but slowly, becoming a formalized but still very small practice used by pioneering and broad-minded companies throughout the country.

The next major crisis for Finland came fifty years after the war. In the early nineties, Finland experienced an unexpected and exceptionally deep recession (Kiander 2004). The recession, together with the fall of the bilateral trade to the Soviet Union and the opening markets of the EU, which Finland joined in 1995, positioned the Finnish industry in a totally new and more competitive environment. (Kalela 2001) Design was seen as a great way to compete in the tougher markets, and the usage of design grew rapidly (Author 2007, book). The education of industrial designers grew exponentially and companies increasingly founded in-house design departments. This coincided with brand building, strategy and then in the 2000s with building the national innovation agenda.

Economic and social crises have thus been fruitful opportunities for the design profession to change. What has been common for these changes is that it has largely been the designers who have strived to develop their own professional practice forward and to ameliorate their professional standing (see Larson 1977, Abbott 1988). It is most likely that the economic crisis we are currently in will affect the design practice, but it remains to be seen exactly how. To get a proper historic view of the development we will need to wait at least another ten years, but we can already see starting phenomena and start formulating a hypothesis of how the design practice might be developing. In order to do so, this paper will first describe current developments in design and then review and analyse three recent cases in design.

RESEARCH APPROACH

This paper aims at showing recent developments within the design profession and at giving them a historical framework. The topic is reviewed from a profession studies perspective. Among the success factors of the design profession have been aligning the professional practice with the dominant ideological structures, such as the national system of innovation, as well as sharing new knowledge through research (Larson 1977, Abbott 1988, Author 2007, book).

This paper will first show the history of how an economic downturn has tended to shift the approach of the design profession and how the practice is currently changing. To review the very recent changes, three sites of development and some of their projects are reviewed as a basis of illustrating and further understanding the current developments within the design practice. All of the three cases are from Finland: the city of Helsinki and its project for becoming World Design Capital 2012, the Aalto University and the role of design in it, and the Finnish Innovation Fund Sitra and its two projects, the Helsinki Design Lab and the Low2No project. The purpose of presenting these cases is partly descriptive – to illustrate recent phenomena in the professional development – and partially analytic. The case descriptions include objectives of why designers are pursuing current directions, as well as key players and steps in initiating the projects.

In addition to the printed material about the three cases, specialists involved in the development projects have been interviewed or their public presentations have been used. These are Pekka Timonen, Cultural Director and Jussi Pajunen, Mayor, City of Helsinki, Mikko Kosonen, President, and Marco Steinberg, Director of Strategic Design, of the Finnish Innovation Fund Sitra, and Tuula Teeri, President of the new Aalto University.

Similar developments within design are now happening around the world in different scales, and the aim of this paper is also partly to give a Finnish perspective to the recent developments in the design field. Many scholars are currently involved in defining what this change is about, and hence the practical examples from one country can serve as an interesting point of comparison internationally.

APPROACHING COMPLEX PROBLEMS THROUGH DESIGN

Currently we are again facing a new kind of marketplace and a recession. This time, however, the starting point for design in Finland is very different than in the early 1990s. The professional practice of design is now fairly well established, and the usage of design as part of product development has become commonplace in most companies. There are now substantially more designers educated than before the 1990s, and their skills in areas such as marketing and strategic thinking are remarkably better.

Since the 1990s there have been many areas of development within industrial design. More and more focus has been moved from product design to the development of services (for Finnish examples, see Järvinen&Koskinen 2001, Miettinen 2007, 2009), to a user-centric focus (Keinonen 2000, Lindholm et. al 2003, Battarbee 2004, Mattelmäki 2006, Hyysalo 2009) to design discourse and to a more research based approach (Karjalainen 2004, Ryynänen 2009).

In general, there appears to be a shared quest for finding more meaning in design. Some, like Klaus Kippendorf, point on the deeper cultural meaning of the products themselves. Others (such as Jordan 2000, Press&Cooper 2003) focus on the more meaningful experiences that can be created through design. Many others, like Walker (2007) and Fry (2009), look at finding meaningful answers to global issues of sustainability. Increasingly the approach tends to be towards finding solutions to large and complex issues and understanding the relevancy of design to the larger whole.

Designers are not aiming for a more systematic view for the first time in history. Even the first wave design theoretics talked about the rationalist and logical designer (Bousbaci 2008,38). The second and third generation models brought the concept of the designer with a bounded rationality and many of the current theoretics, with the starting point of Donald Schöns *The Reflective Practitioner* (1983) talk about designers as reflective practitioners. Bruce Archer wrote *Systematic Method for Designers* as early as in 1981. He saw design research as a systematic search for and acquisition of knowledge related to design and design activity.

Currently the ability to reflect over practice and to approach large systemic issues is frequently viewed through the concept of wicked problems, originally put forward by Rittel and Webber in the 1960s (Rittel & Webber 1973; 1984,136). The notion is that there is an entire class of social system problems, which are ill-formulated, where the information is confusing, where there are many clients and decision makers with conflicting values and where the ramifications in the whole systm are thoroughly confusing. The relationship between these issues and design thinking has been taken forward by Buchannan (see for example Buchannan 1995) and partly also by Nelson & Stolterman (2003).

Many researchers have focused on the creative abilities of designers to view things differently and to make the unforeseen future more tangible. Kippendorf (Mitchel 1993,71) talks about the designers' ability to invent or conceive possible futures and their ability to work with how desirable these futures are. Laurel (2003,17) notes that there is an emerging paradigm where the old working processes are being inverted, where design is seen as a front-end method, aiming at a set of methods and practices for getting insight into what would serve and delight people.

Some push this ability to affect the future even further. Fry (2009, viii-3) wants design to make a standpoint in the field of political action. He claims that the design community should forget design as a territory and practice that can be laid claim of (the drive of professionalization), stop talking to one selves (the internal dialogue of design events), give up repackaging design with design (codesign) and start talking to other people, other disciplines; broaden ones gaze (beyond the design process, design objects and design's current economic positioning), and engage the complexity of design as a world-shaping force and help explaining it as such. He sees the modelling of design problems, design solutions, design experience and creativity all becoming applications of "intelligent systems" for creating and delivering "design tools". (2009,14)

The role of design, and the definition of what design is, is again changing. Design is now seen as a potential contributor to improving our relationships with each other, our communities, our cultures and our democracies. Design is seen as not only serving the needs of our businesses, but also determining and working towards the greater good for society and government, education and the environment. (Lunenfeld 2003,14) Design is no longer considered to be an isolated activity within one profession, but its contribution to the society and larger collaboration is vividly discussed. Focus has moved from design and design activity to the whole world and larger social issues, as Nicola Morelli is asking if designers can "Industrialize" Socially responsible Solutions and is proposing a shift of designers' activities from products to systemic solutions. (Morelli 2007,6)

FINLAND AS A HOTSPOT

In Finland, the rapidly changing environment is once again forcing the society to look for new innovation. The previous recession meant a major competitive shift in the Finnish industry and design was seen as one of the solutions. The usage of design grew rapidly, partly because of the shift in industry, partly because the designers promoted themselves and what they could do and aligned their work with the dominant ideology in order to ameliorate their own situation.

Now we are in the middle of a recession again, but in addition to this we also need to tackle problems like global warming, aging population and failing healthcare systems. This time it is not designers aiming to ameliorate their own situation but the entire society, the government, city and academia, believing that design, or design thinking, might be part of the solution for its complex problems.

The approach to societal development has also changed through time. According to John Kao (2009) several countries now have end-to-end innovation eco-systems and innovation is increasingly becoming the new wealth – and typically comes from blending disciplines. As part of this new approach to innovation, design is increasingly seen as a thinking tool for solving large, indefinable challenges. Kao defines Finland as one of the new hotspots of the world, where a small country with a strong innovation ecosystem and many informal connections among the different players can pioneer large-scale, holistic solution finding.

In Finland, there are currently many activities embracing this new way of design thinking. In this paper, I will cover three initiatives: the inclusion of design in municipal systemic thinking through Helsinki and its Design Capital 2012 approach, the formation of a new university and the relevance of design in a broader cross-disciplinary curriculum at Aalto University, and design as systemic approach to global issues through the activities of the Finnish Innovation Fund Sitra. What is common to all of these is that it is no longer the professional practice of design alone that is promoting new usage of design, but large, social institutions being formed on the principle.

CASE 1: EMBEDDING DESIGN IN SOCIETAL DEVELOPMENT

Design as a new way to think about complex issues has been embraced on municipal level and integrated into the development of society. The Finnish capital Helsinki was recently chosen to become the Design Capital of 2012. Altogether 46 cities from 27 countries applied for the designation. An international jury first shortlisted Helsinki and Eindhoven of the Netherlands and then awarded the designation to Helsinki. Helsinki's theme in its World Design Capital year 2012 is Open Helsinki – Embedded Design. Embedded design is seen as an enabler of an open city that boosts social, economic and cultural development and as a connector between different disciplines aiming to meet the inhabitants' needs with desirable solutions. The influence of design is also described in the city's strategy.

The process of applying for the Design Capital has largely been on the shoulders of the people working in the municipality, most remarkably on its Cultural Director Pekka Timonen. However, the entire design community has participated actively. The original idea for applying came from the Designers association of Ornamo, and individual designers also did some background work before the application process started. Once the city decided to apply, all the work of driving the process further has been done by the city, albeit through the participation of many designers. This may be part of the secret of why this process has been so successful: all players in the design fields have felt that the theme of embedded design is inviting to them and participated eagerly in the development process, but a player outside the field itself has been the one to hold all threads together.

Mayor Pajunen points out that design should be seen from a broad perspective. “Our goal is to build a better city and to improve our quality of life. Among other things, design-oriented thinking can be used to reform public services. The basic values of good design include user-friendliness, sustainable development and enjoyment.”

This approach to design, called embedded design, ties design to innovation from the very beginning whenever solutions to citizens’ needs are sought. Thus embedded design helps to render new innovations, technologies and systems sustainable and brings together human needs, aesthetic qualities and functionality. Helsinki approaches design from a broad perspective, and design underlies all processes that bring about social, economic and cultural improvement. This municipal approach is part of the larger national scheme of Finland’s National Innovation Strategy. The strategy expands innovation policy from traditional innovations to new areas and makes user- and demand-driven needs the cornerstones of the policy.

CASE 2: APPROACHING NEW KNOWLEDGE

Another area where many changes have happened is within the Universities. The whole university system is undergoing a major reform in Finland. According to a Government Programme, the financial and administrative autonomy of universities will be increased. In this connection, university governance and decision-making is reformed. From August 2009, all Finnish universities will be either institutions under public law or foundations under private law and all universities will cease to operate as part of the state budgetary system. Part of this process has been the foundation of the new Aalto University, consisting of the previous Helsinki University of Technology, Helsinki School of Economics and the University of Art and Design Helsinki (TaiK). It started in January 2010 and comprises a total of around 17000 students and 4000 staff. The Government has made a commitment to finance this foundation- based university with an extra 500M€.

The whole concept of combining the three universities was first put forward by the then Rector of University of Art and Design Yrjö Sotamaa, in his speech for opening of the school year in September 2005 (5.9.2005). Since then, a lot of work within different bodies has been done. Within the universities eight transformation groups with various focus, supported by the three existing rectors and the Aalto University Foundation Board, were actively trying to define what the new university should be about. In each of the transformation groups there has been people with a design background, but also specialists from other fields. In total, 400 of staff and students were represented in the working groups. In spring 2009 the university got its first President, Tuula Teeri, who has since then been heading this development process.

Aalto University has a unique combination of knowledge and the university approaches many of its initiatives through design thinking. The mission of Aalto University is to strive to change the world through top-quality interdisciplinary research, pioneering education, surpassing traditional boundaries, and renewal. Aalto University is to educate responsible, broad-minded experts with a comprehensive understanding of complex subjects to act as society’s visionaries.

In order to do so the Aalto University develops strong teaching and basic research in each of its three disciplines, creating professional researchers, designers, artists, engineers and economists. In addition to creating strong professionals the university actively develops new platforms, where different professional competences work collaboratively. One of the most prominent is the concept of Aalto Factories.

The three Aalto Factories, in the area of Design, Media and Services, all use design in grasping complex problems, providing learning, teaching, research, and co-operation environments in which the academic teams, companies and communities work together. The workshops are based on open innovation, an interdisciplinary attitude and new ways of learning and teaching.

Design and design thinking has also been defined as part of the universities focus areas. In order to define and evaluate the different research specialities, a large Aalto University Research Assessment Exercise (RAE) was conducted in 2009. The Research Assessment Exercise was conducted as a peer-review assessment by nine international panels with 62 highly esteemed experts. Altogether the research of 46 units (departments, institutes or equivalent entities) was assessed and the results were published in September 2009. The RAE was complemented by a separate report by the Academy of Finland called Research in Art and Design in Finnish Universities, also published in 2009.

The findings of the Aalto RAE suggest that the most distinctive strength of research at Aalto University is the level of its societal impact in general, and its interaction and cooperation with industry in particular.

The Academy of Finland report sees artistic activities as naturally integrating in nature. They claim that in solving complex problems we need, in addition to analytical research, the holistic way of working and thinking which is typical in artistic activities and design. Art has also a communication dimension, as visualization is needed in understanding many problems. They continue that the artistic activities at Aalto University include the study of societal and cultural heritage as well as formulating a worldview through creating and experiencing art. Art is thinking and its criterion is the skill that is based on the individual's experience and the connection to other people that it makes possible. What is central is the experience that is created through a meeting of the worlds of art and of those who experience it, where new meanings, new adaptations, creativity and innovations are born.

In the Aalto RAE the research on usability, user-centred design, user experience design and domestication of design carried out at the School of Design at TaiK was assessed as being of outstanding international level and comparable to the best international groups in the same field. Integrating this research with a high-quality artistic practice based approach was considered to provide a great opportunity for further development. Moreover, Aalto University was seen as creating brand new possibilities for this area of research to interact with various disciplines. In particular, user-centred design combined with sustainability and technology was seen as forming a starting point for a multidisciplinary engineering design approach, including media technology, within Aalto University and to contribute to economy and society in a new and innovative way.

CASE 3: PUSHING FOR SYSTEMIC CHANGE

A third player to push new thinking in design has been Sitra, the Finnish Innovation Fund. Sitra is an independent public foundation with a mission to build a successful Finland for tomorrow. In Sitra, the aim is to help Finland prosper as a global pioneer in systemic changes that generate well-being. Sitra defines systemic change as broad, far-reaching change that simultaneously affects the structure of the society and the everyday life of its citizens. Sitra engages in foresight activities and advances these changes in cooperation with other actors.

Lately, many of the Sitra programmes and strategic processes have included or consisted of design activities. Two of them will be presented here. The Helsinki Design Lab (HDL) gathered a global community of designers and decision makers interested in using design as a strategic tool to resolve complex challenges facing contemporary society. Their idea is that Finland as a small, well integrated, forward-looking society is an ideal place to prototype systemic change that may be too difficult to initiate elsewhere.

For three days in June of 2008, a group of 108 people from around the world, each a leader in their respective field, converged in Helsinki to discuss the potential of design. HDL2008 sought to develop a manifesto for design that produces 21st century solutions to 21st century challenges. This manifesto saw design as synthesis; visualization; holistic; human centric; and integrated to provide more effective solutions to "big picture" problems afflicting today's societies. It continued with twenty points of what design should be, including design tackling real problems, real stakeholders, real collaboration, and real resources, design being socially relevant and design as a political tool.

This dialogue is continued at the Helsinki Design Lab 2010 that will in September 2010 convene a global community of designers and decision makers interested in using design as a strategic tool to more effectively resolve the complex and systemic challenges facing the contemporary society. This time the HDL will focus on bridging the gap between thinking and doing, building a more effective link between design and government.

As HDL is moving towards execution, Sitra is also pushing for systemic change in a project called Low2No. The aim of the *Low2No Jätkäsaari City Block for Sustainable Construction* project is to develop and demonstrate energy efficient and innovative solutions in urban design and construction. The solutions developed in the project will serve as examples in Finland and internationally.

With the completion of Vuosaari Harbour in 2008, the urban structure of Helsinki is undergoing its most radical transformation since the industrial era. The city's cargo terminals and heavy road and rail traffic are now consolidated to the eastern edge of Helsinki in this new harbour facility. As a result, as many as six large logistical spaces (including Jätkäsaari) are being redeveloped to meet the needs of Finland's modern information economy with office and commercial space, residences and infrastructure. Moving the ports out of the city centre provides the rare opportunity to reconsider the city's urban structure and systems. The master plan for the Jätkäsaari area covers 100 hectares of mixed-use development and infrastructure. It is expected that by the completion of all phases of the master plan in 2025, Jätkäsaari will house 16.000 inhabitants and 6.000 new jobs.

As part of this development, Sitra is moving its own headquarters to the area and using the building block and its environment as an opportunity to improve sustainable building practices, creating an example of the construction of passive and plus energy buildings. In order to do so Sitra together with the City of Helsinki launched a sustainable development design competition.

More than merely a single design, Sitra has been asking the competitors for a credible strategic framework for change, and the principals upon which the framework was built. With the selection of a team comprised of Arup, Sauerbruch Hutton, Experientia and Galley Eco Capital, the competition is moving from ideas to implementation. This next phase includes not only design development of the architectural and strategic solution, but also many activities targeted at raising the level of awareness and sophistication of Finland's national sustainability discussion.

SO IS DESIGN USED IN SOLVING SYSTEMIC ISSUES?

Economic downturn has made the design profession change and redirect its activities many times, and typically an economic downturn has also made designers more aware of the moral aspects of their work and more concerned about global issues. Now we are in this situation again, as the economy is taking a major turn. Although we cannot yet give the exact results of the current development it is quite obvious that new design thinking is forming. Internationally, a large body of litterature on what this new design thinking is about is appearing, and the current debate and development in rhetoric suggests this type of movement. Design has moved from the designing of individual products and services to a more holistic approach, and this systemic thinking is generally applied in solving larger issues within the society.

This paper has shown three case examples where large social structures are being established, which clearly support this new approach of design. They show design as a means to solve larger problems, to attack social issues that wouldn't be easy to tackle using more traditional means of science as well as a structural player in thinking about large issues in a more creative way.

The Finnish case examples clearly show that broader societal issues are approached through design. It is also obvious that this time it is not only designers developing their own profession, but a larger societal movement including others than designers. The fact that the development is not in designers' hands alone also makes the potential outcome of this development more difficult to predict, and it might mean that something we cannot predict at all will come out of it. It will change the way we see what a designer is, and challenge how we educate them.

Time will show if the new systemic approach will change the professional practice as strongly as the change caused by the previous economic shift did, but it looks quite likely. The challenge is whether designers really have the competences needed for the work that is now expected from the profession. This time the change is not quantities, about how many designers are educated or how many companies use design, but it is about the whole view of design quality, why the profession is to be exercised and what constructs good design. Or in the words of Mayor Pajunen in the Open Helsinki application: "Design is everywhere, everything is design and design is for all. In the end, everything is just a question of good or bad design - a question of quality".

Explaining and Relating Different Engineering Models of Functional Decomposition

Dingmar van Eck, Department of Philosophy, Delft University of Technology, Delft, The Netherlands, D.vanEck@tudelft.nl

Abstract

In this paper I analyze the use of different models of functional decomposition in engineering design. I consider models that refer to sets of desired behavior-functions, to sets of desired effect-functions, and ones that refer to sets of purpose-functions. It is argued that the choice for a particular model is affected by whether or not its construction will be based on known function-structure connections for the functions in the model or on known behavior-structure relations that implement the functions in the model. It is then argued that whether or not such knowledge is taken into account is affected by specific design objectives. Finally, I thus argue that the choice for and suitability of particular models of functional decomposition depends on the design objectives for which these models are employed. Based on this result, it is concluded that the co-existence of different functional decomposition-models has engineering value, defining the remaining task to relate them. To this end, a strategy is proposed for relating different models. The above analysis is focused on three approaches that advance particular models of functional decomposition: the Functional Basis approach in which models refer to sets of desired behavior-functions, the Functional Interpretation Language approach in which models refer to sets of desired effect-functions, and the Dual Stage approach in which models refer to sets of purpose-functions.

Keywords

functional decomposition-model; design objective; design knowledge.

As evidenced by a recent review of Erden et al. (2008), engineering design research has produced an impressive number of functional modeling approaches. In these approaches a variety of definitions of functions, representation schemes for functions, and strategies and representation schemes for the decomposition of functions into sub functions are formulated. It is however acknowledged in the literature that this richness of different conceptualizations has its price: it can lead to cross-communication problems between engineers working with different functional frameworks (e.g. Rosenman & Gero, 1999; Deng, 2002). In the review given by Erden et al. (2008) the authors state, for instance, that not all reviewed approaches are compatible with one another. This sets a research challenge for establishing human and automated communication across functional frameworks. Different responses are given in the engineering literature to the diversity of functional frameworks. Erden et al. (2008) suggest that incompatibilities between approaches are due to different educational backgrounds and different application domains they are aimed at. Yet, at the same time, these authors aim with their review to develop a common framework for functional modeling that rises above the domains. Achieving this aim however suggests the discarding of a number of approaches for, otherwise, it seems that due to these incompatibilities the envisioned framework cannot provide the desired common frame that transcends particular application domains, and functional modeling thus will remain domain-specific (cf. Vermaas, 2009). Other authors seem to acknowledge the worth of keeping different functional frameworks side-by-side, considering them useful for different applications, yet at the same time they voice preferences for particular ones (cf. Umeda et al., 1996; Deng, 2002).

In this paper I evaluate the merits of adopting a single and common framework for functional modeling. The benefits of adopting such a common framework are immediately obvious: cross-communication problems will presumably be solved. However, adopting a common framework may at the same time narrow down the application scope of functional modeling. I will assess by means of a case study how a single and common modeling framework fares when employed in different application domains. Focusing this analysis on models of functional decomposition, graphical representations of organized sets of functions, I identify three particular notions of functional decomposition-model and three specific engineering objectives that are advanced in the functional modeling literature. These models and objectives are derived from: the Functional Basis (FB) approach (Stone & Wood, 2000), the Functional Interpretation Language (FIL) approach (Price, 1998; Bell, Snooke, & Price, 2007), and the Dual Stage (DS) approach (Deng, Tor, & Britton, 2000a; Deng, Tor, & Britton, 2000b; Deng, 2002). Framed in the context of this case, this paper addresses the research question whether the use of one of these three models of functional decomposition is suited for achieving each of the three objectives. This case study shows that, rather than favoring a single framework-proposal (and displacing a number of models), particular models are suited for specific objectives, implying the engineering value of keeping different models of functional decomposition side-by-side. Given this result, the challenge then becomes — with an eye to the cross-communication context mentioned earlier — to relate different models of functional decomposition. This paper also briefly outlines a strategy to meet this challenge.

I start my investigation of the different notions of functional decomposition-model in terms of an analysis advanced by Vermaas (2009). His analysis shows that specific meanings of the concept of technical function are used in engineering to advance specific descriptions of technical devices. Since these descriptions are all useful to engineering, he thus explains why the concept of function is used with more than one meaning in the field. He identifies three archetypical meanings of the concept of technical function: desired behavior, desired effect of behavior, and purpose. Using this analysis, I argue that FB models refer to sets of behavior-functions, FIL models refer to sets of effect-functions, and that DS models refer to sets of purpose-functions. In the research of Vermaas (2009), the choice for advancing a specific meaning of the concept of function, apart from the connection between a specific function meaning and a specific description of a technical device, is a question left implicit. In the case of functional decomposition, it is argued here that (i) the choice for a particular model is affected by whether or not its construction will be based on known function-structure connections, as laid down in engineering knowledge bases, for the functions in the model, and that (ii) whether or not such knowledge is considered is affected by specific design objectives that engineers aim to achieve with their models of functional decomposition.

This research is conceptual and example-based. It focuses on the internal structure of the FB, FIL, and DS approaches, in particular the use of knowledge bases. Empirical examples of functional decomposition-models as specified in these approaches are analyzed, compared, and used as demonstration. This paper is organized as follows. The account of Vermaas (2009) is introduced in section 1. Different models of functional decomposition are discussed in section 2. Design objectives and the use of design knowledge bases are analyzed in section 3. Conclusions are given in Section 4.

1. Simplifying full descriptions of technical devices: relating goal to behavior and/or structure in different ways

Vermaas (2009) has presented an analysis of the flexible meaning of the concept of function as it is used in engineering. This analysis is developed in terms of the notions of a full and a simplified description of a technical device. Vermaas identifies five key concepts in full descriptions of technical devices (see Figure 1): *goals* of agents that refer to states in the world that agents desire to realize by using devices; *actions* that refer to intentional behaviors that agents carry out when using devices; *functions* that refer to desired roles played by devices; *behaviors* that refer to physicochemical state changes of devices; and *structures* that refer to the physicochemical materials and fields of devices, their configurations, and their interactions.

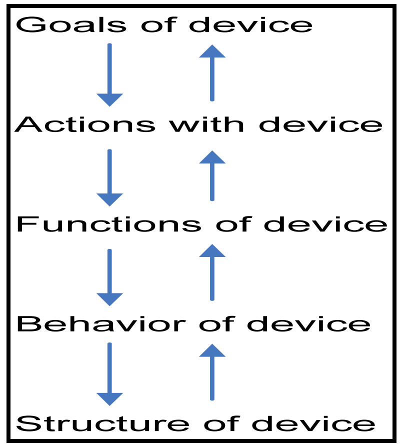

Figure 1 Full description of a technical device in terms of five key concepts (adopted from Vermaas, 2009)

Vermaas asserts that the concept of function is used with different meanings and that this flexibility affords different ways in which such full descriptions of technical devices can be simplified. Full descriptions in terms of the five key concepts are elaborate, and in particular engineering settings it makes sense to simplify them by "by-passing" one or more of the key concepts. Vermaas (2009) demonstrates this by-passing of certain key-concepts in terms of three approaches toward the modeling of or reasoning with functions, each advancing a different meaning of the concept of function: the FB-approach of Stone and Wood (2000), the Multilevel Flow (MFM) approach of Lind (1994), and the Function-Behavior-Structure (FBS) approach of Gero (1990).

Vermaas (2009) argues that in the FB approach, the concepts of action and behavior are "by-passed" and that the concept of function is used in its meaning of *desired behavior* (by specifying the role a device should play in terms of its behavior) to relate goals to structure (see Figure 2). FB-functions are modeled as operations-on-material, energy, or signal flows. Vermaas argues that these descriptions refer to physical behaviors since they represent conversions of matter and/or energy in which the input quantity matches the output quantity, meeting physical conservation laws. A function of an electric screwdriver, for instance, that is described as 'converting electricity into torque and heat' (Stone & Wood, 2000) in which the energy of the electricity equals the sum of the energies of heat and torque. In the FB approach, the concept of behavior is thus bypassed and the concept of function is instead used to refer to behavior(s). Vermaas asserts that in the MFM approach the key concept of action is by-passed but not the concept of behavior (see Figure 2). And he argues that in this approach the concept of function is used in its meaning of *desired effect of behavior* (by specifying the role of the device in terms of the effects of the device's behavior) to relate goals to behavior. Functions in MFM are represented in terms of operations and flows, and may be represented in terms of only input or output flows. A function example may be, say, 'producing torque'. This description also refers to (features of) behavior but does not meet conservation laws, referring only to the desired effects of behavior (which makes good sense, since the concept of behavior is used to account for the conservation of matter and energy). His analysis of Gero's FBS approach further broadens the spectrum of engineering meanings of the concept of function. His analysis of the simplified descriptions advanced in this FBS framework shows that the concept of function may also be used to refer to a *goal* desired by an agent. A function example may be, say, 'having a rotational force down a shaft'. This description refers to a state of affairs in the world, intended by an agent. Vermaas (2009) considers two ways in which simplified descriptions in this FBS framework may be interpreted, due to the shifting position of Gero on the meaning he ascribes to the concept of function: either as functions as goals to behavior, and then structure, by-passing the concept of action (see Figure 2), or, alternatively, as side-stepping both the concepts of goal and action, and reasoning from functions as desired effects to behavior, and then to structure.

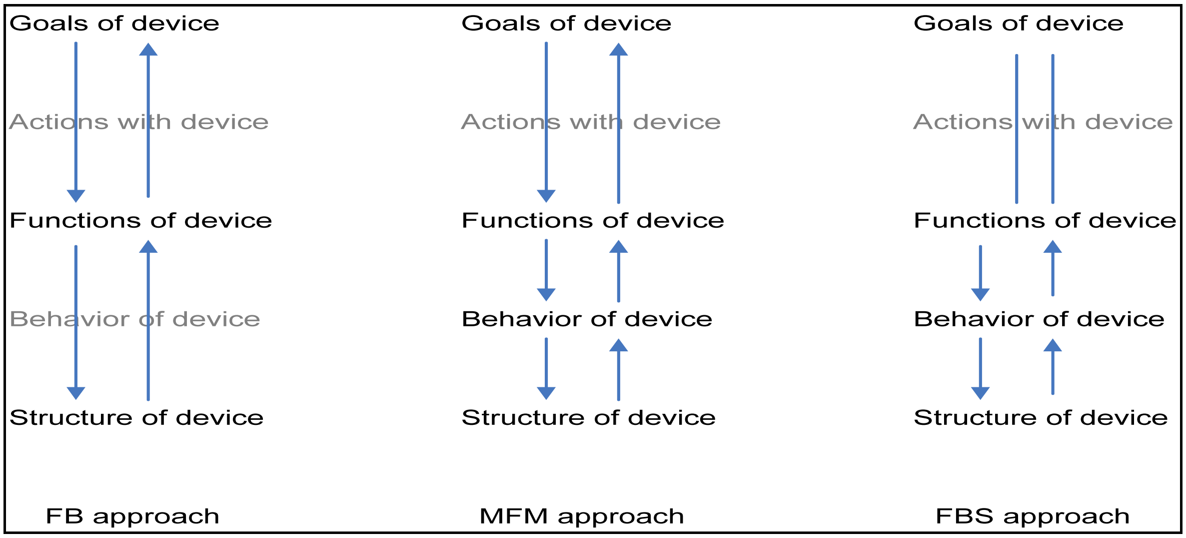

Figure 2 Simplified descriptions advanced in the FB, MFM, and FBS approaches (adopted from Vermaas, 2009)

2. Engineering models of functional decomposition

The foregoing analysis shows that different meanings of the concept of function are employed in relating goals to structure and/or behavior: desired behavior, desired effect, and goal. To distinguish goals of users from goals of designers, I coin the latter purposes. Purpose-function descriptions hence refer to states of affairs in the world, intended by designers. These different meanings of function are given in Table 2.

Behavior-function: desired behavior of a device
Effect-function: desired effect of behavior of a device
Purpose-function: purpose for which a device is designed

Table 1 Three meanings of the concept of function

These three types of functions are also described in models of functional decomposition, graphical representations of organized sets of functions, and the flexibility in the way goals (or designer purposes) are related to structure and/or behavior is also in play in the functional decomposition case. Often, in engineering design, models of functional decomposition (that make up an overall function) are advanced to relate goal (or purpose) to structure (cf. Stone & Wood; Deng et al., 2000a, b; Chakrabarti & Bligh, 2001). In this section I give an analysis of 3 approaches toward functional modeling, each advancing a different model of functional decomposition (*fm_D*) by which goals (or purposes) are related to structure and/or behavior. These three models are depicted (and abbreviated) in Table 2. Behavior function-*fm_D* 's are advanced in, for instance, the FB approach, the Systematic approach (Pahl & Beitz, 1988), and the Functional Reasoning approach (Chakrabarti & Bligh, 2001). Effect function- *fm_D* 's are advanced in, for instance, the FIL approach and the MFM approach. The third notion of purpose function-*fm_D* is advanced in the DS approach. (I do not consider here the use of the concept of function to refer to a user action, nor the description of such functions in models of functional decomposition. See Van Eck (2010a) for these details).

Functional decomposition model of organized set of behavior-functions (behavior function-fm_D)
Functional decomposition model of organized set of effect-functions (effect function-fm_D)
Functional decomposition model of organized set of purpose-functions (purpose function-fm_D)

Table 2 Three models of functional decomposition

Based on this analysis, I then develop the position in section three that the choice for particular models of functional decomposition is affected by particular design objectives that engineers aim to achieve with them.

2.1. Functional Basis approach

The Functional Basis (FB) approach, developed by Stone and Wood (2000), is an approach to functional modeling that is aimed at supporting the engineering designing of new products in the electro-mechanical domain, as well as the archiving, and communication of functional descriptions of existing products. In the FB approach, an overall product is described in a verb-object form and represented by a black-boxed operation on flows of materials, energies, and signals. A sub function, describing a part of the product's overall task, is also described in a verb-object form but represented by a well-defined basic operation on a well-defined basic flow of materials, energies, or signals. The black-boxed operations on general flows representing product functions are derived from customer needs, and the basic operations and basic flows representing sub functions are laid down in libraries of operations and libraries of flows, together called a *functional basis*.

To support engineering designing, Stone and Wood (2000) present a three-step methodology to develop functional decomposition-models. The method starts with describing a product function in a verb-object form, derived from customer needs and represented by a black-boxed operation on flows of materials, energies, and signals. A chain of operations-on-flows is then specified for each black box input flow, transforming that flow step-by-step into an output flow. These operations-on-flows are to be selected from the FB libraries. Finally, these chains of operations-on-flows are aggregated, completing the model of functional decomposition. Such models are intended to provide a "form-independent blueprint" of the functions of a product-to-be-designed, meaning that no known technical solutions for sub functions – structures – are taken into account during its specification. Not taking such existing function-structure connections into account during specification of a model is intended to support creative, and innovative designs (Stone & Wood, 2000). And in order to support such mappings after completion of a model, the sub functions in it should be small and easily solvable ones. The FB approach currently includes a web-based repository in which functional decompositions of existing products are archived, as well as components counting as design solutions for the sub functions that are part of these decompositions, supporting such mappings systematically.

Functional decomposition-model

Relative to the behavior, effect, and purpose meaning of technical functions, FB-product functions and sub functions can be taken to refer to desired behaviors (which may include their effects) since they represent conversions of matter and/or energy in which the input quantity matches the output quantity, meeting physical conservation laws (cf. Vermaas, 2009; Van Eck, 2009). For instance, the sub function 'converting electricity into torque and heat' (see section 1 and Figure 3). FB-models thus are behavior function-fm_D 's, organized such that the output flows of preceding behavior-functions constitute the input flows of succeeding behavior-functions (Figure 3).

Relative to the five key concepts, the concepts of action and behavior are bypassed and sub functions in FB-fm_D 's relate a goal – customer need – to structures (components as archived in the FB repository).

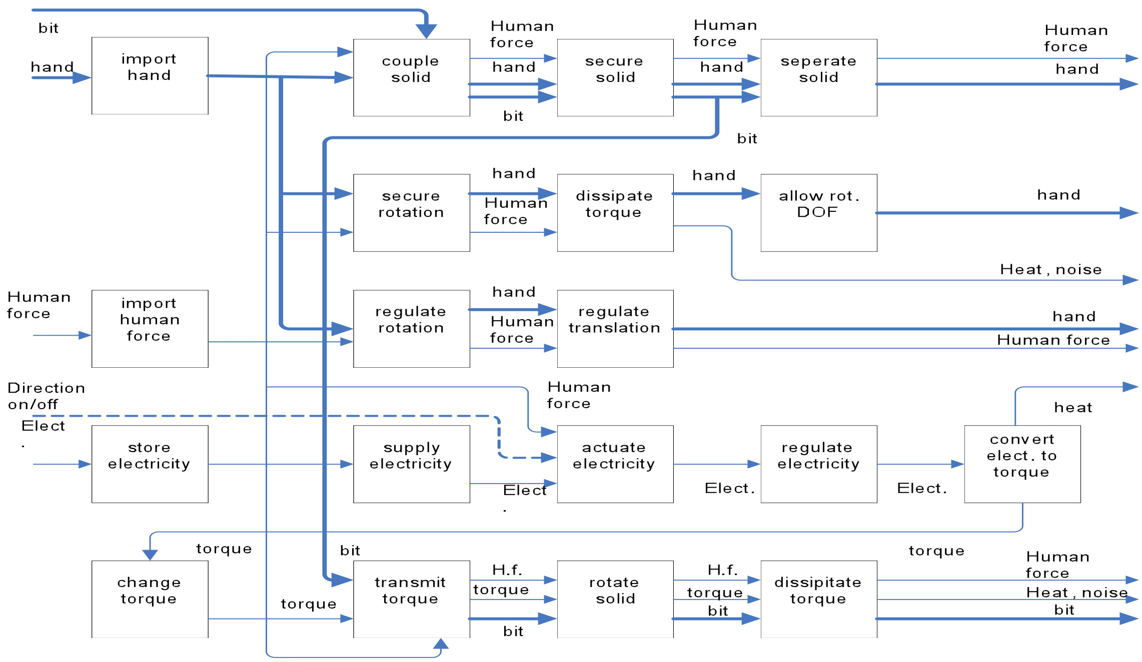

Figure 3 FB behavior function-fm_D of a power screwdriver (Stone & Wood, 2000)

2.2. Functional Interpretation Language approach

The Functional Interpretation Language (FIL) approach (Price, 1998; Bell et al., 2007) is an approach to functional modeling that is aimed at supporting design analysis tasks, such as failure analysis and design verification, mainly in the electro-mechanical domain. In this approach functions of technical devices are taken as and represented by trigger-effect pairs. An overall function is represented in terms of three elements: the "purpose" achieved by the function, the "trigger" of the function, and the "effect" of the function. Purposes in FIL refer to goals that agents aim to achieve when using devices. Triggers and effects in FIL describe the boundaries of a technical device, and are intended as labels that allow linking to relevant properties of its behaviors (in a design analysis context). Sub functions are either represented in terms of these three elements or as combinations of two out of these three elements, depending on the type of device analyzed.

In a design analysis setting, an overall function is decomposed into sub functions when its achievement depends on more than one trigger and effect, or when different trigger-effect pairs can achieve the overall function. In a model of functional decomposition that results, the triggers and effects of the sub functions then replace the trigger and effect (originally) associated with the overall function. Such models allow linking (in a design analysis context) to relevant properties of the behaviors of a technical device, both for tracing the cause of failures and for verifying whether a device's behavior implements the effects that are desired. This is done by checking the "on/off" states of triggers and effects. For instance, in a functional decomposition-model of a room light-function a sub function is represented by the trigger-effect pair "switch on-light on". Now, say, if the lamp switch position is "on" (trigger) and the effect "light on" is absent, this sub function has failed (Bell et al., 2007). This trigger-effect relation allows tracing those behavioral properties that cause this failure, say, an electrical short circuit. Such functional decomposition-models describe the (sub) functions of devices of which its required behaviors and structures are known.

Functional decomposition-model
Relative to the behavior, effect, and purpose meaning of technical functions, FIL overall functions and sub functions can be taken to refer to desired effects of behaviors. For instance, the sub function of the room light-function above only refers to the desired effect of the light being on, and not to the behavior due to which this effect is displayed, say, the conversion of electrical energy into light and heat. FIL-models thus are effect function-fm_D ‘s. (Figure 4)

Relative to the five key concepts, the concept of action is bypassed and sub functions in FIL-fm_D ‘s relate a goal – FIL-purpose – to behaviors.

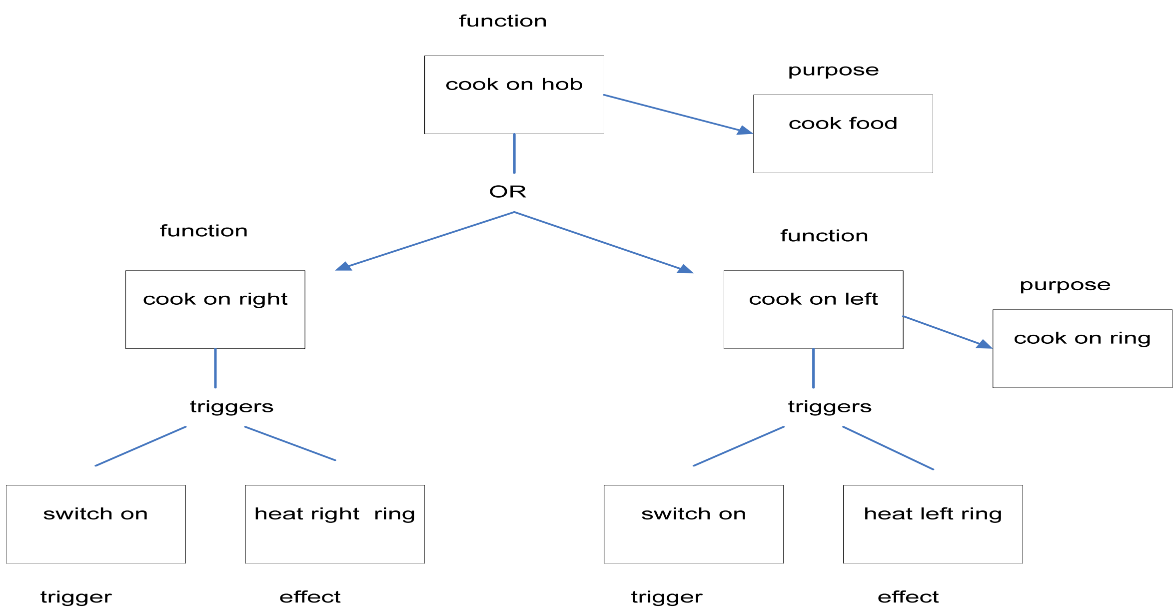

Figure 4 FIL effect function-fm_D of a two ring-cooking hob (Bell et al., 2007)

2.3. Dual Stage approach

The Dual Stage (DS) approach, developed by Deng, Tor, and Britton (2000a, 2000b, 2002), is an approach to functional modeling that is aimed at supporting the engineering designing of products in the mechanical domain. In this approach two types of functions are defined: purpose functions and action functions (Deng, 2002). A purpose function refers to a designer’s intention or purpose of a design. An action function is defined as an abstraction of intended behavior. Both types of function are represented by verb-noun descriptions.

To support engineering designing, Deng, Tor, and Britton (2000a, 2000b, 2002) present a knowledge base-assisted method to develop functional decomposition-models of an overall purpose function. First, an overall purpose function is decomposed into purpose sub functions, using a function-library in which existing functional decomposition design-knowledge is stored. This library archives descriptions of purpose functions that have “pointers” added to them, linking them to sub functions and to functions of which they are a functional element. An overall purpose function is decomposed into those sub functions to which it is linked in the library. Then, these purpose sub functions are mapped onto structures using a physical structure-library, in which descriptions of commonly used structures are archived. The purpose sub functions stored in the function-library also have pointers to the structures housed in the physical structure-library that are suitable to implement them, thus supporting function-structure mapping. These steps constitute the first stage of the DS-modeling framework. When functions from the function-library do not have pointers to physical structures as housed in the physical structure-library, hence cannot be mapped onto structures, a physical phenomena-library is then employed to carry out function-structure mapping. This library stores descriptions of commonly used physical behaviors and their effects, which have pointers added to them, linking them to structures in the physical structure-library. Action functions refer to behavioral effects (Deng, 2002). This physical phenomena-library is searched to retrieve those behavioral effects – action functions –- that are deemed suitable to achieve an unmapped purpose sub function. By linking a purpose sub function to a behavioral effect, which has a pointer added to a physical structure, purpose function-structure mapping is supported. These steps constitute the second stage.

The usage of these libraries in specifying models of functional decomposition (and supporting function-structure mapping) is aimed at employing past design knowledge in a systematic way to assist engineering designing (Deng, 2002). Models of functional decomposition are constructed that consist of sub functions for which structures are known. For instance, Deng et al. (2000a) specify a purpose sub function of the overall purpose function of a rivet setting device as "to exert certain force on the rivet by a working head, during the process the working head moves down a specified distance" (p. 43), which contains a pointer to the structures of "working head" and "rod". This type of designing in which known function-structure relations (and function-behavior-structure relations) are employed in constructing functional decomposition-models is also referred to as design-by-analogy or analogy-based-design (Goel & Bhatta, 2004).

Functional decomposition-model

Relative to the behavior, effect, and purpose meaning of technical functions, DS-purpose functions and sub functions can be taken to refer to states in the world desired by an agent-as-designer. For instance, the sub function above refers to the desired state that a rivet has force applied to it, come about by a sequence of states pertaining to the position of the working head. DS-models thus are purpose function-*fm*$_D$'s (Figure 5).

Relative to the five key concepts, the concepts of action and behavior are bypassed in the first stage and sub functions in DS-*fm*$_D$'s directly relate designer purposes to structures. (In the second stage, the concept of behavior is not bypassed and effect-functions are used to relate designer purposes to behavior. In this stage the step from goal to behavior is taken via a single function, not via a model of functional decomposition).

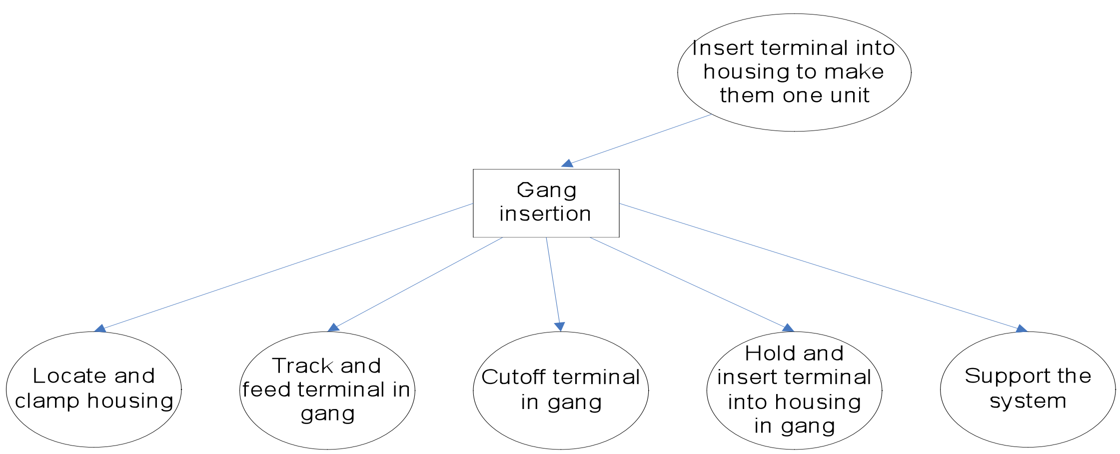

Figure 5 DS purpose function-*fm*$_D$ of a terminal insertion device (part of an automatic assembly system for manufacturing electronic connectors, the block "gang insertion" refers to knowledge about physical structures that implement the functions, depicted in the oval nodes) (Deng, 2002)

3. Choosing functional decomposition-models: design knowledge employment and design objectives

Returning to the notion to discard a number of functional modeling approaches and settle for a single and common framework for functional modeling, here an alternative position is developed. I will argue that the choice for constructing particular models of functional decomposition (behavior function-fm_D 's, effect function-fm_D 's, or purpose function-fm_D 's) is based on their suitability for achieving particular design objectives. And that none of these three models alone is (best) suited for achieving the three considered objectives of innovative design, design analysis, and design-by-analogy. Given the suitability of particular models for particular objectives, one can both explain and defend the keeping of different models of functional decomposition side-by-side (and the approaches in which they are advanced) in engineering design.

Consider that, due to particular design objectives, particular design knowledge is or is not used in the construction of models of functional decomposition: construction of a model can be based on known function-structure connections for the functions in the model (DS), known behavior-structure relations that implement the functions in the model (FIL), or, instead, not based on such (types of) knowledge (FB). Precisely the type of design knowledge that is or is not employed, as due to design objectives, makes the models suitable for achieving the objectives for which they are advanced.

Consider FB-models that are used to support the objective of innovative design: relating goals to structures by fm_D 's without employing known function-structure connections or behavior-structure relations during construction of these fm_D 's. Since behavior and structure are not taken into account in the construction phase, behavior function-fm_D 's are suited for relating goals to structures since behavioral descriptions (which may include effects) are detailed enough to support the selection of structures after the model is constructed. Purpose function-fm_D 's and effect function-fm_D 's, instead, are too coarse-grained to allow the selection of structures in any precise way, when existing knowledge on behaviors and structures is not considered in the construction phase of such models. The use of such models, skipping reference to behaviors and effects in purpose function-fm_D 's and to behaviors in effect function-fm_D 's, does not give (in a precise manner) those structures that exercise certain behaviors, resulting in certain effects that are suitable to achieve the goals one wants realized. In the case of purpose function-fm_D 's, the designer may choose to select structures already known to him/her to achieve the purpose-functions in the model, but this changes the objective of innovative design into design-by-analogy (precisely the objective for which models of functional decomposition are employed in the DS approach). The use of effect function-fm_D 's to relate goals to structures, skipping reference to behaviors, also seem to provide insufficient precision for selecting (potentially innovative) structures that exercise behaviors which result in the effects desired (although more precision is gained than using purpose function-fm_D 's). For instance, a car's headlight effect-function "light on" may be sufficient to select well-known structures of an incandescent lamp or halogen one, but without a desired behavioral specification, the choice for, say, a more recent LED lamp (which differs in its behaviors by which the effect "light on" results) is not obvious (again the design objective would shift from innovation to analogy).

Now consider FIL-models that are used to support the objective of design analysis: relating goals (FIL-purposes) to behaviors (of structures) by fm_D 's that are constructed based on known (and required) behavior-structure relations of an existing design. Since behavior and structure are known, effect function-fm_D 's are suited for relating goals to behavior, since they allow verifying whether the behaviors exercised by structures display (in the intended fashion) the effects that are desired for contributing to the goals of the device. Using a purpose function-fm_D, instead, skipping reference to effects, does not give the precision to ascertain whether or not the desired effects are indeed manifested *in the intended way* by the behaviors of the device. For instance, the purpose function "illumination in a room" seems sufficient for determining whether the behavior of the device implements the effect-function “light on”. Yet, only an effect function-description, say “switch on-light on”, is suited for verifying whether the behavior of the device implements this effect in the intended way: say, the switch might be “off” while the light is still on. The device’s behavior, in this case, implements a desired effect but not in the intended fashion. This goes undetected with the purpose function-description “illumination in a room” (More elaborate behavior function-fm_D ‘s may also do the trick, but are unnecessarily complex in this setting).

Consider, finally, DS models that are used to support the objective of design-by-analogy: relating purposes to structures by fm_D ‘s that are constructed based on known (purpose) function-structure connections for the functions in the model. Since these connections are known, purpose function-fm_D ‘s are suited for directly relating purposes to structures. Constructing more elaborate behavior function-fm_D ‘s or effect function-fm_D ‘s is unnecessary for this objective, only adding additional complexity to the design task and decreasing efficiency (if, however, there are no structures available for the purpose functions, behavior function-fm_D ‘s or effect function-fm_D ‘s do become suited for relating purposes to structures. See, for instance, the use of effect-functions in the DS approach for relating purpose to behavior and then structure).

In sum, different models of functional decomposition are suited for different objectives (and as the “switch on-light on” example above shows, particular representational frameworks are suitable for particular objectives as well). Therefore, I submit that the co-existence of different approaches, advancing specific fm_D ‘s, has engineering value and is to be preferred above a single and common framework for functional modeling. A task remaining is then to relate different fm_D ‘s.

This step of relating different fm_D ‘s is developed in more detail in (Van Eck, 2010a,b). The idea behind it is that in order to relate behavior function-fm_D ‘s to effect function-fm_D ‘s or to purpose function-fm_D ‘s, the information expressed in the effect function-fm_D ‘s or purpose function-fm_D ‘s must be expanded in order to relate them to behavior function-fm_D ‘s. For instance, whereas an effect function-fm_D only represents desired outputs such as ‘producing torque’, a behavior function-fm_D contains more elaborate descriptions such as ‘conversions of electricity (input) into torque and heat (output)’. By expanding the desired effect (or purpose) descriptions with input and (other) effect descriptions (such as ‘electricity’ and ‘heat’), the descriptions become behavior-function descriptions that meet physical laws. Such descriptions are the ones advanced in behavior function-fm_D ‘s. By rephrasing effect-function (or purpose-function) descriptions as behavior-function descriptions by expanding them one can thus relate different fm_D ‘s. Vice versa, one can move from behavior function-fm_D ‘s to effect function-fm_D ‘s or purpose function-fm_D ‘s by selecting and describing only specific elements of behavior function-descriptions, namely their desired effects.

4. Concluding remarks

In this paper I have analyzed the use of different models of functional decomposition in engineering design. I considered models that refer to sets of desired behavior-functions, to sets of desired effect-functions, and ones that refer to sets of purpose-functions. It is shown that the choice for and suitability of particular models of functional decomposition depends on the design objectives for which these models are employed. Based on this result, it is concluded that the co-existence of different models has engineering value and is to be preferred above a single and common framework for functional modeling.

Approach for Designing Elderly Care Homes

Susann Vihma, Aalto University School of Art and Design, Finland

Abstract

Most research has been unable to combine organisation, management and design studies. This seems a major shortcoming when looking at elderly care homes, because well-being in these institutions depends on all three approaches. Hence the aim of our research is to produce new knowledge on the interdependence of the three aspects. Special emphasis is put on planning processes. Numerous new buildings for the elderly will be planned in coming years and, at the same time, renovations of old buildings will be carried out. We will especially look at the design objectives for these undertakings.

This paper is about a work in progress by a team consisting of researchers and doctoral students in organisational and management studies at the University of Eastern Finland and design research at the Aalto University School of Art and Design. The four-year project started in 2009 and is funded by the Academy of Finland. Already in the early phase, the multidisciplinary team has produced inspiring new ideas.

One of the research methods has been to use photographic documentation of municipal and private elderly care homes. During visits to cares homes in North Karelia, systematic documentation was created. Selected photographs were, then, discussed by six focus groups representing various stakeholders. This research material, experiences and documentation of visits and sessions, was used to describe and analyse conditions and concrete product environments, in order to lead to better understanding, planning and organisation in the future. In this paper, the concept of homeliness is examined from a design point of view and as a part of well-being, based on empirical data and literature.

Keywords

Elderly care home, design, organization, homeliness, well-being

Our study conceives well-being as a process that starts from early conceptions of care in a design context and continues to evolve in the activities of care organisations in actual centres. Consequently, the embodiment of goals and values in design, organisation, and the actual environment is conceived as a process. A specific feature of our research is looking into the actual functions in care centres and collecting empirical data from various existing institutions. One of the case studies concerns small care homes, both private and municipal, in North Karelia; another case is situated in the Helsinki area. Interviews have been and will be carried out with elderly people, personnel, managers, designers, entrepreneurs, financial planning personnel, owners, municipal officials, the construction industry and other stakeholders. Data gathering methods include visits, documentation, focus group sessions and interviews. Environmental conditions, power structures, schedules and conflicting viewpoints in the care home practice will be brought to light in order to enable stakeholders to understand the processes and discuss their outcome.

The central concepts of the study are *well-being* and *homeliness*, which frequently appear in literature and various discourses (e.g. Cold; Lundgren; Wahl). These concepts have been and are still used as basic goals for organisation, leadership and design; in many countries, guidelines have been made for achieving these broad aims.[1] When looking more closely at the written research literature, documents, and the actual centres, it appears that these concepts are always used in some way. New technological applications may reduce homeliness while curtains may increase it. However, they seem too vague, unspecified or narrow for design purposes. According to the early results of our study, the actual care centres look very different even if research based recommendations and guidelines have been applied.

Photographic analyses

Our research has set out to look for all kinds of favourable qualities in existing care homes, as well as to identify and observe negative features by using various methods. One method is to analyse photographs. To do so, we set out to meet and converse with people who had different backgrounds and viewpoints in relation to care homes. To analyse and find out how the different stakeholders conceive of care homes, six focus groups were formed. In the summer of 2009, all in all 30 persons discussed photographs in groups of five: two groups of elderly persons inhabiting care homes, one group of personnel and entrepreneurs, and one group with experts in design. Design researchers, some of whom had experience of design research related to elderly care, formed a fifth focus group, and the sixth group comprised interior design students who were familiar with the design of care homes for the elderly.

The groups discussed photographs of four different private and municipal sites. The pictorial material for the sessions was selected from a vast amount of photographs taken systematically during 2008-2009 in North Karelia for the most part by two interior design students, led by Hannele Komu and Mirja Kälviäinen.[2] The same four spaces were chosen from each home: living room, dining room, toilet/bathroom and corridor. All spaces were semi-public. These were depicted in a total of 16 photos for the focus groups, each of which was led by one of the researchers in our group.[3]

[1] See Kälviäinen and Miller.
[2] They visited 17 care homes in 2008 and early 2009. Then, two researchers, Hannele Komu doctoral student who is well familiarized with the problematic of elderly care homes and Dr. Mirja Kälviäinen Senior Design Researcher from our research group visited the four selected care homes before the focus group sessions. The photographic material is supplemented during the whole research process.
[3] Before carrying out the group discussions, our group Rissanen et al. had planned the sessions and how to handle their outcomes.

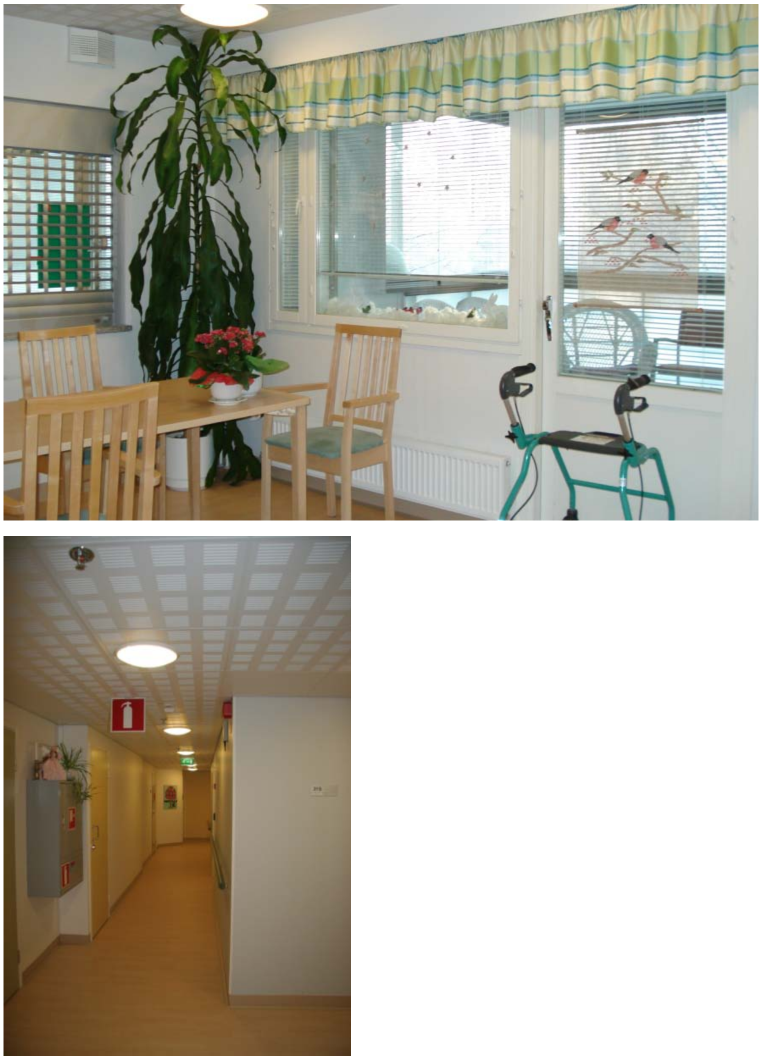

Figure 1. Three examples of photographic documentation of the care homes: a living room, a dining room, and a corridor.

Before the actual focus group sessions, the researchers discussed the difference between looking at pictures of spaces and actual visits. Clearly, a lot is left out of pictures, remaining outside of the frame, and the experiences differ in many important respects.[4] Yet many conclusions can be drawn on the basis of carefully taken and well-grounded photographs while being aware of the difference in experience and of the fact that a photograph is always an individual's personal view seen through a lens. The focus group sessions consisting of designers and personnel were well aware of this discrepancy.

For the group discussions, five introductory questions were formulated and agreed upon to help focus the topic of conversation and, for later research purposes, to help compare the different group sessions. The groups were asked to verbalise their impressions and thoughts of the

[4] Some of the features of experiencing real places, such as sound, smell, changing atmosphere, people's activities, etc., were documented during the many visits to the same centres. These aspects can be combined with the pictorial material thanks to the notes and dates, to provide a more comprehensive view.

spaces pictured in the photographs, and to indicate what they liked. They were also asked to think of what they would want to change. Lastly they were asked if they would like to live in the places pictured. The sessions ended with discussions on views and ideas about the topic and about elderly care homes in general. The discussions were recorded and transcribed. The material is being processed according to different points of view during the research.

Content analyses and design semiotics

To begin with, for the purpose of design research, I collected all the adjectives from the recordings of the group discussions. I also listed all the interior details mentioned and all descriptive nouns referring to spaces. All these words can signify positive or negative aspects in the discussions and can be checked later when necessary from the recording, where they are uttered in context. At this stage of my study the point was firstly to acquire an overview of all the possible aspects expressed with the adjectives mentioned (and later also to see what was left out). Secondly, the aim was to look closer at some of the salient qualities revealed by the material and then to compare the findings with results given in research literature, with our experiences of visits, with photographs of other care centres, etc. By clarifying the actual discourse in this way research results can support the design of the milieus.

Adjectives

The most frequently used adjectives (n=101) were without doubt *homelike* or *homely* (referring to *homeliness*), *messy*, *well-lit* and *institutional*. At this phase of the study it is not important to concern ourselves with the specific users of the words, because the aim is only to show the full variety of the adjectives and, then, to analyse why some of them appear more frequently than others.

The first one, homely, was probably popular because it relates to the public discourse of several recent years in Finland about institutional living in general. In actual fact, homeliness has been the prevalent goal lately. This goal has most likely spread to people's everyday discourses through its use in political discourse and the mass media – notably also to people other than the elderly. The aim highlighted by the national discourse has been to organise living and accommodation that is less institutional or clinical. But, without detailed or critical descriptions of this desired quality, the aim may fail. Naturally the concept also refers to the place where the elderly come from, their previous homes. These homes are places they have lost or gave up when they moved to the care centre. Their homes were created by them to a greater or lesser degree, and the elderly (perhaps also many other stakeholders) may have a tendency to compare the care centres with them. This is why it may be worthwhile to look into the respondents' personal histories and residences.

Despite the ensuing loss of concreteness, it seems important to focus on the central concept of homeliness and to analyse its potential meanings, even if they are often not well articulated in our verbalized data. With the help of content analysis (e.g. analyses of words in our data) and relate it to the photographs and research literature, we can specify and exemplify homeliness; we may concretize its meaning, and visualize and demonstrate it; we may compare different conceptions of it. In this way we can approach homeliness and achieve something that also concretely contributes to it, if it is the aim of the design and organization.

Possible references of the concept of homeliness (the many words and descriptions used to describe it) and its concrete embodiments (in the care centre setting) will be interpreted. Care home milieus will be conceived as semiotic signs (cf. Peirce) as referring to qualities and things.

Some of the frequently mentioned adjectives that can be construed to relate to homeliness and its positive connotations were *uncluttered* (as opposed to messy), *soft*, *cosy*, *spacious* and *colourful*.[5] These connections and relations will be further scrutinised, thematized and exemplified by design options.

However, at this stage of our research, the big underlying question remains: should homeliness be the general aim of design and organization? Or should the goal be formulated in another way by using more specified concepts or descriptive examples? If the actual references to homeliness seem too far-fetched, then heavy arguments can be made against using the concept at all. The concept often seems an empty slogan or too large an entity, which is tough to deal with. We can see this manifested in the actual institutions. Due to the vagueness of the concept, it may be that designers, entrepreneurs, personnel, etc. understand the term in their own ways and are not in fact discussing the same thing. They may also be unable to articulate it and identify its full potential.

Moreover, it may be useful to look at the most negative adjectives, which were often direct opposites of the positive ones. *Dark*, *colourless*, *narrow* and *cold* were among these. *Long* most often referred to a corridor and was given as a negative attribute. Long corridors (which actually are not very long at all) seem to emphasise uncertainty, anguish and impersonal features.

The range of adjectives was surprisingly large, at 101 words used during the sessions. It repeatedly included different shades of the same quality, e.g. dark, blackish, gloomy, murky, shady and sombre, or calm and restful.

Other descriptive wordings

All in all, 38 items from the interior spaces were mentioned in the six focus group discussions. The groups were not asked to list the depicted items in the rooms, but discussed characteristics by pointing out specific items as examples of what they meant. The items (words denoting objects depicted in the photographs) were therefore a part of either positive or negative comments and belonged to the more general discourse. Among the items were pieces of furniture, fixed interior details, vases and curtains, as well as collections of items. Our research will look into the policies of choosing and arranging these items. Who bought them and when, and who decorated each room?

In addition to the adjectives and list of items occurring in the discussions, I found 30 descriptive nouns that were used to illustrate the character of a space. Among these were common nouns related to the function of the room, such as *kitchen*, *corridor*, *hallway* or *toilet*. There were also many descriptive formulations such as *contemplation room, class room, cafeteria, flea market, nest*, *hotel*, etc. This approach to the data exemplifies people's awareness of the items and the overall quality of the product environments, as depicted in the photographs or as remembered. The photographs presented to the viewers visible existent items and their conditions, interior design, colours, materials, etc. At the same time the items and their placements connoted attitudes, habits and possibilities for various activities. We can clearly identify what is impossible or not allowed, and argue about the justifications and reasons of this. These aspects will be included in the next step, the semiotic analysis, where the reference relations of items will be interpreted in use in actual care homes, supported by photographic and other documentation.

A design semiotic analysis will demonstrate *how* various meanings are embodied in care home environments, especially in the semi-public areas. Items in a room embody specific styles; they

[5] With the help of the transcripts we can check the context or topic in which each adjective is used, and also link them to the photographs, and to the actual centres.

refer to similar forms in other contexts; they point at production methods and their origins. They function as metaphors that may also unconsciously connote emotions and moods, traditions and habits, ideologies and beliefs. Items function as symbols whose content should be carefully interpreted by all parties. These connotations are crucial in a multicultural setting.

For the designer, metonymic relations are also important. This means that items affect our interpretations based on their proximity in the space. Qualities can be transferred from one item to another nearby one. The metonymic aspect is not often made explicit in the planning process or in actual design solutions. Metonymic relations analysis is one way of demonstrating how concrete manifestations of the organisation and management function. By studying items' relations in office spaces, entrances, corridors, layouts, information systems, schedules, meetings, etc. the character of the arrangements can be illustrated. Our research will point out metonymies, which can or should be changed to better serve the aims of the care home.

A new home or something else?

Moving into a care centre signifies a change into another form of living: from a private home to a collective dwelling. The move includes crucial changes in the lives of the elderly, to fixed schedules, unfamiliar faces and contacts, unexpected meetings with strangers, smaller private areas, limited age variation in human contacts, diminished areas for own activities and initiatives, etc. Such major changes can easily also narrow the conception of the *homely*. Should, then, the institutions be called homes or something else? We have not yet answered this question. In any case, the goals for this new form of living should be formulated in a motivating and supportive manner for the benefit of the elderly, the personnel (including managers), friends and relatives. *Homeliness* may include many of the necessary qualities. But, what are they? For an answer, the concept must first be analysed together with the other important requirements. A hierarchy of the necessary qualities can perhaps be construed to permit the use of the concept homeliness.

Our research will produce new information with regard to the organisation and design of care homes based on empirical data and on literature. The content and formulations of guidelines and recommendations produced in Denmark, Norway, Sweden, the UK, and the US will also be analysed. This is a work in progress, and it is still too early to present well-reasoned findings. However, it seems apparent to me that care homes share the typical characteristics of all kinds of institutional living and accommodation. Standards and recommendations are important to follow, but what matters are their formulation, style and signification to the stakeholders. Do they inspire designers to develop new forms and create novel solutions to some of the routines that again and again seem to bother the stakeholders and, in fact, reinforce the negative aspects of these institutions?

The results of our study may be helpful for other institutional accommodation programmes and renovations, too. Moreover, in our prior studies we have found similar features and difficulties outside of Finland, in other European countries.

Furthermore, new kinds of communication tools are needed for designers, staff, relatives, visitors, the elderly and other to continuously follow the processes in practice and to understand the point of view of the different stakeholders. The care centres are living areas, social semi-public spaces, workplaces, communal institutions and private enterprises. All these aspects reflect the attitudes of people and the society towards the culture of ageing, and are manifested in the concrete care homes and their organisations.

L'Utilisation du Geste dans des Réunions de Conception Architecturale

Willemien Visser, CNRS (UMR 5141, LTCI) Télécom ParisTech – INRIA, France, willemien.visser@telecom-paristech.fr

Résumé

L'importance de l'utilisation, dans l'interaction humaine, d'autres modalités d'expression et de représentation que l'audible (le "verbal") a été reconnue largement dans le domaine du *cognitive design research*. A quelques exceptions près, ce n'est toutefois que le graphique qui a fait l'objet d'études en tant que modalité d'expression et de représentation visibles (le "non verbal").

L'objectif à long terme de notre recherche est de déterminer la contribution relative de chacun des différents systèmes sémiotiques (verbal, graphique, gestuel et autres modalités d'expression et de représentation visibles) et leur articulation dans l'interaction entre des personnes dans des situations de collaboration. Dans ce texte, nous nous focalisons sur l'utilisation du geste dans la conception collaborative. Pour analyser celui-ci, nous avons conduit deux études empiriques basées sur des enregistrements vidéo de réunions de conception architecturale.

C'était sur la base de données verbales et, dans une moindre mesure, graphiques, que nous avions élaboré notre approche de la conception (Visser, 2006). Nos analyses antérieures de la conception collaborative avaient conduit à y distinguer deux grandes familles d'activités, représentationnelles et organisationnelles.

Dans nos travaux sur l'utilisation de gestes dans des réunions de conception architecturale, nous avons retrouvé ces deux types de fonctions. En effet, les gestes y contribuent également à la construction de la représentation de l'artefact et à l'organisation des activités de conception et de l'interaction. L'analyse présentée ici montre en plus qu'ils le font d'au moins deux manières: dans une combinaison intégrée avec la parole ou de façon autonome, c'est-à-dire sans coexpression verbale.

Mots-clés

gestes; interaction multimodale; conception collaborative; représentation; cognitive design research; architecture

Abstract

The importance of the use, in human interaction, of other modes of expression and representation than the audible (the "verbal") has been widely recognised in the field of cognitive design research. With few exceptions, however, the graphic mode has been studied as *the* expression and representation modality of the visible (the "nonverbal").

The long-term goal of our research is to determine the relative contribution of each of the different semiotic systems (verbal, graphic, gestural and other modes of visible expression and representation) and their articulation in the interaction between people collaborating on a task. In this text, we focus on the use of gesture in collaborative design. Therefore, we conducted two empirical studies based on video data collected in architectural design meetings.

It was based on verbal, and to a lesser extent graphic data that we developed our vision of design as the construction of representations (Visser, 2006). Our previous analyses of collaborative design led to distinguish two main families of activities, representational and organisational.

In our work on the use of gestures in architectural design meetings, we found again these two types of functions. Indeed, gestures contribute both to the construction of the representation of the artefact and to the organisation of the design activities and of the interaction. The analysis presented here shows in addition that gesture does so in at least two ways: in an integrated combination with speech or independently, that is, without verbal coexpression.

Keywords

gesture; multimodal interaction; collaborative design; representation; cognitive design research; architecture

L'importance de l'utilisation d'autres modalités d'expression et de représentation que l'audible (le "verbal") a été reconnue largement dans des études sur la conception dans le domaine du cognitive design research (domaine qui englobe, mais dépasse celui de l'ergonomie cognitive de la conception). A quelques exceptions près, ce n'est toutefois que le graphique qui a fait l'objet d'études en tant que modalité d'expression et de représentation visibles (le "non verbal"). L'utilisation du geste a été peu examinée dans ce contexte (encore moins l'ont été des modalités comme le paraverbal, le regard, la posture ou les mimiques; dans Visser, 2010a, nous avons commencé l'analyse du regard et de la posture dans une réunion de conception de logiciel). Il est pourtant connu aujourd'hui dans le domaine de la pragmatique interactionnelle que les gestes jouent un rôle essentiel dans la communication, l'interaction et la collaboration.

L'objectif à long terme de nos recherches est de déterminer la contribution relative de chacun des différents systèmes sémiotiques (verbal, graphique, gestuel et autres modalités d'expression et de représentation visibles) et leur articulation dans l'interaction entre des personnes dans des situations de collaboration. Dans ce texte, nous nous focalisons sur les gestes dans la conception collaborative. Pour l'analyse, nous utilisons des données vidéo recueillies dans des réunions de travail entre architectes, travaillant en face à face et colocalisés (réunions en présence ou "en présentiel"). A partir d'exemples tirés de ces réunions, nous illustrons les fonctions et types de gestes, les différentes formes qu'ils peuvent prendre et les différentes manières dont ils s'articulent avec le verbal.

"Gestes". Les gestes que nous analysons sont des "gestes" dans un sens restreint: il s'agit de mouvements des mains et des bras qui sont accompagnés de parole—même si ce n'est pas toujours au moment même— et qui sont coexpressifs avec celle-ci (notez que, plutôt qu'une simple description, ceci est une position théorique, formulée et défendue par McNeill, 2005).

Organisation du texte. Après une section présentant des analyses du geste dans la conception collaborative effectuées dans des études antérieures, nous présentons les différents types de gestes que nous avons identifiés, prolongeant nos analyses effectuées précédemment sur la fonction des gestes dans la conception collaborative. Dans la troisième section, nous présentons les différentes formes d'articulation de gestes et verbal, aspect que nous abordons ici pour la première fois. Dans la Conclusion, nous formulerons surtout des questions évoquées par notre étude.

L'utilisation du geste dans la conception collaborative: études antérieures

Des études sur la communication et l'expression humaines ont montré que l'on n'utilise pas seulement des gestes dans des situations où l'on est face à face avec d'autres personnes ou visible par elles. On en utilise, par exemple, également au téléphone (Bavelas, Gerwing, Sutton, & Prevost, 2008); des personnes malvoyants font aussi des gestes (Iverson & Goldin-Meadow, 1997). Ici nous ne nous intéressons toutefois qu'aux gestes utilisés dans l'interaction avec d'autres, dans des réunions de travail en conception.

En comparaison avec l'interaction verbale ou graphique, l'utilisation de gestes dans la conception collaborative a été peu examinée. Dans l'une des premières études sur la conception collaborative (conception d'un combiné de commande à distance), Tang (1991) note que l'expression de nouvelles idées se fait autant de façon gestuelle que graphique ou écrite. Cependant, les gestes jouent un rôle particulièrement important dans la gestion de l'interaction: plus de la moitié des gestes ont cette fonction.

Bekker, Olson et Olson (1995) (conception d'un bureau de poste automatisé) observent des gestes de caractère spatial (pour indiquer la taille, l'emplacement ou la distance). Ils remarquent, par ailleurs, que l'utilisation de gestes peut servir, à côté de la conception proprement dite, la gestion et la régulation de la conversation en général.

Dans son étude portant sur une équipe d'architectes, Murphy (2005) analyse l'activité de ces concepteurs en termes d'"imagination collaborative". Les architectes observés utilisent des gestes pour imaginer des caractéristiques des entités de conception (leurs mouvement, structure et fonctionnement) et des expériences d'utilisateurs (actions que ces derniers produisent sur les entités de conception).

Parmi les fonctions des gestes identifiées par ces auteurs, nous voulons souligner les deux que nous avons également identifiées comme importantes dans nos analyses. (1) Le geste offre des possibilités spécifiques pour, d'une part, exprimer des qualités spatiales et des qualités ayant un rapport avec le mouvement de l'artefact et, d'autre part, représenter des séquences d'action à travers la simulation mimée de celles-ci. (2) Le geste a un rôle organisationnel important dans l'interaction.

C'est dans deux études empiriques sur des projets architecturaux que nous avons commencé l'analyse du geste. Il s'est agi de deux réunions dans des étapes amont des projets en question.

Dans une première étude, nous nous sommes restreintes, quant au geste, au dessin virtuel que les concepteurs peuvent effectuer en gesticulant avec une main ou un stylo sur des représentations externes, notamment des plans et des calques (Détienne & Visser, 2006; Détienne, Visser, & Tabary, 2006; Traverso & Visser, 2009; Visser & Détienne, 2005).

Sur le deuxième corpus (données DTRS7[1]), nous avons analysé les gestes en cherchant d'abord à identifier leur fonction dans le processus de conception collaborative. En accord avec nos travaux antérieurs, nous avons pu diviser les gestes en deux grandes familles, gestes représentationnels et gestes organisationnels (Visser, 2009). Dans un second temps, nous avons analysé la relation entre la fonction et la forme physique des gestes. Nous avons conclu que cette relation n'est pas systématique: des gestes ayant une fonction identique n'ont pas toujours la même forme, et des gestes ayant la même forme n'ont pas invariablement la même fonction (Visser, 2010b). Dans ce texte, nous ne reviendrons pas sur les liens entre la fonction et la forme physique des gestes.

Pour les analyses présentées dans ce texte, nous avons repris le deuxième corpus, qui concerne un projet de conception d'un crématorium. Par rapport aux analyses effectuées précédemment sur ce corpus (Visser, 2009, 2010b), nous avons effectué, d'une part, une analyse fonctionnelle plus poussée des gestes représentationnels et organisationnels identifiés jusqu'ici. D'autre part, nous avons procédé à une analyse des gestes sur une nouvelle dimension, à savoir, leur articulation avec le verbal (analyse structurelle).

Deux types de gestes: représentationnels et organisationnels (analyse fonctionnelle)

D'un point de vue théorique, nous analysons la conception en termes de construction de représentations (Visser, 2006). Le modèle classique en *cognitive design research*, hérité de Simon (1969/1996), analyse la conception comme une activité de résolution de problèmes—ce que la conception est en effet, d'un point de vue formel. Toutefois, une vision et analyse de la conception en termes de construction de représentations permettent, à notre avis, de mieux rendre compte de la richesse des activités et structures mises en œuvre dans la conception.

[1] Ces données proviennent du "*DTRS7 dataset*" (P. Lloyd, J. McDonnell, F. Reid and R. Luck, 2007), un ensemble de données mises à la disposition des participants au 7[ième] Design Thinking Research Symposium (McDonnell, Lloyd, Luck, & Reid, 2009). Ces données ne sont pas publiquement disponibles. Nous remercions les participants à la réunion de nous avoir permis de les filmer et d'analyser leur activité.

C'est sur la base de données verbales et, dans une moindre mesure, graphiques, que nous avions élaboré notre approche de la conception. Nos analyses de la conception collaborative avaient conduit à y distinguer deux grandes familles d'activités, représentationnelles et organisationnelles. Comme noté ci-dessus, nous avons retrouvé ces deux types de fonctions dans nos travaux sur l'utilisation des gestes dans des réunions de conception architecturale. En effet, nous avons observé que les gestes peuvent, d'une part, contribuer à la construction de la représentation de l'artefact (désignation et spécification d'entités de conception) et, d'autre part, avoir une fonction organisationnelle (organisation des activités de conception et organisation de l'interaction).

Dans ce qui suit, nous détaillons ces différentes fonctions des gestes.

Construire une représentation de l'artefact à travers des gestes

L'utilisation de gestes pour la construction d'une représentation de l'artefact peut prendre des formes diverses, en ce qui concerne leurs fonction, forme physique et mode de production et les types d'attributs de l'artefact exprimés gestuellement.

Représentation d'attributs spatiaux de l'artefact. Comme nous avons souligné dans la présentation des études antérieures, les gestes se prêtent particulièrement bien à l'expression d'attributs spatiaux de l'artefact, liés à des caractéristiques spatiales (notamment 3D), au mouvement de l'artefact ou à son utilisation dans l'espace. Ainsi, les dimensions de l'artefact ou de parties de celui-ci sont spécifiées souvent de façon gestuelle. Tant qu'il s'agit de dimensions précises, ce type d'attributs se laisse bien indiquer de façon verbale ("… 57,8 cm.…") ou graphique. Dès qu'il s'agit, cependant, d'approximations ou d'éléments flous, le geste permet plus facilement de "donner une idée" qu'une expression verbale (cf. aussi toute la littérature sur les difficultés de l'utilisation des systèmes de CAD ou autres qui demandent une expression précise de l'élément spécifié; cf., par ailleurs, l'ambiguïté possible de gestes, v., par exemple, Streeck, 2009, p. 2, Note 1).

Représentation de la référence du discours. Le caractère spatial est aussi particulièrement présent dans de nombreux gestes qui permettent d'indiquer la référence du discours, le "ce dont on 'parle'". Cette référence est, en effet, souvent de nature spatiale, un objet sur le plan ou un objet dans le bâtiment. Par exemple, Adam, le concepteur principal dans la réunion analysée, disant "you've still got another toilet there" ("vous avez là encore une autre toilette"; AM1, 699, Ad[2]), indique, en pointant d'un doigt, un espace sur l'un des plans qu'il a faits et apportés à la réunion avec ses deux clients (un geste "déictique").

Caractère plus ou moins circonscrit de l'entité représentée. La référence du discours peut être assez bien circonscrite (comme dans l'exemple donné ci-dessus), comme elle peut être plutôt globale. En tant que cliente dans la réunion analysée, Anna dit qu'elle aimerait consulter des utilisateurs (des entrepreneurs de pompes funèbres et, surtout, des personnes qui portent le cercueil). Adam demande "can we do that soon because the idea of this meeting is for me to go away with what I can knowing how to rev up the design to get it into planning?" ("est-ce que nous pouvons faire ça rapidement car pour moi l'idée de cette réunion est d'en partir avec tout ce qui est possible en sachant comment je peux monter en régime le projet pour passer à la planification?"; AM1, 1204-1206, Ad). En disant cela, il passe avec sa main droite ouverte, doigts étendus, au-dessus du plan, qui représente, dans ce cas, le projet global (v. Figure 1, page suivante).

Caractère plus ou moins concret de l'entité représentée. L'entité représentée peut être plus ou moins concrète. Dans l'exemple que nous venons de donner, elle était quelque peu abstraite: "le projet". Un autre exemple de référence abstraite, de nature bien différente est un simple "ceci" renvoyant à une partie du discours énoncée préalablement dans laquelle une entité complexe a été élaborée à l'aide d'un geste. Ce "ceci" est accompagné maintenant du même geste, de sorte que

---

[2] Les extraits du corpus sont pourvus du code de la réunion ("AM1" correspondant à la première réunion de conception architecturale), la ligne dans la transcription et le code du concepteur ("Ad" = Adam; "An" = Anna; "Ch" = Charles).

seuls les participants ayant été présents à la création du geste peuvent le comprendre (v. Becvar, Hollan, & Hutchins, 2008).

Figure 1 "Couverture" du projet global

Caractère plus ou moins statique de l'entité représentée. A côté de telles entités "statiques", il y a des entités "mobiles". Ainsi, des mouvements, des déplacements, des itinéraires et des indications de direction sont souvent spécifiés gestuellement. Ce type d'attributs de l'artefact est d'ailleurs difficile à signifier sans faire appel à des gestes. Par exemple, décrivant les trois parcours différents qu'il envisage pour pouvoir entrer dans le bâtiment, Adam les trace d'un doigt (geste "déictique" ET "iconique"). Figure 2 montre quatre moments dans la description du deuxième parcours: "the second route is round the end of the pond" ("le deuxième parcours contourne l'étang à son extrémité"; AM1, 1134-1136, Ad).

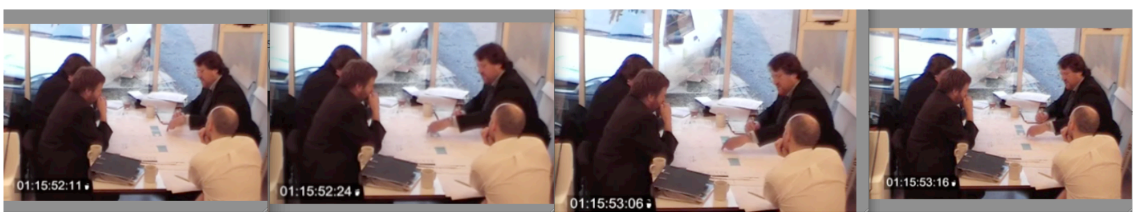

Figure 2 Traçage d'un parcours

Caractère métaphorique de la représentation. D'autres exemples d'attributs abstraits que ceux présentés plus haut sont des qualités de l'artefact liées à l'atmosphère que celui-ci dégage. Ainsi, Adam utilise des gestes pour traduire des qualités du bâtiment comme, par exemple, "intime", "audacieux", "privé" ou "calme". Il s'agit de gestes dont l'expression a un caractère métaphorique. Ainsi, afin de qualifier un espace comme "intime", le concepteur enclot avec ses deux mains un espace, comme un adulte qui entoure de ses bras un enfant. La métaphore conceptuelle que le concepteur semble adopter est celle de "l'intimité est un espace clos, protecteur".

Charles, l'autre client dans la réunion, affirme que, pour passer l'étang, il faudrait "something that’s solid" ("quelque chose de résistant"; AM1, 1178-1179, Ch). Il indique cette "quelque chose" en traçant avec sa main droite une surface qui peut supporter des poids, en faisant la traversée de l'eau au-dessus de la représentation de celle-ci sur le plan (v. Figure 3, page suivante). Ce geste combine des caractéristiques iconiques (un objet qui traverse l'eau) et métaphoriques ("quelque chose de résistant").

Différentes techniques de représentation. Les concepteurs utilisent différentes techniques de représentation dans l'expression par geste. Pour exprimer, par exemple, la forme de l'artefact, un concepteur peut dépeindre celui-ci en deux dimensions (en le dessinant avec un doigt et/ou en en traçant les contours), le modeler (en en faisant un modèle en 3D en le "sculptant" avec une partie de son corps—doigts, main, bras) ou encore en jouer l'utilisation (comme dans une pantomime) (Kendon, 2004).

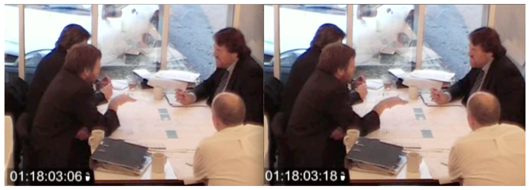

Figure 3 Expression iconique-métaphorique de "quelque chose de résistant" pour passer l'eau

Typologies classiques de gestes. Dans la littérature sur les gestes, de nombreux auteurs ont proposé des typologies et classifications. Un schéma de classification, proposé par McNeill (1992) et repris souvent par la suite distingue "déictiques", "iconiques", "métaphoriques" et "bâtons" (v. ci-dessous, pour un exemple de ces derniers). En dehors de son schéma, McNeill (1992) cite aussi les "emblèmes" (v., ci-dessous, l'exemple de "Stop!"). La classification de McNeill (1992) est utilisée beaucoup dans des études IHM, mais est souvent abandonnée par des chercheurs analysant la richesse des gestes que les personnes font dans des situations de la vie courante, car ces distinctions absolues sont souvent inappropriées. On a vu déjà qu'un geste représentationnel peut être "déictique" ET "iconique". Par ailleurs—comme on l'a montré également—de nombreux gestes représentationnels ne sont pas clairement "iconiques" OU "métaphoriques". Un autre exemple en est donné par Adam quand il dit, d'un espace où les voitures avec les cercueils arrivent, "this is all again under a roof" ("tout ceci est de nouveau sous un toit"; AM1, 1211-1212, Ad) et fait, avec sa main gauche, un geste qui couvre l'espace en question. Il ne représente pas de façon "fidèle" un toit: son geste exprime qu'il y a "quelque chose" qui est "au-dessus" d'un espace et qui "couvre" celui-ci (v. Figure 4).

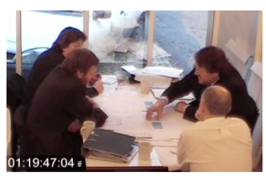

Figure 4 "Couverture" d'un espace par un toit

Organiser la réunion à travers des gestes

L'utilisation de gestes organisationnels peut également prendre de nombreuses formes. Il s'agit de gestes qui contribuent à la gestion de l'interaction (les gestes "interactifs," v. Bavelas, Chovil, Lawrie, & Wade, 1992) et à l'organisation des actions de conception fonctionnelles (la "conception" à proprement parler). Les trois participants font usage de gestes organisationnels (mais v. ci-dessous, notre observation au sujet du caractère idiosyncrasique de l'utilisation de gestes). Pour interrompre les autres et/ou attirer leur attention, ils font, par exemple, le geste "Stop!" ("emblème") en ouvrant la main avec sa palme parallèle au corps, l'ouverture vers le(s) interlocuteur(s).

Un autre exemple sont des gestes qui modulent le discours. Concernant ces gestes en particulier, le corpus de la réunion montre dans quelle mesure l'utilisation de gestes a des caractéristiques idiosyncrasiques[3]. Anna est bien plus expressive que les deux autres participants à la réunion. Souvent elle module son discours de manière particulièrement forte en soulignant ses mots de nombreux gestes bien appuyés. Par exemple, elle ouvre ses deux mains et les étale en face d'elle,

[3] Un autre exemple du caractère idiosyncrasique de l'expression gestuelle se trouve dans la réunion analysée dans la première étude, où l'un des trois concepteurs ne "dessine" que gestuellement: l'architecte en question fait seulement du "dessin virtuel".

disant "so I’ve sent off for [that book] but you try and get them to raise a SAP order for it and you get how often will we need the Spire books company" ("j'ai donc fait chercher [ce bouquin] mais tu as beau essayer de les faire passer une commande SAP[4], tu reçois en réponse avec quelle fréquence on aura besoin de la maison d'édition Spire"; AM1, 39-41, An) (v. Figure 5).

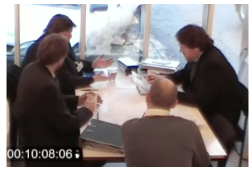

Figure 5 Modulation gestuelle du discours

Bavelas et al. (1992) qualifient ce type de geste interactif de "geste de partage d'information" (dans la classification de McNeill, 1992, ce type de geste est qualifié de "bâton"). Ici, Anna ne partage pas tant une information factuelle que son émotion (irritation) au sujet de celle-ci. Bavelas paraphrase ce geste de "comme vous savez!"—mais les deux autres participants à la réunion ne savent probablement pas autant qu'Anna combien "l'administration" peut vous freiner dans de "simples" commandes.

Deux formes d'articulation de gestes et verbal: intégration ou autonomie (analyse structurelle)

Les gestes peuvent donc contribuer à la construction de la représentation de l'artefact et à l'organisation de la réunion. Par rapport au verbal, ils font cela de plusieurs manières: dans une combinaison intégrée avec la parole ou de façon autonome, c'est-à-dire sans qu'il y ait une contribution verbale.

Les gestes présentés ci-dessus étaient presque tous intégrés avec la parole. Nous avons identifié peu de véritables gestes "autonomes". Un geste interactif comme "Stop!" décrit ci-dessus en est toutefois un exemple.

Caractère plus ou moins concomitant de gestes et parole intégrés. Même si gestes et parole sont intégrés, les deux ne sont pas systématiquement réalisés en même temps. Les gestes sont, en général, suivis, et ceci dans un délai plus ou moins bref, par leur coexpression verbale. Un exemple d'un geste qui précède nettement sa coexpression verbale est le suivant. A un certain moment, Adam tente de qualifier le sanctuaire et n'y arrive pas immédiatement. On voit qu'il cherche (décrire comment on voit cela reste à faire). Ne disant que "it just" ("ça a juste"; AM1, 337, Ad), il ouvre ses deux mains, quelque peu en ovales, paumes l'un orienté vers l'autre, bougeant un peu ces mains de haut en bas, comme tenant—ou formant—dans ses mains un ballon de football americain et le remuant; il reste silencieux quelques secondes et dit ensuite "yeah I felt that architecturally it needed to be a great deal more bold to make a statement about it being a very important" ("ouais je sentais que d'un point de vue architectural ça devait être bien plus audacieux pour faire une affirmation concernant le fait qu'il soit très important"; AM1, 337-338, Ad) (v. Figure 6, page suivante). Déjà auparavant, Adam avait utilisé le geste en question pour exprimer le caractère audacieux du sanctuaire.

La représentation de ce type d'attribut abstrait semble difficile à effectuer verbalement. On a présenté ci-dessus déjà l'utilisation d'une métaphore pour son expression. La difficulté de celle-ci permet d'expliquer que le concepteur y a recours en premier et/ou plus aisément par rapport au verbal. Anna, de son côté, ne sait dire, en réaction à Adam, que "yeah wasn’t enough" ("ouais [ce] n'était pas

[4] Une commande SAP est basée sur une certaine méthode de gestion d'entreprise.

suffisant"; AM1, 334, An)—et elle, bien que particulièrement expressive en général, ne fait ici aucun geste.

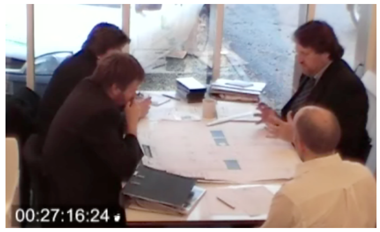

Figure 6 Geste précédant l'expression verbale.
Expression métaphorique du caractère "audacieux" du sanctuaire

Différents types de relations entre gestes et parole intégrés. Même si un geste est fait de façon intégrée avec la parole, son apport peut avoir différents types de liens avec le verbal. Parfois, le geste semble fournir une expression parallèle à ce qui est exprimé en mots. D'autres fois, le gestuel raffine, nuance, précise ou restreint ce qui est exprimé verbalement. D'autres fois encore, il fait le contraire: il est global tandis que la parole circonscrit la chose. Il peut aussi présenter des aspects qui ne sont pas présents dans l'énoncé verbal (Kendon, 2004, p. 161).

Conclusion

Le Tableau 1 présente un résumé de nos résultats.

Tableau 1 Résultats de l'étude

Notre étude, exploratoire et descriptive, apporte donc de nombreuses données. Elle évoque aussi de nombreuses questions. C'est sur ces questions que nous centrons cette conclusion.

On aimerait savoir comment l'utilisation de gestes influence le processus de collaboration. Cette question nécessiterait des études dans lesquelles on aurait, au moins, deux conditions: collaboration avec et collaboration sans accès au geste—et éventuellement au regard et à d'autres modalités d'expression (cf. les différentes études effectuées par Perron et par Lefebvre, présentées dans Lefebvre, Perron, & Pauchet, 2007; Perron, 2005).

Nos données proviennent de réunions professionnelles entre architectes, travaillant en face à face et colocalisés. Pendant ces réunions, les concepteurs utilisent des plans en papier qu'ils modifient et ils font des croquis sur du papier-calque (les plans "définitifs" sont faits avec des systèmes de DAO, hors réunion). De telles données peuvent inspirer des idées quant à l'utilisation du geste dans des situations de travail collectif à distance où la communication est médiée par l'intermédiaire de systèmes informatiques. Elles montrent, par exemple, que les gestes sont fréquents et ont de nombreuses fonctions différentes. Elles montrent aussi que les gestes ne constituent pas simplement des "illustrations" de ce qui est dit et "dont on pourrait se passer". Il est possible de formuler des hypothèses prédisant des gestes particulièrement utiles (ou fréquemment utilisés), ou même indispensables. Toutefois, la spécification de systèmes informatiques pouvant "médier" dans des situations de collaboration à distance (des systèmes de Travail Coopératif Assisté par Ordinateur, ou, plus généralement, des systèmes de Communication Médiée par Ordinateur) demande, à notre avis, des études spécifiquement dédiées à cette question.

Notre étude ne permet pas d'affirmer que certains types d'attributs s'expriment mieux ou de façon privilégiée de façon gestuelle plutôt qu'en utilisant un autre système sémiotique (verbal, graphique). Nous faisons toutefois l'hypothèse que l'expression de tout ce qui est dynamique, mobile (par exemple, des itinéraires, ou plus généralement, l'utilisation de l'artefact) se fait de façon plus aisée par des gestes que verbalement—et que cet "avantage" vaut aussi bien pour l'expression que pour la compréhension. Nous conjecturons aussi que les gestes constituent un système privilégié pour l'expression de certains attributs abstraits—tels que l'atmosphère que l'artefact dégage.

Une autre question concerne l'influence de la langue, et plus largement de la culture des concepteurs. De plus en plus d'entreprises sont le résultat d'une collaboration internationale et leurs projets de conception font appel à des équipes interculturelles (dans l'automobile, par exemple, France et Japon; dans l'industrie aéronautique et spatiale, par exemple, France, Allemagne et Espagne). Dans la réunion analysée, les trois participants sont anglais, mais, "naïvement", on peut noter des différences importantes dans la gestualité entre les trois qui ne semblent pas uniquement idiosyncrasiques (cf. la Note 3). On peut faire des hypothèses "préscientifiques" sur l'origine de ces différences; les conceptualiser et opérationnaliser pour pouvoir les examiner reste toutefois une autre affaire!

Willemien Visser

Chercheuse en psychologie cognitive à l'INRIA (Institut National de Recherche en Informatique et Automatique), Willemien Visser travaille au CNRS (LTCI, Laboratoire commun en Traitement et Communication de l'Information, Télécom ParisTech). Spécialiste reconnue dans le domaine du *cognitive design research*, elle présente, dans son livre *The Cognitive Artifacts of Designing*, d'une part, une revue critique de la recherche effectuée depuis les quelque 25 ans qu'elle travaille dans ce domaine et, d'autre part, sa propre vision de la conception comme une activité de construction de représentations. Ses recherches actuelles portent sur l'interaction multimodale entre personnes ayant des activités collaboratives, notamment sur l'articulation entre les différents systèmes sémiotiques auxquels ils font appel, en ce qui concerne leur rôle et contribution respectifs.

Designing a design competition: the client perspective

Leentje Volker, Faculty of Architecture, Delft University of Technology, the Netherlands, L.Volker@tudelft.nl

Abstract

Design competitions are part of the design tradition since ages. Still structured empirical research about this topic is lacking. This paper describes the results of six months participatory observation as a member of a project team responsible for the organization of an international ideas competition. The data include observations, interviews and document analysis. The results for this paper focus on the design of the competition and stakeholder participation from a client perspective. The findings show four combinations of aspects that underlie several problems of design competitions as currently perceived by architectural practice: the dynamics of the brief, the balance between professionalism and ambition, the link between participation and competition aims, and the influence of expertise at client obligations. It is this constant search for a balance between ambitions, aims, opportunities and needs that make clients experience numerous difficulties during the design of a competition. It is however the same search that makes every competition unique and a wealth of information about clients and architectural design.

Keywords

architecture; case study; client; design competition; management; participation

Starting at the latest with the Greeks, competitions have traditionally been a vehicle for the creation of major civic buildings and public spaces, such as government buildings, performing art centres, educational facilities, public libraries, museums and housing (Strong, 1976). The purposes of design competitions are several fold (de Haan & Haagsma, 1988; Larson, 1994; Spreiregen, 1979): disclose new talent, challenge 'convential wisdom', create a dialogue on design, enlarge support, increase competition, select an architect, educate students, gain insight in competences, contribute to the cultural dimension of the built environment and expand the boundaries of design. Svensson (2008) adds the aims of marketing a project, assuring quality through jury assessment, running architecture politics and coordinating different fields of interests. Information on both past and recent design competitions is fragmented, inadequate and frequently unrecorded (Lipstadt, 2005). Still design competitions are considered as a treasury of the profession (de Haan & Haagsma, 1988). The relevance of design competitions is acknowledged worldwide in the world of architecture. Historically competitions have proven to be a breakthrough for several architects. They have produced high profile projects but also a lot of debate, dispute and affairs (Strong, 1996). "Competitions clearly represent for the hopeful contestants the possibility that the best person may win at least for this once, what happens next after that is another story" (Larson, 1994, p. 475).

Spreiregen (1979) talks about three myths in case of design competitions that remain to be persistent: competitions cost money, competitions take more time and competition designs never get built. In the long history of design competitions hardly any attempt has been made to observe, analyze or evaluate the selection process of architects (Strong, 1996). Most publications on design competitions show the diversity of the competition and a statement by the jury on the relevance and quality of the entries for the architectural profession (e.g. de Haan & Haagsma, 1988; Glusberg, 1992). Others describe the aims, procedures, potentials and pitfalls in a historical perspective (Lipstadt, 2005; Spreiregen, 1979; Stichting Bouwresearch, 1980; Sudjic, 2005). Recently a few scholars studied the judgement process of jury panels in the current context of design competitions (Kazemian & Rönn, 2009; Kreiner, 2006, 2008; Spreiregen, 2008; Svensson, 2008) and the strategies of architectural teams that join competitions (Kreiner, 2007a, 2007b; Manzoni, Morris, & Smyth, 2009). These publications indicate that problems in competition mainly concern the honesty of (criteria for) selection of the participants, the requirements of the client, the composition of the jury panel, the objectivity of the jury's judgement, and the financial compensation compared to the amount of work. All these issues are based on decisions that clients make during the organisation of a competition. Yet research from the client perspective is lacking. The main research question is therefore: which difficulties do clients experience in designing a design competition in architecture? This paper addresses four main difficulties that I distinguished from empirical research about clients organizing a design competition.

Background of the study

Competition design

An increase of the amount of invited competition makes competitions more of a public negotiation (Rönn, 2008). In an attempt to address issues of fair competition, the EU has imposed strict rules for the tendering of public contracts. The selection of an architect is considered as the allocation of a contract for architectural design services (European Parliament & Council of the European Union, 2004). Even though the design contest is offered in the EU Directives, most Dutch public commissioning bodies choose to use the restricted tender procedure to select their architects (Geertse, Talman, & Jansen, 2009). In a way Dutch public clients break with the tradition of design competitions by using other EU procedures than the design competition. At the same time they include elements of the traditional design competition in their tender procedure, such as the submission of a design proposal and an open debate about design quality. The accustomed anonymous assessment of the proposals and the expert jury panel is often replaced by other procedures, while it is these elements that secured fairness of design competitions.

In general the amount of design competitions is limited compared to other ways of commissioning jobs, such as tenders. The competition principles are usually incorporated in national regulations, standardized formats and model competition conditions. There are two main competition structures (open and invited); two main competition populations (national and international), and two main competition objectives (ideas or designs) (Lipstadt, 2005). Not every procedure is suitable for every aim. Table 1 provides an overview of the options of general and tender competitions in relation to the specific ambitions of the project. Recent numbers show that in the Nordic European countries (Sweden, Norway, Denmark and Finland) about 100 architectural competitions yearly take place about equally spread over several areas in architecture (Kazemian & Rönn, 2009; Rönn, 2008). About 60 to 75% of these competitions are completed within four (!) years and 15 to 30% is cancelled. The fact that in the Netherlands about 140 restricted tenders and 20 competitions take place per year to select an architect shows the current significance of studying design competitions (Geertse, et al., 2009).

Table 1 Overview of project ambitions and characteristics in relation to possible tender procedures for general projects (based on Heynen, 2001)

Project ambitions / Possible competition and tender procedures * assumes anonymous examination of the plans; # assumes autonomy of the jury panel	Open tender procedure	Restricted tender procedure with presentation of vision	Restricted tender procedure with design proposal	Open design competition #	Restricted design competition #	Ideas competition *#
Exemplary function with stakeholder interaction			+	+	+	+
Stimulation young talent	+			+		+
Complex and/or important location			+		+	
Exploration of concepts and possibilities				+	+	+
Specific project requirements needed		+	+		+	
Specified project definition available			+		+	
Interaction with participants desired		+	+		+	
Limited time and money available	+	+				

Competitions need to be well prepared and realized with great care. Design competitions always involve the development of a design to the point where it realistically prefigures a realizable building. In every architectural competition there are several entrants with an identical problem they try to solve by prescribed rules and procedures (Strong, 1996). A systematic and independent assessment by a panel of assessors is used to select a winner. Spreiregen (2008) describes a competition process in seven components of planning, competition announcement, design, receiving and processing, jury, design announcement, and post-competition phase. The competition programme include three basic sections of general conditions, instructions and a brief (Strong, 1976). According to Kreiner (2006) the competition brief reads as half instruction, half inspiration and should be both unambiguous and non-constraining. He shows the inherent tensions and ambiguities of 'from versus function', 'tradition versus change' and 'requirement versus suggestion' in a brief. A jury report serves the purpose building of trust between the clients and participants, just as it serves "to inform the sponsor of the reasons for the selection of the winner, to clarify the general objectives being sought in the particular design experience at had and as a record and reference of a particular moment of design thought and awareness" (Spreiregen, 1979, p. 234).

Participation

The character of a design competition has a lot to offer in sense of participation options with stakeholders of the future building. Preferences of a jury do not always correspond with those of users and visitors (Nasar & Kang, 1989) because they tend to focus on the meaning of designs instead of convenience and durability (Nasar, 1999). Nasar therefore pleads for systematic visual quality programming as pre-jury evaluation among all groups of people that might experience the building as, especially users. This should be followed by an unbiased evaluation process that is based on insights from environmental psychology about preferences and meaning of design and completed by a post occupancy evaluation to see how the building actually performs (Nasar, 1999). According to Collins (1971, p. 194) "the problem of establishing architectural ideals today is not so much due to the difficulty of weighing the relative importance of 'firmitas, utilitas and venustas' as to the difficulty of creating a realistic understanding in the lay mind of the difference between price and value." This implies that average citizens can do an effective job of decision making if they are provided with accurate and relevant and organized and presented in a way which is meaningful without being patronizing (Crosby, Kelley, & Schaefer, 1986; Robinson, 1972). Crosby et al. (1986) introduce the American concept of the 'citizens panel' which include four days of regional and state wise staff presentations on the topic, witness testimonies of several stakeholder groups and making up a report of the panel members about the recommendations. Evaluation shows the concept as flexible, effective, fair but relatively expensive with a limited power to convince the people in charge. In design and urban planning co-design provides an interesting option because designers and planners work with instead of against community groups (King, 1983). After all, "experiences in the participation process have shown that the main source of user satisfaction is not the degree to which a person's needs have been met, but the feeling of having influenced the decisions" (Sanoff, 2006, p. 140).

Research approach and methods

A client fulfils a very important role in the design of a design competition. The choices made during the preparation phase determine to a considerable extent the results and appropriateness of the competition, as well as the style of the architectural design. Considering the current problems in the field of design competitions, I identified a gap between the structures that are provided and the actual behaviour of clients. Existing knowledge about competitions remains scattered and is not used adequately by the client organizations. Therefore this research focused on exposure of underlying structures and behavioural phenomena of project team during the organization of a design competition.

This paper describes the results of a single case study. The method of studying cases makes it possible to study decision making in a real life context on different levels of individual, group and organizational decision making (Yin, 2009). In this case the representative of the commissioning body, the Dean of a Dutch Faculty of Architecture invited the author to take an active role in organizing the competition. This created a revelatory case, "a situation in which an investigator has the opportunity to observe and analyze a phenomenon previously inaccessible to social science inquiry" (Yin, 2009, p. 48). Since I was already a staff member of the Faculty the entry-exit problem that is common for participation studies was therefore relatively easy to overcome (Bechtel & Zeisel, 1987).

A large set of data was collected by using different methodologies. I was involved as a full member of the project team for 32 weeks in order to organize an international ideas competition. During this period I kept a research log. At least once a week I recorded the activities of that week, the considerations and arguments that led to a certain decision, and I filed all documents including press releases and news paper articles. Personal reflections were noted in a special section of the log. After the project had ended, I conducted semi-structured interviews with the jury members and the project leader. The analysis was conducted a few months after the project was finished and data collection had ended, to create a certain distance to the data. All data were first analysed in Atlas.ti, a software package to support the categorizing of the data. The analysis resulted in a distinction between the actors, the competition characteristics and the competition design, which comprehends the brief, the procedure, stakeholders involvement and the jury process. For the purpose of this paper I take the categories of the brief and the stakeholder involvement central.

Case description

The impetus of this international open ideas competition was a fire that destroyed the old faculty building in May 2008. It can therefore be characterized as a rare event of with important learning effects for the organization (Christianson, Farkas, Sutcliffe, & Weick, 2009). The official objectives of this competition were to collect inspiration for a new building brief, to encourage creativity among the younger generation and to stimulate research and debate. In total 471 international participants joined to win €60.000 of prize money. Preparations for the competition started in July 2008; the winners were announced in March 2009. The evaluation procedure consisted of an assessment phase and an evaluation phase. During the assessment phase the entries were analysed by two internal analysis teams on the content of the proposals and checked against the rules and assignment of the competition by the project team. The results of the assessment, a typology and a quantitative analysis of the entries, were made available to the jury for an anonymous two-day evaluation process. The jury selected six prize winning entries and two honourable mentions in two rounds based on an integral judgement. During the first day 50 submissions were selected, on the second day these 50 were reduced to 8 nominees and finally six winners; three first prizes of €15.000 (see Figure 1) and three second prizes of €5.000. The winners and their ideas were announced during an award ceremony during which a jury report was presented.

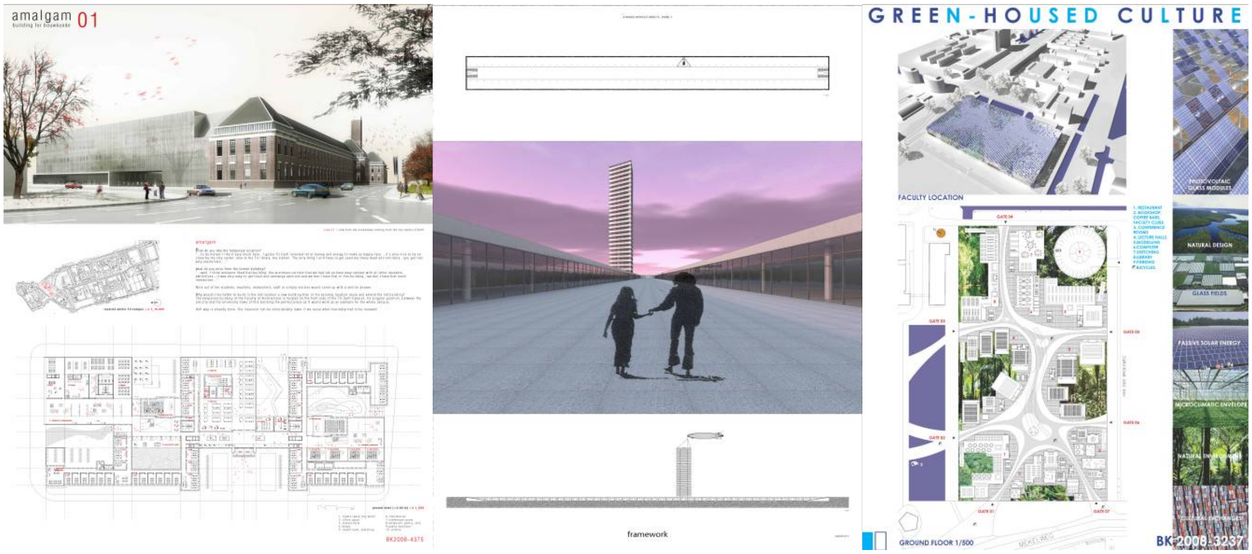

Figure 1 First price winners of the competition: amalgam from Laura Alvarez (the Netherlands), A world without objects from Gijs Raggers (the Netherlands), and Green-housed culture from Marc Bringer & Ilham Laraqui (France)

In the competition the main actors were the steering committee, the project team and the jury panel. The project team consisted of a project leader (externally hired), the Dean of the Faculty (chair), an additional project coordinator (the researcher) and the head of marketing and communication. The website and submission system of the competition was made by a consultancy firm, and the project team was supported by a secretary of the Dean's office and several student assistants. The steering committee consisted of the President of the Executive board of the University, the Head of the Real Estate department of the University, a professor in Real Estate Management and the Dean of the Faculty. Main task of the project team was to write the competition programme, provide the information for the website, prepare the jury meeting and coordinate the whole competition. On several occasions the steering committee provided input for the competition programme and some of the managerial aspects (e.g. finances). In line with tradition in architecture, an international jury was assigned to assess all submissions and decide about the winner. Because the Dean was a member of all actor groups, he acted as the connecting link. Right after the opening of the competition in September 2008 the Dean fell seriously ill, and remained absent during the rest of the competition period. He was not replaced in the jury committee. His responsibilities were assigned to another member of the steering committee.

Findings

Analysis of the complete data set of this case showed a distinction between the actors, the project characteristics and four elements of competition design: the competition brief, the competition rules, stakeholder involvement and the evaluation process of the proposals. This paper focuses on the issues of competition design and the involvement of stakeholders and addresses four combinations of aspects that cover the main difficulties as experienced by the client in organizing the competition: 1) the dynamics of the brief, 2) the balance between professionalism and ambition, 3) the balance between participatory means and competition aims, and 4) the influence of expertise at client obligations. These aspects are mostly based on insights from observations and interviews.

Dynamics of the brief

The dynamics of the brief were mainly caused by the changes in time and context of client organization. The launch of the competition at the opening of the Biennale in Venice (Italy) in September 2008 provided as strict deadline and meant that the competition needed to be set up in two months. There was no clear deadline for the end of the competition, apart from the dates that were announced in the competition programme. The planning was based on the intention to start with the new building project within two years after the fire because of the conditions of the insurance policy. As the competition progressed, the time frame for assessment was extended and the context had changed: the temporary accommodation for the Faculty performed above expectations, the resources of the university were cut down, negotiations with the insurance company were running, the jury date was difficult to set and the initial planning for follow up activities did not seem realistic anymore. This did not lead to an extension of the submission deadline, but did change the date that the nominees and winners were announced. The Dean provided the project team with most of the input for the vision and ambition of the project assignment and criteria in three sessions. His input appeared to be a combination of the needs of a faculty as a client, the expectations of the professional community about the role of the faculty as a client, and his own experience and expectations as an architect about a faculty building. Reflecting on the process of ambition formulation, it seemed fragile that only the Dean, probably influenced by some of his close contacts and network, provided input for the ambition and brief.

The awareness of the importance of the brief increased during the course of the competition. In order to reach the objectives of the competition regarding to stimulation of creativity and debate, the assignment for the competition brief was kept relatively open to any direction possible. During the development of the competition programme the project team was constantly faced with conflicting issues on client and building related issues (see also Kreiner, 2006; Rönn, 2008). Most important in defining this competition brief was the balance between familiarity and innovation. During this process the project team experienced a need for innovation as well as a need to maintain the positive qualities of the old situation. For example, the old building structure provided a 'street' on the ground floor for meeting and group gatherings. At the same time this structure created vertical traffic in the building which did not encourage interaction between the departments and lacked flexibility on the floors. In the assignment social interaction became a central theme, just as flexibility. Another example of the balance between familiarity and change was the location of the faculty building. The old faculty building was situated at the middle of the campus. On the campus map this location seemed relatively central, but in practice most activities and facilities are situated in the northern part of the campus. The project team did not know at the time of publication which location would be best and therefore this issue was left open. The brief created the possibility to choose ‘a well-argued, alternative site’, but only 13% of the submissions proposed another location. These findings suggest that the competition brief should indeed be read as half instructive and half inspiration as stated by Kreiner (2006).

The results show a difference in the availability of information between local and international participants. Because locals were aware of the positive experiences with the temporarily accommodation the dynamics of time, the equality of information among the participants diverged. Participants have to rely on the fact that all information in the brief is valid and reliable because theoretically it should provide the basis for their ideas. Especially for foreign participants the information on the competition website is the primary source of information. Further analysis of the traits of the winning participants showed that five out of six (had) studied or worked at the Faculty as an (exchange) student or employee. These findings show in line with Kreiner (2006) that specific information and a feeling for the relevance of information would improve the chances of winning because the ideas provide a better match with the assignment.

Professionalism and ambition level

The competition rules determined the kind of entrants, format of the submissions, the process of assessment, the communication of the justification of the decisions and the use of the entries after the closure of the competition. The format of the submissions was to be a very important topic of the rules because it influenced the amount of submissions, the amount of information and therefore the process of assessment and evaluation greatly. Among the members of the project team enthusiasm about the submissions grew with the realization of the potential of a competition. This enthusiasm could, however, easily have turned into a situation in which too much was asked of the participants. The project team aimed for a professional jury to assess the submissions because they would be able to judge large amounts of information in a relatively short period of time. Still the project team realized that as a professional client they should be realistic and modest in setting up the requirements for the submissions. The following examples show that a professional client needs to balance between pragmatism and ambitions in designing the submission and assessment format for the design competition. The results indicate that existing competition models do not stress the required balance in the design of the format enough to make clients realize its importance.

A first example of a well considered decision about the competition rules is the balance between the detail of a design proposal and the conceptual power of an ideas competition. The decisions about the format of the submissions have a clear impact on the potential of the ideas. A tradition exists in architecture to present designs on boards, sometimes supported by a scale model. The Dean explicitly wanted the ideas to have at least the level of sketch design because he wanted it to create a characteristic architectural design competition. Based on previous experiences the Dean was convinced of the additional value of a scale model during a competition. However, at the start of the project it was decided among the project team members that the whole competition would be done digitally through a website. A scale model would not fit a digital format. Next to that it would require the entrants to mail the scale model which would results in additional costs for participation. After consulting other organizations who organize design contests more regularly and further discussion within the project team it was decided that a scale model would not be asked. All submissions therefore consisted of A1 posters with a short explanation in A4. Further analysis of the submissions showed that 90% of the entrants decided to submit two posters, while the format provided freedom to submit one poster only. Although all nominees submitted two posters, the number of posters did not seem to increase the chances of winning: the amount of submissions using two posters remains equal in the final 50 (92%). These findings could indicate that one poster might be enough for to assess the quality of the proposal. This could decrease the workload of participants as well as client organizations.

A second example about the decision about the display of the posters showed that not every decision needs to be innovative. The digital poster format offered some additional innovative options for the jury members to assess the submissions with, for example, online assessments, individual voting and teleconferences. This proved to be a bridge too far for some jury and project team members. Therefore the project team decided to select a secured location near the university to meet with the jury. First intention was to lay all posters on the floor. The idea behind this was the flexibility of rearrangement, the informal atmosphere, and the lower costs in preparation. According to the chair an expert needed only a glance at the posters, which could easily be done from above. Finally displays were chosen to hang the submissions on because this would look more professional and did not lead to possible back problems of the jury members (See figure 2). Still jury members could walk along the posters and personal contact among the jury members was ensured. The displays made it possible to present all submissions in one room which benefitted the atmosphere during the jury meeting greatly. This showed the great value of the social element of a jury meeting in the competition design.

Figure 2 Overview of all submissions as presented on the displays and example of personal contact among the jury members

Participation and competition aims

Because of the tremendous effect of the fire within the architectural community, the competition was also organised to support employees, (former) students and the professionals in the field of architecture in the process of coping with the loss of the old building. Ideas about the involvement of the press were strategically formulated from the beginning of the project. The project team did not consciously design a participation strategy for the stakeholders of the case, but developed several participation options with different levels of influence on the final decision of the competition. Further analysis of the different options showed distinctions between the means of consultation, group decision making and delegation, which is in line with the participation model of Vroom and Yetton (1988) or Arnstein (1969). In this perspective assessment by staff as part of the project and analysis team can be considered as part of the consultation, jury processes can be considered as group decision making processes and a steering committee appointing a jury panel to select the winners is a good example of delegation.

The actual influence on decision making was limited. For most stakeholders decisive or advisory options, such as being part of the jury or joining an assessment team, were only available by personal invitation of the Dean. Other professionals, student and employees could participate by joining the competition. For the competition jury decisions were binding. Therefore jury members could influence the outcome of the competition the most. The steering committee did not have a say in the outcome of the competition but did have to consider the results of the competition to advise the board of the University. The members of the steering committee (apart from the Dean) nor the board of the university were, apparently for strategic reasons, part of the jury panel. The data do suggest that if the competition would have been an official tender, the composition of the jury panel would probably have also caused more discussion between the project team and the steering committee because of the larger impact of the decisions. Table 2 provides an overview of the stakeholders that were involved in this case, the participation options, and the actual potential influence in the development of the future faculty building.

Table 2 Overview of participation options and influence on the future building

Stakeholders and options for participation 1 = decisive rights 2 = advisory rights 3 = being informed and provide support CR = Competition rules CO = Competition outcome F = Future direction of Faculty accommodation	Steering committee (by invitation)	Project team (by invitation)	Jury panel (by invitation)	Competition participant	Analysis teams (by invitation and voluntarily)	Invited open activities (e.g. final symposium)	Open activities (award ceremony, publication, exhibition)
Commissioning body (Executive Board)	2-F						
Representatives of client (e.g. Faculty staff)		1-CR	1-CO; 2-F				
Shareholders and supervisors (e.g. Ministry, municipalities)							3
Daily users (e.g. employees, students)		1-CR	1-CO; 2-F	2-F	3	3	3
Non-daily users (e.g. alumni, exchange students & professionals)			1-CO; 2-F	2-F			3
Representative groups (e.g. BNA, student board)						3	3

Based on the results of this case a competition can be seen as a participatory event in itself in which stakeholders from outside and inside the client organisation act as consultants for a jury panel that also consists of stakeholders. In this case, the primary competition aims of stimulation of debate, young talent and creativity, and the hidden organizational project aims to provide a podium for stakeholders and become internationally famous seemed to have strengthened each other. This resulted in an overwhelming amount of high quality ideas for the future faculty as well as a tremendous international exposure of the faculty. Yet despite the amount of participation options, critical comments were heard from the employees because they never had the chance to give recommendations for the jury.

In the retrospective interviews with the jury members they stated that they were satisfied with the level of participation by the stakeholder groups. At the same time they did not seem to be very interested this issue, nor in the level of the requirements set for participation in the competition regulations. The jury members actually considered participation to be a given in architectural culture: organizing a competition implies participation in itself. The client sets the rules and the jury members reconcile to these rules, on the condition that they can do their job properly. At the time of writing most resistance among alumni and staff related to the lack of communication from the management board about the accommodation strategy for the faculty and the follow up of the competition. Improvements on the temporary accommodation still take place but no official announcements are made about the decision to build a new faculty building that is based on the outcomes of the competition. These results suggest that without tangible effects or communication about the resulting actions as performed by a client, participation has probably limited impact on the satisfaction of stakeholders.

Expertise and client obligations

This competition was unique because of the direct relation of the competition to the core activities of the client as a Faculty of Architecture themselves. The level of expertise of employees and students of the organization was consequently relatively high. In the preparation of the jury assessment support could easily be found within the organization. A lot of decisions about regulations and participation were based on tradition and culture within the field of architecture, with which the Dean was very well acquainted. As a former Chief Government Architect the Dean was aware of the potential of a competition, and he felt enthusiastic about creating this opportunity for the field of architecture. These results indicate that a positive perception of the opportunities that a competition can offer and the available support within the organization influenced the approach of the project positively. On the other hand, working with highly experienced and deeply involved stakeholders created a high level of expectations about the quality of the competition. The competition therefore also had an exemplary function, which created additional pressure on the work of the project team and the jury panel.

The findings indicate that competitions have to be perceived and set up as true projects. The level of expertise of the client organization could not prevent tensions in the project team. Most tensions were found in common project management issues, like the input of personnel, inter organizational politics and available finances. Most conflicts originated from a difference in the temporary project aims of the competition and the long-term aims of the organization. The rushed character and sudden impetus of the case surely contributed to these tensions. From the beginning on the tasks and responsibilities were not clearly defined among the members of the project team. This could partly be attributed to the leadership style of the Dean. Trust was lacking among some members of the project team who never collaborated before and appeared to have different styles of working. Especially after the Dean had fallen sick, differences of interests appeared between the internal and externally hired members of the team about patterns of spending and authority within the organization. The conflicts were, for example, shown in relation to the accuracy of information and feelings of responsibility in communication to the professional practice. This resulted in a mistake in a press release and an adjustment in the timing of the announcement of the winners. Overall the competition is considered by the client as a successful event, especially if the limited time span is taken into account. Taken from an overall perspective I sincerely doubt if a less professional client could have done the same.

Conclusion

While within the architectural community most interest is shown in the outcome of design competitions and the chances of winning, the results of this case show that a client determines the playing field of the competition by setting the rules. Participation in the project team of the competition proved to be as successful method to gain insight in the client perspective of a design competition. The results demonstrate that the rules and regulations currently available for clients usually do not address the difficulty of the decisions that precede the official opening of the competition. A considerable amount of expertise is needed to make sense of the decisions that are needed for the design of the competition. I found four combinations of aspects that cover the main difficulties as experienced by the client in organizing the competition: the dynamics of the brief, the balance between professionalism and ambition, the balance between participatory means and competition aims, and the influence of expertise at client obligations. It is the constant search for a balance that makes every competition unique providing a wealth of information about clients and architectural design. Since there is no one formula for success, designing a design competition will always be challenging for every client, not matter the amount of experience and level of professionalism. The findings of this case indicate that competitions do have a lot of participation potential, but that the power of a jury panel does not leave a lot of room for other stakeholder to have decisive rights and therefore influence the final outcome. The large amount of submissions from all over the world indicates that in this case the project team did a good job. Most of the aims of the competition were reached, although one could argue if the full potential of the results is already taken advantage of in relation to research-by-design and stimulating architectural debate. For the future I hope that other clients will open up their organizations in order to supplement our interesting database of this competition with new data to enable a structural comparison.

Findability of Commodities by Consumers: Distinguishing Different Packaging Designs

Regina W.Y. Wang, National Taiwan University of Science and Technology, wyw@mail.ntust.edu.tw

Mu-Chien Chou, National Taiwan University of Science and Technology / Chungyu Institute of Technology, f1234860@ms36.hinet.net

Abstract

What package design features can help consumers find commodities faster? This study assumes that the factors in distinguishing different packaging designs of commodities differ due to consumers' different personal experiences. Thus, this paper studies the findability of commodities by consumers through distinct packaging designs. It consists mainly of two stages: (a) the first stage reviews the existing literature to determine the application of different package designs; (b) the second stage is a focus group interview designed to investigate the factors influencing consumers in distinguishing different package designs. In the investigation process, (i) samples of package bottles for testing were collected through natural observation and convenience sampling; (ii) a focus group interview was conduced to determine how a consumer recognizes the differences among packages; (iii) a grounded analysis model was employed to transfer and encode the data collected from the focus group interviews to construct a conceptual frame for trade dress and the classifications of trade dress, which can interpret variations in the recognition of packaging design differences. The results of the focus group interview showed that consumers focused more on three kinds of "trade dress": property of commodity, label design, and bottle shape design when looking for differences in packaging designs. The "bottle shape design" was the most important factor that the focus group used in distinguishing different packaging designs. The distinction in the different package designs by consumers is not limited to design elements (image, language, color, shape, etc.) only; more importantly, the distinction lies in the relationship between "trade dress" and "classifications of trade dress," which can better reflect the differences in packaging designs.

Keywords

commodity packaging; differences in packaging design; findability; trade dress.

The findability of commodities influences consumer decisions (Brown, 2008). Two-thirds of consumers' buying decisions are influenced by the packages on the shelf (Lundberg, 2004; Nilsson & Öström, 2005; Rettie & Brewer, 2000). Hence, the kind of packaging that is easy to find is a thesis worth investigating. Packaging gives appeal and provides distinction from other commodities. Furthermore, it stimulates the buyers' desire for consumption. An effective package design catches consumers' attention and experience, prolongs lingering time before the shelf, and consequently causes sales opportunity to take place directly (Cheverton, 2004; Doyle, 1996; Mikunda, 2002).

Experience in various commodities is connected with brand identity, packaging design on the shelf, and attempt to link with consumers' personal experiences (Schmitt, 1999). Therefore, design elements such as character, figure, color, brand, shape, size, material, and texture employed effectively by the package designer can create a different package and communication experience (Schmitt & Simonson, 1997; Sonsino, 1990). There are different types of cognition towards the communication design of package comprehension between consumers and designers (Author, 2007). Hence, designers have different preferences in their own design communication owing to their different senses and cognitions of the commodity itself (Antioco, Moenaert, Feinberg, & Wetzels, 2008).

This survey investigates the findability of packages. A literature review on packaging design differences is first presented, and the results of the group interview aimed at exploring the factors affecting consumer recognition and distinction of packaging design differences are then discussed.

Findability and Evaluation

Findability is a popular term on today's web (Morville, 2005). The size, shape, color, and location of an object in the physical environment will all affect its findability. The significant role of a package designer is to develop an effective package design so that the product can easily be found when searched visually. Through an effective design, the location of one commodity and its difference from others can be distinguished. Some research shows that package findability is worth exploring, as it can help consumers quickly find a specific commodity on the shelf. In terms of findability, the most decisive factor is the packaging design (Young, 1987).

Package findability tests can generally be divided into three types: (a) visibility test, which is used to evaluate the readability of the logo and font type on the package (functional comparison among different elements or between functions of packages); (b) image test, which is used to evaluate the fundamental attitude of the consumer towards one product; and (c) usage test, which is used to measure the relevant reaction to package function (Schwartz, 1971). The package designer should dedicate himself in integrating the visible and distinguishable elements on the package design to create a package with higher findability that can attract the attention of consumers.

Visual Search and Object Discernment

When searching for and discerning a commodity on the shelf, the object is first located in space. Visual searching has been widely used in visual recognition studies to evaluate various features abstracted from the visual system (Wolfe, 1994). As for the visual communication mechanism, the designer avails himself/herself of the design elements to trigger one's vision and discern the object within his/her line of sight, attract the curiosity of the watcher, and finally achieve visual communication (Chen & Guan, 2007).

Psychologists have put forward various object recognition modes, including Gestalt psychology, template matching, feature analysis, and prototype recognition (Anderson, 2004). The process of discerning is a course in which an image of one object is received and searched visually, or one is attracted by some distinctive features. The individual then matches the features with the image template existing within him/her, produces the identity sign, and then finally understands the connotation behind it (Giles, 2005). Two factors must be set for discerning the packaging design: the stimulus produced by the differences in the outer packaging design and the one's past knowledge and experience in packaging design differences. These two factors interact and lead to the discernment of the packaging design. This thesis is concerned with the kind of information that can be abstracted from consumers' visual system, which can be explored through visual searching.

Package Design Differences, Trade Dress, and Trade Dress Classification

Elements such as shape, brand, logo, color, information appended, auxiliary packaging material, material structure, and volume lead to differences in packaging design (Lan, 2008). Through visual communication, the package design expresses the trait of one commodity to help consumers find it and to realize buying behavior. Thus, in this study, differences in packaging design is defined as the distinct visual differences among packages brought about by the employment of the elements of packaging design (CommCraft, n.d.).

All firms or companies convey their names, brands, containers, packaging, appearance, and other features. Through these elements, the object's trade dress, such as font, language, sound, figure, sign, number, image, color, and shape, which can express or deliver its commercial value or conceptual behavior is presented to the consumers (Garner, 1999). Trade dress can be categorized into two groups: product design and product packaging. Product packaging refers to the combination of all the design elements and their arrangement, including the logo, pattern, color, and color combination, among others. Product design, on the other hand, includes the shape, surface configuration, and other design features (Handelman, 2008). In this thesis, trade dress refers to the design features embodied in the product or in the visual appearance of its package, while classification of trade dress involves the design elements in constructing the trade dress.

The existing package design research is fragmentary and incomplete. There is a need to investigate the differences in design elements and the findability of relevant trade dress designs on the shelf. Through a literature review, this thesis attempts to explore the concepts of package findability, trade dress, and classifications of trade dress. Subsequently, it investigates how consumers sense and recognize the differences among packaging.

Purpose of the Research and Implementation Method

The factors influencing each testee's recognition of design differences were assessed through a focus group interview. Thereafter, the conceptual model for recognizing packaging design differences was constructed. The investigation flow is as follows (Figure 1):

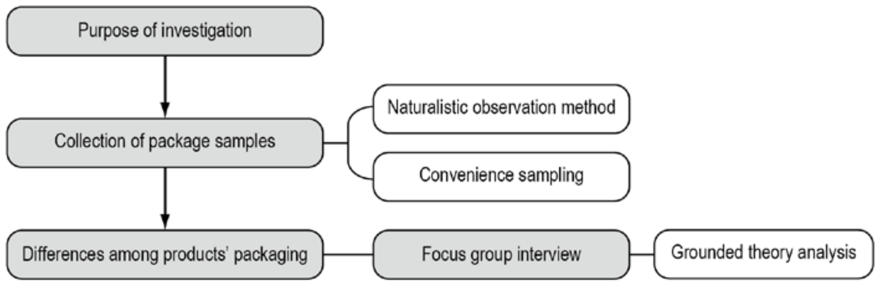

Figure 1 Factor exploration flow chart of packaging design differences recognized by consumers

The stages of the investigation are as follows: (i) samples of package bottles for testing were collected through natural observation and convenience sampling; (ii) a focus group interview was conduced to determine how a consumer recognizes the differences among packages; and (iii) a grounded analysis model was employed to transfer and encode the data collected from the focus group interviews to construct a conceptual frame for trade dress and classifications of trade dress, which can interpret variations in the recognition of packaging design differences.

Collection and Creation of Test Samples

Collection of Test Samples

Samples were taken from the hypermarket. However, not all the articles were included in this thesis because of their diverse package categories. Thus, actual samples were restrictively selected. The following steps were employed:

(i) From naturalistic observation, products with plastic bottles are the most common in the market. Thus, for convenience, samples were chosen from products with plastic bottles.

(ii) Samples with identical shapes and surface designs and packaging designs with similar sizes were excluded from this thesis to diversify the survey samples. When package designs were approximately identical, one article was selected at random. Four hundred twenty-eight actual samples were finally collected.

Design and Creation of Test Samples

Samples were presented in picture cards during the focus group interviews. The sample pictures were made and designed as follows:

(i) Given the cost and interview space, shrunken cards were employed in this study. Four pieces of packaging bottles with the smallest sizes were selected from the samples. Colorful cards were made to represent the real objects visually. The figures were drawn in proportion (10-100%) to the actual sizes of the products. A total of 10 cards were made (see Table 1).

(ii) Subsequently, 16 volunteer testees (aged 20-42) were invited to conduct the visual reading test on the surface information found on the bottle packaging. From the 10 cards, they selected those with unclear proportion thresholds. After self-judgement on the visual threshold value of the product packages, 2 testees were able to read the contents of the 10% card, 7 for the 20% card, and 8 for the 30% card. Sampling cards with a size of 30% of the actual product were made using 10×10 cm cards.

◎Selection of Samples and Testing Procedure

Before testing, the size of the screen was adjusted to the actual proportion of 1:1 after measuring by a ruler. The testees were told to look at the 10 pictures of the product and to choose their threshold values only by subjective judgment. The researchers recorded and indicated the values. Finally, the most reasonable minification of the product card was determined.

Table 1 Size of card, samples, and procedure

Display of Samples

The testing place was set in a quiet and closed assembly room to make the focus group interview run smoothly and to avoid any outside interference. Ordinary lighting was provided (see Figure 2).

Figure 2 Focus group interview and sample display

Selection of Testees

Sixteen volunteer testees, aged 23 on average, were invited to participate in the focus group interview. They were grouped according to gender and frequency of product consumption (buying at least once a week in the hypermarket).

Implementation Procedure of the Focus Group Interview

The researcher induced the group members to express their opinions on the factors that can help them recognize the differences in the given samples. Their responses were timely recorded. To determine the mental working mode of the testees, they were asked to carry out hierarchical grouping tasks on the packaging design differences (Chang, 2007; Chang & Wu, 2009; Peeper, Shrestha & Oliva, 2004; Ramanarayanan, Bala, Ferwerdab & Walter, 2008). A hierarchical grouping task is used to resolve the problem of categorizing heavy and complicated data, while clustering is a way to group apparently similar objects together and to sort data into new types (Chang, 2008; Guo, Peuquet, & Gahegan, 2002; Peeper, Shrestha, & Oliva, 2004; Sherrill, Moy, Reilly, & Bonato, 2005).

Differences among packages were discussed among the focus group members, and proper and rational ways of classifying the packages into two groups were found. The group members continued the sorting until a single sample was identified. To avoid fatigue caused by the long group interview, which might influence the interview quality, a five-minute break was taken every 30 minutes. The entire interview ran for nearly 270 minutes. Its implementation procedure and agenda are shown in Figure 3.

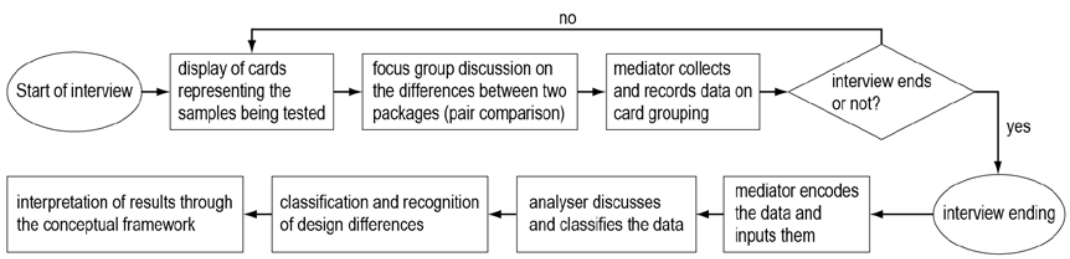

Figure 3 Implementation procedure of the focus group interview

Collection of Interview Data

The focus group interview process and the observations were recorded with a camera. The factors identified by the group members and their judging standards after two group differences were recognized and recorded. Protocol analysis was subsequently carried out. The ATLAS.ti software was used to deal with the content emphasis of the focus group interview on the aspect of data input (Figure 4). A conceptual network chart (see Figure 5) was set to complete the interpretation of the conceptual framework.

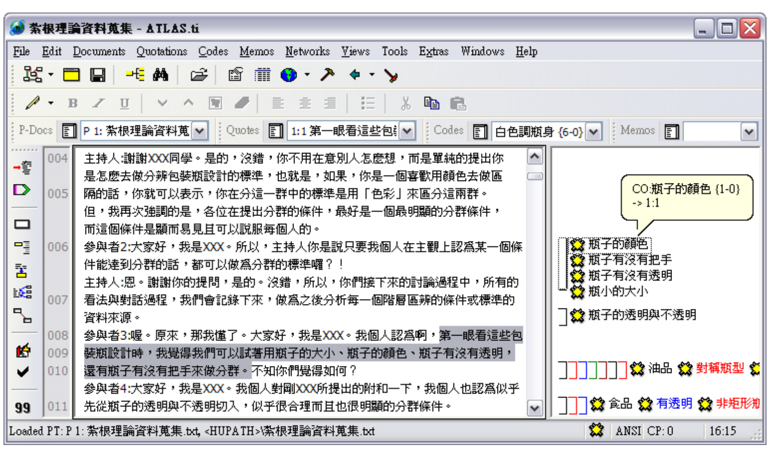

Figure 4 Data sort-out by ATLAS.ti and the decoding process

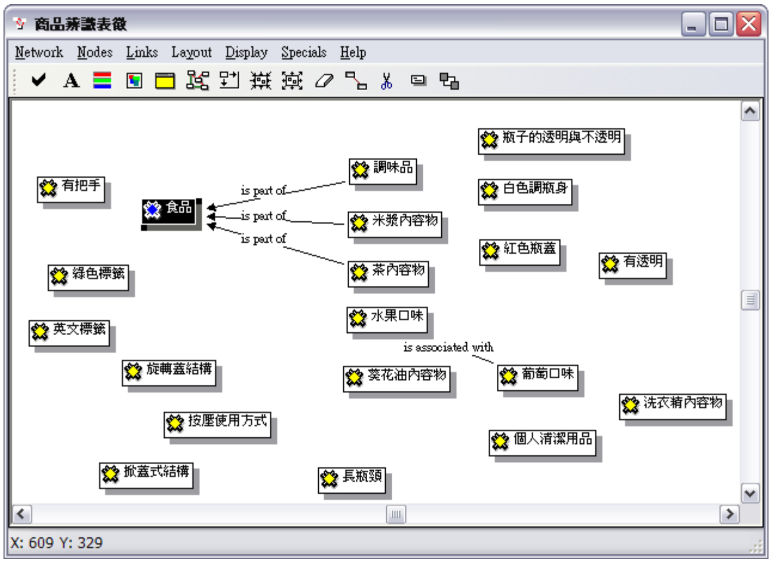

Figure 5 Grounded conceptual network

Establishment of the Grounded Analysis Model

There are three relevant grounded theory designs: open coding, axial coding, and selective coding. Open coding is a process designed to find the conceptual and attributive faces of the defined data. It can be used in conceptual categorization, induction, and transforming and focusing data. Axial coding deals with correlative categories and sub-categories, while selective coding involves a process of integrating and refining to construct a scientific theory needed to interpret the differences in packaging designs.

Table 2 presents the textual analysis results and their corresponding explanations. According to the selective coding in the table, the focus group was influenced by different variables in the identification of the differences among the packaging designs. The group members tended to change their opinions according to their individual perception, memory, association of the package content with the actual product, and the interaction among various visual searching interference variables. Cognitive factors that aided the focus group in determining the differences among packaging designs were further analyzed and generalized. A conceptual framework created to interpret properly the findability of a package is shown in Figure 6.

Stage One		Stage Two		Stage Three	
Open Coding	Instruction	Axial Coding	Instruction	Selective Coding	Instruction
Package content	Identify the contents of the product being tested	Item	Distinguish products through their item differences	property of commodity	Judge the property of commodity to determine package design differences
Users' group	Identify the product being tested				
Product's flavor	Identify the contents of the product being tested				
Usage of product	Identify the use of the test object				
Name of commodity	Identify the information relevant to the name of the commodity being tested	Naming of the brand	Distinguish products by identifying the differences		
Brand name	Identify brand information in the commodity being tested				
Manufacturer	Identify manufacturer information on the test object				
Language	Comprehend the language used in introducing the commodity	Language used on the label	Distinguish products in terms of the language used on the labels	Design of the label	Judge the design label to determine the design differences in the appearanc e of the packaging
Image	Indentify specific images on the test object	Image of volume label	Distinguish products through image differences		
Abstract graph	Indentify the abstract graph on the appearance of the test object				
Color matching on the label	Indentify the color matching on the appearance of the test object	Color of the label	Distinguish products according to differences in label colors		

Predominant color of label	Indentify the predominant color of the entire test object				
Size of the package bottle	Indentify the appearance or capacity of the testing object	Capacity of the bottle	Distinguish products by capacity differences	Shape design of the bottle	Judge shape designs to determine the design differences
Length of the bottle's neck	Determine the length of the bottle's neck from its appearance	Height of the bottle's neck	Distinguish products through the length difference in bottles' necks		
Length of the body	Determine the length of the bottle's body from its appearance	Height and width of the bottle's body	Distinguish product in terms of the size of the bottle		
Width of the body	Determine the width of the bottle's body from its appearance				
Angle of the bottle's shoulder	Determine the angle of the bottle's shoulder from its appearance	Angle between the shoulder and neck of the bottle	Distinguish product by the angle of the shoulders of the bottles		
Lifting-type bottle cap	Identify the lifting-type cap used near the bottle's mouth	Usage of the bottle's mouth			
Bottle mouth with press structure	Identify the press structure designed on the bottle's mouth				
Nozzle bottle mouth	Identify the nozzle designed at the bottle's mouth				
Turning-mold cap	Identify the turning-mold cap set near the bottle's mouth				
Bottle without a handle	Identify the handle designed near the bottle's mouth	Practicality of the handle	Distinguish products through the structure of the handles		
Bottle with a handle	Identify the handle designed on the body of bottle				
Color of the bottle cap	Identify the color matching on the bottle cap	Color of the bottle cap	Distinguish the products by the differences in the color of bottle caps		
Color of bottle's body	Identify the color matching on bottle's body	Color of the bottle	Distinguish the products by the colors of the bottles (body)		
Lines on the bottle's body	Identify the shape lines on the bottle's body	Shape of the body	Distinguish the product by the differences in bottle shapes		
Shape of bottle	Identify the external shape of the bottle's body				
Popularity	Acknowledge the popularity of the test object	Memory	Distinguish the products by popularity and memory	Interfering factors	Identify the factors influencing the recognition of packaging designs
Familiarity	Acknowledge the testee's memory of the test object				
Association	Associate the information about the images of the test object	Cognition	Distinguish the products through the differences in relevant design		
Distinguishing sequence	Arrange the actions stimulated by the test object	Attraction	Distinguish the products by the attraction they generate during a visual search		

Table 2 Overall instructions for open coding, axial coding, and selective coding

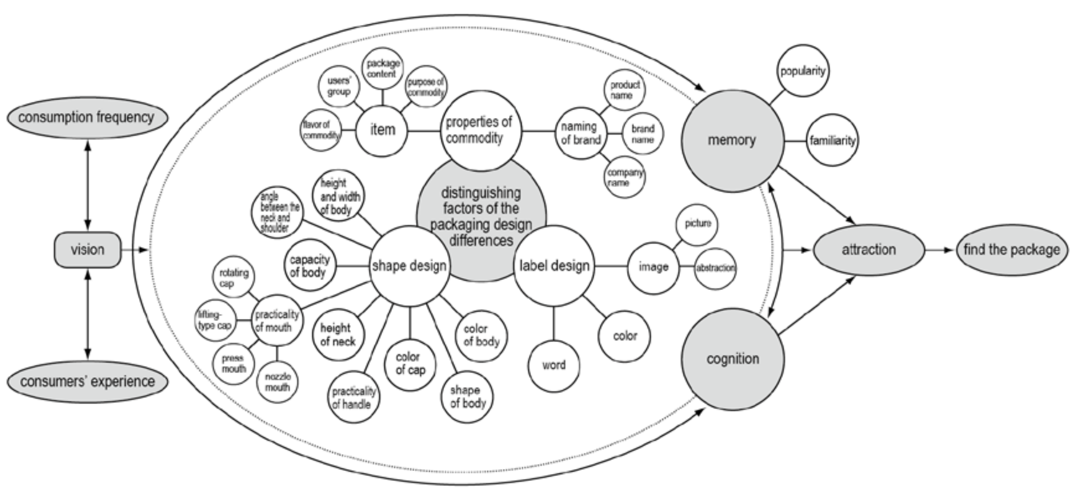

Figure 6 Conceptual framework of the focus group's interpretation of the packaging design differences

Results of the Investigation on the Factors Affecting Package Design Differences

Property of commodity, label design, and design of bottle shape in selective coding were defined as “trade dress" in this research. Based on these codings, statistical analysis was employed to determine the factors affecting package design differences.

Hierarchical Summarization of the Distinguishing Factors

After being identified by the focus group, a single independent sample was separated until it reached the fifth stage when pairing groups were distinguished one by one (see Table 3). As observed from the hierarchies tested, the total samples were up to 300 from the 5th to the 9th hierarchy. The distinctions were completed at a qualifying rate of 70%. From the result, it can be seen that the finished hierarchies were influenced by the quantity of the commodities when the consumer identified the differences among packaging designs from a heap of complex commodities. However, it does not mean that distinguishing the differences in the packaging designs would be easy with fewer commodities.

Number of Hierarchies	1	2	3	4	5	6	7	8	9	10	11	12	Total
Number of Samples	0	0	0	0	4	33	54	99	110	71	36	21	428
Proportion (%)	0	0	0	0	0.93	7.71	12.6	23.1	25.7	16.6	8.41	4.91	100

Table 3 Number of testing samples completed in each hierarchy distinction and their proportions

Summary of Classifications of Trade Dress in the Differences in Packaging Design

The quantity of classifications of trade dress was further explored when the focus group distinguished the differences in packaging designs (see Table 4). There was no absolute standard in grouping the focus group, but the distinguishing trade dress was found in the design differences among various groups. Therefore, similar items of trade dress could be adopted for grouping. The distinguishing factors of the different classifications of trade dress were only adopted in the statistical computations.

Layer	1	2	3	4	5	6	7	8	9	10	11	12	13	14	Total
Number of the Sample	0	0	29	113	132	92	52	10	0	0	0	0	0	0	428
Proportion (%)	0	0	6.78	26.4	30.8	21.5	12.1	2.34	0	0	0	0	0	0	100

Table 4 Amount of classification of the testing samples and their proportion after distinguishing in each hierarchy

Five trade dress classifications were employed by the focus group to complete their distinction of 132 pieces of test packaging samples in this research, accounting for 30.8% of the total test sample. Four trade dress classifications were then used on 113 pieces, accounting for 26.4%, and then six trade dress classifications were adopted on 92 pieces, accounting for 21.5% of the total test sample. These three numbers of trade dress classifications added up to 80%, which clearly indicated that four to six items are inclined to be used in distinguishing packaging design differences.

To illustrate the outline of the packaging design differences, proportions of trade dress classifications leading to the differences used by the focus group as distinguishing factors were calculated. “Item” in the classification of trade dress has the highest frequency of employment at 65 times. This means that “item” is used by consumers as a distinguishing factor 24.90% of the time. Subsequently, “shape of bottle” was used 46 times (17.62%) and “color of bottle’s body” was used 44 times (16.86%). Other classifications of trade dress were employed for less than 10% of the time (see Table 5).

Based on the above analysis, three classifications of trade dress (i.e., item, shape of bottle body, and color of bottle’s body) are inclined to be used as the axis of distinction by the focus group, accounting for 60% of all the classifications of trade dress. On the contrary, words on labels and image on the labels were ignored by the focus group; both of these classifications were below the usage frequency of 1%. This phenomenon reflects the consumers' personal experience and habit. The transparency of the package bottle was also noticed by the focus group. The color of the package bottle was deemed an important factor in its findability. If a product's color is more different from that of the rest, then it will be found more easily.

Classification of trade dress	1	2	3	4	5	6	7	8	9	10	11	12	Frequency(n)	Proportion (%)	Preference sequencing

Table 5 Classification table of trade dress in distinguishing the differences among packaging designs by the focus group

Summary of the Trade Dress of Package Design Differences

All the frequencies were summarized to compare with the importance of trade dress represented by each classification (Tables 6 and 7). Based on the proportion of trade dress, the "shape of bottle" is the key factor in distinguishing packaging design differences used by the focus group, accounting for more than 50%, which is greater than "property of commodity" and "label design."

In Table 5, "item" is used with the highest frequency in the classification of trade dress. But this doesn't make "item" inferior to "color of bottle" as a distinguishing factor in the first hierarchy of distinction. It can be explained that various kinds of commodity packages cover diverse categories and items of many products. This leads to their complexity, and thus they cannot be divided simply by item classification. On the contrary, whether or not the bottle is transparent is distinct on the first stage as a distinguishing trade dress classification. In the second stage, the property of commodity and shape of bottle compete with each other during the course of distinguishing packaging design differences.

Classification of trade dress	Usage frequency (n)	Proportion (%)	Sequencing of usage preference
Commodity's property	85	32.57	2
Shape design of the bottle	166	63.60	1
Design of the label	10	3.83	3
Total	261	100.00

Table 7 Distribution table of the classifications of trade dress for distinguishing packaging design differences by the focus group

Conclusion

This research investigates how consumers sense and distinguish differences in package designs from the commodities on sale. This thesis is creative based on two points. First, a focus group interview was employed to distinguish the differences among various packaging designs comprehensively. This thesis was not confined within the design elements. Second, hierarchical relations between the trade dress and the classifications of trade dress were assessed based on grounded theory designs. The property of commodity includes two classifications of trade dress, label design includes three classifications of trade dress, and the shape of the bottle includes nine (see Table 7 for details). The items of packaging design included in this research are more specific, and the results are more focused than those of previous research.

Significantly, label designs are worth our attention. When the focus group distinguished the differences among packaging designs, item or brand name, as a factor for distinguishing the hierarchy of two pairs of groups, was not emphasized (not included in the label design). Item and brand name were only emphasized when the groups with high homogeneity elements on the label, such as different words (Chinese vs. English or Japanese), different images (specific and abstract), or different colors, were taken as the distinguishing factors. However, there is a close relationship among item, brand name, and label design. None of the classifications of trade dress can exist on the bottle independently. However, the focus group was habitually inclined to regard them as a whole. Thus, the significance of the label design remains unclear.

As to the association with the commodity, consumers most easily and directly associated the item and brand name with the product content. Next, they associated the image, words, and color on the label with the product content. Finally, bottle shape was associated with the product content. Thus, with respect to the association between packaging design and product content, the trade dress is ranked from highest to lowest as property of commodity > label design > design of bottle shape.. More importantly, the distinction lies in the relationship between "trade dress" and "classifications of trade dress," which can better reflect the differences in packaging designs.

Author Biography

Regina W.Y. Wang

Regina W.Y. Wang is an Associate Professor in the Department of Industrial and Commercial Design at National Taiwan University of Science and Technology. She specializes in graphic communication and ERP in visual perception that involves readability and emotion dimensions. Quite a few of her papers have been published by design journals and in international design symposium proceedings.

Mu-Chien Chou

Mu-Chien Chou is a lecturer in the Department of Digital Media Design at Chungyu Institute of Technology. He is also a Ph.D. Candidate at National Taiwan University of Science and Technology. His research is devoted to the application of visual perception in communication/media design practice that involves consumer behaviors and package findability. Not a few of his papers have also been published by design journals and in international design conference proceedings.

Interdisciplinary Design: The need for collaboration to foster technological innovation to create competitive and sustainable products.

Peter Wehrspann, Carleton University, Canada

Lois Frankel, Carleton University, Canada

Abstract

This paper explores an integral relationship between industrial design, advanced technologies, science, economy, and the environment to realize a logical trajectory for the future of product design. Through an investigation of current literature, key aspects and critical factors of interdisciplinary collaborative work are explored. By realizing the benefits and obstacles, this paper suggests a framework in which scientists, engineers, and designers can work together successfully to create innovative solutions for product design. The paper discusses the possibilities of material synthesis through the scientific field of biomimetics. It also suggests that the Industrial designer's role must evolve into a position of project facilitator and communicator. To conclude, this paper mentions technologies utilized currently in this fashion and ideas are proposed to further guide this framework.

Keywords

Synthetic Biology, Interdisciplinary Design, Cross-Functional Teams, Biomimetics, Industrial Design, Product Design, Advanced Technology, Sustainability.

As the world's population grows and and the amount of resources that are available to be extracted from the earth does not, there is going to be an inevitable and drastic difference in the supply and demand of energy and resource for product manufacturing in the years to come. For example, "conventional crude oil production in the United States is forecast to terminate by about 2090, and world production will be close to exhaustion by 2100" (Edwards, 1997). This threatens the environment, the global economy and in turn social well-being. Either consumption and production of industrial and consumer goods cease or we must find new ways to produce or to create materials and technologies. The former is unlikely to happen. The latter is what is probable and is in flux. As material scarcity threatens the world and its inhabitants, environmentally incompatible material production processes threaten them also. The world's industrial nations must find solutions to reduce the burden that is being placed on our earth through the removal of finite stores of resources and the creation of harmful industrial effluents.

This paper is concerned with the role that scientists, engineers, and designers will have in finding solutions to the problematic relationship between consumption and resources, environment and production. Not only is this paper concerned with these individual disciplines, it is primarily concerned with establishing a framework for these diverse schools of thought to interact in a cooperative fashion to reach the solutions necessary to address the problem effectively. Interdisciplinary approaches to knowledge creation are crucial to solving problems of this magnitude. Only through the synergy of disparate schools of thought will the world render the creative solutions necessary. Interdisciplinary work between scientists, industrial designers, and engineers holds great potential for dealing with environmental issues concerning new product development. Biomimetics, a broad scientific approach, has great potential to bring dissimilar schools of thought together to form such solutions.

Overview

This paper begins with a literary overview of works by relevant scholars. This investigation explores:

1) How an interdisciplinary design approach is paramount to finding innovative solutions.
2) How critical factors of group dynamics and theoretical knowledge about interpersonal communication foster such research.
3) How interdisciplinary work between designers, engineers and scientists, representing the most advanced technologies plays an integral role in imagining and engineering the best product solutions.

Following the literary overview, in section 2, is a discussion of the findings. Section 3, based on these findings, will suggest solutions, a framework for future interdisciplinary design, and possible interdisciplinary trajectories.

Key Aspects of Interdisciplinary Design Collaboration

Combining disparate schools of thought is crucial when dealing with complex problems. We have drawn from several academics who support this notion. There are a few terms that are used to define these types of teams: these include interdisciplinary teams, multidisciplinary teams, and cross-function teams. For the purposes of this paper these three terms will be used loosely. Each is similar in the sense that they define teams that have a relationship within an organization. What is most important and shared among these classifications is the sense of team. Holland and Gomes (as cited in Cohen & Baley, 1997) define it as:

> A team is a collection of individuals who are interdependent in their tasks, who share responsibility for outcomes, who see themselves and who are seen by others as an intact social entity embedded in one or more larger social systems, and who manage their relationships across organizational boundaries” (Holland, Gaston & Gomes, 2000).

This paper is most concerned with concepts of togetherness and common goals. These are critical factors that are the crux of collaboration towards an agreed upon end. Other critical factors will be discussed in the following section.

An interdisciplinary project according to Professor and Director of the School of Industrial Design, Carleton University, T. Garvey, (2009) consists of disparate disciplines or professions involved in tackling a problem with the application of new knowledge. Each is an equal stakeholder. The difference according to him between interdisciplinary and multidisciplinary is that the latter does not integrate the disciplines. Each discipline is responsible for individual results and the knowledge represented will change contingent to the proposed challenge.

Many academic institutions and commercial enterprises are currently practicing some form of interdisciplinary learning approach. In Canada, Carleton University presently is in its second year of its MDes program which focuses on interdisciplinary design research. In the United States, Stanford and MIT have their specific brand of interdisciplinary design research. Delft Technological Institute, in The Netherlands, also has a program that focuses on strategic design planning, heavily slanted toward multidisciplinarity. The transnational corporation Nortel, in its hey-day, had a faction of its organization called Design Interpretive delegated to cross-functional product design development that helped pave the way for this type of thinking (Frankel & Tsuji, 2005). These organizations have realized the need for collaboration among disparate disciplines to come up with innovative ideas. Academics discussing the subject suggest it is crucial. Relevant to the context of this paper Persson and Warell (2002) not only suggest there is a need for integration of industrial design and engineering functions but also assert that it is a prerequisite to render innovative solutions that will successfully meet market and environmental needs.

Benefits of Cross-Functional Teamwork

Nations are built from the contribution of many. Governments, Hollywood film crews and championship baseball teams only function due to the contribution of many participants in which strengths fill in for others' areas of weakness. For collaboration in the area of product design the requirements are the same. Sonnenwald (1996) suggests participation in group design efforts from different domain representatives is widely accepted as a prudent approach to developing innovative and competitive products while at the same time reducing costs. Furthermore, the benefits to this type of organization are plentiful. Holland et al. (2000) attribute nine benefits to cross-functional teams. Increased speed is perhaps the most important. When dealing with competitive markets this benefit cannot be overlooked. A teams' ability to deal with complexity is also important. When taking into consideration the complexity that environmental and economic issues have, which this paper is concerned with, simple solutions are not likely. Professor Bjarki Hallgrimsson (personal communication, November 18, 2009) claims interdisciplinary or cross-functional approaches increase in importance as a project increases in its complexity. When dealing with such complexity, single points of contact, informational quality, and learning within the organization--so everybody is 'on the same page'--are pertinent to the teams success (Holland et al, 2000). Holland et al. (2000) attributes these three benefits to cross-functional team approaches. A fostered intrapreneurial and entrepreneurial culture within the organization is important. This supports healthy competition integral to innovation which will extend beyond the walls of the particular organization. Another benefit suggest by Holland et al. (2000) is that of motivation. Whether it is team or individual motivation it can be encouraged through a competitive organization. Enhanced creativity and customer focus are the last two benefits suggested by Holland et al. (2000). Both are important to the scope of this paper.

Obstacles Confronting the Collaborative Design Approach

As benefits are apparent, there are hurdles to interdisciplinary design teams that can vitiate successful outcomes. The literature recognizes communication problems as a major issue to be dealt with in collaborative design teams. Berryman (2002) recognizes that there are often daunting hurdles faced by interdisciplinary teams and one of them is language.

It is currently recognized within the field of interdisciplinary design research that there should be a unified body of knowledge (Love, 2002) that fosters an understanding for all disciplines that participate. This further supports the issues of language barriers facing interdisciplinary design team efforts. Unifying a body of knowledge in this field is not as easy as one may think. As the field grows in its scope and more disciplines participate in this type of organization, it becomes difficult to create vernacular that can support such an endeavor (Love, 2002). The issues that can arise due to this lack of a unified body include theoretical conflicts between researchers, lack of theory validation, unclear scope, and an inability for new researchers to identify sound epistemology (Love, 2002).

Chiu (2002) recognizes four areas of communication, which can lead to less than the desired effect. These include:

I) The media problem in which design information must be conveyed properly.
II) The semantic problem where symbol transmission is lost due to noise.
III) The performance problem that deals with issues in receiving intended information and reaction of the receiver as the sender wished.
IV) The organizational problem where information is lost or reduced in integrity through its travel within the hierarchy i.e. ‘broken telephone’.

The larger the group the more intricate the hierarchy and thus the more chances that information is altered. This challenge of communication effectiveness is not the same significant issue when communicating face-to-face. Usually it is not the lack of know-how or expertise that creates the problem. It is the non-representation of information that is lost. Safoutin & Thurston (1993) refer to this as failure in design mechanisms. Many design failures are attributable to commonly understood mechanisms, suggesting that they are not due to a real lack of expertise within an interdisciplinary design team but rather to communication errors at key decision points (Safoutin & Thurston, 1993).

Hurdles faced by interdisciplinary design teams cannot be attributed to communication functions alone. Sonnenwald (1996) claims “knowledge exploration can be difficult for design participants.” Unique experiences and confidence in ones’ skill can lead to what Sonnenwald calls “contested collaboration.” This happens when individual perceptions vary and participants challenge or contest another’s contribution.

Holland et al. (2000) identifies six areas that hinder cross-functional efforts. These include conflicting organizational goals, competition for resources, overlapping responsibilities, conflicting personal goals, no clear direction or priorities, and lack of co-operation. Kim and Kang (2008) (as cited in Wall & Lepsinger, 1994) also identify obstacles that overlap and confirm what other researchers are finding.

> The key issue, affecting 80%...was the tension that exists between team goals and functional priorities, surfacing in the form of: conflicting organizational goals; competition of resources; overlapping responsibilities; conflicting personal goals; a lack of clear direction or priorities; and a lack of cooperation (Kim & Kang, 2008).

Safoutin and Thurston (as cited in Steiner, 1972) add that “process loss always occurs in real groups, and stems from informational, behavioral, and organizational factors that impede the application of existing group resources to the problem at hand.”

Group dynamics have not changed much over the last few decades. This paper assumes that is because people, for the most part, have stayed the same. However, it is the application of this honed knowledge about interdisciplinary teams towards solving complex issues that is the focus of this paper. Through this and other investigations, this field of study comes closer to pinpointing the critical factors that increase the chances of successful interdisciplinary design efforts.

Critical Factors Affecting Collaborative Approaches

There is much to learn about interdisciplinary approaches to knowledge creation. Although it is a popular topic among academics, there is still a lack of insight into what is critical to the success of teams comprised of dissimilar disciplines. Holland et al. (2000) suggest that "the emergence of cross-functional teams is one of the most dramatic recent trends in organizational design." Although, it seems interdisciplinary practice is exceeding the amount of scholarly research, There is plenty of room for error within organizations that are intending to successfully implement these types of design teams. As interdisciplinary design research and product development is crucial to solving complex issues, these teams do not always function as they should. Noted above are hurdles teams face on a regular basis. To excise these impediments researchers suggest factors that teams must possess that are critical to successful outcomes. As failures in communication are common and are what is most responsible for negative outcomes, quality communication is one of these critical factors. Dr. W. Wehrspann (2009) asserts personal relationships do not operate properly without effective communication. This being so, it is unlikely that business relationships within a complex organization will operate succinctly. Holland et al. (2000) and Frankel and Tsuji (2005) discuss the critical factors leading to successful interdisciplinary or cross-functional design team efforts. Their findings among others are reviewed below.

Management

Holland et al. (2000) suggest quality management, shared goals, quality communication, organizational structure, creative output, constructive conflict, psychosocial traits, and resource availability as some of the critical factors. This paper is concerned with these because they best reflect its scope. "The fish stinks from the head down,'' is a common chide on bureaucracy. It stresses the need for good leadership. At the tip of the organizational iceberg, leaders or managers must perform functions successfully to assure other critical factors are met. Shared goals by disparate members are possible but it can be better fostered through quality management. Berryman (2002) suggests that collaboration can be a struggle. However, this struggle can be effectively managed "with a solid strategy involving basic tenets of good project management" (Berryman, 2002). The organizational structure is also quite dependent on the management. Holland et al. (2000) suggest leaders to be educators and communication facilitators. This will allow for a flexible but structured organization in which roles are not rigid and responsibilities do not overlap. If this is not so, innovation qualities are greatly lost. As innovation is important, so too is creativity. The literature review suggests there is a strong co-dependent relationship between the two. Dankbaar and Vissers (2002) suggest innovation is supported by an organic structure and creativity is fostered by group autonomy. Within an organizational structure, which allows for fluidity of information, creativity is spawned and creativity begets innovation.

Social Factors

Often people attempt to avoid conflict. This investigation suggests that there is functional conflict and dysfunctional conflict (Holland et al. 2000). Conflict cannot be avoided. However, there are positive conflict outcomes. For this to work, ideas must be expressed freely and team members must be willing accept constructive criticism. This relies heavily on the psychosocial traits of the team members. It is suggested that embracing characteristics such as empathy, active listening, overall emotional intelligence, and "a sense of humor as a group...to shed stress" (Frankel & Tsuji, 2005), can put a positive spin on conflict. Though each individual's personality traits affect the overall psychosocial dynamic of the group, it is up to management to support an organizational structure that develops a team which is greater than the sum of its parts.

Within Nortel's Design Interpretive team, Frankel and Tsuji (2005) explain the need for self-motivated members who carry mutual respect for one another. They suggest an organization that functions horizontally rather than a vertical hierarchy. Their investigation supports notions about sensitivity to constructive criticism. Team members must also be experts and all should be mutually responsible for the outcome.

Resources

Holland et al. (2000) mention resources as a critical factor. Not enough resources and a team cannot have the appropriate organizational structure. Members take on too many roles and have too much responsibility. This can affect team tenure (Dankbaar & Vissers, 2002) and spoil overall outcomes. It must be noted that though there is lack of resources, at times it can spur innovation.

The above investigation mentions some of the significant factors that would contribute to the successful outcome of interdisciplinary teams. What is noted here, is that all teams cannot function using a universal template. Critical factors will depend on complexity and nuances of the project itself.

Interdisciplinary Teams and Advanced Technology

The previous sections have discussed ways to support interdisciplinary design efforts and outlined what is needed to increase chances of succeeding. We now review interdisciplinary approaches within the context of advanced technology. The professions that most concern the scope of this paper are industrial design, engineering, and science. Each plays an important role in finding solutions for prescribed issues for this paper. The industrial designer is responsible for vision and communication. Scientists represent the most advanced technologies. The engineer's role is the application of that technology. Specifically within engineering and science this investigation is interested in the roles of material engineers, chemists, biologists, physicists, and environmental scientists.

As designers who are part of an international community, there is a realization that greater and more complex issues are arising in new product development with respect to resource availability, environmental health, economic stability and sociocultural environments. Frances Bronet states,

> There is a growing recognition that significant challenges await us in the years ahead if the nation is to compete successfully in a highly competitive global economy, while also seeking to share social well-being and restore the natural environment upon which all life and technology depends (Bronet, 2003).

The designer's role is changing to take on more responsibility. This responsibility lies in envisioning future products and facilitating the disciplines that are necessary for developing advanced product solutions. This requires an industrial designer to be well-versed within their own discipline, requiring artistic and engineering abilities, and have a deep understanding of the sciences and economics. Having a degree in Communications would not detract from a designers ability.

Interdisciplinary study within the realm of science is not a novel or groundbreaking concept. The idea that industrial designers are integral to this interdisciplinary approach to the science of materials, is.

All the scientific disciplines we are aware of today stem from an original parent discipline. Whether it is alchemy or physics, there is cross-pollination of knowledge all along the board. It is not a stretch to suggest interdisciplinary scientific research is beneficial to advance material processes and product design. Montgomery (1999) realizes this. He asserts scientists and engineers have a crucial role in these activities. Other research unveils the benefits of such interdisciplinary efforts in science. Fox and Rohlich (1967) view “interdisciplinary inquiry as essential for the solution of certain kinds of environmental problems” (Fox & Rohlich, 1967).

Biomimetics

The field of biomimetics in essence is interdisciplinary. “The well-organized multifunctional structures and biogenic materials found in nature have attracted the interest of scientists working in many disciplines” (Rao, 2003, pp.660). Rao (2003) defines biomimetics as a “field of scientific endeavor, which attempts to design systems and synthesize materials through biomimmicry” (Rao, 2003, pp.659). Bio means life and mimesis means imitation. Fish (2009) defines biomimetics as an approach that seeks to incorporate design research from living organisms into engineered technology by mimicking organic processes.

Prior research strongly supports the idea that biomimetics--which includes but is not limited to chemistry, biochemistry, geologists, physics, biology, material engineers, material scientists, and environmental scientists--holds strong potential in dealing with complex environmental and economic issues. For example, Rao (2003) explains that “material scientists view biomimetics as a tool for learning to synthesize materials under ambient conditions and with least pollution to the environment” (Rao, 2003). Geologists are interested in the biomineralizaton of biomimetics. Biochemists are interested in biomimetics because of the interaction of biopolymers with ions of metals, which leads to mineralization in living organisms (Rao, 2003). This paper is thus concerned with advanced technologies derived from scientific discovery within the scope of Biomimetics. The study of biomimetics offers the greatest potential in the creation of materials and technologies that are benign to our environment.

In the first half of the 20th century researchers found insights into complex physical and chemical phenomena. This led to the current day understanding of nanoparticles and marcroparticles which are termed synonymously with colloids and polymers respectively (Fish, 2009). These are the building blocks for miniature stable tissues. There are also multicellular and single-celled organisms have the ability to produce structure tissues like bone, teeth, shells, skeletal units, and spicules (Sarikaya, 1999, as cited in Lowenstam, 1981). “Natural materials are mostly constituted from organic, inorganic crystals” (Rao, 2003). These crystals give rise to materials that can be used practically to produce products that fulfill human needs without extracting finite resources from Earth.

The following are advanced technological processes that have similar capabilities. Synthetic biology can construct biological systems through manipulation of genomes to construct novel biological systems (Fish, 2009). Bionanotechnology can create materials via peptide-based production (Rao, 2003). Reticular synthesis is the construction of crystalline solid-state materials from molecular building blocks (Yaghi, O’keefe, Ockwig, Chae, Eddaudi & Kim, 2003). It is this synthesis of materials via manipulation of biological means that holds the potential solution to solving the issues relevant to present day production processes. Although these technologies are not without their controversies, they suggest production means that do not have harmful effluents. They are compatible with the ecosystem. Yaghi et al. (2003) claims that the synthesis of new materials is recognized as a crucial stepping-stone in the advancement of technology.

The main idea behind the science is to create inorganic particles that can ultimately produce technologically stable materials for creation of solid-state products. Yaghi et al. (2003) confirms to date these materials have been used for medical products and electronics. There is potential to create other materials that can branch apart from these products into other industries. These materials include silk, ceramics, and other materials with elastic fibers (Rao, 2003).

Possibly the most interesting work in the field today is that of Neri Oxman and her founded Materialecology. Being an architect--MIT Phd Candidate--a medical scholar and computer engineer, she is internally interdisciplinary. Her work spans many disciplines in which biomimetics is at the heart of her innovation.

> Materialecology was formed in 2006 by Neri Oxman as an interdisciplinary research initiative that undertakes design research in the intersection between architecture, engineering, computation, and ecology. As such, this initiative is concerned with material organization and performance across all scales of design thought and practice. As such, it seeks to promote and define a design research agenda which is ecological in nature, in ideology and in material practice; it aims at embracing the evolving elements of change in both social constructs and environmental descriptions of the ever changing built environment. Materialecology undertakes research in advanced digital applications for architectural practice and pursuits using their contribution to design a paradigm promoting generative design processes (Oxman, 2006).

Oxman's efforts exemplify the design leadership needed in this vastly complex world of products and resources. These types of interdisciplinary examples are becoming more popular as we move into the murky future. As suggested by this paper, there will be adversity to overcome. But this adversity is far outweighed by the benefits of such collaborative and advanced approaches.

Discussion

Collaborative effort into scientific knowledge creation has been a continual process that parallels the evolution of man. It is evident that these efforts are integral to moving forward into the future of product design. Interdisciplinary approaches vary depending on the complexity of the project. When it comes to environment and economy which balances an inexhaustible amount of needs and vested interests, the complexity of the issue is unimaginable. This means a coherent body of knowledge detailing how best disparate disciplines should work together is paramount to future design and engineering efforts. Benefits to interdisciplinary design efforts are numerous. The most important benefits being that of speed and an ability to deal with complexity. Strength in numbers is also a benefit. Members' strengths supplant for others' weaknesses. The positive contributions of a team are evident. Goal orientation and group motivation become catalysts for innovation and creativity. Though there are benefits to interdisciplinary design teams, there are also hurdles to be reckoned with. Failure of communication mechanisms is a major hinderance. Lack of unified understanding also vitiates interdisciplinary team efforts. Murky organizational goals do not help the process. If resources are scarce, roles and responsibilities are compromised. There can be a loss of information when it transfers down and upstream. This goes back to the failure of communication mechanisms mentioned above (Safoutin & Thurston, 1993).

Currently the practice of interdisciplinary approaches exceeds the research. Vernacular is difficult to pin down. Theories become unclear. These impediments give rise to a necessary set of critical factors which are relevant dependent on the complexity and details of any given project. Holland et al. (2000) and Frankel and Tsuji (2005) give us examples of these important factors. These include high quality of leadership, mutual respect between members, group accountability, flexibility, humor, and organic but structured organization. Insensitivity to constructive criticism and emotional intelligence among members is important. These factors increase the chance of a successful interdisciplinary team project.

There are several different advanced technologies that have the potential to produce the outcomes that product design needs to fulfill environmental and economical issues that are the concern of this paper. Whether through synthesis of polymers or inorganic materials, the fact that they have the ability to be manufactured biologically is what makes these technologies so promising. This is currently being applied and there is hope for more widespread use within industrial design.

Biomimetics is a long standing scientific field that is interdisciplinary in its nature. Disparate disciplines are interested in its potential for varying reasons. Geologists are curious about biomineralization; while chemists keep tinkering with the genome. On any scale there is vast potential in figuring out and altering biochemicals and processes to create engineered technology.

Proposal/Conclusion

As technologies advance in biomimetics and material synthesis science, industrial designers must become more involved in the process. Industrial designers must look forward to the future and as Wayne Gretzky did (he is considered the greatest professional hockey player ever to play); he went to where the puck was going, not where it was. Scientists will no doubt move forward with technological advancement. It will be up to designers and other entrepreneurial types to envision the future uses of synthesized materials. A framework for an interdisciplinary approach should be created now for the time when these processes are introduced into the mass market. The beginning of such a framework is suggested in Figure 1 on the following page. The four circular domains represent different specialized knowledge. The volume of those domains correlates positively with the amount of information that flows within. Two-way arrows suggest the controlled free flow of information. Disciplines must be communicating within their domains, suggested here, for this model to be successful. The industrial designer's role within this model is, as suggested before, part communicator and part visionary. To do this effectively the industrial designer must be a generalist of sorts. They must posses information from all domains including the critical terminology and cultural awareness of each. This would allow the industrial designer to move in and out of these domains offering and borrowing information for application towards their product vision. If this job of "creative messenger" is done effectively, there would be unmatched synthesis of original ideas that will foster the creation of breakthrough products and processes for many industries.

As mentioned, the industrial designer within this model must be a generalist to do so. This would require a deep understanding of economic principles, advanced scientific theory and of course the artistic and engineering skills that are currently required for the present day industrial designer. This leaves a bevy of educational pathways to be pondered. Suffice it to say, the future industrial designer would benefit from having more than a B.I.D.

This framework is already in flux because relevant disciplines are part of a technological and design oriented continuum that is not separate from the historical and sociocultural fabric. Designers, scientists, and engineers must realize that in the the last half century this continuum has increased in speed to a dramatic degree. Realizing this will allow them to assert control over product, technology, and science, doing so in an interdisciplinary fashion. It is the interdisciplinary nature of these sciences that has moved technology to this point. It is also the interdisciplinary nature of science and its collaborative knowledge creation through which the field will progress. Designers will have to play an integral role in understanding new knowledge of materials, its capabilities and application. They will also need to be savvy communication facilitators, using general knowledge of many different disciplines to foster synergy between those disparate fields of study. It is an exciting but also a dire time wherein innovation and interdisciplinary efforts are pertinent to our future standard of living on Earth.

Author Biography

Peter is a furniture designer, metal artist and woodworker. He holds a degree in Mass Communications from Wilfrid Laurier University and an advanced diploma from Sheridan College in furniture craft and design. He has also had the privilege of continuing his studies overseas at Danmark Design Skole, Copenhagen. Peter currently is a Masters of Design candidate at Carleton University. Between design research and product development Peter spends his time operating his Toronto-based business, Holtzundmetal. As an award winning designer he has showcased across Canada and internationally.

Author Biography

Lois is an Associate Professor and past Director at the School of Industrial Design at Carleton University. The primary focus of her work is simplifying the relationship between people and computer-enabled products.

Thinking about design experience: A semantic network approach

Donna Wheatley, The University of Sydney, dwhe0020@uni.sydney.edu.au

Abstract

Social network analysis software has been used in this study to reveal individual and collective perceptions of space from different perspectives. The paper outlines how to analyse an 'environment-response' semantic network of a user group and that of the architect. The semantic network of the designer was found to be quite different from the users of their designs, a starting point from which to question how far designers of space are able to anticipate what impressions and reactions their designs elicit in users.

Determining what thematic clusters or topics emerge (called 'metatopics' in the study) from the networks is a primary aim. The networks usually contain 4-7 metatopics. A range of network analysis algorithms, calculating measures such as centrality and proportional strength of ties are applied to identify important constructs and help identify metatopics. These metatopics can also themselves be ranked and compared through network analysis indicators. Through these tools, new observations on the structure of collective mental representations of built environments are gathered.

Key words

Semantic networks, network analysis, perception, designed environments, interviews

The assumptions that designers make about the effect their designs have on end users is a vital part of the design process as well as a key part of the design. Social network analysis software 'Pajek' has been used in this study to visualize and analyse the mental constructs toward a particular environment. How people respond to a designed environment has not previously been explored as a network of thoughts, yet this could be a productive use of network analysis given that human relationships with the environment (natural and built) is gaining prominence as a research topic.

The paper discusses two 'environment-response' networks that were derived from a new workplace: one for the user group and the other for the architect. The network of the designer is quite different from that of the user group, thus calling into question in how far designers of space understand what effect their designs will have on users.

The paper firstly outlines why network analysis can be a useful and valid research tool in investigating human responses to the environment. The middle section describes the data used for deriving the networks. The final section, using a case study, discusses analysis of the environment-response user group (consensus) network before showing the designer's environment-response network for brief comparison. Results of this method could be used contribute to discussions on how and why designers conceptualise space differently to users

Thinking about design experience: A semantic network approach

Donna Wheatley, The University of Sydney, dwhe0020@uni.sydney.edu.au

Abstract

Social network analysis software has been used in this study to reveal individual and collective perceptions of space from different perspectives. The paper outlines how to analyse an 'environment-response' semantic network of a user group and that of the architect. The semantic network of the designer was found to be quite different from the users of their designs, a starting point from which to question how far designers of space are able to anticipate what impressions and reactions their designs elicit in users.

Determining what thematic clusters or topics emerge (called 'metatopics' in the study) from the networks is a primary aim. The networks usually contain 4-7 metatopics. A range of network analysis algorithms, calculating measures such as centrality and proportional strength of ties are applied to identify important constructs and help identify metatopics. These metatopics can also themselves be ranked and compared through network analysis indicators. Through these tools, new observations on the structure of collective mental representations of built environments are gathered.

Key words

Semantic networks, network analysis, perception, designed environments, interviews

The assumptions that designers make about the effect their designs have on end users is a vital part of the design process as well as a key part of the design. Social network analysis software 'Pajek' has been used in this study to visualize and analyse the mental constructs toward a particular environment. How people respond to a designed environment has not previously been explored as a network of thoughts, yet this could be a productive use of network analysis given that human relationships with the environment (natural and built) is gaining prominence as a research topic.

The paper discusses two 'environment-response' networks that were derived from a new workplace: one for the user group and the other for the architect. The network of the designer is quite different from that of the user group, thus calling into question in how far designers of space understand what effect their designs will have on users.

The paper firstly outlines why network analysis can be a useful and valid research tool in investigating human responses to the environment. The middle section describes the data used for deriving the networks. The final section, using a case study, discusses analysis of the environment-response user group (consensus) network before showing the designer's environment-response network for brief comparison. Results of this method could be used contribute to discussions on how and why designers conceptualise space differently to users

(Cross 2006; Lawson 1997) and is an aim of the larger study. This paper refrains from making generalisations of theory in order to present one worked example of a new design research method. The intention is to indicate the utility that social network analysis offers to researchers interested in understanding the thought structure that individuals and groups of people have about a designed environment.

Theorising an environment-response network

This section of the paper provides an overview of key theories that provide a rationale for developing an environment-response network: environmental psychology confirms the existence of a human environmental response; the science of semantic networks explains that thoughts exist as a type of network; an overview of networks as an abstracted set of elements and connections that can be mathematically and algorithmically analysed and represented; and finally, the reasons for applying an environment-response network to a workplace setting.

Environmental psychology

Any environment has a psychological effect on users (Norberg-Schulz, 1980; Rasmussen 1964). Many researchers have attempted to understand what elements of the environment can enhance quality of life (Alexander, Ishikawa & Silverstein, 1977; Gifford, 2007; Zeisel, 1984). The hope is that designers armed with this knowledge could create environments that reduce stress, enhance mental acuity and emotional response and any other desirable outcomes. However, research in this area is generally inconclusive, based on intuition or small-scale studies and has not kept up with scientific advances in other fields.

This year Oxford University Press published *Brain Landscape: The Coexistence of Neuroscience and Architecture* to “challenge neuroscientists to study how architecture affects the brain” (Eberhard, 2009, p.xii). The emphasis the book presents to readers is that the brain, which controls behaviour, is influenced by the environment. Neuroscientists have found that connections between neurons in the brain to continuously ‘re-wire’ to adapt to environmental stimuli all through our adult lives (Gordon, 2000, p.72). Architecture, it is supposed, can change our brains and our behaviour.

Semantic networks

Following on from studies on the network structure of neurons in the brain is a notion that thoughts would also follow a network-like structure. Thoughts about a subject or object (such as architecture), have been considered a type of network in order to “create abstract representations of the general features of input data” (Spitzer, 1999). Spitzer describes these ‘semantic networks’ as relating to associations between words as a form of knowledge representation. Semantic networks were first studied as a concept called *associationist psychology* (John Locke and David Hume) and later *free association* (Sigmund Freud, Sir Francis Galton and Carl-Gustav Jung). Later, it was theorised that words themselves are stored in a network like structure in the brain (Collins and Loftus, 1975). The use of semantic networks as a tool used to examine how thoughts occur has also been used in the context of developing artificial intelligence (Sowa and Borgida, 1991). Concepts underlying semantic networks are relevant to this research project, in which word-associations, extracted from interview transcripts, generate abstract semantic networks that represent respondents’ concepts of architectural spaces. It takes as a starting point the notion that the abstract structural type of the network are tied closely to how subjective ideas about objects such as architectural environments are represented in the brain.

Network analysis

A network refers to any collection of interacting parts, which satisfies certain laws of form and organisation (Buchanan, 2002, p.18). The architecture of networks can be analysed meaningfully and patterns observed where previously none could be seen. To analyse a network its 'parts' are understood as a set of discrete elements (vertices) and connections (edges) between them. Extracting these features provides clarity to a question that would be impossible to answer, were all details to remain (Newman, Barabási & Watts, 2006, p.4). In addition to powerful visualisation capabilities of software, network analysis techniques allows for mathematically rigid measurement of the structure of the connectedness of a network independently of its content.

Sociologists and statisticians have been advancing the field of network analysis since the 1930s, but software for analysing networks really only began appearing in the 1990s when computer scientists became interested in modelling increasingly complex domains. Fields that use network analysis include information technology (including computer networks such as World Wide Web), biology, and the social sciences.

Why look at workplace settings

Many people spend a significant part of their lives at a workplace. Robert Gifford, eminent environmental psychologist, says that "the physical environment at work is crucial to employees' performance, satisfaction, social relations and health" (Gifford, 2007, p.372). Research into people's response to workplace settings focuses on employee productivity and satisfaction (Brill, 1984; Becker & Steele, 1995), but other important areas are to be investigated, especially in an increasingly knowledge-based work environment: collaboration, interaction, social behaviour, being part of a team, control over environment, flexibility, comfort and health (Worthington, 2006). To map out the human response to the workplace environment, Gifford (2007) draws on extensive research to find that five variables of workplace settings primarily contribute to behavioural response: 1) sound, noise, and music, 2) indoor climate, 3) air, 4) light, colour and windows and 5) density and arrangement of space.[1] John Eberhard, author of *Brain Landscape*, also devotes a chapter to workplace design (2009, pp. 135-153). His purpose is to identify areas for further research. It can be concluded that this architectural setting has elicited limited empirical research on the user response, yet is an important architectural type to investigate in terms of its psychological impact on society.

[1] These variables can be observed in the environment-response network, but so do other features, such as technological devices that enable free and easy movement as shown in the later graphs. The usefulness of an environment-response network is that it captures variables in total, so that their relative importance can also be examined.

Fig 1. An atrium inside case study *workplace x*. The environment-response network will reflect the thoughts and feelings of employees that use the space, positively and negatively. (Photo: author)

Data in the environment-response networks

The data was collected from interviews, coded into spreadsheets then transformed into a Pajek readable file.

Data Collection

Data was gathered from in-depth interviews at a series of workplaces (this paper focuses on one, *workplace x*, as an example). Nine to fifteen employees at each case study workplace were asked to talk about their experience of their physical surrounds using metaphors. Metaphors involve understanding one thing in terms of another and are assumed to shape new thoughts (Gibbs, 1992). This technique has been used in the field of psychotherapy to help patients make unconscious experiences more conscious and communicable (Kopp, 1994) and in consumer market research (Zaltman & Coulter, 1995). The use of metaphors is stimulated by a range of images provided to interviewees to help illustrate their thoughts. This technique was used to collect data for the environment-response network as it offers a way to go beyond the interviewee's conscious self-perception of their response to their workplace environment. Once a metaphor, thought or feeling has been stated by a participant they were then asked to elaborate on it and to connect it to an aspect of the workplace that most strongly gave them that response.

Coding the data

Data in the interview transcripts are coded in environment-response pairs, response-response pairs and occasionally, environment-environment pairs. When a thought or feeling is mentioned, its link to the workplace environment or other thoughts or feelings is recorded. Between 40 and 80 pairs are identified for each respondent.

Linguistic research in syntax, the study of the rules of language and sentence structure, is beginning to examine the basis of language as links between words and actions when they share an object of reference. Richard Solé uses this notion to turn linguistic constructs into networks: “two words are linked if they have been syntactically combined in a collection of sentences. Different languages share the same scale-free structure, with most words having few syntactic links and a few of them being connected to many others” (2005). While linguistic theories are being developed, there is not much literature on research methods that translate speech into a network model. What has been done in this study is to assemble networks from meaningful constructs that are connected by association within in a related set of sentences.

Structure of the network data

Each analysed network of a user group has approximately around 100-120 vertices representing meaningful constructs and 600-1000 edges (comprised of 40-80 edge pairs from each individual interviewee). Vertices are either thoughts or feelings about an environment (shown as circles in the network) or workplace environment features (shown as squares). The number of duplicate connections (connections made by several individuals) provides a weighting to an edge. In the visualisations the vertices are sized according to the number of participants mentioning the corresponding construct. The graphs are also undirected as the directions of connections between constructs in interviews are not able to be coded with certainty due to language syntax complexities.

In the consensus network one-off responses are removed so that it only reflects connections about which there is a certain consensus within the respondent group. This consensus data, displayed as a network, provides visual information about the pattern of perception and emotional response to space for the group.

A key feature of the environment-response network is that it demonstrates links between workplace environment features and thoughts and feelings. This allows tracing of how particular responses were generated. While the networks have been abstracted, they demonstrate that responses to any given environment are complex and interrelate with many different parts of the environment. Social network analysis tools enable unpacking and interpreting of that complexity. In reading the networks, caution must be exercised towards the generalisation that certain features will, if installed in a different environment, lead to similar responses. The aim of this paper is instead to demonstrate the potential of analysing the overall environment-response network to observe perspectives on the one environment by different involved groups of people.

Analysing environment-response networks

Analysis of environment-response networks takes, using social network analysis (SNA) terminology, a ‘sociocentric approach’, in which the structure of the entire network is analysed as opposed to focusing on the position of one of the constructs of the network, or an ‘ego-centered’ approach, although this can be done on a case-by-case basis when much more information specific about a case is desired. In addition to the visualisation capabilities of network analysis software, the network analysis operations used for the environment-response network are proportional strength of ties, removal of edges, centrality measures (degree centrality and closeness centrality), cut points and bi-components.

To analyse the environment-response network it was first considered what analysis was desired from the network. Determining what thematic clusters or topics emerge (which we've called 'metatopics') from the networks is a primary finding. The first step is to reduce the number of nodes on the user group network by removing one-off responses. The reduced network is then visualized by drawing vertices with strong connections close together. Important vertices are identified. These include the most highly connected workplace environment features and thought or feeling responses, and the most central workplace environment features and thought and feeling responses. The vertices that, if removed, break the network are found, as they are important links in the overall perception of the workplace as well as possibly indicating the location of clusters in the network. The identification of metatopics follows on from the above steps and through domain knowledge. These clusters can be ranked and compared through number, sizes, values and density of their nodes and the location of the cluster in the network. Highlighting metatopics reveals additional pivotal vertices in the network, such as vertices that connect clusters together, but whose importance as a link may not been so clearly seen without domain metatopic clustering. This section presents these steps using the data gathered from interviewing a user group of case study *workplace x*.

The automatic layout to generate all depictions of networks uses the Kamada-Kawai algorithm. For small networks that have less than 500 vertices it produces regularly spaced and stable results (Nooy, Batagelj & Nooy, 2005, p.17).

Reducing and drawing the network

The vertices are sized proportionally by the number of respondents mentioning it and the edges thickness by the number of respondent mentioning the link. Drawing all the connected constructs or vertices, totalling around 100-120, makes for a very difficult to read graph (Fig. 2). Removing one-off responses makes the graph more valid and helps to focus on items that are important across individual conversations.

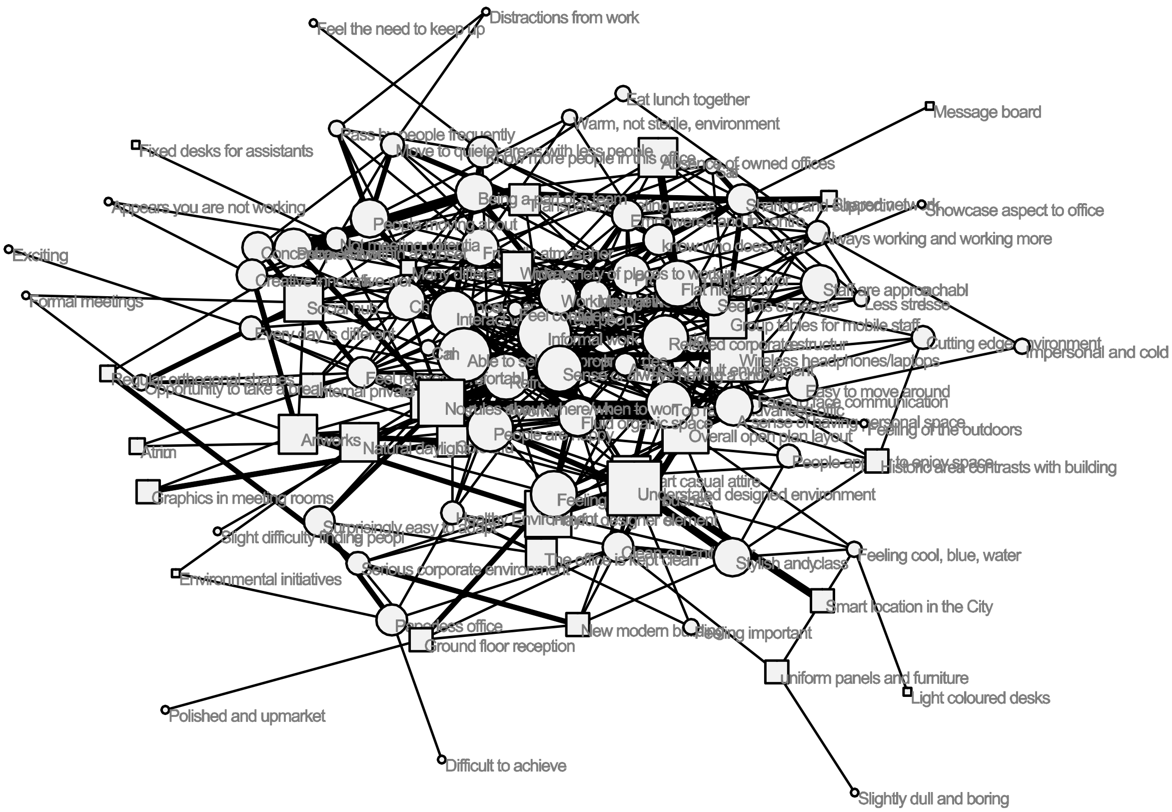

Fig 2. The complete environment-response network for the group of users interviewed in workplace x. The network is difficult to read when all the coded responses are included.

The reduced consensus network is drawn by positioning vertices with strong connections close together using proportional strength of ties (Fig. 3). Visualising proportional strength of ties helps identify categories of themes later, but is shown now so that the same graph layout may be used to demonstrate all the following analysis steps. The calculation considers the importance (or exclusivity) of an edge. It is calculated as the edge weight of a tie to a vertex divided by the sum of all ties incident to that vertex. A tie is not very important for a vertex if it has a low edge weight and is just one of many. For each edge there are two results depending on the vertex the strength is calculated relative to. For instance, in Fig. 3, the ties between *sense of having a choice* and *fluid organic space* have two values. The vertex *sense of having a choice* is one of three ties that *fluid organic space* has and the connection has a value of 0.33. In the opposite direction the tie is much weaker with a value of 0.08 as *sense of having a choice* has many more ties, several of them also having stronger edge values.

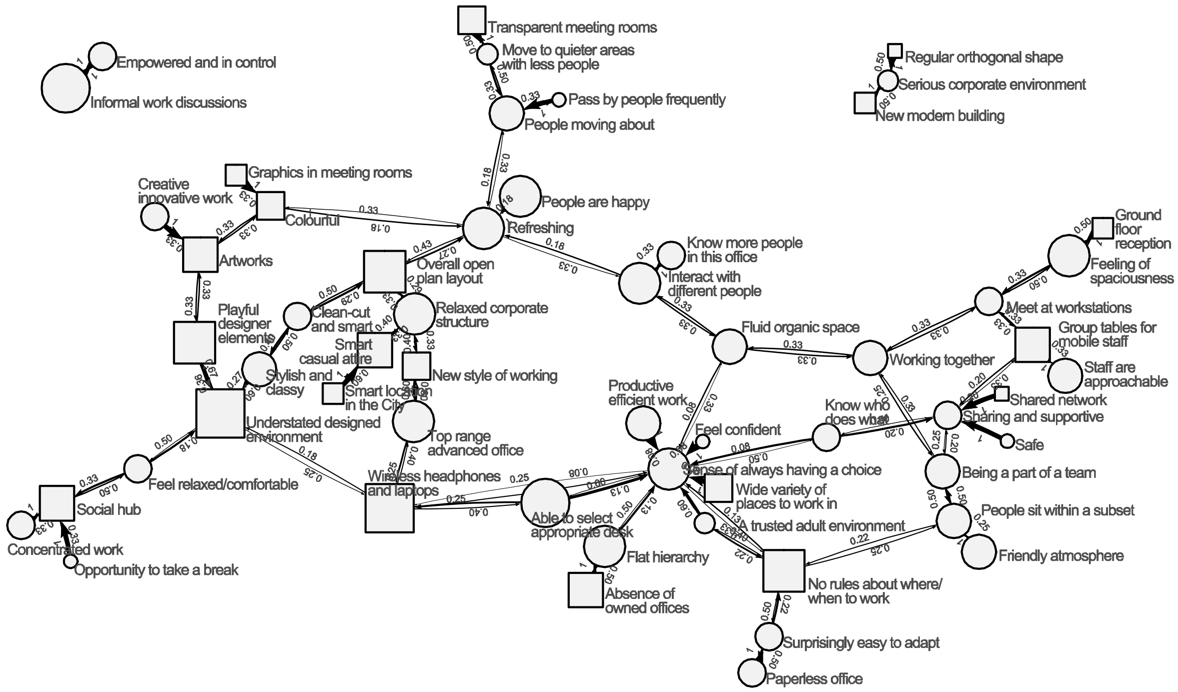

Fig 3. A consensus environment-response network for a user group in *workplace x*. One-off responses are removed and vertices with strong connections are drawn closely together. The squares are workplace environment features and circles thoughts and feelings.

Most highly connected vertices

Highly connected environmental features control a constellation of feelings about the workplace, and highly connected thoughts or feelings are quite permanent and strong. A vertex ‘degree’ is simply the number of lines incident with it. They are likely to be found in dense sections of the network.

The most highly connected workplace environment features (squares) are shown in grey in Fig. 4. These three elements of the workplace (*understated design, wireless headphones/laptops, no rules about where to work*) have the most control and influence over how the user group thinks and feels about the experience of the workplace. Removing or changing these features will have a major impact on the structure of the network, thus perception of the workplace.

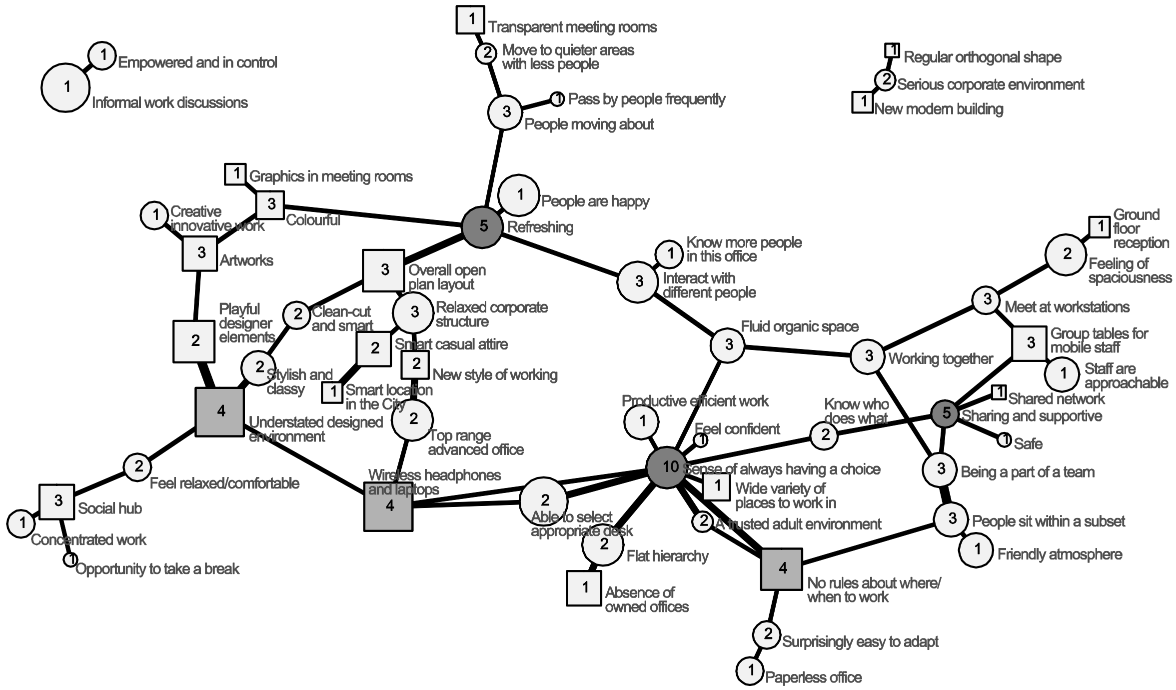

Fig 4. Highly connected vertices (degree centrality). These show the most controlling/influential vertices on the environment response network.

The most highly connected thought or feeling responses to the workplace (circles) are shown in a darker grey in Fig. 4. These thoughts are quite permanent and strong. Many workplace changes are needed to change these thought responses. For example, the feeling that the workplace is *refreshing* is connected to five other constructs. Interestingly, only one, s*ense of always having a choice*, is directly connected to one of these influential workplace features. The degree average for all vertices in the network is 2.18.

Most central vertices

These are the most central or embedded vertices within the network. Their centrality is brought on by often distant nodes in the network, making it difficult to determine the impact changing a workplace feature (square) will have, or what features effect a central thought or feeling (circle). They are found using a closeness centrality algorithm. This is based on the total distance between one vertex and all the other vertices, where larger distances yield lower closeness centrality scores. The closer a vertex is to all other vertices the higher its centrality. The degree centralities for all vertices are given in Fig. 5, with the most central ones in grey. The closeness centrality calculation results in continuous rather than discrete scores, which enables Pajek to draw the vertices according to its closeness centrality value. The arithmetic mean for closeness centrality across all constructs is 0.186 (from a range of 0.035 to 0.296).

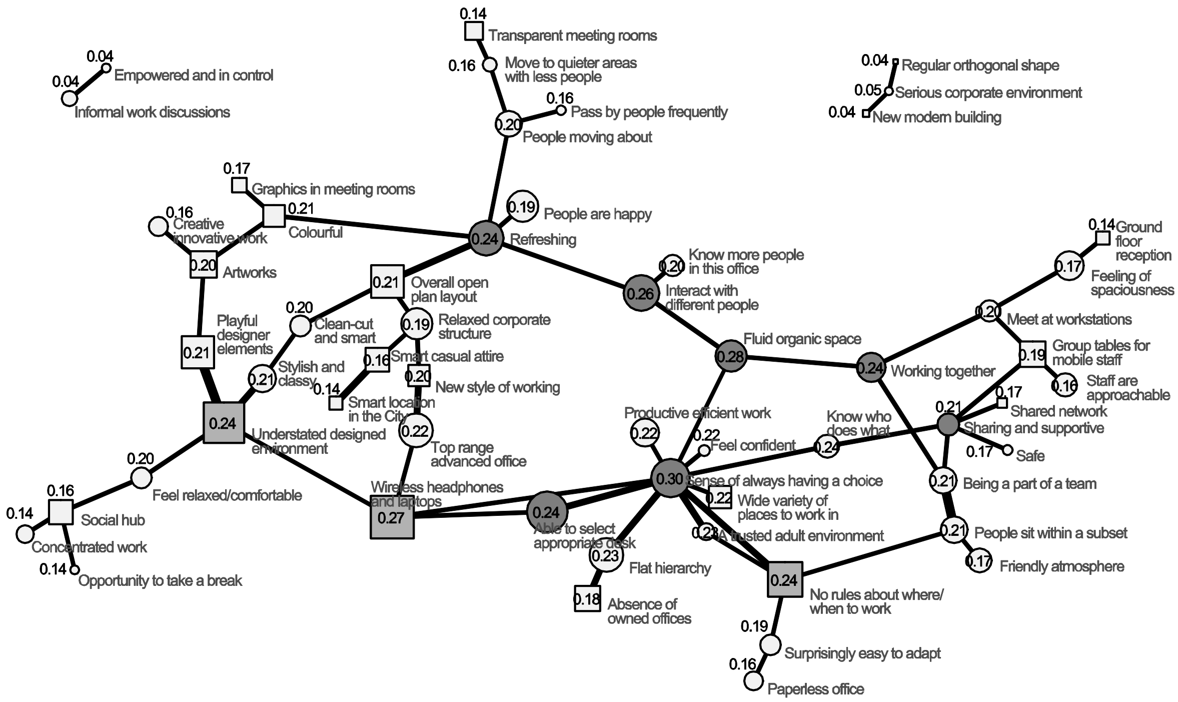

Fig 5. Central vertices (closeness centrality). Vertices are sized according to their closeness centrality values.

Vertices that break the network

Identifying cut-vertices and bi-components can be helpful in locating clusters in the network. Cut-vertices are all vertices whose removal, and all edges incident with it, breaks the network into more than one component. The numbers on the vertices in Fig. 6 refer to the resulting number of components should the vertex and its incident lines be removed from the network. It identifies vertex constructs that are necessary to link constructs (in particular chains or subnetworks of constructs) to the bigger picture. These linking vertices control the flow from one component of the network to another.

Bi-component operations are a subset of cut-vertices. It identifies those vertices that break a network into components whereby each vertex in the subnetwork connects to at least two vertices. They can indicate a more strongly clustering of vertices within the network. No positive result occurs in this example network.

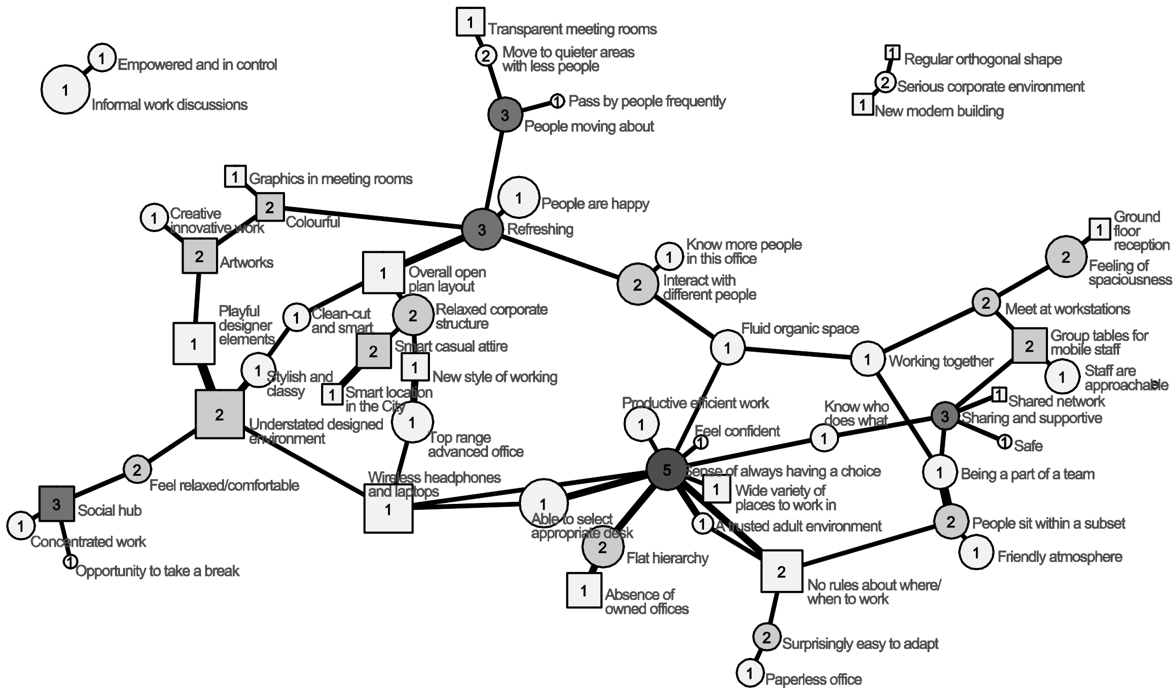

Fig 6. Vertices that break the network (Cut vertex). The vertex values show the number of components that would result should the vertex and its incident lines be deleted.

Metatopics

All previous network analysis steps help to understand where clusters of themes or topics may emerge from the network. But separating vertices into thematic clusters also requires domain knowledge of which vertices can be grouped together in a meaningful way, and to be able to define and name metatopics represented by the clusters.

In the users' environment-response network (Fig. 7) there are six metatopics, labelled *creative*, *stylish and professional*, *social*, *freedom and choice*, *team* and, separate from network, *serious*. The most important metatopics are identified by observing the number of nodes, sizes of the nodes, how closely they are drawn together, their interconnectedness (or density), the centrality values of its nodes, the location of the cluster within the network (does it take a central position by having connections with other clusters?) and the connectedness of the cluster to other clusters.

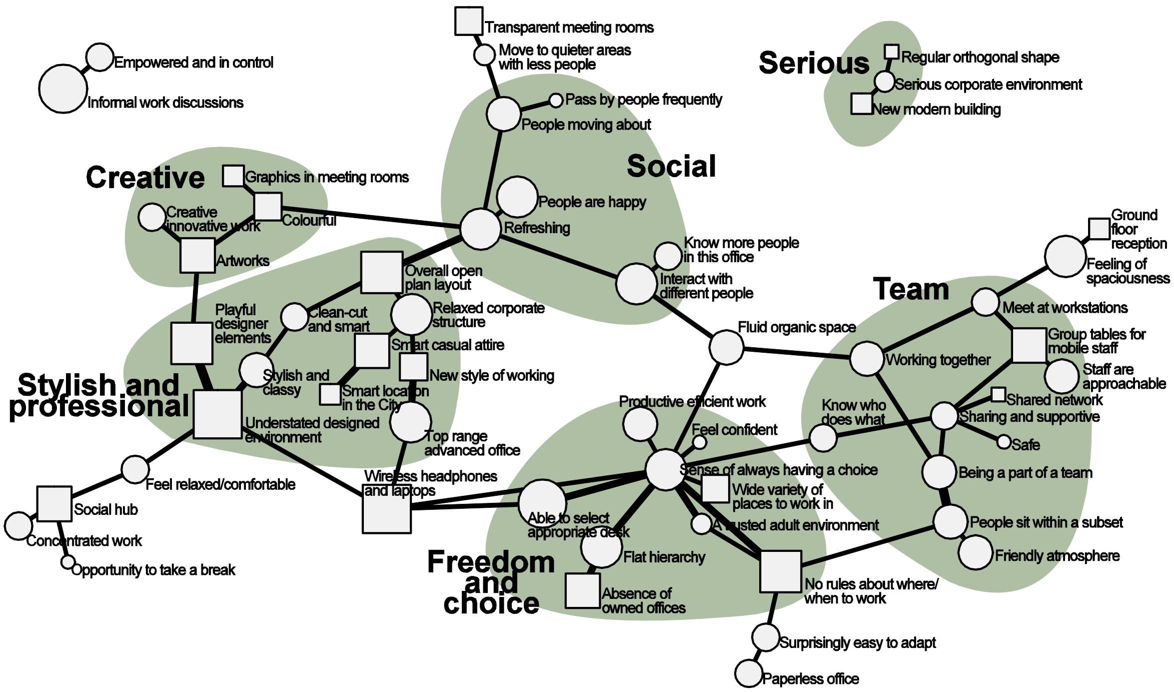

Fig 7. Metatopics for the user group of *workplace x*.

In this network the cluster *freedom and choice* is the most prominent cluster by these measures. Although it is not the cluster with the most vertices it contains the highest scoring vertex on both centrality measures (*sense of always having a choice*), a central workplace environment feature (*no rules about where/when to work*) and a high value closeness centrality vertex (*able to select appropriate desk*). It directly connects to two other metatopics and another indirectly, and its vertices connect to each other with multiple weighted edges. At the opposite end, the metatopic *serious* takes a minor role in the user response. While it is a recurring subject in user responses, it takes no influential role on the other thoughts and feelings that the users have.

One of the most pivotal vertices in the network is *fluid organic space*. It connects to the metatopics *social*, *freedom and choice* and *team*, and at the same time is not a part of any of these categories. While its degree centrality is average, its three edges are key in connecting metatopics. Its significance is better indicated by its closeness score, which reflects its average distance to all other vertices. The closeness centrality score is 0.28, the second highest in the network. Although the feeling that the workplace is a *fluid organic space* is a key finding in the network analysis, this certainly is not something that can be easily seen when visiting the workplace. It would also be a difficult property to be asked to 'design' into an environment. Another notable element is the workplace environment feature *wireless headphones/laptops*. It only connects two categories, but it does rate highly on both centrality measures. This indicates it is influential as to how the workplace is thought about.

Comparing the users' network with the designer's

All the steps mentioned above, involved in the network analysis of the user group, also took place to define the clusters of thoughts or metatopics that the designer has towards *workplace x* (apart for step one because it is an individual rather than consensus network). The same colour coding from the user's network (Fig. 7) is used in the architect's (Fig. 8) to allow identification of similar metatopics, with a dotted grey outline used to indicate themes the architect does not share with the user group. Both networks exhibit themes of *serious*, *team* and *social*. Interestingly in the designer's environment-response network *serious* has become one of the more significant metatopics. In this network it contains a greater number of vertices, with increased density (interconnectedness), and it is, albeit at some distance from the rest of the network, now connected to the network. The categories of *team* and *social* match the user group network reasonably well. The architect does not include the themes of *creative*, *stylish and professional*, or *freedom and choice*. Instead, categories of *uplifting*, *informal*, *cutting edge* and *easy* are added. The fact there is no metatopic corresponding the one the users mostly use to categorise their environment, *freedom and choice,* is quite surprising. In this case the users see the workplace generally more positively than the designer does. Further studies may help to clarify what factors contribute to a discrepancy in this direction.

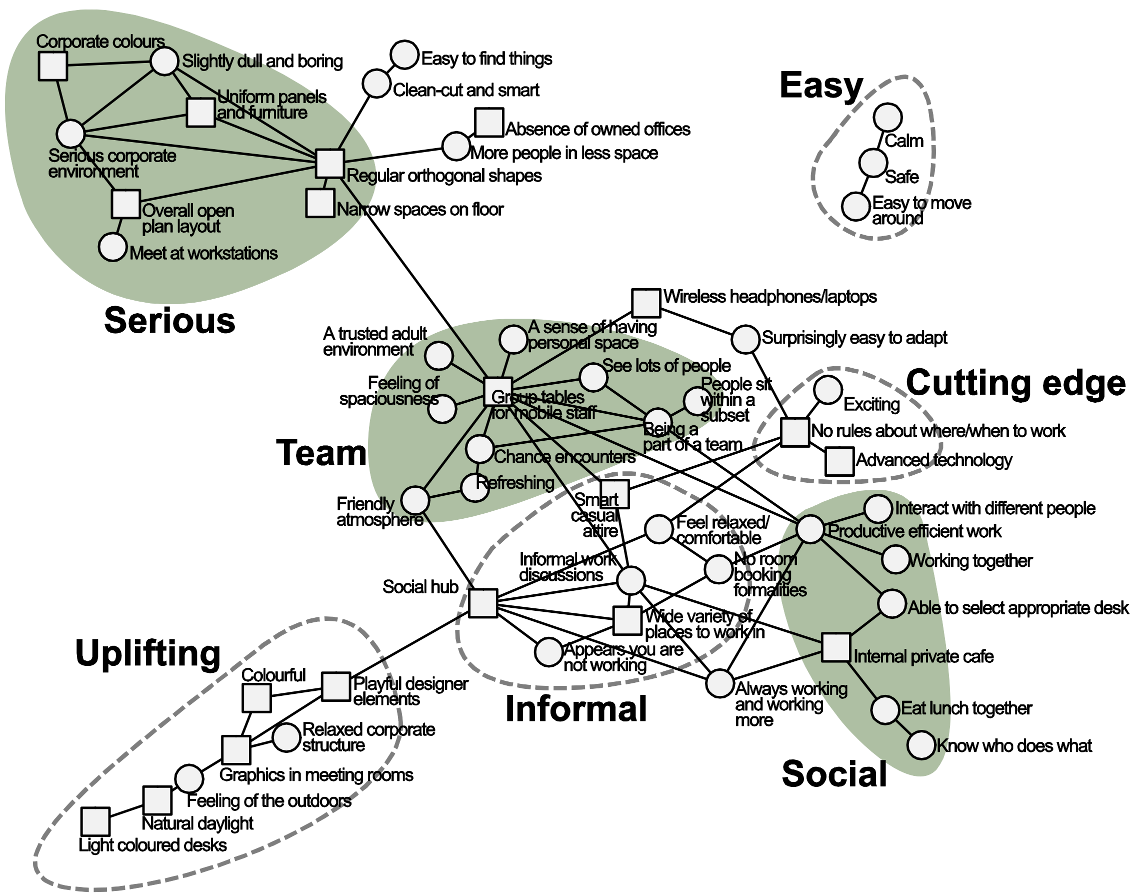

Fig 7. Metatopics for the designer of *workplace x*. The grey clusters indicate metatopics shared with the users' and the dotted clusters are metatopics unique to the designer.

There is no pivotal thought or feeling characterising the environment for the designer. In fact, the construct *fluid organic space* that was so prominent in the user network does not register at all in the designer's response. On the other hand, the workplace environment feature *wireless headphones/laptops* connects, yet stands apart from, two categories in both networks. It also exhibits high centrality within the network of the architect's responses.

Also interesting is that many of the vertices (workplace features or thought constructs) correspond to similar ones in the user group network, but forming different combinations, and thus metatopics. For example, in the user network the workplace feature *overall open plan layout* is allocated to the category of *stylish and professional*, but in the designer network it is connected to very different vertices and is allocated to the metatopic *serious*. In the user network the *social hub* is perceived as somewhat marginal, but for the designer it is an important feature (and has higher centrality values in this network).

It might be expected that workplace environment features would take central positions in the designer's network due to their focus on being on the physical elements of the workplace, with thought constructs taking secondary roles. But this is not the case. In both networks the central elements are roughly equally divided between workplace environment elements and thoughts and feelings.

Conclusion

The application of network analysis to interviewee response constructs demonstrates a way in which networks can be used to visualise 'group think'. The significance of being able to analyse centrality of constructs and identify clusters using network analysis is highlighted in this case by the fact that the user environment-response network is quite different from that of the architect who is professionally expected to predict the implications of design decisions on the users' perception of space.

By using network analysis to help identify central vertices (constructs that control a constellation of themes) and metatopics (collective orientations or themes), observations are gathered on the structure of collective mental representation of built environments. This is considered an initial step towards further research into interaction between designer and users.

Donna Wheatley

Donna has worked as a consultant, researcher and architect in international architecture firms and tutors architectural design, history and theory. Her PhD research has received a number of awards and prizes. Donna has two first class degrees in architecture and a Graduate Certificate in Innovation and Enterprise. Donna is interested in bringing innovative and strategic thinking to the field of architectural design.

Assessing Creativity in the Context of Architectural Design Education

Anthony Williams, The University of Newcastle, Australia, tony.williams@newcastle.edu.au

Michael Ostwald, The University of Newcastle, Australia

Hedda Haugen Askland, The University of Newcastle, Australia

Abstract

In a study on architectural education in Australasia, Ostwald and Williams (2008a; 2008b) found that one of the most contentious issues facing architecture and design education is the assessment of creativity. The problem is not new, yet, despite ongoing criticism of the frameworks used to assess creativity in architecture and design, the assessment of students' creative work remains a vexed issue. Central to the problem of assessment is the lack of an unambiguous disciplinary definition of creativity. The concept of creativity has been understood in different and often conflicting ways, and across the design disciplines there is no shared understanding about creative processes and, in particular, how they apply to learning and teaching experiences. The paper briefly outlines the main problems related to assessing creativity before exploring the complexity embodied in the notion of "creativity" as it relates to design education. The research presented in this paper is derived from an extensive and critically framed literature review and forms part of an ongoing research project concerning the question of creativity within design education.

Keywords

Creativity; Assessment; Design Education

The constant and radical changes which are characteristic of the modern world makes it, as Dineen and Collins (2005: 44) observe, impossible

> to base our future on the certainties of the past. Unable to define *what* we need to know, we have begun to focus on *how* we will need to know, on the flexibility and openness which characterises creative thinking. Creativity is now seen to be the wellspring of human adaptability and social development.

Creativity, often defined as the development of ideas or work that have the quality of being both useful and original (e.g. Amabile, Conti, Coon, Lazwnby, & Herron, 1996; Elton, 2006; Mayer, 1999; Paulus & Nijstad, 2003; Sternberg & Lubart, 1999), plays an important role in the process of cultural reproduction, technological advancment, innovation and intervention (Runco, 2004). A significant force for innovation and change is design, of which creativity is considered a key element. Whereas other sciences are concerned with the analysis and description of existing realities, design is about the imagination and synthesising of new realities; that is, central to a designers' work is the search for novel and unexpected solutions to problems. Moreover, in contrast to the arts, design "is essentially guided by human purposes and is directed towards the fulfilment of intended functions" (Alexioua, Zamenopoulosa, & Johnson, 2009: 623), accentuating the importance of meeting requirements and developing appropriate and influential solutions.

Design is often described as pertaining to "ill-defined" or "wicked" problems (e.g. Casakin, 2007; Rittel & Webber, 1984) that require creativite solutions. As Casakin (2007: 22) explains, "the exploration of unfamiliar and unconventional design solutions requires creative skills […] Creativity enables the talented designer to transcend conventional knowledge domain[s] so as to investigate new ideas and concepts which may lead to innovative solutions"; it enables the designer "to perceive a problem from unorthodox and innovative perspectives" (Casakin, 2007: 21). When conventions are challenged, design moves from routine solutions towards innovative, non-routine solutions. Though design activities encapsulate the spectrum from routine to non-routine design, the groundbreaking designs are those which possess innovative and creative qualities; that is, design that changes the design variables in such a way that the results are solutions that were previously unknown (innovative design) or design that introduces new variables and that subsequently produces entirely new products (creative design) (Gero & Maher, 1993).

Judgement of design products will always, even at its most basic level of distinguishing routine from non-routine design, reflect a consideration of creativity. To be more precise, creativity is one of the requirements that design is being assessed against. However, despite the preliminary definitions of the concept, exactly what is meant by creativity remains unclear and definitions of the concept are in many respects vague and ambiguous. This situation has serious implications for design education wherein "creativity" is often a stated learning objective. This paper aims to initiate discussion about the concept of creativity as it relates to the design disciplines. It begins with a brief outline of some of the challenges facing design education in relation to assessing creativity. This is followed by a discussion of the concept of creativity as it relates to education and, more specifically, design education.

The problem of assessing creativity

In a study on architectural education in Australasia, Ostwald and Williams (2008a; 2008b) found widespread confusion and disagreement surrounding assessment practices for design. They identified three key problems related to creativity and design education: firstly, there is a lack of understanding of the pedagogical dimensions of creativity in architecture and design; secondly, there is a lack of appropriate strategies to understand where different levels of creativity occur and how they should be assessed; and, thirdly, there is a lack of appropriate models or tools to support the assessment of the creative component of design. These problems relate to a paradox embedded in contemporary design education; namely the contradiction between Australian universities' quality assurance protocols, which call for objective or transparent assessment of all students' work, and the complex, heuristic nature of design, which require evaluation that is inevitably subjective.

In response to the demands of objectivity and transparency, there has been a growing regional trend to develop marking criteria for design and to adopt a complex combination of quality assurance and assessment protocols to provide a level of objectivity. However, there is a clear distrust within the discipline of this trend and it has often led to further problems. The student participants in Ostwald and Williams' (2008a) study, for example, argued that over-defined learning and assessment outcomes 'stifles' their opportunities to be creative and that teachers fail to recognise their creative efforts. But, where such protocols are not in place students express high levels of stress surrounding the assessment of their creative works (Bachman & Bachman, 2006; Ostwald & Williams, 20081, 2008b) and they experience difficulties in identifying aspired learning outcomes, further causing frustration and dissatisfaction.

The problem facing design education is therefore twofold: it is a legal/administrative problem (how can we assess creativity in a way that meets national standards for quality assurance?), and a pedagogical problem (how do we assure that students receive appropriate and useful feedback, and how do we ensure a common understanding between students and staff with regards to assessment criteria of creative works?). These problems are at the core of the research project of which this paper forms part.[1] Whilst the project as a whole will address the problems and propose solutions, the paper explores the conceptual issue underpinning the problems; namely, the questions of what creativity means in relation to education and, more specifically, design education. The purpose of the paper is not to solve the problems of assessment, but instead to initiate a discussion about creativity as it relates to design education.

---

[1] The research project, *Assessing Creativity: Strategies and Tools to Support Teaching and Learning in Architecture and Design*, is funded by the Australian Learning and Teaching Council (ALTC). The project aims to create a conceptual framework for understanding creativity and to generate a set of shared terms and concepts that can be used when assessing the creative component of students' work. The project is set to finish at the end of 2011.

Creativity and education

During the latter half of the 20th century there was an upsurge in research into creativity and, in response, training to support creativity took a new direction. Calls for educational forms of teaching that could encourage creativity were repeatedly made, propagating ongoing discussion about whether or not creativity is a trait of a few individuals and whether or not it can be taught, promoted or fostered (Cropley, 1997: 83). At this point of time, creativity was generally held to be the trait of particularly gifted children. This notion of creativity as a "gift" can be traced back to Immanuel Kant (1724-1804) and the so-called romantic model of creativity. The Kantian notion of creativity portrays the creative individual as someone who possesses "an extraordinary innate 'gift' that is beyond the grasp of mere mortals" (Cowdroy & Williams, 2006: 100). It is a later version of the romantic idea first posited by Plato, who saw creativity as a result of divine inspiration, a process of unfettered and undisciplined "agonised" searching (musing). The romantic belief of creativity as something that lies beyond the rational conscious and that rational deliberation interferes with creative processes (Sawyer, 2006: 15) suggests that creativity is an innate (or divine) force that cannot be promoted or fostered; creativity, as divine inspiration, is the result of an artists' undisciplined and unfettered agonised searching (Cowdroy & Williams, 2006; McIntyre, 2008).

In 1963, in an emotional plea to reconsider current practices of educating "the gifted child", E. Paul Torrance (1981[1963]: 6) argued that gifted children had been regarded as "mysterious, beyond human understanding, evil and unrighteous". He proclaimed that, as a result of an "unwillingness to accept a realistically complex picture of the human mind and personality" (Torrance, 1981 [1963]: 7), gifted children had suffered. During the time of Torrance's writing, a common perception of gifted children was that they held superior potential and should therefore be able to look after themselves; gifted children were seen to "already have more than others" and questions were therefore made as to why society should "be concerned about giving them more" (Torrance, 1981 [1963]: 6). Torrance responded to this belief by proposing that the very complexity of the human mind and the respect for human values demand that education and guidance make room for both convergent and divergent thinking, discipline and creative behaviour. In fact, "order, discipline, organization, guidance, purpose, and direction are necessary, even for creative behaviour, and are not incompatible with creativity" as long as "order, discipline, and organization [… are] flexible enough to permit change and to allow one thing to lead to another" (Torrance, 1981 [1963]: 17).

The level of understanding of creativity and giftedness has changed significantly since Torrance's research was first published. The idea that children should be able to develop their potentialities to the fullest has gradually transformed educational practices to emphasise the role of creativity, both as a *tool for learning* and as a *desired educational outcome* (in terms of enhanced creative ability and performance) (see also Plucker, 2002). Educators have moved away from a narrow view of creativity as a trait of particularly gifted children, to emphasising the psychological aspects of creativity that are present, at least as potentials, in everyone. Despite this conceptual change, the combined issues of creativity and education remain contested. A general view is that the modern school system, with its focus on conformity, may discourage students' curiosity, ingenuity and, ultimately, creativity, and that pressure to conform and to satisfy prescribed standards present obstacles for creative personalities to unfold and develop (Chamorro-Premuzic, 2006). However, as was noted by Guilford as early as 1950, education has a role to play in relation to creativity (Guilford, 1950). Of importance to the development of creativity are knowledge, experience and readiness for ideas (Cunliffe, 2008; Pederson & Burton, 2009), all of which can be expanded through education. Education provides opportunities for students to engage in creative activity and learn about creative endeavours; it broadens their knowledge base and experience, subsequently enhancing their chances of creative success.

The idea that creativity can be fostered and promoted rests on the proposition that, by providing a favourable environment and appropriate learning conditions, the characteristics underpinning creativity can be developed (Cropley, 1997: 83). Accordingly, when speaking about creativity in relation to education, a holistic approach to creativity is required. This means that the romantic idea of creativity must be replaced by a rationalist model, which emphasises creativity as being "generated by the conscious, deliberating, intelligent, rational mind" (Sawyer, 2006: 25).[2] As Cropley (1997: 107) concludes in his discussion of how to foster creativity in the classroom:

> [w]hat is needed is an approach in which all aspects of teaching and learning adhere to basic principles for fostering creativity. These involve […] not only intellectual, but also personal, motivational, emotional, and social aspects of creativity […] children need contact with complexity, ambiguity, puzzling experiences, uncertainty, and imperfection.

In recent years there has been a move away from the traditional teacher-centred approach to learning towards a student-centred approach that emphasises problem-based learning and enquiry-based curricula, this change being particularly evident at the university level.

It is today commonly held that a curriculum that makes the students responsible for their own learning process will encourage creativity. In contrast to traditional teaching methods, where the instructor is responsible for teaching and the student for learning, in the student-centred approach teachers should serve as "facilitators of learning" and support the students in their endeavour (Elton, 2006: 131). As Lindström (2006) maintains, creative ability is developed through investigative work and inventiveness. In the educational context, investigative work refers to the use of assignments that allow students to explore central themes in the domain over extended periods of time. Inventiveness, on the other hand, concerns the need to emphasise process as well as product, and to provide opportunities for research, experimentation and revision. This last point addresses the role of the teacher, who, as Lindström (2006) argues, must be sensitive to students' signals of creative behaviour, such as being adventurous and willing to take risk. The teacher must show appreciation and approval of the students' courage. Moreover, the teacher must encourage students to integrate production with perception and reflection, to engage in self-assessment and to be open to feedback from teachers and peers. The question of self-assessment refers to the need for *criticality* (Elton, 2006); for learning to be possible and creativity to be encouraged, it has to be accompanied by the ability to separate bad ideas from good ones, to assess process, performance and end product, and be open for critique from others. The question of criticality and self-assessment indicate a social, interactive aspect of creativity. An important part of creativity is evaluation; through self-assessment and review, the creative idea moves through stages towards the final product.

Creativity and design education

In contrast to other disciplines, the very essence of architectural and design education is project-based, or problem-based, learning.[3] It does not seek a single correct answer, but instead encourages students to make speculative and exploratory propositions that reflect their competence and knowledge of the field. This teaching strategy is conducive to creative thinking, which, as stated above, is the *raison d'etre* of architecture and design. However, there is an inherent paradox within the traditional teaching models of design. While the traditional model seeks to promote and encourage creativity, the very paradigm on which it is founded defies critical and empirical examination, teaching and assessment.

The traditional teaching methods in architecture and design, including the one-to-one master-apprentice teaching style, the *Beaux-Arts* "neo-classical" teaching method and the Bauhaus "modernist" educational approach, reflect the romantic notion of creativity: the apprentice model of vocational education is founded upon the idea that creativity is a gift, it is innate and cannot be taught; the studio model is based upon the assumption that creativity can be taught in larger

---

[2] The rationalist model of creativity can also be traced back to ancient Greece; more specifically, to the writings of Aristotle who emphasised that conscious work, rationality and deliberation is required in order to complete creative inspiration. In Aristotle's view, creativity was potentially more humdrum than previously anticipated and it included the creation of uncomplicated or predictable objects. It was, however, first during the English Renaissance that the romantic idea of special talent or unusual ability, a manifestations of an outside spirit, was seriously challenged. This epoch valued reason above all, and the emerging rationalist model emphasised reason, knowledge, training and education as essential to creativity.

[3] The word "problem" is used in this context to refer to wide range of situations, some of which may be framed as opportunities, open-investigations, or as "wicked" or "ill-defined' settings."

groups, though only by long and direct association with a talented patron; and, the competency-based teaching models of vocational education reflect a reproduction model of creativity which suggest that creativity can be taught *en masse* but only by reproduction of the work of past masters (Cowdroy & de Graaff, 2005; Cowdroy & Williams, 2006). Whereas these models emphasise different stages of the design process (schematisation and execution), they do not focus on the imaginative conceptualisation, which, according to Cowdroy and de Graaff (2005: 511), is "the highest level of creative ability". This is problematic as "conceptualisation is of the essence of creativity […] if it is neither taught nor assessed, then it must be accepted that creative ability as a whole is neither taught nor assessed" (Cowdroy & de Graaff, 2005: 511).

This conclusion rests upon a particular hierarchical definition of creativity that emphasises the cognitive processes underpinning creative works. The definition presented by Cowdroy and de Graaff (2005) is developed further by Cowdroy and Williams (2006) in the article, *Assessing creativity in the creative arts*. They argue that there are three "agreed" types of creative ability, each representing a progressive stage in the movement from initial idea to realised work. The three hierarchical stages are conceptualisation, schematisation and actualisation, each of which require a particular type of memory (emotional, declarative, and procedural) and thinking skills (imaginative, originality; recollection, orientation, extrapolation, planning, innovation, inventiveness; and, development of abilities to accommodate innovations and inventions). Creative abilities, they argue, require

> combinations of particular types of memory, particular types of thinking skills and particular crafting skills. At the schematization and actualization stages, the thinking and behavioural aspects could be considered separate. At the conceptualization stage, however, only thinking is clearly involved [...] high-level creativity involves progression from conceptualization to schematization to actualization, and [...] a decision (commitment) must be made (perhaps unconsciously) in order to progress from one stage to the next stage, and a further decision on how to maintain continuity of the originating idea must also be made (Cowdroy & Williams 2006: 107).

Cowdroy and Williams (2006) identify the connecting thinking points as "facilitative thinking" and they conclude that this form of thinking is intentional and directional and, as such, represent a strategic thinking behaviour.

This definition of creative ability proposes a framework within which teaching, learning and assessment strategies can be developed. The definition, set within a cognitive psychological framework and "tracking the psychological processes of inspiration and complex decision-making" (Cowdroy & Williams 2006: 97), represents an innovative approach to creative design education. It illustrates the importance of the creative process as an object for teaching an assessment, and it moves beyond the generic definition of creativity according to the descriptors "originality" and "appropriateness". Understanding, teaching and assessing design creativity require a definition of creativity that transcends these descriptive nouns; whereas it allows judgement of creative products, it is problematic when considering other aspects of creativity, in particularly the creative process.

Although definitions of the creative (design) process exist, there is no consensus within the design disciplines as to what creativity really is and exactly what is being taught as creativity remains unclear. The romantic model of creativity and individualist approaches that perceive creativity as spontaneous, unconscious or as an inner spirit retain their influence on conventional understandings of the concept, despite scientific evidence that reject such notions as inaccurate or misleading. Lacking a clear disciplinary definition of the concept of creativity, these, as well as other myths and popular stereotypes, further complicate an already complex field. As stated earlier in this paper, exactly what constitutes creativity—as an object for teaching and assessment—remains vague, and a lack of stated, recognised standards suggests that the teaching and judgement of design creativity inevitably relies on the instructor's subjective understanding of creativity. This, in turn, may potentially diminish transparency and consistency in teaching and assessment practices, and students may find themselves confused as to the requirements of their creative tasks.

The design process is a dual procedure that involves two continuous dimensions; namely *problem solving,* wherein the process begins with a set goal, and *concept generation*, wherein the process begins even when the goal is absent (Yukari, 2009). Creativity has often been defined as a process of problem solving, but, as is suggested by the parallel process of concept generation, there is more to the process than this. Creativity and creative processes are as much about *problem definition* as they are about problem solving. This is identified by Sternberg and Lubart (1993) who argue that there are three insight processes that may lead to creative thinking, namely (a) *selective encoding* (noticing what is potentially relevant to understand and solve problems), (b) *selective comparison* (relating new and old information), and (c) *selective combination* (correlating appropriately connected information). These processes require knowledge and familiarity of the relevant field and domain.

These assumptions suggest that when teaching and assessing design creativity, it is necessary to consider, not only the final product, but equally the creative process leading up to it. The definition of creativity as the production of original and useful work emphasises the tangible outputs of creativity, but fails to consider the creative process, the creative person and the creative environment. Whereas the process and product are of main concern to design educators, attention should also be paid to the creative person (personality traits, intuition, intelligence, values, personal attributes, intrinsic motivation, experience and skills) and the creative environment (external motivation, social dynamics, pressure on the creative process or on creative individuals). The four aspects (person, process, product and press) have often been considered independently in the literature. However, as Margaret Portillo (1996) argues in her study of implicit theories of creativity in beginning design students, these four are interconnected. Portillo defines creativity as a multidimensional construct involving person, process, product and place (environment/ press). She argues that an understanding of the creative person and how personal factor intercedes with the three other aspects of creativity is essential to understanding creativity. Understanding creativity requires an understanding of cognitive characteristics as they relate to the creative process (aesthetic taste, imagination, integration and intellectuality, decisional skills and flexibility), motivational attitudes as they relate to the creative product (goal-orientation and seeking recognition for creative work), and personality traits as they relate to place (being unorthodox, challenging societal norms).

Portillo's theory can be classified as a confluence theory of creativity. Confluence approaches form part of what is often referred to as contextualist approaches to creativity, distinct from the individualist approaches characteristic of much of the psychological work on creativity. The contextualist approaches to creativity emerged during the 1980s when a group of psychologists turned to other social sciences such as sociology, anthropology and history with the aim of expanding the notion of creativity. They moved beyond the psychological emphasis on the individual and considered how creativity, creative abilities, creative processes and creative products reflect an interactive engagement between the individual and the social environment. In contrast to other contextualist approaches that emphasise the manipulation of environmental variables to increase creative production, confluence approaches perceive the sociocultural milieu as only one of many variables that form part of the concept of creativity. An example of such a theory is Mihaly Csikszenmihalyi's (1988; 1996; 1999) system theory. Csikszenmihalyi argues that:

> [i]f creativity is to retain a useful meaning, it must refer to a process that results in an idea or product that is recognized and adopted by others. Originality, freshness of perception, divergent-thinking ability are all well and good in their own right, as desirable personal traits. But without some form of public recognition they do not constitute creativity (Csikszenmihalyi 1999: 314).

Creativity is a phenomenon constructed through the interaction between producer and audience; that is, creativity is the product of "social systems making judgements about individuals' products" (Csikszentmihalyi 1999: 314).

Central to Csikszentmihalyi's theory are the concepts of domain and field. These concepts refer to two salient aspects of the environment within which individuals operate; namely, the cultural, or symbolic, aspect (domain) and the social aspect (field). Creativity occurs when an individual makes a change to the symbolic system and when this change is adopted by the social organisation of the domain (the field). That is, creativity as a product occurs "at the intersection where individuals, domains, and fields interact" (Csikszentmihalyi 1999: 314). Csikszentmihalyi summarises the system view of creativity as follows:

> For creativity to occur, a set of rules and practices must be transmitted from the domain to the individual. The individual must then produce a novel variation in the content of the domain. The variation then must be selected by the field for inclusion in the domain (1999: 315).

Csikszentmihalyi's system perspective maintains an emphasis on the contribution of the person to the creative process through an emphasis on cognitive processes, personality traits and motivation. It also identifies how these personal characteristics are insufficient (perhaps not even necessary) and that beyond the rules of the domain and the options of the field creativity cannot exist.

Csikszentmihalyi's theory represents only one example of many confluence theories that can help bring light on the question of creativity and establish a framework for teaching design creativity. It suggests that, although individual traits such as self-esteem, tolerance for ambiguity, risk-taking and willingness to persevere are linked to creative production (Gallagher, 1994: 175), more tangible factors which may be developed, improved and assessed are also part of creative performances. Moreover, Csikszentimihalyi's theory identifies the protracted nature of creative thinking and, accordingly, provides a framework for assessment in which creativity requirements reflect the educational stage of design students. This pragmatic definition of creativity is important to design education. As Jeffries (2007: 487) contends, the outcome of a design education is, ideally,

> that students produce historically original work; ultimately, designs that are fresh and new to the domain. Pragmatically though, in terms of educational development, there is a hierarchy of attainment: achieved personal originality first then build towards historical originality with educational progression.

Conclusion

As previously identified, further research is required into the concept of creativity, the teaching of creativity and the subsequent assessment of students' creative outcomes. Creativity is a focus of design education and it is a stated learning outcome of the discipline. Accordingly, the need to confront the issue of creativity, including the challenge of defining it and developing strategies to facilitate its development, is a priority.

The above discussion illustrates how academics are only starting to fully appreciate the complexity of the concept of creativity. It has become apparent in recent research that creativity cannot be dismissed as being simply an innate capacity which happens, despite intentions and purposes. The evidence presented above identifies that creativity can be enhanced through effective teaching and learning strategies and their supportive assessment frameworks. The task in the coming years is to enhance the development of such teaching and assessment practices through the application of research-lead teaching.

Author Biography

Associate Professor Anthony Williams

Associate Professor Williams is currently the Head of the School of Architecture and Built Environment at The University of Newcastle, NSW, Australia. He is a winner of multiple University Teaching Awards, as well as a National Awards for Teaching Excellence. A/Prof Williams has worked extensively in curriculum design and implementation both at program and course levels. He is highly regarded in this area and has worked as a curriculum consultant both nationally and internationally. A/Prof Williams' primary research field is Design Methodology. He is widely published in the field of Design and Engineering Education, with over 100 publications in these particular professional fields. A/Prof Williams is the chief investigator of the research project *Assessing Creativity: Strategies and Tools to Support Teaching and Learning in Architecture and Design*.

Professor Michael Ostwald

Professor Ostwald is the Dean of Architecture at The University of Newcastle, NSW, Australia. He is a past President of the Association of Architecture Schools of Australasia (AASA) and an Australian Research Council (ARC) Future Fellow. He has a PhD in architectural theory and a higher doctorate (DSc) in design mathematics. Professor Ostwald has more than 280 scholarly publications including 22 books. Professor Ostwald is the project leader of the research project *Assessing Creativity: Strategies and Tools to Support Teaching and Learning in Architecture and Design*.

Dr Hedda Haugen Askland

Dr Askland has a Masters of Social Science and a PhD in anthropology. She has previously conducted research with asylum seekers from East Timor and expatriate East Timorese living in Australia. Dr Askland is the project manager of the research project *Assessing Creativity: Strategies and Tools to Support Teaching and Learning in Architecture and Design*.

Insights into insight – How do in-vitro studies of creative insight match the real-world complexity of in-vivo design processes?

Stefan Wiltschnig, Copenhagen Business School, Denmark, sw.marktg@cbs.dk

Balder Onarheim, Copenhagen Business School, Denmark

Abstract

This paper presents approaches to study insight in the context of creative (design) processes. Evidence for the discrepancies between experimental and observational studies of insight moments is collected from the literature. Implications for conducting integrative research that addresses the complexity of real world design environments are discussed. Preliminary results from two case studies looking for insight moments of design teams working on real world design tasks at a medical appliance manufacturer and within an interior design project are reported. A multi-methodological framework inspired by in-vivo-in-vitro research together with ethnographic and practice based approaches is developed and applied.

Keywords

Creativity; Insight; Design Process; Engineering Design; Interior Design

Innovations and the creative processes of coming up with "novel and useful" ideas, products and services in various areas have gained increased attention in political, societal and economic arenas during the last couple of years (EU Commission, 2008; OECD, 2009). A central element in reports about experiences on the path of creating something new that qualifies to be considered as a profound innovation later on is the phenomenon of insight. The experience of insight or an "AHA-moment" describes situations where in an instance suddenly and unexpectedly the solution to a problem becomes apparent together with feelings of clarity and satisfaction (Seifert, Meyer, Davidson, Patalano, & Yaniv, 1996, p. 66f). "Insight is thought to arise when a solver breaks free of unwarranted assumptions, or forms novel, task-related connections between existing concepts or skills." (Bowden, Jung-Beeman, Fleck, & Kounios, 2005, p. 322)

Since the publication of the still often cited early process model of "productive thinking" by Wallas (1926) the field of creativity research has developed rapidly into a variety of approaches. Narrative accounts by distinguished scientist and artists were soon complemented with experimental studies that developed into a wide range of paradigms and tasks (Weisberg, 1996). Other strands of research focus at the context and personality traits of creative persons with historiometrical and correlational methods (Simonton, 2000) or try to observe and describe creative processes in "real world" environments with ethnographically inspired methodologies (Dunbar, 1996).

If one looks at these more and more specialised and distinct approaches, it becomes quite apparent that terms are frequently vaguely and incongruently defined, and what is studied in lab experimental paradigms has often little to do with the complexity of the real world settings in which the experiences behind the narrative accounts of creative insight were originally encountered (Simonton, 2003). Most of the lab paradigms are structurally different from the real world problems of interest and operate on different time scales for reaching the solution which is considered to be an insight (Csikszentmihalyi & Sawyer, 1996).

The aims of this paper are:

1. Collecting and presenting evidence from the literature on insight studies for the gap between lab and real world studies on creative processes.
2. Discussing the (im-)possibilities of overcoming the challenges in linking the data from (in-vitro) lab studies of insight problem solving and (in-vivo) real world reports of creative insights.

3. Compiling suggestions for more integrative approaches to understanding insights in creative processes that are capable of matching the real world complexity of the phenomenon.
4. Introducing two field studies set out to explore insight moments in real-world design settings.
5. Presenting some preliminary results from the early stages of these studies.

The following sections contain a discussion of the phenomenon of insight and how it has been studied previously, the context dependence of both lab experiments and real world observations, the research design that we are experimenting with in our ongoing studies and two examples from these studies. We conclude with a discussion of these preliminary results and an outlook on future work.

Approaches to studying insights and creativity

In this part we present an overview of selected contributions to the literature of studies of creativity and insight that are vital to the illustration of our further argument. We briefly summarise the development of approaches observing respectively describing insights embedded in creative processes in real life settings and experimental approaches in the lab. Due to the scope of the paper and limited space we refrain from discussing correlational studies on e.g. personality traits here.

Comprehensive compilations of the current state of the field of creativity studies can be found in Sternberg (1999), Weisberg (2006) and Sawyer (2006). A specific focus on different approaches to studying insight and insight problem solving is present in Sternberg and Davidson (1996). Knoblich and Öllinger (2005) provide a rich description of the chronological development of insight studies during the 20th century which we used as the temporal framework for most of the following mapping of selected key ideas and protagonists.

Insights embedded in creative processes

Anecdotes about flashes of insight as the origin of solutions to tough problems can be traced back to the ancient Greek, namely the story of Archimedes and his proclamation of “Eureka!” after understanding the principle of specific weight while entering his bathtub. During the 18th and 19th century more and more of these anecdotes especially about the origins of scientific ideas and concepts can be found in the literature. Attempts of generating descriptive models from these stories and introspective accounts were following (Knoblich & Öllinger, 2005).

One of the historical roots of scientific studies of creativity in the 20th century times can be traced back to Graham Wallas who suggests in his book “The art of thought” (1926) a 5-stage model of the creative process. This early but still well cited model is based on narrative accounts by Helmholtz and Poincaré on arriving at some of their most memorable scientific ideas as well as his own experiences of thinking about challenging self-chosen problems. He distinguishes preparation, incubation, intimation, illumination, verification stages but focuses mainly on the incubation, intimation and illumination stages in the further course of his book, with the question how new insights can be obtained and elaborated at the core of his considerations.

The idea to conceptualise creative processes in stages has become a common theme in research ever since, even though they might include iterative, repetitive or recursive movements. A recent and quite comprehensive overview of process models stemming from a psychological background in that tradition and linking them to process models from the field of (engineering) design is provided for example by Howard, Culley and Dekoninck (2008).

From observational to experimental studies of insight

A first wave of experimental studies of creativity and insight was performed by key figures of the “Gestaltist”-movement mainly before the Second World War (Duncker, 1935; Köhler, 1921; Wertheimer, 1959). They performed observational and experimental studies with animals (chimpanzees) and humans trying to solve problems that require somewhat novel approaches and tool usage. The idea of restructuring of the problem in order to obtain a solution is considered an essential trait of insights by these researchers (Mayer, 1996).

In his book “Productive thinking”, Wertheimer (1959) tries to inquire beyond purely logical and associationistic concepts. He distinguishes between “sensible thinking” and problem solving that is achieved solely “by recall, by mechanical repetition of what has been drilled, by sheer chance discovery in a succession of blind trials” (Wertheimer, 1959, p. 11) cited in (Knoblich & Öllinger, 2005). This can be considered as an early manifestation of what later turned into the debate between advocates of “special process” vs. “normal thinking” approaches. Even though Wertheimer provides little suggestions for experimental settings to test the ideas and concepts brought forward based on a lot of observational and phenomenological material, his accounts are still a source of inspiration. His emphasis of the importance of being able to perceive the structure of a situation and discover gaps and tensions as prerequisite for success in endeavours of “productive thinking” seems to be still a challenge for researchers, designers or managers seeking profound innovations.

Karl Duncker, a student of Köhler and Wertheimer, esteemed to develop a complete theory of insight. He was very imaginative in developing numerous clever experimental set ups to study his theories and ideas (Duncker, 1935). His distinction between partial and total insight provides a first framing of what is currently studied as analogical thinking. The description of conflict analysis, material analysis and goal analysis as three central heuristics of thinking anticipates ideas from Newell and Simon´s seminal book “Human Problem Solving” (Newell & Simon, 1972).

Most of the contemporary experimental studies can be traced back to the problem solving paradigm brought forward by those two authors. The theory of a “problem space” or “possibility space” in which a solution is sought for by algorithmic or heuristic means is one of the central ideas. Structurally it is assumed, that if the problem is defined and the desired goal state is defined, problem solving is creating a search path through the problem space to the desired solution (Perkins, 1996, p. 508ff). The underlying goal of this approach is to develop a “general problem solver” which is open for computational, algorithmic implementations. Herbert A. Simon´s proposal to distinguish between problems in the natural sciences and problems in the realm of artificial human creation is of specific interest for design and studies of design practices (Simon, 1996).

From new experimental tasks back to ethnographic observations

Within the framework of “insight problem solving” cognitive psychologists have developed a number of experimental tasks that they use for their lab studies (Weisberg, 1996). Besides some newly developed tasks (e.g. matchstick arithmetic (Knoblich, Ohlsson, Haider, & Rhenius, 1999), coin moving (Chronicle, MacGregor, & Ormerod, 2004)), most of the studies on incubation and insight rely on somewhat traditional paradigms (Sio & Ormerod, 2009).

Application of new neuroscientific visualisation methodologies like fMRI spark some innovations in the experimental tasks (e.g. Puzzles with Chinese characters (Luo, Niki, & Knoblich, 2006) or newly developed compound remote associates (Bowden & Jung-Beeman, 2003)) recently. It is important to note that the transfers of experimental settings from cognitive psychology into the realm of neuroscience favour tasks that specifically suit the technical requirements of the brain scanners (Bowden & Jung-Beeman, 2007).

Studies conducting ethnographically inspired observations of creativity and insight in real world tasks and practices try to (re-)evaluate the theoretical concepts that underlie experimental settings for researching creative problem solving or even get ideas for new experimental paradigms. An interesting suggestion to capitalize on the cross-pollination of ideas between lab and real world settings exists in Kevin Dunbar´s “in-vivo-in vitro methodology” developed in the realm of studying scientific creativity (Dunbar, 1996; Dunbar & Blanchette, 2001). Since then there have emerged an increasing number of protocol studies of design meetings and semi-natural/artificial tasks (McDonnell & Lloyd, 2009).

Critique and call for integrative approaches

Even though we have just presented new developments and pathways of the evolution of the study of insight in the context of creative processes, most of the debates about "The Nature of Insight" (Sternberg & Davidson, 1996) are still unresolved. Ill defined concepts and discussions around seemingly opposing conceptualisations e.g. "special processes vs. normal thinking" are still subject to criticism and call for further integrative efforts. The prior chronological overview shows that from the initial narrative descriptions of the phenomenon of insight and creative processes very different approaches were developed to study the phenomena under scrutiny in the laboratory as well as in real world settings.

Insight as (too) broadly defined concept

When working with the concept "insight" one faces the challenge of varying and rather broad definitions. How extraordinary should a leap in a creative process be to qualify as an insight? Does an insight have to be useful, or can any surprising new idea be considered as an insight? And what about seemingly irrelevant insights that cause another and more useful insight – or even a series of insights that redefine the problem and/or the solution space? Disputes continue with the question whether insights should be considered as originating from special cognitive processes or as results of normal thinking.

Structural differences between "insight tasks" and real world experiences

Most lab experiments use tasks for which the solutions are known upfront. For creative problem solving in real world settings most of the time the solution is not known before it has been found as the outcome of a creative process. The underlying assumption for many tasks to study insights in the lab is that they per se cause insights if and when a "right" solution is reported. Solving the insight task is equated to having experienced an insight and thereby forming a somehow circular justification. Such assumptions are neglecting the possibility of other "non-insight" ways of getting to the solution. Another structural difference concerns the timeframes of the tasks in use. Whereas in lab settings most tasks are performed in the range of seconds or minutes, narrative accounts of insight problem solving are talking of hours or days of engagement.

Group Creativity as Blind Spot

Studies investigating individual performance in insight problem solving are neglecting to investigate how new ideas emerge from interactions among group members. "Unfortunately, most laboratory experiments on this subject use unrepresentative participants (viz., college students) and unrepresentative problem solving tasks (e.g., ones that require no division of labour or special expertise), thereby undermining their ability to be generalised to real-world problem-solving groups." (Simonton, 2003, p. 488) In recent years a movement to elucidate this blind spot and to investigate "group genius" (Sawyer, 2007) has started though.

Call for integrative approaches

Simonton concludes from his studies in the field of scientific work, that "the creative process is far less logical and deterministic than often claimed" (Simonton, 2003, p. 488). According to him, creativity has three essential components which should be integrated: the products that contain the creative ideas, the persons who conceived those ideas and the processes the persons involved used to do so (Simonton, 2000). This argument is well suited to encourage the quest for new integrative approaches.

We are convinced though, that such integration should be informed by Neurology and Cognitive Science and consider physiological plausible models of creative processes and insight moments. Socio-cognitive approaches could provide access to the experiences, states of mind and structures of thought that build the foundation for the abilities to perceive and associate items of relevance in processes of knowledge creation (Ringberg & Reihlen, 2008). The integration of experimental and observational approaches remains a crucial topic also for these considerations.

Matching lab experiments with observations of real world complexity

When setting out to study insight, two main approaches were considered so far: (1) Ethnographic studies of the phenomenon in context of real life practices and (2) laboratory experiments seeking to isolate the phenomenon to study it in a controlled environment. As we soon realised, both of these approaches have their challenges when it comes to study an “in flux” phenomenon. Studies of the real world are not necessarily reproducible outside their original context, and results from the lab are only valid for the controlled and stable conditions under which the experiments were carried out (Robson, 2002).

In this sense, both approaches share a general challenge: they are context dependent. If you change one factor in the context of the study, for example a team member, a time constraint or design company, the results from the study are questionable. This is as crucial for lab studies as it is for real life studies, and we concluded that lab-experiments or real world studies alone are unsatisfying for understanding the complexity of insights. From a more philosophical point of view, the relationship between the universal and the particular can be seen as interdependent: ”It is, ..., the fundamental principle of cognition that the universal can be perceived only in the particular, while the particular can be thought of only in reference to the universal” (Cassirer, 1955, p. 86).

In cognitive psychology, the same challenge has been described in relation to studying design of technological artefacts by Ball and Ormerod (2000) amongst others. They suggest developing and applying “cognitive ethnography”, first introduced by Hutchins (1996), as a method to study technological change. Hutchins develops the idea that cognition in real world settings can and should be conceived as being distributed way beyond individuals and including other actors as well as artefacts, thereby meshing up a complex system which as a whole is responsible for the outcomes of the cognitive processes (Hutchins, 1996).

In the study of insight we have therefore set out to design our studies based on a combination of the two perspectives, the particular (the lab) and the universal (the world). If we explore the structurally possible combinations the following options appear:

1. Either – or:
   We could stick to the historically developed disciplinary and methodological camps and either do observational or experimental studies.
2. Both at the same time:
   We could deploy studies on the same task in the lab and in real world settings simultaneously.
3. Integrating/mixing:
   We could perform experiments in real world settings (field experiments) resp. bring “real” tasks into lab settings - an approach that some of the current video/protocol studies are taking.
4. Jumps between both:
   We could move back and forth between the two modes and perform a couple of iterations in one project of longer duration.
5. Neither nor:
   We could come up with something completely different or move to another field of study, which e.g. Knoblich (2009, personal note) decided to do, based on the ill defined character of many of the concepts and the problems for experimental research in cognitive psychology due to that.

From the presented option we feel most inspired by the option to go for integrating/mixing respectively jumping between experimental and observational studies. This calls for crafting research settings that are able to meet up to the promises of an in-vivo-in-vitro-strategy.

Crafting and exploring integrative research settings

Obviously we should try to integrate findings from different approaches and even disciplines to account for the complexity in design thinking and practices (Cross, 2001, 2007) rather than trying to boil it down and reduce it to the extent that the phenomenon might vanish. Methodology wise it seems fruitful to play with observational, reflective and experimental approaches and look for possible combinations in one project to increase the richness of the knowledge created (Müller, 2008). The challenge is here too, to work with 1st, 2nd and 3rd person perspectives and accounts of insights at multiple levels simultaneously, and collecting them "in vivo" in an unfolding open ended process without too much interference and disturbance.

As epistemological assumption we are thinking about "embodied, situated cognition in relations to other actors and things" and thereby looking for distributed cognition, construction of meaning and sense-making. Such an epistemological stance is very well aligned with practice based studies (Corradi, Gherardi, & Verzelloni, 2008; Gherardi, 2000, 2009) integrating a range of ethnographically inspired and action based approaches. With the "practice lens" for our observation we want to lay the groundwork for studying the complexities of design processes in an "in-vivo-in-vitro"-manner (Dunbar, 1999; Dunbar & Blanchette, 2001). Concerning the format we follow Weisberg´s suggestion to use extensive case studies (Weisberg, 2006, p. 592ff).

Our motivation for conducting exploratory case studies is to get a first hand personal experience how well current theoretical accounts and concepts fit evidence from self-collected data. We are specifically interested in a better understanding of creative design processes including the tools in use as well as conversational and cognitive heuristics and patterns applied in the surrounding of insight moments. We will conduct our observations along the following lines but still keep the openness for unexpected surprises and

- follow the unfolding process
- look for claims of insight moments and analyse the circumstances (close to the event) especially the expression of the content of the insight at this point of time in order to be able to distinguish them from later stages of verification and refinement
- try to trace and accommodate past memories and experiences, environmental cues, random surprising events and coincidences as possible triggers
- look for openness and constraints in the process at the same time
- inquire into motivation and intention to select and pursue a challenging problem that calls for insight solutions.

Experiences from two case studies

In the following we present two case studies (Study A and Study B) exploring insight moments in real world design processes that are currently in progress. For each of both we provide a short outline of the context of the study, the layout, methods in use as well as preliminary results of the observations. We then discuss the implications and further potential for the study of insights in real world settings and the transfer of findings into improved lab settings and research paradigms.

Study A

Context

Study A is conducted at a major international corporation specialized in medical plastics (Company A) and aims at understanding the evolvement of design requirements in an engineering design projects as a consequence of insights in the design teams. The project is looking at process level from early stages of defining new markets to the stages of finalizing new products. Especially in the early stages the project is focusing on the role insights play on defining design requirements.

Set up of study

To achieve a better understanding of the role of requirements and insight in engineering design, the following strategy is tried out in Study A:

1. Ethnographic study: Real world engineering design in Company A
2. Laboratory experiments 1 (Lab 1): Based on observations from Company A, laboratory studies with design teams are used to compare different situations observed. Using both experienced and novice designers, the experiments might also reveal some variances between the preferences for the two groups.

3. Laboratory experiments 2 (Lab 2): This series of experiments seeks to optimise the most successful strategies observed in Lab 1 and finally to conclude what strategy to implement further on.
4. Real world testing: After Lab 1 and Lab 2, the results are taken back to "the real world" and implemented in a controlled setting in Company A. The satisfaction with the suggested changes will be explored through interviews and questionnaires.

The project starts from research question(s) grounded in experience and theory. Based on the research questions, field observations are made, followed by relevant theory, which feed back to the observations and potential new observations. Based on this mix of theory and observations, a hypothesis is made and then tested in experimental settings. The testing feed back to the formulation and scope of the hypothesis, and the final results from the tests are evaluated – and form the fundament for future research questions.

Methods in use

In Study A, the following methods are in play: Participatory research, field observations, practice-based research, experiments, video and voice recordings, interviews and data analysis.

Observations so far

Below, one example from the case study that might be relevant for Lab 1 will be presented:

The researcher is participating in an early-stage innovative process in Company A as a member of an interdisciplinary design team consisting of 5 other members. The task for the team is to define an initial product profile for a new solution to a physical problem related to a specific medical condition. The team members are all from different backgrounds (engineering, marketing, sales, management, manufacturing, design) and from different departments (R&D, marketing, concept, design) within the company, and with limited prior knowledge regarding the medical condition the product is meant for. Since the project start-up, the team members have been finding and sharing knowledge in such a way that the team has a more or less common knowledge base regarding the condition.

In the third meeting, the team was interviewing nurses with special education and long experience with the relevant medical condition. The team asked questions to the nurses, based on the collected and shared information about the condition. Late in the meeting the following occurred: One of the nurses stood up and, using an existing product from the user category, demonstrated a specific user challenge with the product. At a certain point in her demonstration she was suddenly interrupted by the design team, as almost the whole team (at least 4 out of 6 team members) were excited about what she was presenting to the group. As it turned out, several members of the design team had got the same idea for a new way to solve the initial problem.

The product demonstrated in the meeting solved the initial problem in a comprehensive way, while the new idea generated in the group represents a very different and way simpler solution to the problem. The novel idea can be considered as an example of a shared insight amongst the team members as it does not have any similarities with the solution to the problem embodied in the product that was demonstrated first. This insight was seemingly triggered by a cue in the demonstration, possibly a combination of gesticulations and oral descriptions, and based on the fact that despite their varying backgrounds the team members had a shared knowledge related to the initial problem and medical condition.

The situation described above is in itself an interesting observation about a shared insight moment, but it might also be used as input to a controlled experiment studying shared insights. By giving a multidisciplinary group a problem definition and a shared knowledge base, can one use cues to trigger shared insights that will lead to ideas that a similar group will not be able to produce? The observation described is just one of several examples from the case study that might be used in the following experiments.

Study B

Context

Study B follows the interior design process for a shared office space for social entrepreneurs in Vienna, Austria. A 400 m² loft is transformed from an empty space into an up and running office during a 4 month period form December 2009 to March 2010. The project is currently in an early stage but progressing fast: The loft was emptied in calendar week 2/2010 and renovation just started. The work with the designers on the interior design started December 2009 as soon as all contracts for renting the place were signed.

At the centre of the investigation is following/shadowing the core team of two Vienna based designers and the two entrepreneurs owning the place/office space together with a designer from the London based global network organisation, linking similar places all over the world. During the planning and realisation process a number of workshops with potential users/clients and interested people are conducted to discuss the existing plans and get additional ideas.

Set up of study

The set up is exploratory and evaluates the development of key ideas and their implementation in the course of the project along a number of mile-stone-meetings. Between those meetings participatory observations are undertaken.

Methods in use

Mainly participatory observation (ethnographic field work, notes) and interviews at different stages throughout the process (audio recordings) were performed, taking a “reflection of action” (Schön, 1983) approach towards analysing the activities and circumstance of the development of key ideas and possible insights. Some basic introduction to the methods of those reflective practices was undertaken for the people involved (Schön, 1987).

The second level of observation is based on a collection and analysis of sketches, notes/meeting minutes and produced artefacts/prototypes in relation to the reflection of the design process in the interviews. The designers were additionally asked to do a basic self ethnography resp. use their working diaries for capturing potential insight moments focusing at the experience as such, its content and its circumstances.

The possibilities for video analysis of selected workshops/meetings are currently explored.

Observations so far

So far interviews on the initial ideas for the room layout and functional areas were undertaken and several rounds of walking through the loft and talking about the different functional areas to be designed and equipped with furniture were observed as part of the renovation/emptying out activities. The conversations observed so far were centred on efforts to combine new ideas and elements that worked in other situations as well as ideas from prior projects of the designers and applying them to the empty space. The content of the conversations focused in the early phase on desired atmospheres and functional settings in different areas of the loft.

Currently the next phase of building things is about to start. The room concept was transformed into a general plan. An iterative design process and rapid prototyping for elements of the installed furniture is planned for the upcoming weeks.

Additionally to the artistic and technical level it will be interesting to observe how the rather tight budget constraints will affect the quality/originality of ideas. This could mean ruling out some ideas and at the same time a call for additional creativity in terms of finding smart ways to cope with this very fundamental framework. As a result a lot of do-it-yourself and re-use of what can be obtained from sponsors or bought on flee markets (as opposed to catalogue shopping) is expected to be happening.

Concerning the phenomenon of insight so far situations of shared ideation can be reported. At this early stage the people involved seem to be building a common understanding of the different requirements for the various areas in the space. Discussions and conversations are focused on bringing together various ideas, elements observed at other places and matching those ideas with the functional requirements and possibilities of the location. Some evidence for combinatorial/associative practices is available.

Summary, conclusions and outlook

In this paper we have presented an overview of approaches to study insights and collected evidence for discrepancies between experimental and observational studies of insight moments. We discussed implications for conducting integrative research that addresses the complexity of the real world design environments. Preliminary results from our efforts to get a personal perspective and feeling for these tensions and debates were reported: Two case studies with design teams working on real world design tasks are in progress where we are applying a multi-methodological framework inspired by in-vivo-in-vitro research together with ethnographic and practice based approaches.

With our work we try to follow the call for interdisciplinary and integrative approaches which are able to connect and bridge different zoom levels and perspectives for a more comprehensive understanding of the phenomena at hand. We very much look forward to further exploring what we will be able to observe and learn about insights in the further course of these studies. Some of the challenges that we anticipate are revolving around the following questions:

- How to obtain further data on insight moments in-vivo and account for the complexity around these events from 1st, 2nd and 3rd person perspectives?
- How to trace back the hints leading towards the observed insight moment?
- How are we going to be able to introduce experiments in the real world environments without compromising the role as participant observer?
- To which extend will we be able to abstract input from these case studies to further advance theoretical models?
- How far does the transferability of observed heuristics and patterns reach to other settings – e.g. analogous argumentations between design practices and management challenges?

Overall it seems to be crucial to embed insight phenomena in a plausible neuro-physiological working-model that will be able to help structuring the accounts from different disciplines as well as experimental traditions and paradigms. In order to get inspiration for the realm of experimental paradigms it seems promising to look again at some of the early work related to the insight phenomena (Duncker, 1935; Wertheimer, 1959). In terms of practical applications we hope to be able to generate some insights ourselves of how to increase the likelihood for profound insights to emerge. When trying to get beyond some of the debates about seemingly opposing theoretical accounts it should be helpful to take the slightly paraphrased title of Weisberg´s journal-comment on a target paper by Simonton (Weisberg & Hass, 2007) seriously: “They are all partly right…”

Author Biography

Stefan Wiltschnig

Stefan Wiltschnig works as Researcher and PhD Fellow at Copenhagen Business School in the EU FP 7 initial training network "DESIRE - CREATIVE DESIGN for INNOVATION in SCIENCE and TECHNOLOGY". He is trained as telecommunication engineer and graduated in business administration from WU Vienna with majors in entrepreneurship and innovation as well as process and project management. Additionally he has studied Cognitive Science at the Universities of Vienna and Ljubljana. In his PhD project he is focusing on insight moments in creative processes with an interdisciplinary approach between cognitive science, management and design thinking.

Balder Onarheim

Balder Onarheim works as Researcher and PhD Fellow at Copenhagen Business School in the EU FP 7 initial training network "DESIRE - CREATIVE DESIGN for INNOVATION in SCIENCE and TECHNOLOGY". His educational background is Industrial design with minors in psychology, management and entrepreneurship. The PhD project is focusing on constraints and requirements in engineering design, investigating how learnings from the requirement engineering literature can be applied to design of medical devices.

The work presented in this paper is funded by the EU framework programme 7 – Marie Curie initial training network “DESIRE - CREATIVE DESIGN for INNOVATION in SCIENCE and TECHNOLOGY”.

Designing Contemporary China: National Design Identity at the Crossroads

Wendy Siuyi Wong, Department of Design, York University, wsywong@yorku.ca

Abstract

China is an ancient civilization rapidly developing in a globalized post-modern context. The country now finds itself at a crossroads, with outside ideologies and forces of “Americanization” and “Westernization” competing against its cultural heritage and communist economic system to form a national design identity for contemporary China. This paper uses the rise of modern design in China, design examples from Hong Kong and Taiwan, the 2008 Beijing Olympics opening ceremony, and Victoria & Albert Museum’s *China Design Now* exhibit to investigate questions of national identity as they pertain to design. It argues that, with the whole world watching China’s rise as a global economic power, the real challenge facing Chinese designers is how they can create a “new” image of China to present to the rest of the world, particularly the West, if they don’t wish to be stereotyped by images from the ancient past.

To discuss the potential impact of Western design and economic influences on the development of a contemporary national design identity, this paper first investigates the relationship between a designer’s ethnic background and creative work to search for a possible direction of development of a contemporary national design identity for China. It concludes that cultural factors do not play a key role in every design project undertaken by Chinese designers in the Greater China region, but rather that decision depends on the nature of the design job. However, the author recognizes the importance of studying the cultural artifacts of this great civilization, as well as the urgent need to establish design curricula with Chinese elements, in order to discover how to establish a modern international style with a contemporary Chinese touch – that is, its contemporary national design identity.

Keywords

China; National Design Identity; Globalization; Design and Culture; Chinese Design; Asian Design

China, one of the four ancient civilizations and today one of the largest countries in the world, has finally opened up to the rest of the world thanks to the Reform and Opening (gaige kaifang 改革開放) Policy the country instituted in 1978. Since then, the communist regime that controls the People's Republic of China (PRC) has initiated tremendous changes in all walks of life, including the creative arts and design. Today, the government no longer condemns the “evil spirit” of commercial arts as Shou Zhi Wang (1989), a Chinese design history scholar once point out, and even embraces the important role that design plays in promoting vital business activities. This paper uses the rise of modern design in China along with work by designers in Hong Kong and Taiwan, the 2008 Beijing Olympics opening ceremony, and Victoria & Albert Museum’s *China Design Now* exhibit to investigate questions of Chinese national design identity.

The designer's ethnic background and visual style in relation to national design identity

According to Woodham (1997), national identity is a conscious construction but is largely "myth" rather than an "accurate" inventory of distinguishing qualities. With a long and rich history of civilization to call upon, Chinese designers and students should have no difficulty finding unique qualities to represent China's national identity in their design work. However, the way in which these historical representations speak to younger generations, so eager to embrace the modern, globalized world, may present potential problems due to "the recrudescence of previously declining cultures, and even cultural resistance" (Knight, 2006, p. 4). As a relative newcomer to the world of design, China's design industry and professionals face the challenge of catching up to international standards. This paper argues that, with the whole world watching China's rise as a global economic power, the real challenge facing Chinese designers is how they can design a "new" image of China to present to the rest of the world, particularly the West.

To begin the discussion of China's national design identity, I will first examine the relationship between a designer's ethnic background and his or her creative work. After centuries of diaspora, it is now common to find designers of Chinese and Asian descent living throughout the world, often without much knowledge of the Chinese culture of their ancestors (Kim, Yang, & Lee, 2009). Having grown up under the increasing influence of Western values like individualism and consumerism since 1980, younger Chinese citizens do not necessarily share the ideological beliefs of previous generations, and it is now possible for young people to live in a Westernized society with little knowledge of traditional Chinese values and practices, much like people of Chinese ancestry growing up in diaspora communities. By examining the relationship between a designer's ethnic background and creative work, it may be possible to forecast the future development of China's national design identity.

In 2007, I published a conference paper investigating the relationship between a designer's ethnic background and creative work by conducting a case study of *Communication Arts*, one of the foremost graphic design trade journals in the United States and with a worldwide circulation (Wong, 2007). I traced award-winning work by designers with Chinese names over the ten-year period from 1997 to 2006 to try to discern whether or not the ethnic background of each designer is reflected in his/her published work, along with questions pertaining to the relationship between design and culture.

For that study, I borrowed Bari Kachru's concept of "three concentric circles" (quote from Bolton, 2000), developed to describe the spread of English language usage in the global context. I applied Kachru's concept to define "Chinese" in the contemporary international context, applying the "inner circle" label to locales where any Chinese dialect (such as Mandarin, Cantonese, and Taiwanese) is the first spoken and written language; examples include China, Hong Kong, Taiwan and Macau. The outer circle would represent countries where a majority of the population uses a Chinese dialect as their first language, such as Singapore, Malaysia, Indonesia and Thailand. The extending circle, then, applies to countries where Chinese has the status of a "foreign language" and that have a visible ethnic community of Chinese origin. Examples of this extending circle are the United States, Canada, the United Kingdom and Europe.

A wide range of work by Hong Kong designers appeared in the *Communication Arts Design Annuals*, including corporate identity, book design, editorial design, self-promotion, and poster design pieces, and the submissions are a mixture of commercial and non-commercial work. Kan and Lau, Alan Chan, Tommy Li, Eric Chan, Michael Miller Yu, and Paul Lam are among the individual designers/art directors/design firms from Hong Kong whose work was published, while J. Walter Thompson and Token Workshop are two agency/design firms that appeared in the

Figure 1: Self-promotion by Lee Ken-Tsai, Taiwan

Communication Arts Design Annual from 1997 to 2006.

Kan and Lau, Alan Chan, and Tommy Li are the three designers/art directors/design firms who received the most entries in the publication. Kan and Lau is the design firm of partners Kan Tai-keung and Freeman Lau, two of the most prestigious designers in Hong Kong. Although most of the Hong Kong designers whose works appear in the publication do have their own unique signature styles, not every piece included reflects that style due to the differing needs of the projects. By examining the submissions by Alan Chan Design and Kan & Lau Design, we can see that the lead designers, Alan Chan and Kan Tai-keung, separated their personal signature styles from the commercial work according to the nature of the projects.

Must a designer always include his or her own signature style and ethnic cultural elements in design? In the cases just mentioned, the designers obviously intended that the design solutions should first serve the nature of the project and the clients' needs, rather than the designers' own personal aesthetic interests. We can find similar design values in the work of Hong Kong designers; it is becoming rare to find so-called "authentic" and "exotic" cultural elements in their work.

A self-promotion piece by Lee Ken-Tsai of Taiwan, who has never been studied overseas, went to New York several years ago to study English and discovered himself while in the midst of the city's rich multi-cultural environment. This self-initiated project was, to a certain extent, a search for self-identity. Lee asked many friends that he met to write his name in their native languages, and then graphically combined the writing with photos he took in New York to create this self-promotion piece (figure 1).

Another interesting work, by designer Chun-Liang Leo Lin, is a poster created for the thematic poster show *Korean Image* held in Taiwan in 2001. Thematic poster shows in the Greater China region became very popular in the mid-1990s; this particular show invited designers from Taiwan and Korea to participate and create work based on the theme, Korea. Lin created this poster using the colours of the Korean flag and an image of a pair of shoes, resulting in a piece heavily embedded with cultural elements.

As for design in mainland China, pieces by designer Wang Xu appearing in *Communication Arts Design Annuals* are mainly his publication design pieces from the *Design Exchange Magazine* (figure 2) and *Master Designers* book series. Unlike Kan Tai-keung and Alan Chan, Wang does not consciously use Chinese elements in his work to establish a signature style. It is difficult to say whether he has taken this approach due to the nature of the work or because of his intent to construct an image of "modernism design" for the Chinese audience looking forward to a

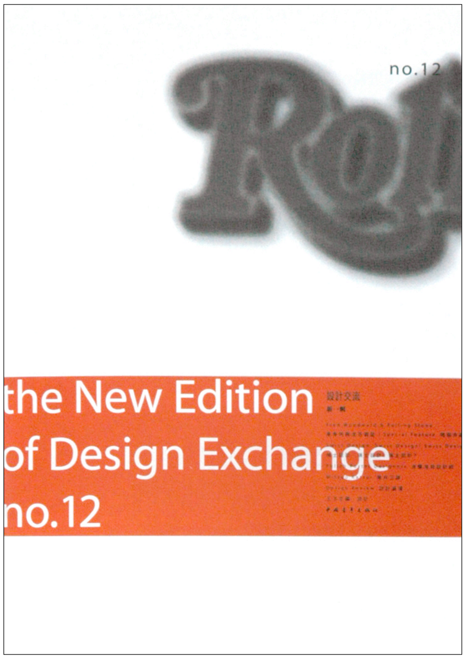

Figure 2: Design Exchange Magazine, designed by Wang Xu

Western lifestyle.

World design development is still dominated by European and North American countries, with Japanese designers also starting to play a major role in shaping the world's "modernism design" landscape. Designers from Asian countries with different cultural settings or from an Asian ethnic background have difficulty asserting their own cultural touches without rational justification for their choices. This is the observation that we can make from studying the pieces created in the "inner circle" Chinese countries.

In analyzing the work assembled from the "outer circle" countries such as Singapore, Malaysia, Indonesia and Thailand, it is difficult to identify the "cultural design identity" of the individual countries. Singapore has the highest design standards in this region and designers from Singapore did pretty well, based on the number of submissions included in the *Annuals*. In 2001, Singapore had four pieces of work selected; it had five pieces chosen in 2005.

What does "Chinese" or being "Chinese" mean in a contemporary global context? In the "extending circle" category, art directors/designers with Chinese names are mainly from major cities such as New York, San Francisco, Seattle, and Los Angeles in the United States, and Toronto, Vancouver, and Montreal, Canada. After almost two centuries of diaspora, people of Chinese ancestry can be found in many parts of the world, and Chinese in North America are no longer restricted to a few vocations, such as railway laborer, mine worker, and laundry or grocery store owner. New generations of Chinese born outside China and with little or no knowledge of Chinese culture are, together with non-Chinese designers, creating a new landscape of "international Chinese."

The works by art directors or designers with Chinese names included in the *Annuals* reveal no distinguishable differences in visual style. Like the examples found in the inner and outer circles, Chinese cultural elements are used when it is appropriate for the project. For example, Vivien Sung's design for Chronicle Books, titled *Five-fold Happiness*, appeared in *Annual 2003* and illustrates the application of design theory to the editorial design of Chinese objects. Chinese elements in this book are found in the contents and the cultural product for selling and consumption. Perhaps the meaning of "Chinese" in a contemporary global context may refer only to cultural products at the consumption level. Being "Chinese" might be only skin-deep.

Another example is a package design for a Chinese takeout food client in Minneapolis, USA, created by a non-Chinese designer, Jillian Frey. Because of the client's needs and the nature of the product, her design solution skips "obvious" Chinese elements, relying instead on different typefaces for the phrase "Asian to go" composed in a pattern. The only Chinese element that is used is the character Chin 陳, a Chinese surname. Although you do not see stereotypical Chinese elements in the pattern, you are left with the sense that the Asian world is full of variety and choices (figure 3).

We began our survey of the works from *Communication Arts* with the question: is there a relationship between a designer's ethnic background and his or her design work? Based on the examples discussed above, we can see that Chinese cultural factors do not play a key role in

Figure 3: Lee Ann Chin, Asian to go, designed by Jillian Frey, Minneapolis, USA

every design project that inner circle Chinese designers undertake; whether or not Chinese elements appear depends entirely on the nature of the project. Chinese elements might be used if they are suitable for the project needs, and their use is not exclusive to designers of Chinese descent, as seen in the work of Minneapolis designer Jillian Frey. And designs created for Chinese clients do not need to use Chinese elements solely.

Jillian Frey's example proves that a designer without any Chinese cultural background can be very successful using Chinese elements. Another success is Henry Steiner, who has been in Hong Kong since the early 1960s and is widely regarded as the father of Hong Kong graphic design (Wong, 2001). Steiner is well known for his "East meets West" style; his 1969 work for the *Hong Kong International Music Festival* demonstrated a new possibility for modern Chinese design after the 1930's Shanghai style.

In this poster, Steiner used a pair of pearls to represent Hong Kong, known as the "Orient of the East," as a set of earrings on ears posed as if a butterfly; together these two images are suggestive of the beautiful, delicate music of the East. This visualization and conceptual approach to modern poster design may have been common at that time in the West, but it was groundbreaking work in the Eastern context. Steiner's achievement became a source of direction and inspiration for Hong Kong designers. What the designer did was simply search for creative direction within culture and everyday life, yet his design solution has a timeless quality that is still refreshing 40 years later.

If design naturally has a close relationship with culture and everyday life, is it difficult for designers and clients to keep cultural elements from appearing in works designed for the global market? The biggest challenge facing many young Chinese designers today is the necessity to catch up to international design standards to promote commercial interests and consumption, not to use design as a tool to improve the everyday lives of people. In order to achieve business objectives for marketing products globally, it is often necessary to produce creative works devoid of cultural elements and, often, without distinct characteristics.

For example, Xie Yong of China was a finalist in the British Council's International Young Design Entrepreneur of the Year award in 2006. The General Manager and Director of E-madesign Co., Ltd. in Beijing, Xie's goal, according to his statement, is to be a "one-stop design service market in China." His selected work clearly reflects his own definition of design as a "service" to the market, rather than any deeper contextual meanings of design to culture and society. On the contrary, a finalist from India, Ramesh Manickam, sees design as a service that should meet the "multifaceted requirements of the Indian market" (British Council, 2006).

Both this designer's statement and his selected work demonstrate the concept of meeting the needs of different segments of society. Manickam's work is an interesting contrast with that of Xie Yong, as the Chinese designer's product is not embedded with elements reflecting the culture and everyday life of his homeland. It is apparent that the young Chinese designer's approach is to promote commerce that is in sync with trends found in the developed Western countries, while the Indian designer's work reflects his consideration of the largely rural and agricultural lifestyle of the Indian population. Perhaps the Chinese designer is responding to globalization trends, trying to minimize the cultural flavor of his work so it will be accepted internationally; the Indian designer may have no such concern.

Questions of national identity in art and design

The very concept of identity is a fluid term, and China is undergoing rapid change and modernization in all aspects of life. But the question of national identity in art and design is not a new one; the debate between scholars and artists can be traced all the way back to the 1930s, when the 1937 publication by the first professional design organization in China, China Commercial Artists Association (Zhongguo Gongshang Meishu Zuojia Xiehui 中國工商美術作家協會), lamented that the mainstream commercial arts (gongshang meishu 工商美術) in China at the time was full of "Western style" imitation work and questioned how ancient Chinese art and craft (gongyi 工藝) could adapt to the modern context (ZGMZX, 1937).

In response to this criticism in the 1930s, pioneer artist Lin Feng-mian (founder of China Academy of Art) advocated design using the best from both Western and Chinese cultures. To achieve this balance, he advocated four main ideas: 1) introduce Western Art; 2) review Chinese Art; 3) balance Chinese and Western Art; 4) rebirth of contemporary oriental art. The ancient civilization of China has been exposed continuously to Western art since it was first opened to foreign powers in the 19th century; the other three ideas, however, are the unfinished business of generations to come, making Lin Feng-mian's suggestions relevant to works being produced by Chinese designer's today (Wong, 2005).

In 2000, I published a conference paper called *Exploring Chinese Graphic Design theory and Pedagogy*, hoping to discover a generalized creative logic and visual system encoded with Chinese elements and Western design principles (Wong, 2000). Most of my examples were based on work from Hong Kong, Taiwan and Macau, with only a few pieces taken from China. In that study, I recognized six creative directions in the work found in the Greater China region, including: 1) Re-invention of Chinese typography; 2) Integration of bilingual typography; 3) Formulizing the mixture of Eastern and Western images; 4) Rethinking Chinese calligraphy and Shiumo painting; 5) Inspiration from folk arts and popular arts from the past; and 6) Appropriation of contemporary everyday life objects.

Since 2000, the increasing scale and volume of works produced by mainland Chinese designers have opened up more potential creative directions for Chinese design; however, if a majority of young Chinese designers want to emulate the work of Western designers as seen in the international design annuals, what will the future of design in China look like? Before China instituted its Reform and Opening Policy in 1978, designers from Hong Kong and Taiwan, conscious of incorporating Chinese elements in their designs, were creating and shaping the contemporary Chinese design landscape. But there is every possibility that these values may not be shared by the younger generation of designers from China, and the number of professional designers in Hong Kong and Taiwan is small compared to mainland China.

With the new creative power of designers from mainland China joining Hong Kong and Taiwan designers, I was very optimistic that a new visual style with a Chinese touch could be established internationally (Wong, 2003); this could be at the surface, symbolic, or even abstract levels as found in the 1930s Shanghai-style works as well as works of Henry Steiner, Kan Tai-keung Wang Xu, Chen Shaohua, Jiang Hua and others. This new visual language using touches of Chinese culture may be the only way for Chinese design to be established internationally.

Designing a national identity for contemporary China

The past couple of years saw a plethora of amazing work produced by the young generation of designers born in the 1970s and 80s. The sheer volume of work produced has diversified and enriched the visual language. Some of them may use a Chinese touch when it is warranted; together, they are producing a new visual language of graphic design in China. Although these young Chinese designers show great potential, they are causing the Chinese government some concern regarding the construction of a national identity through popular media (Wang 2002), including design. As Knight (2006) points out, "a prominent theme in the Chinese discourse on globalization is that China's culture must not be allowed to become 'Americanized' or 'Westernized,' for this would constitute a serious challenge to the integrity of the Chinese nation" (p. 19). China's leaders are cognizant of the important roles popular media, design, and globalization play in China's economy and culture, and have thus set up a ten-year plan to handle the transformation from a traditional economy to a knowledge economy. The country's stated ideological position, the establishment of "a socialist country with Chinese characteristics," makes it clear why China's leaders don't wish to see a "Western" design identity coming to represent China.

A perfect example is found in the opening ceremonies of the 2008 Beijing Olympics, an image of modern China carefully crafted by the country's leadership. The ceremony arguably was the product of design, a mixture of creative concept, branding, props, costuming, lighting, and so on. Carefully planned and crafted under the strict ideological guidelines handed down by China's leadership, the ceremony was executed by world-famous film director Zhang Yimong, with support from Hong Kong action director Chin Siutong. The stunning result was a movie-set constructed identity, with astounding visual effects aided by cutting-edge technology, massive choreographic coordination of thousands of performers, and props and costumes effectively reconstructed to present a glorified picture of the Chinese civilization's ancient heritage.

Scenes of the four ancient inventions, Confucius chanting, torches flying across the cityscape and breathtaking fireworks displays educated viewers worldwide about the knowledge and symbols of Chinese civilization. These constructions not only fit the perceptions of Western viewers who imagine the East to be quite mysterious, but also aroused the national pride of Chinese viewers. As Woodham (1997) reminded us, national identity is a conscious construction, and China will have no problem finding unique qualities to represent its national identity. However, with contact with the outside world an inevitable part of the process of globalization, the great Chinese civilizations can no longer stand still but must accept the fluid nature of cultures in the modern era.

If the extravagant 2008 Beijing Olympics opening ceremony had a weakness, it was in the apparent lack of a modern, contemporary identity for the civilization, unlike the Tokyo Olympics of 1964, in which graphic designer Yusaku Kamekura shocked the world with his contemporary design absent any obvious national cultural symbol (Art Directors Club, n.b). Japanese design at that time had already found a way to develop a sophisticated contemporary national design identity. Although Kamekura's 1964 poster design did not borrow any iconic symbols, viewers could nonetheless feel the Eastern aesthetic from the composition. The Japanese experience of hybridizing East and West and old and new can provide a possible framework for China's national identity development; however, because of the vast ideological differences between the countries, China's leaders will not wish to see its culture or identity developing in an "Americanized" or "Westernized" direction. Nevertheless, after three decades of reforms and development, design in China is now at a cross-road reflecting the absence of long-term planning once advocated by Lin Feng-mian.

The *China Design Now* exhibit held at the Victoria and Albert Museum from March to July 2008 may have best summarized the landscape of design in China over the past three decades. This exhibit took a contemporary approach to explore "China's hopes and dreams – from the entrepreneurial spirit of individual designers, to society's aspirations at a moment of tremendous change, and the global ambitions of a nation" (Zhang and Parker, 2008, p. 19), displaying artifacts from graphic design, industrial design, architecture, fashion design, toy design, new media, branding, and so on. Rather than embracing stereotypical symbols and icons, as seen in the 2008 Beijing Olympics opening ceremony, this exhibit showed the intermingling of elements of traditional heritage, socialism, and global influences from the West with the creative energy of contemporary China that is barely known to the world. Due to its very nature, this landscape has been a chaotic one, causing the curators to acknowledge that, “[w]ithin a globalized post-modern context, China’s process of modernization – the overlapping of state and market, the co-existence of both formal and informal economics – has, however, broken free from classic paradigms of modernity, either capitalist or communist” (Zhang and Parker, 2008, p. 29). This chaotic context makes the construction of a national identity for contemporary China through creative media more challenging.

Possible future directions

To tackle the currently chaotic context for the construction of a national identity, I suggest that current design education should play a great role in the future development direction of Chinese design. Since China implemented its Reform and Opening Policy in 1978, design schools have had no shortage of overseas experts and academic scholars to lend their suggestions. Design students in China are potentially a very valuable commodity for overseas design education institutions looking to recruit students from abroad. To a certain extent, design at the commerce and marketing levels is a skill that can be transferred without coding and cultural values. The introduction of overseas design education curricula and practice will certainly help Chinese designers and design students to catch up in the world design scene, like the latest design education program announced in Shanghai in April 2009, a partnership with the world-renowned Studio Dunbar of Rotterdam (Bustler, 2009) (figure 4).

Figure 4: New design educational program in Shanghai and Rotterdam Launched, April 2009

However, these joint-educational programs with overseas institutions do not necessarily understand the translation of cultural factors into design education in China. The issues confronting Chinese design education are enormous and require in-depth research into how to produce "design with Chinese characteristics" in the contemporary context. In a journal article published in 2001, two professors from the Hong Kong Polytechnic University proposed that China address the “endemic problems” for their future design education development without acknowledging the struggles of traditional arts and crafts heritage with the modern education system over several decades (Fung & Lo, 2001). I support this critique and look into the possibilities of developing a cross-cultural communication approach in teaching design, in which students are required to understand and apply their knowledge of at least two cultures to their designs, which is basically what Lin Feng-miang once proposed.

Today, people in China are not lacking information from the outside world and the Reform and Opening Policy will ensure that this influence from the West continues. The overarching question is how a balance can be struck between Chinese and Western art/design. These questions are not new and were debated as far back as the 1930s, when China was full of design and designers imitating Western style. In the contemporary context, the definition of "Chinese touch" must remain fluid and inclusive, as proposed by film scholars Wang and Yeh (2005) in their studies of globalization and hybridization of Hollywood-produced Chinese film titles.

Conclusion

The past two decades have seen the explosive growth of business opportunities in design and design education, beginning with graphic design and progressing to Industrial Design, fashion design and, most recently, animation and new media. The boom is no longer restricted to the large urban centers like Shenzhen, Shanghai and Beijing, but is also spreading to inland cities (Xu, 2007; Zhang and Parker, 2008). Because of the publicity given the design professions by a wide variety of leisure magazines, along with mass media coverage of prominent, financially successful artists and designers, Chinese parents don't hesitate to support a child's interest in pursuing a career in design arts. Professor XU Ping of Central Academy of Fine Arts estimates that, in 2006, there were at least 1.1 million students enrolled in Design-related programs at university/college level in China, with another 2.7 million prospective students failing to gain entrance to those programs (Xu, 2007).

I believe design education in China needs to explore a pedagogy that includes teaching how to use cultural symbols in design in a global context. Students need to be educated on the importance of respecting their cultural heritage and learn how to incorporate their cultural symbols into their design output. I am confident that the desire among young Chinese to find a unique national design identity will only increase as they gain more opportunities and exposure to the outside world. It is in this process of searching that a contemporary national identity will most likely emerge. Finally, I would like to conclude this paper with by restating the urgency of creating design curricula with Chinese elements, or the future design identity of China will become even more challenging to develop.

Wendy Siuyi Wong

Wendy Siuyi Wong teaches in the Department of Design, Faculty of Fine Arts at York University. Dr. Wong has been conducting research in the area of Chinese and Hong Kong visual culture and history including graphic design, comics and advertising images. She is the author of *Hong Kong Comics: A History of Manhua* (2002) published by Princeton Architectural Press, 4 books for Chinese readers, and numerous articles in academic and trade journals. Dr. Wong served as a visiting scholar at Harvard University from 1999 to 2000, and was the 2000 Lubalin Curatorial Fellow at the Cooper Union School of Art, New York, USA. She also curated two major exhibits on Chinese Design held at the Cooper Union School of Art in 2000, and Design Exchange in Toronto in 2008. She has taught in the United States and Hong Kong before she moved to Canada.

Creating an Electronic Patient Held Health Information Card

Andrée Woodcock, Coventry University, UK. email, A.Woodcock@coventry.ac.uk

Jackie Binnersley, Coventry University, UK.

Panos Kyriacou, City University, UK

Viktor Rybynok, City University, UK

Abstract

In many areas of health care, professionals rely on patients to provide information about their medical history. However, patients may not be able to remember details or communicate essential information relating to, for example, current conditions, medication and allergies. Currently no central system exists which serves all the UK .Therefore, an electronic, patient held health record system has been proposed as a way of improving patient safety. This development has been driven by a user centred process, from requirements capture to iterative development, longitudinal trials and dissemination. Through this process the project has raised debate and awareness amongst the public and medical professionals about power relationships within the health service and the need for the public to take a greater responsibility in matters related to their own health.

Keywords

user centred design, health, IT systems

Although it has been suggested that patients taking responsibility for their records could improve safety, few studies in the UK have considered attitudes towards this, the design of such a system or potential barriers to use. An American study by Ross *et al* (2005) found widespread support for shared medical records across a broad range of ethnic and socioeconomic groups. In the UK, a study by the Department of Health (2008) reported that although the majority of participants were in favour of electronic records, reassurance was needed that records would not be viewed by other organisations.

For many years, paper forms of patient held health records have been successfully used in the maternity care (Phipps, 2001) and child health (Hampshire et al, 2004). These are rarely extended to other areas of health care. A patient held electronic record system was successfully trialled in the UK, between 1989-1992 (NHS, 1990). 13 000 patients were provided with smart cards containing health information that only they and the professionals treating them were able to access. Although the trial was successful, technological limitations meant that this was not continued or extended.

In terms of the design requirements for patient held records, Jones *et al* (1999) found that almost all the patients who participated in the study thought that a patient held record system should include information about medications, allergies and vaccinations. Liaw's (1993) study of doctors showed that allergies, adverse drug reactions, relevant medications and immunisations should be included. Giglio and Papazian (1986) conducted a trial with four types of patient held record devices in the USA, finding that a wallet sized card was most preferred because it was the most portable.

The aims of the current study were to assess the public's and medical professional's attitudes towards a patient held, electronic health system, with a view to informing policy and the development of a prototype device. The project therefore followed a *research through design* approach, with the development of the My*Care* card (see Figure 2) acting as a catalyst to discussions about the content and ownership of health care records and how such a system could work in practice.

The user centred approach adopted meant that the starting point was not prescribed at the outset. Instead decisions on the form of the device and the interface were informed by the attitudes and user requirements of patients and health professionals. This information was fed into the design of prototype systems, which were evaluated in the laboratory through the development process by usability experts, health professionals and representative end users. User trials were concluded with a month long, limited real world trial to discover how the cards might be used by people who have different health needs. Finally, dissemination activities were undertaken via roadshows to demonstrate the project to the wider public and discuss the implications of such a system for the health service. The paper provides an overview of all stages of the project

The *MyCare* Project

Stage 1: Attitudes towards patient held records and user requirements

The aim of this stage was to collect information about attitudes towards and requirements for a patient held electronic record device and to

- assess levels of support for patient held records
- identify potential barriers to the acceptance of patient held record devices
- identify what form of device would be acceptable as a means of carrying electronic health records
- determine what information devices should contain and who should be able to access this

Separate surveys were conducted with 258 members of the public and 260 health professionals. In the public survey, participants had to be over 16 and visitors to the pharmacies used for data collection. These were situated in different socio economic areas of London and the Midlands. Pharmacies provided the opportunity to collect data from participants with a wide range of demographic characteristics and who were concerned with their health at the time of the survey. The age range of the participants was 17-89, with a mean age of 45 years. 43% were male and approximately two thirds were of white European origin. 61% of the participants lived in the Midlands, 39% in London. 26% considered themselves to have a long term health problem and 13% had been given part of their records to look after.

The survey of health professionals included doctors, nurses, ambulance staff, pharmacists, physiotherapists, occupational therapists and others. Collection was carried out at their places of work in different areas of the UK, including the Midlands, South West and Wales. 50% had used a form of patient held record in their practice. 85% of the public and 94% of the health professionals thought that patient held electronic record devices could be helpful for sharing information. Over 60% of all participants stated that they would prefer a device in the form of a smart card.

More detailed comments were provided in focus groups, such as`*Patient records seem to be a good way forward in both giving patients responsibility and ensuring information is passed on*.` Another participant thought patient held records would be useful for anyone who had a serious allergy, saying, `*Well, I`m allergic to penicillin and if I ever had to go into hospital and was unconscious and didn`t have anything with me, they wouldn`t know I was allergic to penicillin and they would probably give me penicillin so I think that`s a good idea if you had a card with all the details on*. ` The findings from earlier studies were confirmed, with the most common concern for the public being that unauthorised people would gain access to the data (64% were worried about this).

94% of the health professionals said that they would find a patient held record device useful, with the most common benefit being `*to overcome communication problems'*. 75% of the health professionals were worried about data security, 80% were concerned that devices might get lost and 74% that the information might not be kept up to date.

The most popular pieces of information that the public participants thought should be recorded were current medication, name, allergies, blood group and long term conditions. The informational requirements of health professionals was not significantly different, including allergies, current medication, name, long term conditions, age, current and previous health problems and next of kin. For both groups, the majority thought that all health professionals should be able to access important pieces of information, but that some form of role based access was necessary to restrict access to highly personal information.

62% of the public and 60% of the health professionals indicated they would prefer a smart card with little preference being shown for other designs (such as computer, key fob or jewellery). 68% of the public indicated that they thought the device should be provided free of charge. Only seven people were willing to pay over £20 for the service.

The present survey replicates the findings of previous research (see above) regarding the type of information which should be included on the device, the form of the device and the level of support for shared medical records. The most common concern for the public related to unauthorised access to the data (64% expressed concern about this). Health professionals were concerned about devices being lost and the currency of information. This is a real concern as a patient held, card based system, requires card owners to take responsibility for the provision of accurate, up to date information and for carrying the card with them at all times. Without such buy in, and widespread adoption, this system will fail as valuable time will be lost searching for cards, reading out of date or inaccurate information, which could have life threatening consequences. Indeed, part of the rationale for having a wallet sized card was that people were familiar with, and used to carrying information in this format.

It is therefore imperative for both members of the public and health professionals to understand and value the potential usefulness of this service and for the device to be easy to use by all demographics regardless of IT and health literacy. For most people, the type of details included on the card will not need changing often. Although this means a reduction in the onus of keeping items up to date, it may mean that they will forget about the card, or not remember to update it when circumstances change.

Advantages of the wallet sized card over other design forms are portability, familiarity and it being inexpensive to produce. A ‘card’ format may also be more acceptable as an input device (e.g. as opposed to a piece of jewellery) as it can be accommodated into existing readers. Additionally the design of the card could convey essential medical information in a visual format – immediately alerting the health professional to emergency conditions.

The survey also revealed that the public had misunderstandings about the operation of the current health service, assuming that all health professionals had access to their records at all times. In the UK, this is not necessarily the case, especially in emergency and out of hours care. It is only relatively recently that a computer based, central system has been introduced. Paper based notes completed by medical professionals still form a major part of the health record system. They may not include detailed information relating to health and well being, which could provide vital information about the overall condition of the patient. For example, it may be useful to record the use of alternative medicines (especially where these might have notable side effects), or patterns of migraine, insomnia or allergic reactions etc.

Accordingly, members of the pubic without long term medical conditions may not understand the need for such a system or how such a system would benefit them. This could be indicative of a narrow conceptualisation of health and wellbeing, a reluctance to participate in a dialogue about health or to understand wider issues around health literacy. Similarly, not all health professionals thought the issue was of relevance to them.

From the survey a set of requirements were established for the software designer. Other users groups (such as the elderly, those with disabilities and communication difficulties) were encouraged to take part in the evaluation of the prototypes.

Stage 2: System Development

System development took place over 18 months, with the release of concepts, semi functional and fully functional prototypes for evaluation. An early prototype is shown in Figure 1. A detailed account of the technical development has been presented in Rybnovik et al (2009). In order to meet the requirements of the users and convenience/ease of use, a traditional smart card was combined with a USB stick as shown in Fig. 2. The USB/ card design combines the advantages of both smart card and USB media types. USB mass storage devices are supported by most computers.

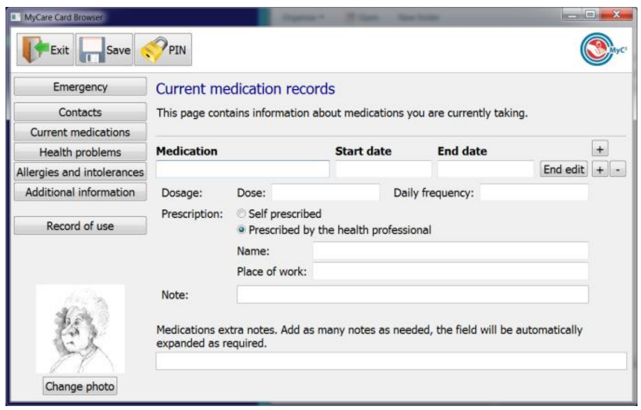

Figure 1: Example of early *MyCare* interface

The *MyCare Card Browser* aimed to be user-friendly, Open Source and community driven, easily extensible, cross-platform, portable, stable, secure and achievable with reasonable development resources and time. To reduce the cost of the development and to minimize dependency on major computer systems manufacturers, Open Source software tools and programmatic libraries were utilized.

Mindful of user concerns about security and unauthorized access, conventional USB mass storage protocol was utilized to store user's medical data, security and authentication data, and the browser software itself on the *MyCare Card*. All data is stored on the card in files, which are available to the operating system services via standard portable disk drivers. The system runs off the card, and information is stored on it. This is different from government initiatives, where data is held centrally and uploaded by health professionals. In the *MyCare* system all data is stored on the card, and entered by the users who type in their pin number to open the system. Medical professionals can access the material on the card by entering their own health number. If the card is lost, the pin number acts as a deterrent to ward against misuse. As the system is standalone, it is not possible to access to user data in other systems.

In further development, for security reasons, additional USB device protocols will be implemented. to protect MyCare Card user medical data and software files from unauthorized access and from accidental corruption. Therefore, files access algorithms implemented in the *MyCare Card Browser* are isolated into interface classes to allow future embedding of security protocols, without affecting other software parts or the overall source code structure.

The welcome page of *MyCare* allows the entering and changing of passwords. The system then comprises a small number of pages in which the user can fill in personal details (including next of kin and GP), allergies, current medication, medical problems and medical history. An access log shows when and what information has been updated and by whom. As the system has been designed to be used by members of the public with limited levels of computer literacy and medical expertise, of central importance was ease of use, learnability and memorability (as the system may not be used regularly).

Stage 3: Evaluation

The evaluation programme aimed to:

- inform the development of the interface and the device
- uncover emergent requirements
- include groups which had not been consulted in the initial survey

A mixed method approach was adopted to the evaluation. Participants were required to verbalise as they used the interface (with breakdown analysis (Woodcock and Scrivener, 2003) being used to focus on usability issues). This was followed by semi-structured interviews and a SUMI questionnaire (Kirakowski, 2007, 2008). Transcripts were thematically analysed (Aronson, 1994). The three main stages included;

1. Evaluation of the early device designs using focus groups. Taking an inclusive design approach, focus groups included participants who had communication difficulties due to disability and language barriers, who would have had difficulties completing a questionnaire or taking part in a walkthrough evaluation. Separate focus groups were conducted with older adults, people with disabilities, people who did not speak English, and people who were not confident about using computers. Several of the participants who had disabilities would have to rely on others to help them to use the system, or in the case of the older adults and those who were not confident about using computers, would require training and assistance to do so. The focus groups provided an opportunity to discuss how such assistance might be provided.

2. Evaluation of early versions of the software commenced with a walkthrough method with five usability experts. The feedback was used to amend the prototype which was then evaluated with 20 members of the public and 10 health professionals

3. A month long user trial of a working prototype in a real-life environment with members of the public. The information entered on to the devices was assessed by five health professionals in order to gauge its potential usefulness.

The initial evaluation occurred on a system with limited functionality (and no help system). Although the system was rated as average on all SUMI scales, participants felt that it was a system they would use if available. Usability issues included:

- Lack of on-line help and support for conducting tasks
- Lack of system feedback (especially on save)
- Use of inappropriate or unfamiliar computer and health terminology
- Poor structure to the forms
- Failure to automatically update information on the summary form
- Inappropriate task formulation for entering medications and health problems.
- The page allowing restriction of access to certain groups of health professionals was poorly received by both health professionals and end users. End users could not understand how to do this; health professionals were worried that they might be denied access to important information. Following discussion this was dropped. By keeping a card, the user acknowledges

that its contents should be accessible to all medical professionals (with an authorized pin number)

An emergent need from the later usability sessions was for an additional form where other information could be entered – almost like a health diary. In the final system this was a free form text field

For the final stage evaluation, 49 *MyCare Card* units were tested in a real life trial. The front of the final wallet sized card is shown in Figure 2 below. This contains spaces for the patient's name, photograph and NHS number. The hole in the top left of the card can be used to attach the card to a key fob or chain. The series of circles along the bottom can be used to visually indicate important medical conditions.

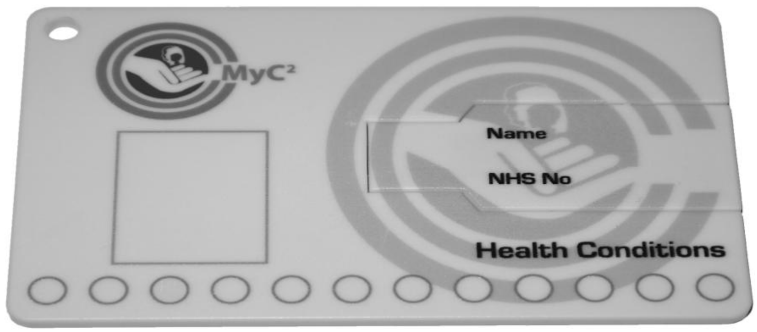

Figure 2: The final version of the *MyCare card*, with integrated USB

Participants were trained to use the cards, asked to input health related information (which could be their own or follow a fictional scenario), and to carry the card for one month, updating the information as necessary e.g. when they went to the doctor, or took medication. They were asked to keep a record of any problems they experienced and discuss these in an interview at the end of the trial.

Not all the participants were able to use their device the whole time. Difficulties experienced are considered to be representative of those that real users would experience, including forgetting the Pin number, detachment of USB stick, inability to easily insert the USB in the computers, preferred computer suddenly failing to recognise the device, loss of device. Five people declined to take part in the trial as they were not PC users.

The age range of the participants was 18 to 94, with a mean age of 41 years. The sample included 57% women. 29% were students, 39% had professional jobs, 8% had manual jobs, 18% were retired and 6% were carers. 55% of the participants considered themselves to have a long term health problem. 16% were parents who used a card on behalf of their young child. 18% were classified as having low computer ability, 22% had medium ability and 59% a high ability. 24% stated that English was not their first language.

At the end of the trial the majority of the participants thought that the system had been useful. Those who had long term health problems were more likely to state that they would use such a system in the future. Suggestions were made for additional features and the improvement of both hardware and software.

In the second stage of the trial, five health professionals reviewed the information contained on a sample of the cards and assessed its potential usefulness. They also made recommendations on design and usability and where the system could add value to current services e.g. by showing where medicines may adversely interact with each other or if the interface could warn the patient that he might be allergic to the medication.

Although they all felt that the card provided a useful guide to information and would be particularly helpful where no other patient information was available, they all expressed concern over the accuracy of the information. One nurse said, `*The more information you have on a patient, the better care you can give.*' All the professionals stated that they would check the information with other sources if this was possible. As one pointed out, `*Patients don`t know what is relevant or important. People may not want information known and withhold information*. `

Concerns were also expressed with regard to the amount of time it might take to help patients to maintain their records. Two professionals did not think they would have time to do this. As one of them said, `*I can`t see how you could sit down with the patient to see if they have added it correctly.*` Another stated '*I don't think it would work in hospital*.' Additionally if professionals did not receive any direct benefit for helping the patients input information, they might not be persuaded to do so. One of them was also concerned that the necessary equipment, training and organisational support might not be available.

This final trial was seen as providing valid information on how the system would be used in the real world. Additionally it generated usability and design problems with both the hardware and software, and new design requirements and features. This part of the evaluation revealed a number of barriers to use, which although in some cases had been anticipated, had not been regarded as insurmountable.

Stage 5: Public Dissemination

Dissemination to the general public was carried out though a small roadshow featuring banners, leaflets and a software demonstration, as a means of attracting people in libraries and shopping centres in various UK cities (Milton Keynes, Preston, Coventry, Redditch, Nottingham and Bristol). Questions used to stimulate discussion included:

- Do you think you would use the *Mycare* system?
- What problems would you have with this?
- What sort of things would stop you or other people using the system?
- Would you be interested in recording your health details on a card, even if you were well?
- What sort of information would you include?
- How do you feel about being responsible for providing health information?
- Do you think the public and health professionals should work together as partners to manage health problems?
- Do you think that you know enough about your health to be able to record useful information?

Informal discussions enabled a range of views to be expressed without the restrictions of a formal interview or focus group, although people were encouraged to contribute their opinions by filling in comment forms. Results were analysed thematically. 122 people participated, their comments confirming many of the prior findings, for example, those with long term medical conditions, or who had relatives with health problems were more likely to see the value of the system.

Problems with current NHS systems included the failure of information to be relayed between medical professionals and failures to be able to remember medical details when needed. One participant with several health problems stated that he was more worried that people would not know about his health problems when they were treating him than about the risk of a breach of confidentiality. Another participant stated, `*I have experience with consultants. You see many, never the same one. And they look on the computer but the information hasn`t been uploaded yet, and it is frustrating. With this, it can be all there, wherever you go, whoever you see. Everything is kept together'*

A community support officer thought, `*it would be good for the police if somebody is collapsed so we could get their name and know about any health conditions*.` A police officer confirmed that she often had to find out information about people who were unable to provide it themselves, such as those who were intoxicated or had been involved in accidents. In these circumstances she would look in their pockets. If she could find information that could be read from a card, detailing the person`s identity and their existing health conditions, that would be very useful.

Reasons for not wanting to use the system included not being able to use a computer and participants not seeing the benefits of the system for them. As one of them said; `*If you had health problems you would probably be more inclined to carry it. I`m healthy so I don`t know if I would bother.* `Others had a general, deeply-held mistrust of electronic data systems. As one said ` *I would not trust any kind of electronic record and I intend to get out of the government database. There is no way of making this kind of thing properly secure'*.

Most participants were ready to take responsibility for their health information. As one o said, `*this is good because you can put on the information that you want; it puts patients in control*.` Another said she would be more confident about the information being accurate if she had provided it, saying `*It would be good to get people to put the information in; there would be fewer mistakes. You could always get someone to check it.* ` Another participant said that she liked the *MyCare* system because, `*it would change the power balance with doctors*.` She went on to explain that she thought it was wrong that doctors were considered to be all powerful and patients expected to accept their views. However concerns were expressed regarding whether the system would provide information in a usable form, and whether the level of cooperation required between the public and health professionals to make *MyCare* work was possible.

Discussion

The study has shown the potential of an electronic patient held health system to improve communication between the public and health professionals. A user centred iterative approach ensured that the design was based on user feedback. However, for any new system to be accepted, it must work with those already in use. The integration and interoperability with central health services was beyond the scope of this project. However, uptake of an 'independently developed' system will depend on the development of appropriate infrastructure, co-operation from from the central system and education and training of users. Adoption of a card system would require the public to take on new responsibilities and knowledge and health professionals to support them and adopt new working practices. A full scale trial with buy in of the NHS and associated healthcare services, support staff, and members of the public, would identify how *MyCare* and other systems could be used in conjunction with existing and future health care information and record systems.

In conclusion, one of the main aims of the project was to assess whether the UK public and medical profession were ready to accept and use a patient held system. Although there is support for sharing medical information, attitudes expressed by participants revealed mistrust of government initiatives towards centrally kept records and an unwillingness by healthy individuals to appreciate the need to keep their own personal records Health professionals were concerned about the currency of the information, and its accuracy as revealed by their unwillingness to accept the accuracy of information entered by their patients without it being verified by other sources.

Acknowledgements

The research was supported by an Engineering and Physical Sciences Research Council grant number EP/F00323411 28/02/2007. The survey would not have been possible without the co-operation of Lloydspharmacy, West Midlands Ambulance Service, Cardiff, Warwickshire, North Bristol and Vale NHS Trusts and , University Hospitals Coventry whose staff participated in the research. The views expressed in this paper are those of the authors.

Victor Rybynok received a higher education diploma in Computer Systems and Networks Engineering from Moscow Institute of Electronic Technology in 2001,an MSc in Medical Electronics & Physics from Queen Mary, University of London in 2003. In 2009, he received a PhD degree in Biomedical Engineering from City University London. His current work in biomedical technology involves the development of non-invasive methods for the blood chemical composition analysis using diffusion spectroscopy techniques.

Pupil Participation in School Design

Andree Woodcock, Coventry University, United Kingdom, e-mail A.Woodcock@coventry.ac.uk

Michelle Newman, Coventry University, United Kingdom

Abstract

Over the last decade, UK policy interventions relating to the (re)design of schools have stressed the importance of pupil participation in programmes such as Building Schools for the Future, Academy Schools, and Primary Capital Funding. A two year project was conducted to explore the possibilities for, and present state of, pupil involvement in classroom (re)design and design decision-making. Through in-depth qualitative data drawn from pupils, school staff, Local Authority officers and other stakeholders, the relationships and tensions between the ideals of participatory design as expressed in national policy statements and the ways in which such participation is happening in practice was investigated.

Keywords

Participatory design, schools, children, ergonomics.

The design of school environments affects the activities and outcomes of teaching and learning. School buildings should make a positive contribution to the academic wellbeing of students, and prmote social interaction, a sense of community and inclusiveness. The Commission for Architecture and the Built Environment stated "*…we know that good design provides a host of benefits. The best designed schools encourage children to learn.*" (DCMS, 2000).

Price Waterhouse Cooper (2001), found a positive relationship between capital and performance and more specifically between the physical school environment and pupil performance, stating that "*The general attitudes, behaviour and relationships amongst pupils and staff are more conducive to learning in those schools which have had significant capital investment*".

Whilst acknowledging the importance of school environmental design on those who spend a large proportion of their time there, UK (and worldwide) legislation has also recognised the need for children to be involved in the design of the spaces they inhabit. UK policy shows (i) greater recognition of the diversity and distinctiveness of children and young people's needs; (ii) a growing imperative for children and young people's participation in decision-making and practices regarding their everyday lives and contexts.

Three major lines of capital investment for school buildings have been provided (i) academy schools; (ii) Building Schools for the Future (BSF); (iii) the Primary Capital Programme (PCP). User involvement forms a cornerstone of these initiatives, as evidenced in the following quote.

> *"Putting the user experience at the heart of all we do is not the same as saying we simply respond to user demand. Our and our partners' role is to prioritise, ensuring resources are used efficiently and effectively in the wider public interest. We need also to be aware that service users have very different capacities to shape services. …..The key lesson for taking forward the Five Year Strategy is this: failing to understand users in the way we design and deliver services means we are less likely to deliver aggregate improvements in outcomes across the system because we are less likely to be meeting the needs of individual service users"*(DfES, 2006, p.36*).*

In addition to the statutory requirements, pupil participation is fundamental to the UK Government's vision for all schools post-*Every Child Matters*:

> "*There isn't a design blueprint for a school of the future: a variety of models will emerge. The main design challenge facing LEAs and schools is to balance the needs of different users, creating inspiring buildings with functional spaces that are appropriate for new educational developments and new technologies but adaptable enough to cater for the changing needs of the future"......... "[The user is] a key player in the success of a building project. It is very important that right from the*

beginning of a school building project there is proper consultation with the staff and pupils of the school and the wider community. The school and its community must decide what they need and want both for the immediate and longer term future… All potential users in the community should be consulted in order to assess local and individual needs… This approach will help to encourage greater use of the building, develop trust between all parties and add to the feeling of community and ownership… Consultation and feedback should continue through the construction period...... Where work is taking place at an existing school, finding ways of linking the project to the curriculum can benefit pupils and encourage a positive attitude to the work taking place" (DfES/SBDU, 2002, p.63).

Project Overview

This research appraised the extent to which the BSF programme delivered its commitment to pupil participation. The programme asserts that pupils and staff have an active role in the development of the design brief, down to the level of what is needed in each room (DfES, 2004a, p.6). However the guidance relating to the PCP suggests the approach to participation may be more tokenistic than implied in the policy documents.

The following sections provide an overview of the results from interviews with representatives of Local Authorities, observations and interviews in 11 schools at different stages of the BSF programme. The results show tension between the ideals expressed in government policy and the reality of participation; both optimism and skepticism towards participation; the importance of the wider school ethos; and the need for better support for schools undertaking pupil participation.

A qualitative approach was undertaken to understanding the situation in schools, with ethnographic observations, attendance of design consultations or design events and interviews with key stakeholders including Local Education Authorities, pupils, architects and teachers.

Results

Examples of Perceived Benefits of Pupil Participation

Interviews with teachers and architects indicated that those engaged in the process saw the benefits of successful participation as relating to:

1. Improvements to the spaces and day-to-day running of school buildings.

   "*.......pupils come up with really perceptive ideas, that can genuinely improve a space. And a lot of things that come from the pupils are mostly cost neutral. They are not asking for the earth – they are very realistic in what they want"* (Architect)

2. School buildings with local 'character'.

   "Getting the pupils involved was crucial – they're the ones who've really helped us to bring a local 'stamp' to the project" (Headteacher)

3. Greater user satisfaction with the school environment.

   "it is particularly good for pupils to be involved… it gives pupils ownership – you know it makes them feel good because it's their school, their role in that kind of decision-making… It makes them feel more at home in their school" (Teacher)

4. Fostering a culture of trust and collaboration.

   "[This] has been a kind of…. bonding exercise really. It does encourage everybody to be enthusiastic about every aspect of a school… It has brought people together" (Headteacher)

5. Reduced vandalism and 'anti-social behaviour'.

   "Giving the pupils something new, something they have a stake in – it's treating them with respect. It's saying 'we trust you'. Our pupils have responded magnificently. They really take pride in it" (Headteacher)

   "Basically – there's no graffiti in the corridors any more!" (Teacher)

6. Opportunities for teaching and learning.

"We've started to link [the school redevelopment project] into the curriculum in all sorts of ways – numeracy, design… learning about the history of the building and looking at old photos and maps" (Teacher)

7 Enhanced design literacy.

"[Involving pupils in school design] gives them a bit of an insight into different parts of the process – design, budgeting, strategic decisions… It expands their knowledge and hopefully helps them to understand things in a different way" (Architect)

8 Raising learners' self-esteem.

"The input [into the development project] made him [son] feel important. He'd come back and tell me what they were talking about in school: they had discussions… I really noticed a difference" (Parent)

' [a group of disaffected students] realised perhaps for the first time that they could have a voice and they could come up with ideas and that people could listen to them' (Deputy head teacher)

9.Familiarising pupils with new school environments.

"You see a psychological impact of consultation as you start to involve children: it has engendered a sense of ownership, and there was no shock for pupils of moving into new environment, because they already knew a lot about the new building, were prepared to move" (Headteacher)

These comments accord with the vision expressed in government documents. However, the following sections reveal a different impression of the practice of pupil participation.

Interviews with Local Education Authorities

15 semi-structured telephone interviews with conducted with LEA officers responsible for school (re)building and (re)design in randomly sampled geographical locations. These representatives held posts directly concerned with school (re)building programmes – such as Head of Planning and Building for Children's Services, BSF/Private Finance Initiative (PFI) Project Manager, School Site Development Manager. These job titles emphasised the connection between children and education, on the one hand, and asset development and building on the other. Interviewees worked on the (re)building of schools cooperating closely with the school's management team, architects and various consultants.

They were responsible for the development of the project brief and oversaw projects to their completion. Thus, these professionals could comment on the ideal of pupil participation as articulated in policy documents and its operationalisation. From a qualitative thematic analysis of the 15 interviews, four major trends were identified (den Besten et al, 2008).

(1) Pupil participation was disappointing.
LEA representatives were optimistic about the benefits and rationale for engaging pupils yet disappointed with the results of participation. They had more modest and realistic aspirations contrasting with the lofty ideas expressed in policy documents. Examples of comments included:

Pupil participation is hugely desirable and we are striving to achieve it. But so far, the level of influence pupils have had on the final design is probably quite limited.

We realise that both pupils' and teachers' participation is desirable – in general, but it has not been possible to a big extent yet.

Pupil participation is desirable but I'm afraid we have only managed it to a very limited level so far.

(2) *Pupil participation was multiply foreclosed by the complexity of the programmes.* The principal barriers to participation included tight financial budgets and timescales; the complexity of the

programme, funding and stakeholders which meant that participation became lost; lack of clarity and guidelines about how to engage pupils;lack of trained facilitators; large number of pupils in the school who could be involved.

Examples of comments include:

> *The overall process is incredibly complex and very competitive. If pupils were involved to a large extent, the process could have taken a significant amount of their curriculum time. There are a whole lot of criteria of how a school building should be, including guidance from DfES concerning which sort of space should be here and there, what areas of children's outside play should be like, etc.*
>
> *We have planned and built mostly nurseries and early year schools, where children are too young to contribute to the process.*
>
> *Children will not see the benefits as they will have moved on.*
>
> *Students move on, so continuous involvement of one group is difficult.*
>
> *If you talk with one group of students they'll come up with one thing; if you talk to another group of students the next year – they could come up with something completely different.*

LEAs, schools and architects showed a clear willingness to engage children in school (re)design, yet the barriers inherent in the multistakeholder, multi stage, protracted school (re)design process inhibited meaningful engagement with user representatives.

(3) Pupil participation was 'modest'.

Interviewees found that pupils' abilities and interests compromised their participation. This led to negative comments. Suggested improvements were regarded as banal, small-scale, predictable and superficial typically regarding social areas, toilets, and paint colours – but little else. Pupils were viewed as showing little creativity in their recommendations or understanding of design techniques, processes and legislature. This could have been overcome by reframing and extending the questions and information asked of pupils. In order to become more creative, pupils required more guidance, direction and knowledge of constraints. Pilot projects have demonstrated that children can understand complex considerations about finance, engineering, design and planning, and that their learning is neither time consuming nor resource-sapping.

Example of comments included

> *In the issues that came up, there was no real surprise. For example, pupils raised the usual issues of uncomfortable environment: that it is cold here or there….; discussed social areas and toilets. The teachers knew those issues already*
>
> *Pupils contribute mostly to their spaces, such as dining spaces, toilet spaces, indoor and outdoor social spaces: for example, playgrounds and common rooms.*
>
> *In one school, the head teacher got pupils to design toilets – it's very important*

(4) Pupil participation was contingent and local.

Interviewees highlighted a number of locally based issues which presented opportunities and challenges for participation, such as the diversity of schools, school attitudes towards pupil participation, the need to manage expectations. Many LEAs used 'advocacy' (by teachers or other professionals) to replace participation where the latter was deemed inappropriate or impossible.

Examples of comments

It [role of pupil participation] varies from project to project and depends on people involved. In many cases, pupils were consulted and notes of their needs made, but it's a bit of hit-and miss probably, it is not a standardised process.

Pupils fed into the vision side of things and that has altered some decisions.

To summarise, LEA respondents identified a number of barriers to participation which stemmed from two sources. Firstly, the financial, organisational and legal processes inherent to school (re)design. Secondly, the positioning of pupils – and their participation – within those processes, both at national and local levels.

From School Observations

The team spent extended periods in each school, talking to staff and pupils, observing the design and use of facilities and attending design meetings. Results supported interviews conducted with the LEAs concerning the individual nature and ethos of the schools, the varied nature of participation, the complexity and protracted nature of build programmes which means that consultation with a wide variety of end user pupils is unlikely.

Taking as an example the experience of one primary school, Newman and Thomas (2008) related found the following typical strategies used to engage students:

- consultation throughout the visioning process;
- a 'Design your school day' where gifted and talented students led other students in designing and making a model of a chosen part of the new school. This method was also adopted by a secondary school which involved a group of disaffected students, on the verge of exclusion, who produced a design of a bridge they wished to see incorporated into the new school design. There was a clear intention to be as inclusive as possible. An assistant head teacher commented that this group ' *realised perhaps for the first time that they could have a voice and they could come up with ideas and that people could listen to them.*'
- PSHE (Personal, Social, Health and Education) lessons used for discussion about student aspirations for the new build;
- the school council acting as a conduit for student voice;
- questionnaires sent home to encourage family discussion about the school in an attempt to involve the wider community.

Studying these events and similar activities has shown that direct or indirect participation is occurring using different methods such as questionnaires, comment boxes, involving different groups of pupils (such as vertical groups, workshops, student councils) and deals with different design issues – from concept design through to the design of specific spaces, or pieces of equipment (such as window locks). The use of these initiatives is felt to add local character, such as the use of natural occurring materials and local design forms. However the extent of participation is determined by the enthusiasm and knowledge of the staff and the school ethos. Unfortunately, the organisation of consultation and participatory exercises was mostly ill structured, with little continuity observed between consecutive meetings

Despite teachers and school management wishing to use the opportunities afforded by BSF to provide a different approach to curriculum delivery, students found it difficult to engage in questions about how they learn best during consultation. Instead they focussed on more tangible, social aspects of the school, such as dining rooms and common rooms. One head teacher said that this was frustrating but not surprising, as it was difficult even for teachers to imagine what education would be like in the future.

Despite the 'design your school days' having positive outcomes, at the two secondary schools involved , students received no design parameters, for example financial constraints or site information. This often led to the creation of inappropriate designs. For example one group spent the day designing a swimming pool, only to be told at the end that a pool would not be funded. This led to cynicism on the part of many students.

Special needs schools visited other schools to see which aspects their children liked/disliked. The school council visited recently built special needs schools, where adults took pictures of things the children appeared to enjoy. The images were based on adult perceptions of children's enjoyment. Here advocacy was used in preference to participation where staff stressed the need to design for children, using their expertise to interpret the needs of pupils who could not verbally express themselves. In some mainstream secondary schools teachers believed that they knew children's requirements better than the children themselves.

Staff and architects frequently cited 'ownership' as a key benefit to children's participation in school design. Involving children in the process was believed to increase the sense of pride in the school building. As vandalism was a problem in several of the schools it was hoped that this could be reduced by involving pupils in decision making. For example one teacher said

> *'It makes them feel that they've had a part of it, an ownership of it….. we're constantly saying to them this is where you belong, this is your school, we want you here. And I think to be part of it, for any child really, they feel they have some ownership, a stake in it and want to look after it better and maintain it better. I get the impression at the moment that they have no respect for the environment that they're in'*

The idea that participation would foster a sense of belonging was an important perceived benefit of participation, although for the schools in the early stages of BSF it was too soon to say whether this would be achieved . Related to this is the belief that inclusion in design activities may also foster a sense of ownership and involvement in the wider community especially when schools are in deprived areas and are required to act as a community resource. For example one school attempted to involve parents and the wider community by sending out questionnaires to families of students asking how their community needs could be fulfilled in the new school building.

Both architects and teachers felt that participation could provide a valuable insight into young people's perspectives on their experience of school and their needs for new builds. A deputy head teacher explained

> '*I think the advantages are as you get older, we don't see, we're not as familiar with what they find, what young people find, attractive and what their needs are'*

This recognises that children are experts regarding their own experiences and needs, and could offer innovative solutions to issues of particular significance to them. For example, an architect related an occasion where a primary school pupil had approached his head teacher with an idea for a design for a covered area in the playground where children who did not want to be involved in boisterous activities could play quietly. He explained that this solved the problem experienced by many children who felt marginalized when the majority of the playground was given over to football. The boy's experience had led him to suggest a solution that was adopted by the school.

Teachers and architects felt that the involvement of young people in the design process would raise awareness of design issues such as empathy. This was demonstrated at one school which was to be rebuilt as a broad spectrum school, accommodating children who had previously attended a special needs school. Children who participated in a 'design your school' day were keen to provide an inclusive environment, meeting the needs of all users. They attempted to address the issues that children with particular physical impairments would encounter in their daily activities. For example having the school on one level to ensure access for everyone, or to include lifts for wheelchair users.

Lastly, the involvement of young people was believed to foster a sense of achievement which may otherwise be unattainable. This was particularly important for children who do not achieve in more traditional ways. As one architect said

> *'The non-academic kids who will never achieve academically but may achieve lots of other good things, that's where greater engagement should be fostered'*

Perceived Drawbacks

However participation was not without its drawbacks. Many staff and architects were concerned about the raising of expectations and that pupils would be disappointed if their inputs were not realised in the final build. This was exacerbated if only selected children were involved or there was no systematic was of including the student voice. This concern was shared by the management team and pupils at two schools involved in 'design a school' day. Despite the success of the day in terms of inclusion and the production of high quality models, there was a danger that this particular mechanism may promise more than it can deliver as students become immersed in producing imaginative, creative and ingenious ideas that are ultimately undeliverable. One student commented:

> *'I didn't see the point when they said to choose ideas and contribute to what you would like in the school…I thought because we are just students at the end of the day and I don't think that they'll actually take our ideas very seriously.'*

He went on to say that the designs would have benefited from constraints to allow for more realistic designs

> *'It would be nice for someone to actually to say "Oh yeah, we've got this budget, we'd really like some realistic ideas that could, you know, we could actually use" instead of people saying "We'll put your ideas down, we want to know", it's a big vague, you don't actually have things to say "Oh, we could get this". They could get to say one idea and it would completely unrealistic, you haven't got enough money to do this.'*

The young people expressed a quite sophisticated understanding of constraints. For example,

> *'they say they're asking for ideas and saying that our ideas will be taken in to account but then if we've been promised a certain amount of something…and then they've kind of let you down saying that you're not going to get it any more because they haven't got enough money to do it or because they haven't got the time or because they don't find that it is necessary or something'*

There is a risk that if young people are asked to produce plans that are later rejected because they are impractical, unworkable, and too expensive or do not fit in with a broader vision, this will lead to further disengagement from the process and the educational system.

The view was expressed that pupils' experience is too limited to enable them to envisage change to the delivery of education. There was little evidence of pupils contributing to discussions about the curriculum or learning styles, as they may not have experienced working and studying in innovative ways. As one head teacher indicated

> *'We've done some work but in my opinion that work is fairly limited, because the students don't know what they don't know. So they're victims of their own experiences and environment.'*

Further problems in meaningful participation may be caused by the time scale involved in building a school, because many children involved in the design process will have left it by the time it is completed.

In many of the interviews, young people exhibited a degree of cynicism about the design process, expressing dismay at what they see as empty promises. This was particularly so in one school in an affluent area where staff believed the school to be a low funding priority compared to more deprived schools. Students and staff expressed the opinion that there was little point in becoming involved, because they believed funding would be withdrawn before the school was built. One example was cited by the school's business manager

> *'Everything we try and bid for we don't get because we're in the wrong area. I spent nearly 2 years putting a lottery bid together to try and improve our school facilities and the reason we failed was because we weren't a priority. Despite the fact that the particular facilities we were looking at, there is none in this area…They still turned us down'*

Such cynicism was reflected in responses from students. One sixth former was asked how much she knew about the proposed rebuild, she commented

> *'I knew they were thinking about rebuilding it... I wasn't really sure and I was like "Yeah, whatever". But you hear certain things, I was in Year 9 and they said that everyone's going to get their own laptop, they were going to get this they were going to get that. But nothing actually ever happened so you just take it on and think whatever.'*

This attitude was not found in other schools, indicating the contingent nature of participation and the extent to which it is dependent on the practices and ethos of each individual school.

Conclusions

The research indicates that schools are not being provided with sufficient guidance or methods to enable pupil (or teacher) participation in the design of new schools. This is problematic given that involvement in the creation of large-scale community projects is believed to increase feelings of ownership and co-operation, the level of investment being placed in the building programme and the belief that this will improve the educational system.

Through observations of typical (as opposed to flagship or academy) schools and interviews with LEAs, we have found that the protracted nature and complexity of the design process severely limits the possibilities for pupil participation. Participation is further hampered through the lack of time and expertise in involving pupils in design on various levels, a lack of trained facilitators and absence of a good-practice guide. Although the type of participation should not be prescribed, guidance should be provided for those new to the process and participatory discussions should go beyond addressing superficial and marginal areas, without unnecessarily raising expectations. Young people can understand budgetary and time constraints, and whilst some of their ideas may be aspirational and unrealistic, they can work with design constraints.

The results show that in many cases, in 'ordinary' schools, the ideal of pupil participation may be foreclosed by contingencies, budgets, issues, debates, personalities and events at grassroots level. Not only are pupils not fully involved in the design and decision making processes, teachers can be excluded as well. Pupil participation, which offers opportunities for the design of more pupil-oriented schools and curricular, as well as real opportunities for first hand experiences in design, is not being supported well enough centrally, with schools and LEAs being left to find out which methods are most appropriate, with little dissemination of best practice.

We conclude that policy-making regarding participatory design/ergonomics should be better grounded in the complex and diverse realities of the (re)design of school environments in practice. The experiences of schools already engaged on the BSF process which have developed approaches to engage their students should be collated to provide a set of methods that could be used by the next wave of schools involved in the programme. Additionally greater attention should be given to the participation of teachers and the types of educational practices the new schools will support.

Outputs

Therefore, the outcome of the project was a set of guidelines to support the first stages of this activity sent to over 3000 schools, LEAs and architects. These remain available electronically at: http://www.coventry.ac.uk/researchnet/d/699. These were written with target end users in mind (including children), providing an overview of the benefits of participation, plus examples of methods which could be used to participation and examples of pitfalls to avoid. A one-day multistakeholder conference was held bringing together teachers, LEAs, architects and others interested in the process. Results were disseminated to participating schools through a one day workshop focusing on design literacy

Acknowledgements

The research was supported by AHRC grant number AH/E507026/1 for the project ‘Realising participatory design with children and young people: A case-study of design and refurbishment in schools’. The authors would like to thank the other participants on the project, Peter Kraftl, Olda den Besten, Matthew Kinross, and Peter Adey.

Cultural Appropriation in Design and 'The Cipher'

Burcu Yancatarol Yagiz, Kadir Has University, Istanbul, burcu.yancatarol@khas.edu.tr

Abstract

Dynamics of globalization redefine objects as agents of cultural exchange in various everyday contexts. Design activity constitutes a significant channel of cultural exchange because it presents objects to a system of social interactions that does not require geographical proximity of cultures. Design's conceiving a cultural element in a product, thus starting the process of commoditization involves practices of cultural appropriation. Appropriation of cultural elements from their local contexts to be designed or re-designed translates the element's cultural value into an exchange value that presents '*negotiated* decodings' (Rogers, 2006) of the 'different other'. Through design channels, '*the cipher'* (Ono and Buescher, 2001), '*a figure through which various commodities with multiple exchange values are marketed*', is produced as '*a social concept that circulates like a commodity'* (Ono and Buescher, 2001, p. 26). *'The cipher'* sets cultural stereotypes by encoding selected characteristics of a culture in a series of products and limits the (articulation) capabilities of design agency down to commodities floating in the market without any original cultural content.

Design's interpretation of culture needs a critical reflection on the processes of commoditization and practices of cultural appropriation. Through this critical reflection, design's capabilities to propose new grounds for cultural exchange as an ongoing process of growth can be explored. This paper discusses cultural appropriation as a key strategy in design's interpretation of culture in products and recognizes cultural appropriation as a practice for creating *'the cipher'* through cultural encoding and decoding. The research project named 'A Kaffiyal Project' presented in this paper focuses on the transformation of the *kaffiyeh* (the Middle Eastern headdress) from a traditional element of cultural identity to a fashion statement in different parts of the world. By using strategies of creating '*the cipher'*, the research explores and documents ways of decoding cultural stereotypes through design processes.

Keywords

cultural appropriation; 'the cipher'; focus group; kaffiyeh; stereotype; participatory design.

'Cultural appropriation, defined broadly as the use of a culture's symbols, artifacts, genres, rituals, or technologies by members of another culture, is inescapable when cultures come into contact, including virtual or representational contact' (Rogers, 2006). Any type of cultural produce (whether tangible or intangible) is subject to cultural appropriation. As a social practice cultural appropriation operates in different spheres of exchange and power structures in the social realm, and therefore is a complex phenomenon. Even though the concept of cultural appropriation has been discussed in law, media and cultural studies, it is an undermined yet significant issue in design studies. Design naturally offers a site of mediation for practices of cultural appropriation by constructing exchange. Design's role in such mediation is critical because the form of exchange determines how cultures interact and have an understanding of each other. Design offers strategies to encipher and distribute ''selected'' aspects of a particular culture in the form of commodities that have some sort of exchange value in global market. Therefore, design's involvement in the appropriation and commoditization of cultures has the ability to create *'the cipher a figure through which various commodities with multiple exchange values are marketed'* (Ono and Buescher, 2001, p. 26).

Recognizing the complex nature of cultural appropriation, Ziff and Rao (1997) express several concerns about appropriation's potential impacts in various domains. The first concern focuses on appropriation's role in causing cultural degradation by harming the integrity of the value system of a culture. Misrepresentation of a culture through appropriation can have *'corrosive effects on the integrity of the exploited culture'* as '*the appropriative conduct can erroneously depict the heritage from which is drawn'* (Riff and Zao, 1997, p. 9). Adolf Hitler's appropriation of the Swastika, symbol of good fortune and luck, demonstrates an extreme case of cultural transformation that determined the destiny of this prehistoric symbol. By claiming authority on this cultural element, Hitler's appropriation positioned the symbol at the heart of the Nazi imagery and changed the way the symbol is perceived forever. '*Before its appropriation by Nazidom, the swastika was used innocently as a design motif on everything from architecture to consumables, signifying good fortune and well being'* (Heller, 2000, p. 81) The appropriator's intention and way of displaying it publicly through propaganda and reproduction drained the cultural values attached to the symbol. Ultimately, Hitler and the swastika became interchangeable in the public eye. (Heller, 2000, p. 12)

Figure 1. Swastika as an appropriated cultural element

Another concern raised by Ziff and Rao is *'the impact of appropriation on the cultural object itself'* (Ziff and Rao, 1997, p. 8). When material elements of a certain culture such as cultural goods, symbols, and traditional and sacred objects are either physically or conceptually removed from their local contexts, their original meanings are altered. Through this alteration, the cultural values attached to the elements are distorted. Commoditization constitutes a major way of de-contextualizing a cultural symbol and distorting its meaning. Basing his example on this concern, Rogers (1996) points at the distortion of Native spiritual traditions by New Age producers and consumers. A third critique identifies the crucial role that the appropriating party's intentions play in the transformation of the cultural element. Related also to commoditization, the concern is that *'those engaged in misappropriation might be occupying the commercial field'* (Ziff and Rao, 1997, p. 14) and exploiting intellectual property of a culture for financial gain. When financial gain is prioritized either by an outsider appropriator or by a member of the particular culture, the element becomes a commodity to be reproduced and consumed until it is replaced by other elements. Commoditization in this sense can 'fail to recognize sovereign claims' (Ziff and Rao, 1997, p. 17) of the particular culture over its cultural property. Generally, the appropriating party ignores the particular culture's claims of authority because power structures and available resources enable them to set the rules. Cultural appropriation's capacity to exploit and misrepresent constitutes the subtext that is common to all the concerns raised. When an appropriating party is not willing to understand the social and cultural function of a cultural element in its native context, the relationship between the original value of the cultural element and its value created by the appropriator lacks meaningful links.

Elaborating on the concerns expressed above, it can be said that processes of commoditization appear to be instrumental for cultural appropriation because commoditization necessitates the removal of a cultural element from its local context. As a consequence of this removal, cultural value of the element is abstracted into an exchange value that inescapably takes on different meanings and functions within the global exchange system (Rogers, 1996, p. 488). While the gap between the element's cultural value and its exchange value defined by the appropriator grows larger, *'the commodity becomes a fetish, representation of values with no intrinsic relation to the object's use value, production or circulation*' (Rogers, 1996, p. 488).

When design practice approaches local cultures for the search for originality and presents a cultural element to the systems of exchange through products, it takes over a critical role in the conceptual distortion of the cultural element and the values attached to it. *'When culture is treated as a resource to be mined and shipped home for consumption'* (Rogers, 1996, p. 486) cultural appropriation appears to be a tool for commoditization of cultural elements. By deciding what to appropriate and interpret in a product, the designer claims authority to define which cultural elements deserve to be exchanged and even to stereotype a specific culture in a product. Such an approach *'presents a simplified view of cultural agency, which tends to be reduced to a set of a priori characteristics'* (Kluyukanov, 2008, p. 212*)* that are encoded and negotiated in products to create exchange value in the global market.

Even though cultural appropriation by design poses threats to the well-being of cultural elements and the cultures they represent, its potential to be used to create meaningful cultural exchange cannot be overlooked. The contribution of cultural appropriation to the evolution of world cultures is strongly related to the way in which the cultural, conceptual and material links are constructed. These links open channels for cultural interaction. Therefore, any cultural interaction that is devoid of any over arching cultural contexts might result in the loss of a set of values and also historical references that would contribute to the collective cultural memory. Even though cultural appropriation can sometimes be a harming activity, it can also be used as a counter-strategy to plot meaningful cultural exchange. Despite its commercial agenda, design practice has the potential to re-direct the commoditization processes of cultural elements and to ''encipher'' values that can integrate to the everyday practices of different cultures. *'Moving beyond an oversimplified view of culture in terms of consumer agency and revealing the significance of it phenomenal nature'* (Kluyukanov, 2008, p. 211*)* can eventually equip design with a social agenda that does not exclude financial agenda yet re-configure healthy overlaps between different agendas.

The Need for Research

The research presented in this paper aims to understand how cultural appropriation can be used as a critical strategy to explore ways of formulating meaningful channels of cultural exchange through design. The research can allow alternative paths of operation for design while approaching cultural and social realms. On the other hand, through this research design's capacities of intervening, translating, mediating relationships and negotiating (Dilnot, 2007) can be discussed in relation to global dynamics that configure patterns of production and consumption. Research-based design process offers an exploratory ground where *'the cipher',* not as a form of commodity but a form of cultural negotiation, can be created and debated. In this process, due to its selective and interpretive nature, cultural appropriation can be used as a key strategy to create *'the cipher'* that does not prioritize financial gain.

The research seeks answers to the questions such as:

- What is the role of design practice in cultural exchange and transformation?
- How can design processes be used as a tool for deciphering cultural stereotypes?
- Is it possible to counter-direct the exploitative dynamics of commoditization to form cultural negotiations?
- Though new design processes, is it possible to recreate the lost links between a cultural element's original context and the new context of use?

In order to develop cultural appropriation as a strategy for the design process, the researcher addressed the need to understand the dynamics of cultural appropriation as a social activity. Documenting specific cases of cultural appropriation in design (including graphic design, industrial design and fashion) and identifying patterns of the appropriated elements global activity were crucial to understand the relationship between the working dynamics of design and cultural appropriation. During the preliminary research, the researcher identified that some cultural elements had already been reduced down to commercial clichés devoid of any original cultural content such as the Indian bindi, Che Guevara image or the Swastika. On the other hand, some of the examples were still going through the process of active cultural appropriation and commoditization.

Figure 2. Gwen Stefani's appropriation of the Indian bindi / Bindi fashioned in stickers

The researcher found it relevant to identify a cultural element that is still going through the process of cultural appropriation by design and follow its path of evolution. By identifying the element's historical evolution, the researcher aimed to identify a pattern of evolution and to draw parallels to similar elements of transformation in progress. The researcher then aimed to create an alternative path of evolution by culturally appropriating the element and creating 'the cipher' to restore the element's original value in proposed designs. This process would also open up to discussion the role of the design practice and the designer in commoditizing cultural elements. The proposed designs would promote ''a cipher as a system of references to the element's original cultural value'', deconstructing Ono and Buescher's (2001) concept of *'the cipher'* that is instrumental in stereotyping a particular culture.

Research Framework

Drawing from the preliminary research on specific cases of cultural appropriation by design, the researcher identified a cultural element that demonstrates both historical and contemporary record of being culturally appropriated multiple times by various practices.

Kaffiyeh (traditional Middle Eastern headdress with a distinctive checkered pattern) has been an object of cultural appropriation throughout its centuries long history. The kaffiyeh, which is associated with violence and terrorism in mass-media, is widely used in film industry to animate characters of Eastern origin. Despite its negative connotations, kaffiyeh's recent transformation from being a symbol of Arab identity to being a fashion statement demonstrates the capabilities of design industry to lead the transformation of a cultural element.

In the beginning kaffiyeh was the symbol of male Bedouin identity. The Bedouin tribe had been dwelling in the desert of Arabia and was famous for its fierce resistance to outside influence. The Bedouin nomads were distinguished from the villagers and townspeople by their kaffiyehs. (Stillman, 1979, p. 66) Kaffiyeh was the tribal symbol that represented not only the resistant nature and the free spirit of the Bedouin, but also the social identity of the Bedouin. A significant change took place in village men's headdresses when the Palestinian Arabs started to unify against the British Mandate of Palestine. (Stillman, 1979, p. 68) 'The Great Uprising' lasted from 1936 to 1939 and changed the status of kaffiyeh for the rest of its life. The first appropriation of kaffiyeh happened around 1930s when the villagers and the townsmen adopted kaffiyeh and agal (the circle that is used to keep the fabric on the head) as the tools for expressing Palestinian nationalism.

Figure 3. Kaffiyeh's historical timeline of appropriation

In 1960s the black and white colored kaffiyeh was appropriated for the second time by Yaser Arafat (Chairman of The Palestine Liberation Organisation) and was introduced to the rest of the world. By making Kaffiyeh globally visible, Arafat started the process of kaffiyeh's transformation from a traditional cloth to an icon of resistance. The distinctive black and white pattern started appearing on the world press and gained public recognition. During 1970s, political dynamics in the Middle East and the uprising resistance to Israeli pressure caused the rise of an armed resistance. Kaffiyeh was appropriated for the third time by the armed rebels and was associated guerilla and violence.

Appropriation 2: Late 1960s Since 1967 to date Appropriation 3: 1970s

Figure 4. Kaffiyeh’s appropriation by Yaser Arafat and its association with violence

In late 1980s, kaffiyeh took its place on the chaotic runways of anti-globalization and antiwar street protests. Arab nationalism transformed into rebellious self-expressions under the symbol of generic resistance.

Appropriation 4: Since late 1980s

Figure 5. Kaffiyeh as symbol of generic resistance

With the rise of the military chic fashion in 1990s, kaffiyeh got popular among subversive youngsters and fashionable rebels who expressed their resistance through clothing. As the popularity of kaffiyeh in public continued to grow, the scarf started to be the subject of design interventions in early 2000s. Fashion and design industries started to use kaffiyeh in design projects and new possibilities for application were explored.

1990s

Appropriation 5: Early 2000

Figure 6. Kaffiyeh as a fashion statement

Despite kaffiyeh's current status as a fashion statement, traditional kaffiyeh has been resisting to outer influence. Even when the Middle Eastern men exchanged their traditional clothes for the western clothes, they kept this article of headgear unchanged and therefore alive. (Scott, 2003, p.105) That's why kaffiyeh is a resistant cultural symbol that makes the male clothing and the hairstyles virtually identical throughout the Arabian Peninsula.

Figure 7. Kaffiyeh in Middle Eastern every day

The decorative kaffiyeh pattern with slightly different variations has been keeping the tradition and the cultural identity unified throughout the Middel East. Therefore the pattern is not only decorative but also functional since it allows the tradition to be distinguished.

Drawing from kaffiyeh's dual status as a traditional everyday element that represents Arab identity and also as a culturally appropriated and commodified cultural element, the researcher decided to intervene on kaffiyeh's evolution process. Kaffiyeh's history of evolution is characterized by multiple appropriations in various social, cultural and political contexts. Through this analysis, the researcher found it relevant to build on kaffiyeh's history and follow its path of evolution to the next level. The research-based design process constitutes the next stage of the transformation of kaffiyeh where kaffiyeh is appropriated one more time by the researcher. By critically reflecting on processes of cultural appropriation, the researcher re-creates 'the cipher as a reference to kaffiyeh's original cultural value' according to the feedback of participants in focus groups that are staged during the design process.

Methods

Research-based design process is threefold. At the first stage of the process, three different focus group sessions were conducted with groups of participants from different cultural backgrounds. These focus group sessions aimed to bring together participants with low level of knowledge about kaffiyeh and Middle Eastern traditions. Initial data collection centered on formulating open-ended questions, recording the participants' answers and opening the sessions for discussion. Each participant's individual responses were documented and group discussions were structured with a round-table approach. Feedbacks received from the focus group participants were decisive in determining the structure and further steps of the design process. By comparing issues across different focus groups the researcher started creating product concepts that demonstrated different forms of appropriation and application of the kaffiyeh pattern. One of the focus groups was exposed to the product concepts and asked for commenting on the relevance of the new context of use. The researcher updated design criteria and production methods according to the participants' responses.

At the second stage of the process, the researcher aimed to present concepts for new contexts of use to a wider audience that is familiar with Kaffiyeh and the Middle Eastern traditions. 'A Kaffiyal Project' website was set up and an online survey was conducted with the members of Arab and non-Arab communities. Through this website, design concepts that were developed according to the outcomes of focus group sessions were demonstrated to the participants.

At the third stage, according to the results of the online survey, the researcher narrowed down the design concepts to form a cipher that reconstructs the original cultural meaning of the Kaffiyeh through a series of products. *'The cipher'* was made public through presentations and discussion groups.

Focus Groups

Throughout the research, focus group sessions played a crucial role in structuring the design process. The researcher planned to set up three different focus groups with the aim of addressing different set of questions. Each focus group session was conducted with 12 participants each. The researcher aimed to:

- Find out the group's level of familiarity kaffiyeh as a tradition that originated from Middle East
- Find out the general impression of traditional kaffiyeh according to the latest political and cultural incidents
- Find out how the impression of the scarf changes depending on the way it's fashioned or depending on the wearer

The questions that the researcher had prepared for the sessions were accompanied with two separate small-scaled experiments that helped the researcher to open up discussion through visual material.

In Focus Group I, which consisted of 12 participants (six male and six female junior college students of different majors), the researcher demonstrated three sets of photographs in which three models of different ethnic origins fashioned kaffiyeh differently. Participants were asked to look at the photographs and comment on the uses of kaffiyeh and its wearer. When the kaffiyeh is fashioned unlike its original way of use, for example fashioned as a belt around the waist, majority of the participants found it hard to associate the headdress with any tradition or specific culture. The way the headdress is fashioned around the waist implied the model as a fashion enthusiast who is not interested in the original cultural value of the headdress. The African-American model that wraps kaffiyeh around her neck gave the participants the impression that the wearer was aware of the origin of the headdress yet still was fashioning it in a sophisticated way. On the other hand the male model projected danger and was identified as a Middle Eastern extremist by the participants. The male model brought up discussions about the role of mass-media and films in constructing stereotypes. All of the participants agreed that the use of scarf in a disguising manner was threatening.

Interpreting the responses of the participants, the researcher concluded that the participants' knowledge on kaffiyeh was based on the stereotypical depictions of Middle Eastern cultures on mass media. Only two of the participants knew about the origin and the tradition of kaffiyeh based on their experiences in Europe. On the other hand, the way the scarf was appropriated by the wearer and positioned on the body was decisive in the participant's perception of the pattern and the scarf.

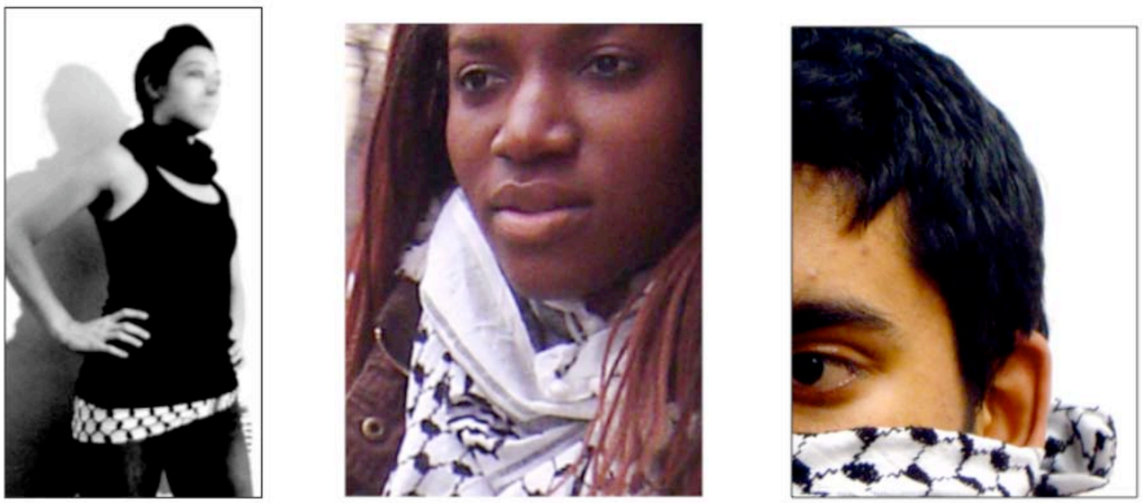

Figure 8. Models wearing kaffiyeh in different fashions

In Focus Group II, the researcher collaborated with 12 junior college students (8 female, 4 male) who were taking the Cultural Anthropology Course taught by Mary Martin at the University of the Arts in Philadelphia. In this session, the researcher experimented with different portions of the kaffiyeh's checkered pattern. Such and experiment was planned to observe the role of the pattern in participant's recognition of the scarf as a traditional element. The researcher also aimed to find out the smallest portion of the pattern that identifies the shown fabric as a Middle Eastern authentic cultural element. The optimal portion of the pattern that is recognized as of Middle Eastern origin would be appropriated and used in new contexts by the researcher.

In this session, the participants were exposed to different sections of the cloth and were asked whether they were familiar with the sections that gradually got larger. This way participant's perception of the pattern as an ethnic/authentic or a Middle Eastern design was observed. Moreover, the earliest level which participants identified as a part of Middle Eastern, ethnic element was addressed. (Number 004 below indicates the smallest recognizable portion of the kaffiyeh pattern that the researcher planned to appropriate.)

Figure 9. Experiments with portions of the pattern

Before stepping into the third focus group session, the researcher appropriated the smallest portion of the pattern (the portion consists of all three elements of the pattern at once) and applied the pattern on various everyday objects. Instead of re-purposing the scarf, the researcher/designer abstracted the scarf into its pattern and reproduced pattern as the essence of the kaffiyeh and its tradition.

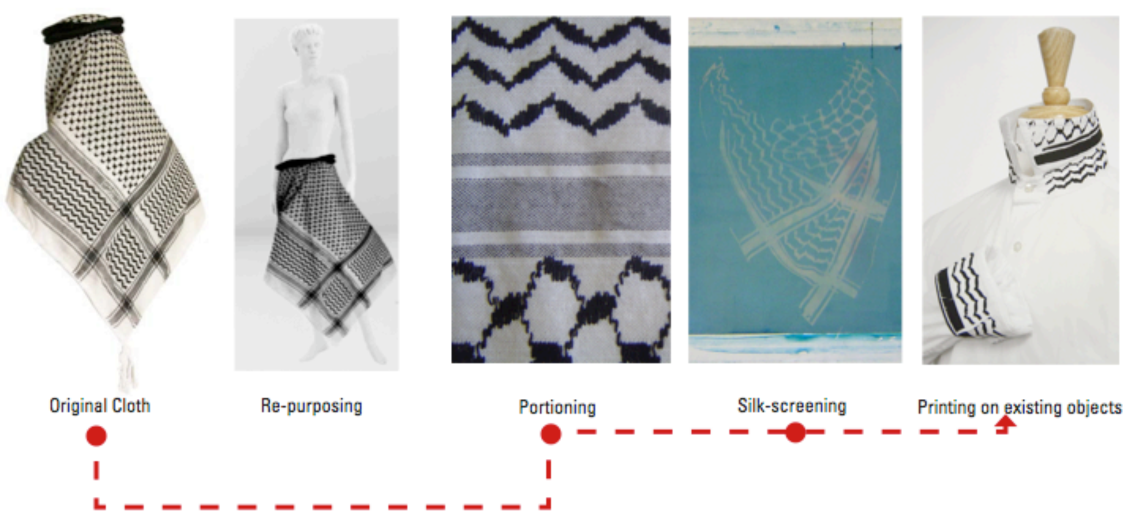

Figure 10. Reproduction process

Having reproduced the pattern on different everyday objects, the researcher moved on to the third focus group session. The participants of this focus group were twelve junior students (8 female, 4 male) who were taking the Middle Eastern Art and Culture Course taught by Professor Mary Martin at the University of the Arts Philadelphia. All of the participants were familiar with Middle Eastern cultures and traditions. After giving detailed brief on the kaffiyeh' original context of use and cultural value, the researcher exhibited the products as the new context of use for kaffiyeh. By placing the pattern on different parts of the body and relating the visibility of the pattern to the structure of the products, the researcher asked for participants' opinion on the relevance of the pattern application.

Figure 11. Researcher's experimentation with the pattern

According to eight of the participants, application of the pattern around the neck could have some vague associations with the original use of kaffiyeh. The participants mentioned that gestural aspects of the shirt and somehow subversive application of the pattern recalled kaffiyeh's association with protest. However, the other applications were considered disrespectful and meaningless.

Drawing from the participants' feedbacks, the researcher revised the design criteria and focused on applications that would:

- Refer to kaffiyeh's original place on the body through the placement of the pattern and the use of the product
- Engage the new contexts of use with everyday life
- Draw meaningful links between the gesture proposed by the new context and the original use of the cloth.

The participants' input in this session was crucial for identifying the next step of the process. Even though the idea of 'the cipher' wasn't mentioned in the sessions, the researcher aimed to formulate a set of products that would relate to different uses of kaffiyeh and values attached to it. Debating this issue over products or material examples helped the designer to charge different aspects of the products' physicality such as material, size, and function. The researcher also found it relevant not to create a new product from scratch but to build on the existing products. This way these everyday objects would host the essence of kaffiyeh and the participants would relate to the objects more easily.

For the next step of the design process, the researcher had enlarged the scope of pattern application to various everyday contexts. The new set of products proposed new associations between the materials or functions of the products and the cultural values represented by traditional kaffiyeh. For example could the lost uniqueness of kaffiyeh within the process of commoditization be restored in a diamond necklace produced in the shape of the kaffiyeh pattern? Or could the significance of this Middle Eastern element be restored by applying the pattern on loaded objects such as a veil? The researcher produced alternatives for different contexts of use and grouped these products under concept that can be presented clearly to a wider audience.

Online Survey

In the next phase of the design process, the researcher conducted online surveys with participants from members of Arab and non-Arab communities that are familiar with kaffiyeh and Middle Eastern culture in some ways. The researcher contacted Arab associations such as Penn Arab Student Society, Arab-American Association of New York, Al-Awda Palestinian Right to Return Group and Arab Women Active in the Arts and Media. The researcher designed a website (www.thekaffiyehproject.com) and displayed her the product proposals under main concepts.

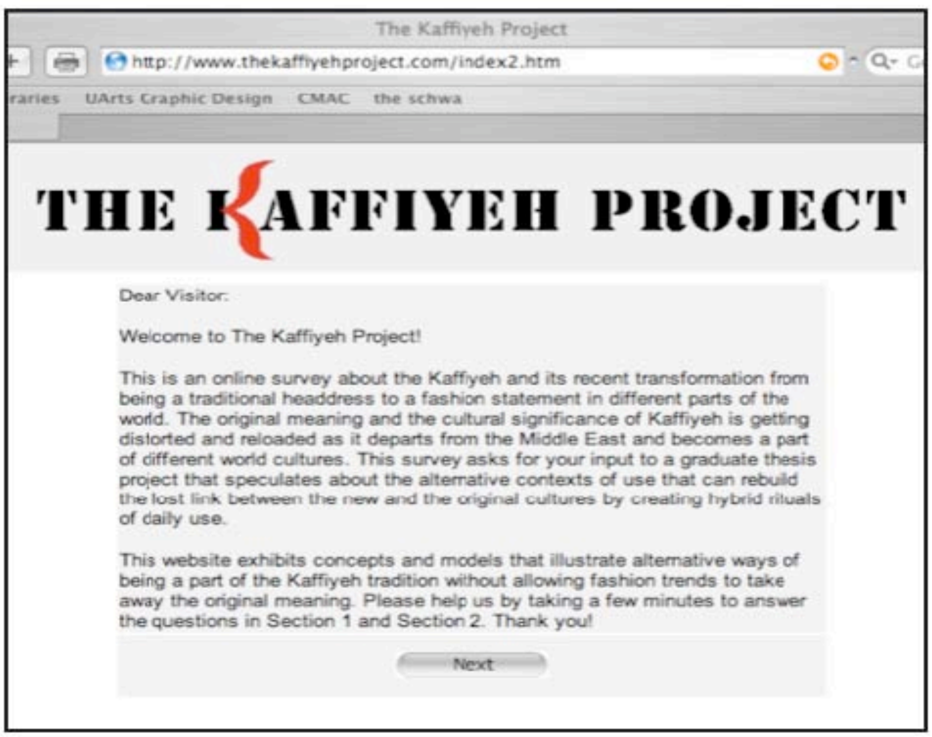

Figure 12. The opening page of the online survey

The survey was composed of an introductory slide show that introduces kaffiyeh to the participants, a short questionnaire that aimed to collect information about the participants and their level of familiarity with kaffiyeh, and the questionnaire about the concepts that were presented through drawings, prototypes and illustrations on each page with 3 questions.

The participants were asked to rate concepts according to:

- The success of the new concepts in relation to the original use of kaffiyeh
- The success pattern application on the level of identification of the pattern as “a kaffiyeh”
- The relevance of the concept to the tradition on the level of connection between the new context of use and the traditional context
- The significance of the concept in terms of the relevance between the choice of materials and the application of the pattern
- The success for the preservation of the essence of kaffiyeh in terms of the relevance of the place that the pattern is applied to kaffiyeh’s original position on the body

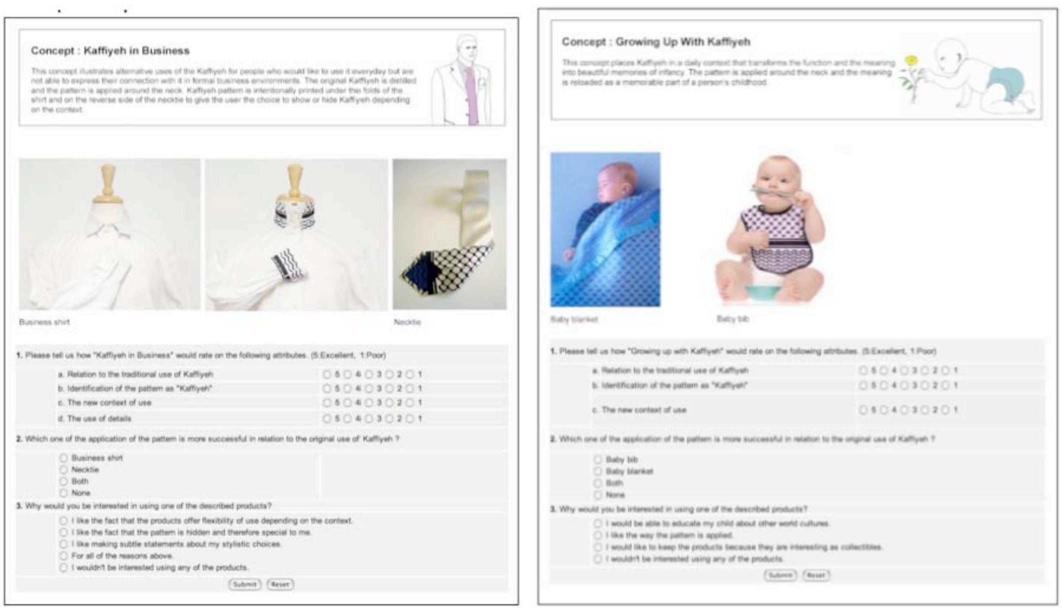

Figure 13. Survey pages from the website

The product proposals were grouped under concepts that could be related to personal stories from everyday life. By grouping the meaning and function of objects under main concepts, the researcher aimed to associate feelings such as comfort, need for expression of identity, security and need for protection with functions of kaffiyeh in its original context. These concepts encipher the essence of kaffiyeh in the material qualities of products.

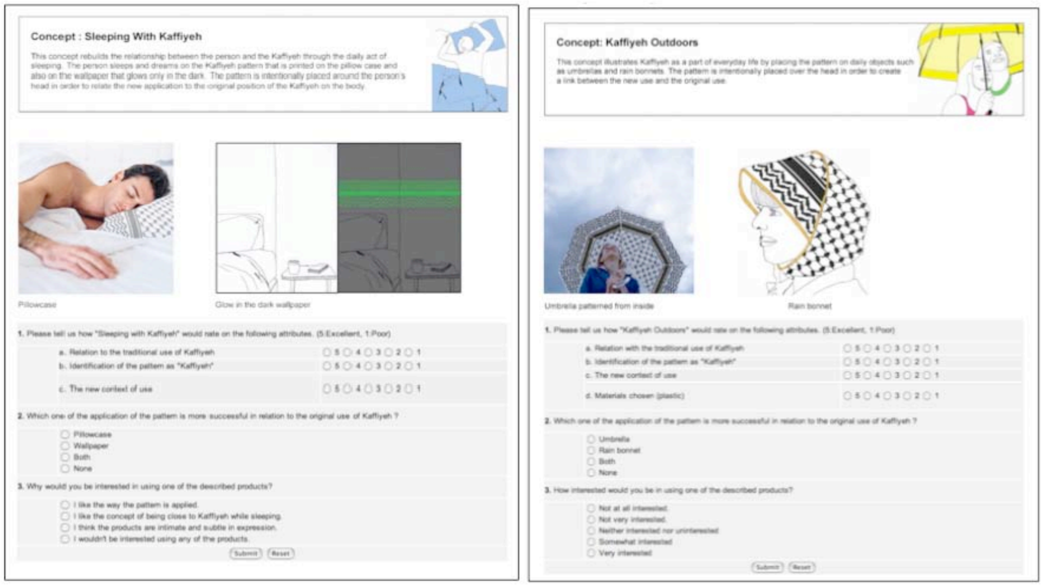

Figure 14. Survey pages from the website

40 participants (23 male-17 female), who took the online survey, rated the concepts and narrowed down the proposals. 32 of the participants were familiar with the scarf and its cultural value. The participants also provided a set of new criteria that the researcher had to consider for the final stage in creating ‘the cipher as a system of references to kaffiyeh’s original cultural value.’

Figure 14. Proposals that received the highest scores

Formulating ‘The Cipher’ and Displaying the Research-based Proposals

Even though various feedbacks from the participants structured the design process, ‘the cipher’ that would create meaningful links between the new contexts of use and the original context of kaffiyeh needed to be solidified according to one last set of criteria. The researcher used kaffiyeh’s original definition as her last set of to produce ‘the cipher.’ By enciphering the original definition of the scarf, a set of references to the original scarf would be created. According to its original definition kaffiyeh is:

- A big square cloth that can be multi-purposed depending on the context of need
- A head-dress that protects the face and the neck from sun, wind and dust

- A sign of modesty and respect
- A resistant traditional cloth with the distinctive pattern
- The signifier of the Bedouin tribe
- The symbol of Arab identity
- Symbol of resistance

When the researcher filtered the results of the online survey through these criteria, the proposals that create meaningful links between original kaffiyeh and the contexts of appropriation formed ‘the cipher’. Each part of ‘the cipher’ refers to an aspect of the original cultural element and creates links between the new context of use and the original context. Along with the product proposals that created ‘the cipher’, the researcher conceived the design of supplementary references that would communicate the cultural exchange the proposals are offering. The researcher designed product tags that refer both to the original and new contexts of use with the help of graphics and text. These tags juxtapose the traditional and new context of kaffiyeh on the front and the back. The text accompanying the new product explains how original function of the scarf transformed into a similar function in a totally new everyday context.

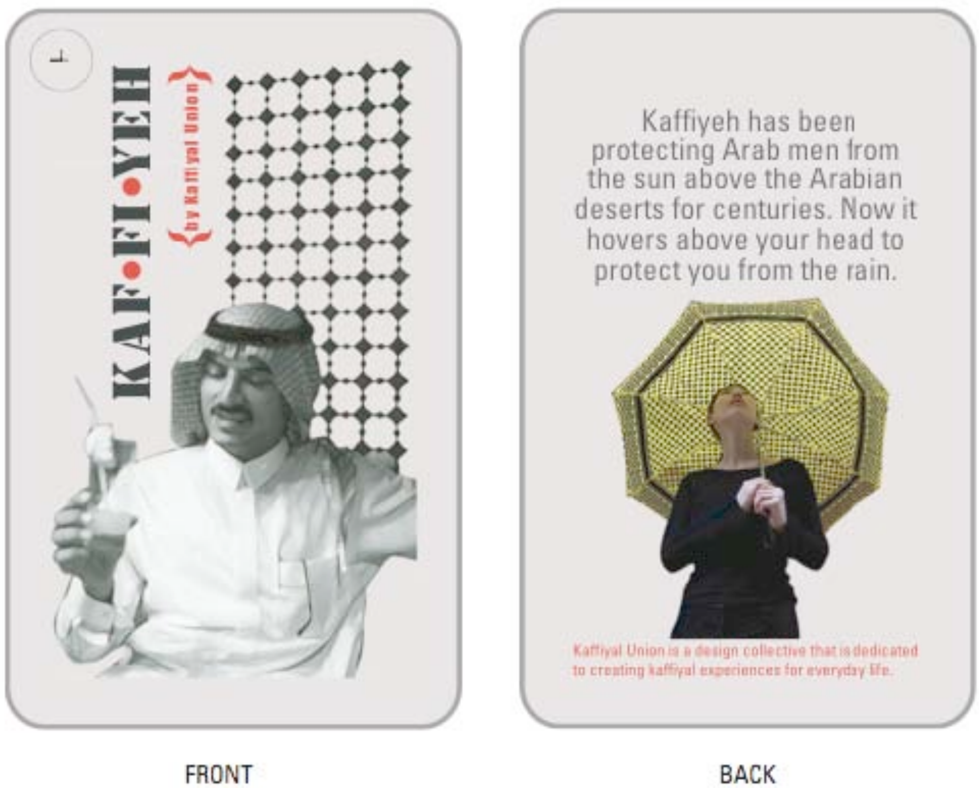

Figure 15. Kaffiyal Umbrella Product Tag / Back and front

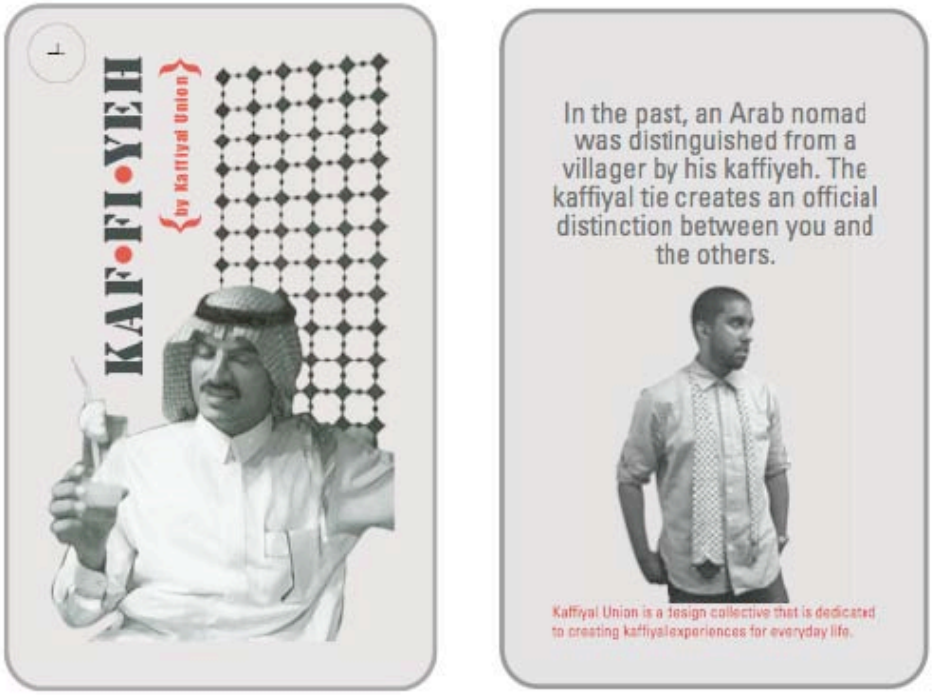

Figure 16. Kaffiyal Tie Product Tag / Back and front

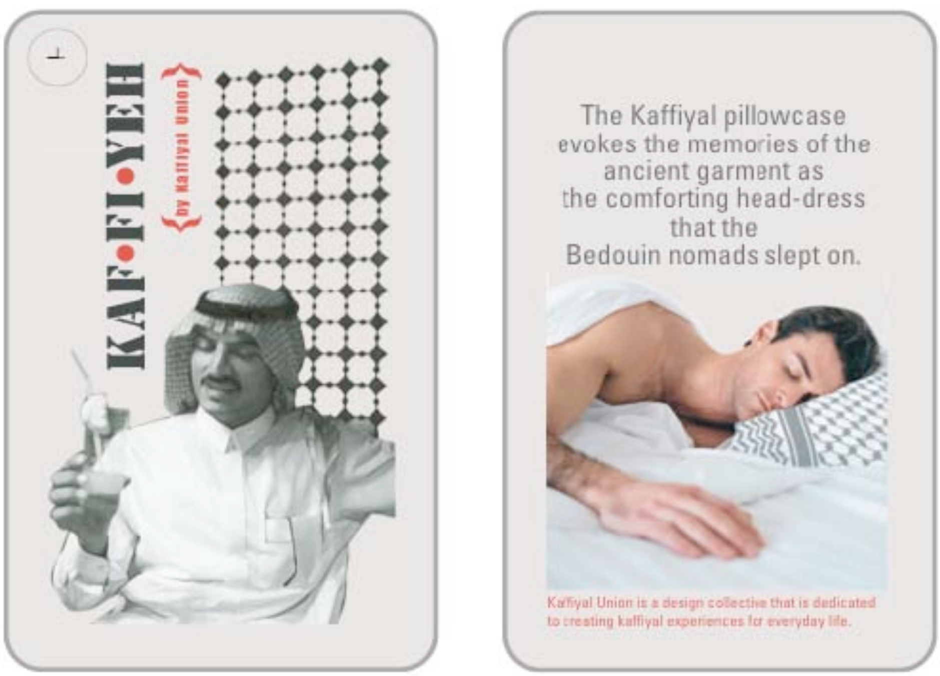

Figure 17. Kaffiyal Pillow Case Product Tag / Back and front

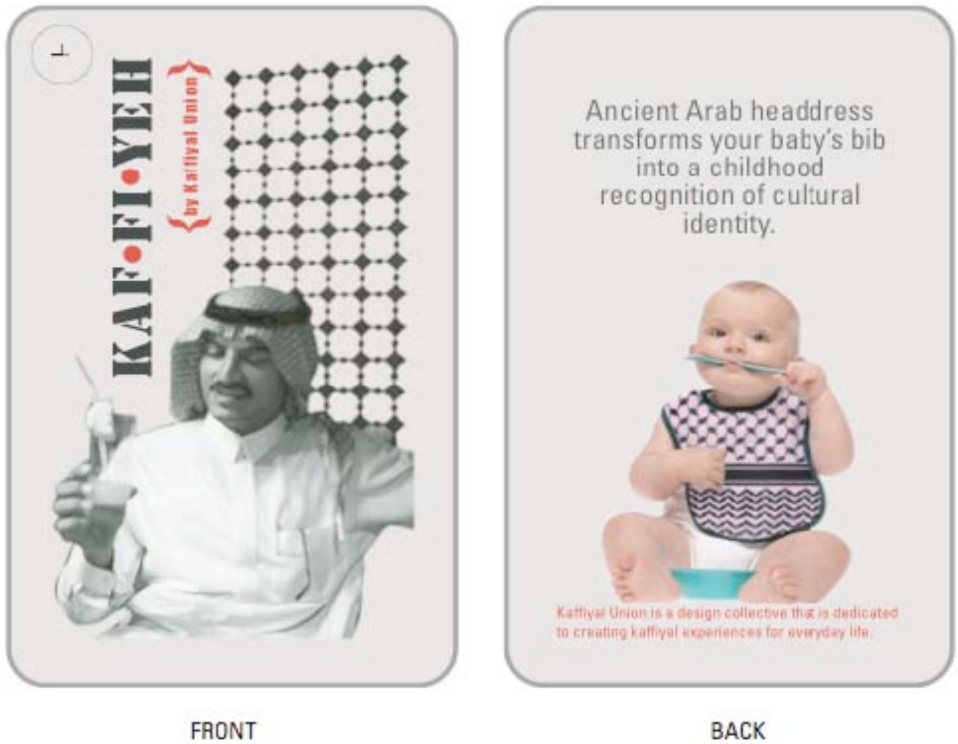

Figure 18. Kaffiyal Bib Product Tag / Back and front

The researcher promoted concept of 'the cipher' along with the product and the tags. 'The cipher' as a system of meaningful cultural references took on an educational yet entertaining role for both the members of the appropriating culture and the appropriated culture. 'The cipher' presents the design practice's potentials to create meaningful distortion that intends to carry the essence of a cultural element within the products. Practice of cultural appropriation is strategized as a tool for creating 'the cipher.'

Conclusion

This paper presented a research based design process that used cultural appropriation as a strategy to commodify a traditional cultural element (Kaffiyeh) yet to protect its cultural content with the help of 'the cipher'. Ono and Buescher's (2001) concept of the 'cipher' as a commodity was transformed into 'the cipher' as a set of meaningful references that travel across two different cultural contexts. The project has been a multi-dimensional and speculative intervention into kaffiyeh's ongoing process of transformation. Concepts of appropriation, cultural identity, cultural stereotypes, cultural exchange and globalization were debated over products.

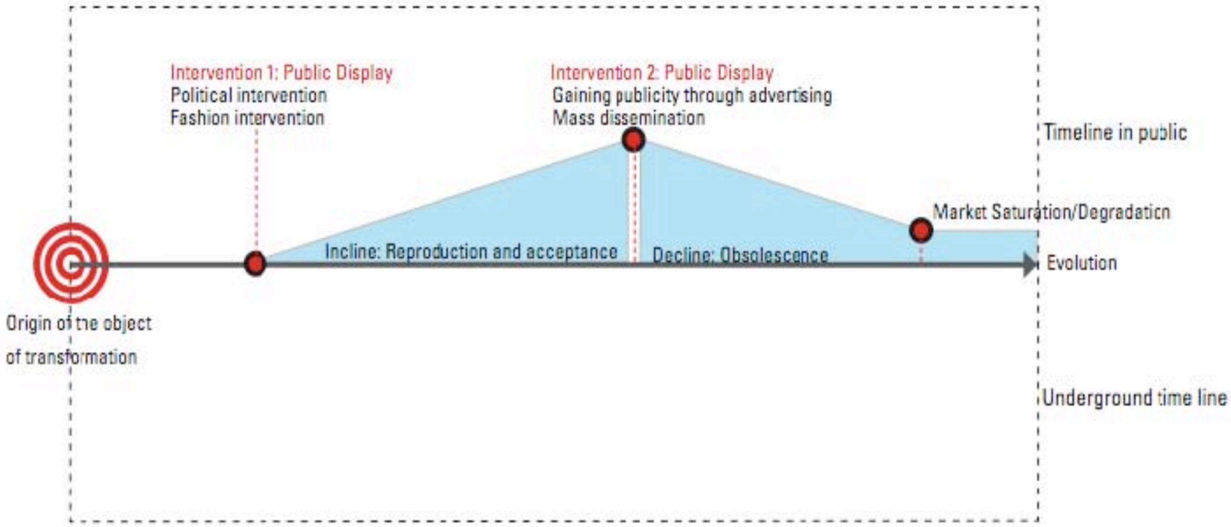

Figure 19. Chart of evolution through cultural appropriation

When a cultural element is removed from its native context through cultural appropriation, its cultural value is abstracted into an exchange value that floats in the market devoid of any cultural content. In a typical process of commoditization, the object of cultural appropriation starts to get away from its origin conceptually with the help of an intervention (design practice, public and political figures, fashion) that presents the cultural element to the public. With this first intervention, the cultural element also interacts with commercial and business cycles. Evolution of the object in public inclines as the public becomes familiar with it and accepts it. At this stage, the commodity is mass-disseminated and reproduced. Before the evolution in public starts to decline, the second intervention happens as a second gesture to re-establish or strengthen status of the commodity in everyday. As the market gets saturates, popularity of the image starts to decline and the public loses its interest in the image of the object. In the end the commoditized cultural element is reduced down to a commercial cliche that continues its life with little public interest.

In ‘A Kaffiyal Project’, the researcher observed the process of evolution and intervened on the process of commoditization at the point where the commodified cultural element was mass-dissseminated. By creating a conceptual underground path (or ‘the cipher’ as a system of reference) that links the cultural element back to its origin of use, the researcher aimed to restore the lost link between two exchanging cultures. This conceptual underground path, ‘the cipher’, redirects the evolution path of the cultural element and elevates it to another level.

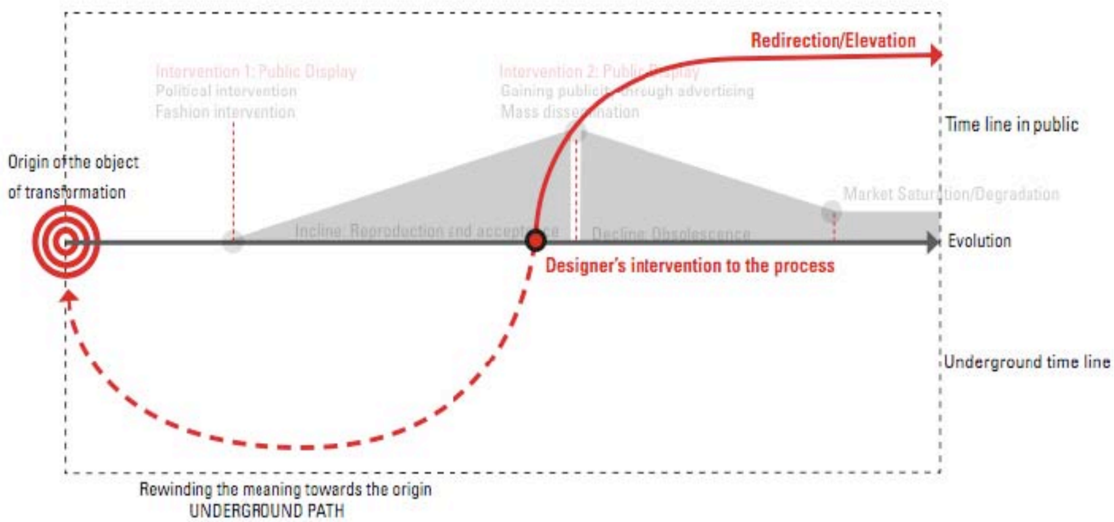

Figure 20. Chart of evolution after design intervention

It is important to recognize that products create channels of exchange in various dimensions. Their material, physical, structural, cultural and social qualities have the potential to host references and change perceptions. Products, through design, have the potential to plot interactions between different set of social and cultural actors. In an increasingly saturated global world where products circulate in closed loops of consumption and taste, it is critical for the design activity to create room for critical reflection. Developing a critical agenda for design requires debate, participation and open-processes of creation.

On the other hand, practice of cultural appropriation needs to be discussed and explored more in the realm of product design as a part of design's social agenda. Design processes have the potential to challenge the destiny of commoditized cultural symbols in ways that share the authority of deciding on the value of a cultural element with the society. Despite its negative implications on culture, cultural appropriation can indeed contribute to the evolution of cultures and redefinition of the boundaries, if the concerns that were stated in the introduction are taken into consideration. Through critical and participatory processes, design practice can generate sensitivities towards processes of cultural exchange and also create awareness on its crucial role in determining the evolutionary path of cultures.

Abstract

Initial research by the authors using an online survey of over six hundred participants analysing what (if any) activities lead to discomfort, particularly in the hand, showed that cleaning tasks and in particular, mopping, sweeping and hoovering led to higher levels of hand discomfort than other ADL's (Carre, 2009). Activities of Daily Living (ADL's) such as cleaning, hoovering, mopping, and so on have had little or no previous research undertaken on them. In 2005, Tresea et al., examined the prevalence of work related injury and explored barriers to, and experienced of, reporting them amongst workers. The results showed that over one year, three quarters of the workers studied experienced work-related pain. With reference to the above study, the authors defined two categories of cleaning activity, termed heavy work and light work. 'Heavy' work was characterized by neutral postures, walking, repetitive movements involving the articulations of the upper limb pushing a 1-6 kg (wet or dry) mop, with occasional more intense effort. 'Light' work was characterized by flexed postures, walking, rapid repetitive movements involving the articulations of the upper limb and the movement of light weights (dusting) or 1-3 kg weights (emptying wastebaskets), with more occasional intense effort (Teresa et al., 2005).

It was proposed to study the process of using cleaning equipment such as a mop, brush and hoover and ascertain what factors may lead to discomfort particularly in the hand. However to inform the design of the questionnaire's, tasks to be analysed and experimental set-up, one of the authors took a job as part of this cleaning team and has worked for over two years as a cleaner, logging their own experiences and activities in a diary and recording the experiences of their colleagues.

This paper details those experiences with comments and reflections from the diary work and demonstrates how the experiential approach led to improved design of experiments and data gathering.

Keywords

Comfort, Grip, Daily Living, Cleaning

Introduction

Whilst cleaning activities were seen to produce the highest pain levels and frequency the authors also wanted to understand the forces in the hand when undertaking these activities. Previous studies carried out on grip force applied to handles but were usually measured on a single axis (Peebles, 2003, Massey-Westropp et al., 2004., Mathiowetz et al, 1985 and Welcome et al., 2004). This approach has been widely used to monitor and control the grip force during glove tests, biodynamic response measurements and many other experiments involving handgrip simulation (Dong et al., 2004, Aliden et al., 2005, Marcotte, et al., 2005). The hand forces in these studies are either grip force or push force.

A few studies have attempted to study the distribution hand force at the hand-handle interface and their dependence on the handle size, grip and push force that could serve as a vital basic for the design handle.

In their 2005 study, Aliden et al., identified the magnitudes and locations of localized pressure peaks occurring at the hand surface as functions of the handle size and static hand grip and push force. In his study, the hand-handle pressure are acquired for three different diameters of circular cross-section handle by using a 16 x 11 pressure sensing grip under different combination of static grip and push force. The result showed that the contact force developed in the vicinity of knuckles and the palm is generally attributed to the push force, while forces at the finger surface are caused by the gripping actions. According to Reidel et al (1995), Rempel et al., (1992), and Radwin et al (1987), the primary factor increasing the risk of cumulative trauma disorders is the operation of some of the tools that demand high grip, push or hand handle contact force.
Fransson and Winkel (1991), Pyykko et al., (1976), found that the contact force between the hand and the tool handle can effect the severity of exposure to the hand transmitted vibration and hand wrist cumulative trauma disorder. They also found that the hand arm responses measured in terms of the hand transmitted vibration, and electrical activity of the muscle flexor carpi-ulnaris and finger-flexor muscle, increase simultaneously with the increase of hand-handle coupling intensity, whilst the peripheral circulation of the finger decreases.
Even though, studies have established the magnitude and hand-handle coupling force and various measures of the hand arm responses, the mechanisms leading to the risk of hand-wrist cumulative trauma disorders have not been identified. High contact forces impose high stresses on the anatomical structure of the hand, which may be strongly affected by many factors such as working posture, weight of the tool, grip and push forces, handle size, individual work habits and hand to handle interface pressure (Marcotte P., et al., 2005).

In 2007 it was decided to undertake a PhD project to understand these mechanisms leading to hand-wrist cumulative trauma in more detail. The successful applicant was Mrs S.R. Kamat (Rahayu), and she has over the last two years been studying a full-time PhD at Sheffield Hallam University, undertaking studies into hand discomfort during performing activities of daily living (ADL's). From initial survey work undertaken by the authors on these ADL's cleaning activities such as hoovering, wiping and so on were seen to rate highly on by pain discomfort and pain frequency when compared to other activities. Hence it was decided to understanding the nature of these cleaning activities in more detail. As part of her studies she decided to take a part-time job as a cleaner with a major employer within Sheffield. The initial aim of taking this job was to understand some of the issues faced by professional cleaners whilst undertaking their normal tasks. Further, the study was undertaken to see how immersive design techniques and the usefulness of those techniques can be used to inform a set of experiments to understand the nature of discomfort and pain during cleaning activities. The diary entries outlined here are purposely in the first person and anecdotal in nature. Typographical errors and language are kept in for authenticity (Rahayu is from Malaysia, and whilst her English is good, it is not her first language and her journal entries were always intended to be informal). The informality of the entries is further emphasized by the use of the term 'Hoovering', which is a British colloquial term for the action of using a vacuum cleaner. Parts of her full diary entries are shown here to how this immersive technique enabled us to design our experiments.

Diary Entries

Rahayu started work as part of an evening cleaning team working 20 hours a week. The team had 20 members with a mean age of 34, (ages 25 to 40) and was evenly split between genders.

> *My experience as cleaner on the first week makes me know how difficult the cleaning activities it is. Most people think the activity is easy, but when I perform the activity frequently every day, I feel more tired and suffer serious pain at my back. The pain increase slightly and continuously up to the present moment. As a part time cleaner in office building, I clean the table, windows and door glass, cleaning bin, washing the cup bin, cleaning the kitchen areas and toilet, mopping floors and hovering around an area (under a table, under chair, edge and lobby) for 4 hour per days and 5 days per week.*

The typical jobs that Rahayu undertakes are shown in the following Figures.

Figure 1: Mopping

Figure 2: Cleaning sinks and toilets

Figure 3: Hoovering

Figure 4: Carry Plastic Bag

Figure 5: Wiping Mirrors, tables and doors

She continues:

> *At first, I thought it is the easiest job. I do not experience any discomfort or pain. However, after a couple of month, think change. I begin to suffer a back pain. As time goes by, it becomes annoying. I begin to feel discomfort after one hour hovering and mopping in 30 minutes.*
>
> *Back pain is one of the bigger problems. Every time when I hoover under the table, the chair, mopping, carrying or washing the cup bin, I have to bend my body. These actions contribute discomfort at my back.*
>
> *After hoovering for about 20 minutes, I felt discomfort at my hand and finger. The vacuum and vacuum handle are so heavy, the air pressure is high and the office areas itself is difficult to hoover especially hoovering under the table, chair and corner. I have to bend my body and give more grip on the vacuum handle to perform it.*
>
> *The second pain is on the shoulder. When I hoover or carry bin and cup bin or even washing cup bin, I feel stress at the tender on my shoulder? Sometimes, I take a rest for 10 minutes before continuing hoover.*
>
> *After 6 months, the back pain becomes more serious. If felt discomfort while doing the hoovering, mopping, carrying and washing cup bin. I take an off for 2 weeks after consulting a doctor. She suggests me to take a rest. All my pains heel after resting in 2 weeks.*

Hence after 6 months of cleaning 20 hours per week Rahayu has had to take time off from her job due to discomfort. After two weeks she returns to work but pains in her back quickly become worse:

> *From the back pain, I begin to experience discomfort and pain in shoulder, arm, hand and finger especially after hoovering, mopping the floor, cleaning water bin and cleaning toilet. My hand and finger become stiffness. Some time I feel tender and cramp at the shoulder and arm.*

The McGill pain indicator questionnaire test is used by occupational therapists (amongst others) to describe and rate levels of pain. First developed in 1971, it attempts to gauge the quality of pain experiences. Rahayu refers to it in this next diary entry.

The discomfort at the hand and finger are increasing from level 2 (mild pain) to level 4 (pain) after frequent cleaning activities. From using one hand, I have to use both hands while hoovering just to reduce the hand grip force, easy to control the vacuum handle and reduce pain at shoulder, arm hand and finger.

We can see here that her experiences are starting to inform her work. It is also worth noting here that these painful experiences have started to affect the nature in the way she undertakes the task. From using one hand originally she now uses two, completely changing the posture of performing the task.

As part of her studies Rahayu produced a diagram to aid her in understanding the location of the pain in the hand when asking participants about their pain experiences. She refers to these locations in the next excerpt from her diary entry.

This diagram is shown in Figure 6 below:

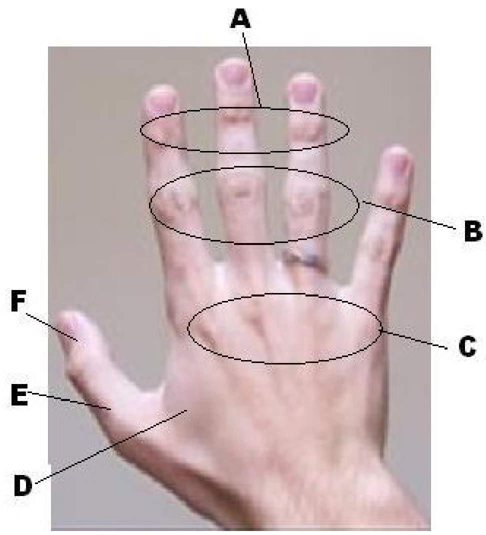

Figure 6: Pain location hand diagram

After 7 months, I feel the similar pain experience when mopping and hovering. My finger and hand felt discomfort at the area F and E after performing the task. The pains heel after 10 minutes. The similar pain at location A, B and C under the muscle occurs when I carry the water bin and dust bin. The level of pain for both activities is still under level 2.

After 8 months, the pain becomes more serious. From back pain, I begin to experience discomfort and pain in shoulder, hand and finger. A lot of hand and finger movement is required during cleaning activity. Therefore, from self experience, I believe that there always discomfort experience by cleaner, especially for those whom work more than 10 years.

During this period the level of discomfort for Rahayu is seen to continue:

In month 8th, I begin to feel discomfort in my back pain from the first week till now. My hand and finger feel discomfort after 4 months working till now. The level of pain increase when I clean for a longer period. Sometimes my hand tingle and wrist pain, especially when the task is repetitive strain such as hoovering,

> *mopping a floor and clean table. I felt intermittent pain along the side of the right hand from litter finger to wrist when I carry the water bin and waste plastic bag. It is similar the pain location is at A, B and C under the muscle pain, but the level of pain increase to level 3.*

> *After 11 months working, the level of pain becomes irritating. My hand and finger become sharp and throbbing at the location C and B. The pain become serious while performing the cleaning activity and the pain cannot heel. Thus I took 2 days medical leave. I put a lotion to reduce the throb. After 2 days rest, I become better. However, I can only work for 2 days.*

Again, Rahayu has had to take time off work to due injuries related to work. However, this time her supervisor decides to change her activities to reduce the impact on her hand.

> *A week after, I come back to work as normal. My supervisor gives me a simple task such as clean tables and hoovering without carrying any heavy thing. Although it is simple, I still feel the pain but not serious compared to last week, I still have to put lotion at my hand on location B, C and D to heel the pain.*

> *A year past, the level of the pain increased to level 3. The pain felt at location A, B, C, D, E and F but more serious about location A, B and C, the thumb not to be serious pain whenever I carry out my daily cleaning activities.*

> *Due to my illnesses, my cleaner supervisor gives me a new task, hoovering the floor. Eventually, it takes about 2 hours to hoover because the floor is too wide. After 2 days hovering, I begin to feel more pain on my hand and finger. Sometimes I have a symptom like numbness in my hand, decrease in griping strength, pain in the finger, pain in the neck and shoulders, tremor in the hand/arms and pain at my back. The level of pain in this task can be categories under level 3 and 4 depend on the certain location. Location A, B and C level 4 and F, E and D under level 3.*

> *Base on my experience doing hoovering, I found that some activities look simple but difficult when doing hoovering at certain place for instance under the table, the chair, at the corner and the stairs. My hand and finger move very frequently during hoovering under the chair and table. From my observation when doing hoovering under the table, chair and corner, I found that it has a connection between hand and finger movement with higher grip force, especially when I am bending my body. While doing hoovering under the table and chair I felt more tired and pain at back, hand and finger.*

Figure 7: Hoovering under a table

Figure 8: Hoovering under a chair

Figure 9: Hoovering in the lobby

I took some photographs of myself hoovering. The photographs show the position of our body while hovering under the table. We need to bend our body to reach the surface that we want to clean. This movement will be irritating if we have to hoover in a longer period. A lot of hand manipulative movement is required doing the hoovering task especially when hand and finger try to control *handle vacuum. As a Cleaner, hovering at the corner and under the table is the most difficult task. The degree in bending our body and hand and finger movement become greater and it needs more force to clean the surface. When I hoover the carpet I do not have to bend so it is easy.*

Hoovering is generally seen as a difficult task, unless hoovering a bare carpet. Rahayu also talks of other easy tasks:

Figure 10: Wiping a door

Cleaning the mirror is one of the simple tasks on cleaning activities. I don't feel any pain, when doing this task. We don't need to bend the body on this task but a lot of hand and finger movement is required during doing this task.

And other 'simple' tasks:

Figure 11: Wiping a computer

Figure 12: Wiping a desk

Cleaning the table is one of the activities give painful at the back. These activities look easier and simple, but I need to bend my body to reach the surface that I want to clean. A lot of hand and finger movement is required during cleaning the table. This movement will be irritating if I have cleaning many tables in a longer period. The degree in bending our body become greater and it needs more force to clean the surface.

A lot of hand and finger movement is required during cleaning kitchen. These tasks are simple but I felt tired when carry the bin and mopping the floor every day.

From the above diary entries we can see various themes emerging. Posture is seen to massively influence comfort and posture is heavily influenced by the task undertaken, i.e. hoovering under table or wiping a low table surface as to hoovering a carpet or wiping a mirror. Changes in posture during the task also led to changes in grip as the user attempted to control the activity. The repetitive nature of the tasks particularly requiring changes in posture and grip led to fatigue and in some cases significant discomfort leading to illness. The illness itself then in turn started to effect the way in which the task was then undertaken.

Obviously a better understanding of the cleaner activities especially on body posture, hand and finger movement and discomfort and painful feeling when undertaken these activities can aid in the design of products that may reduce instances of discomfort or enable the allocation of work activities so that there is less impact on the body.

Within Lab4living at SHU we have access to motion capture systems and thin-film force sensors to study posture and grip. From the experiences outlined above a series of tests were designed to utilize this equipment with regards producing this improved understanding of posture and grip. Further by embedding herself as part of a cleaning team made access to willing participants for the test work relatively easy.

Methods Used (In Situ and Laboratory Studies)

From the above diary entries several themes emerged that informed the experiments that we wished to undertake. Hoovering was seen as a common task that leads to fatigue and discomfort. Further hoovering posture due to the nature of what the cleaner was actually hoovering (i.e. under a desk, table or chair as opposed to a lobby) was also seen to effect comfort both in the back, shoulder, arm and hand. Changes in posture as well as manipulation of the vacuum cleaner handle were seen to be contributory factors leading to this discomfort.

As stated previously, whilst there have been several previous studies undertaken to analyze the activities of shoulder and arm muscle during force generation in different shoulder and positions when performing and force using the epidemiological and electromyography (EMG). However little previous studies have been undertaken on the force and hand and finger movement related with discomfort or pain while doing the ADLs activities.

From the diary entries outlined earlier several studies were proposed. Firstly, the authors decided to concentrate on understanding the hoovering task as this was the primary task that lead to most discomfort for Rahayu and tied in with opinions provided by the online survey. Secondly, it was decided to undertake studies both *in situ* and in the laboratory. The *in situ* studies would help us understand which hoovering task created the greatest force in the hand since from Rahayu's dairies some tasks were seen as more difficult than others. The *in situ* studies consisted of using the Tekscan thin-film force sensors on the handle of the vacuum cleaner and measuring the grip forces as the cleaners worked. Over 20 professional cleaners were studied. Figure 13 shows one of the cleaners using the equipment and Figure 14 a close-up of the sensor.

Figure 13: Thin Film Force sensor on vacuum handle *in situ*

Figure 14: Thin Film Force sensor on vacuum handle

Results from the sensor are displayed as pressure 'patterns'. To aid in helping us understand the relationship between these pressure patterns and discomfort the patterns were mapped onto a simple schematic of the hand as shown below.

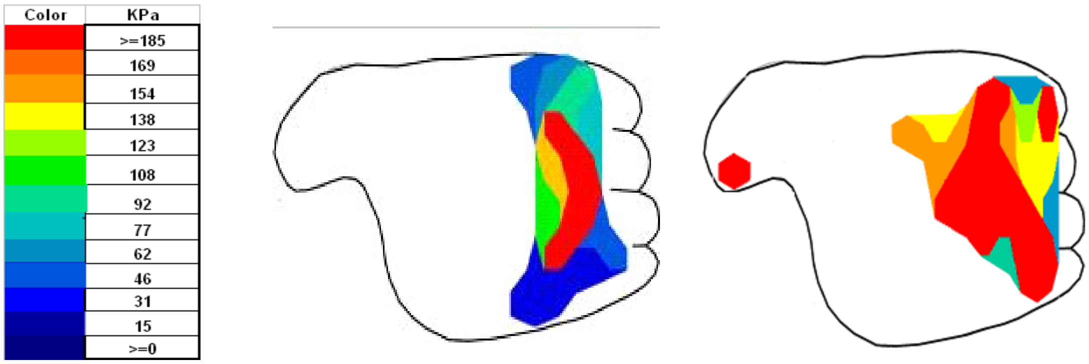

Figure 15: Pressure Distribution on the hand whilst hoovering

The hand on the left is a female cleaner gripping the vacuum handle gently before undertaking the task with the pressure distribution on the right the same cleaners hand during hoovering under a chair. The pressure patterns were seen to be affected by hand size and the task undertaken. Further results are not presented here since this paper is about how the experiential learning informed the experiments. The results from this work are currently under review elsewhere. Following on from this *in situ* work that identified which tasks created the highest 'pressure patterns' the same tasks were repeated in the laboratory combined with motion capture. Motion capture allows for the real-time measurement of movement through tracking of highly fluorescent markers using specialized infra-red cameras. Figure 16 shows the marker set-up including the markers and Tekscan thin-film sensor. Twenty cleaner professional were tested hoovering a carpet, in the corner, under a chair and under table. The cleaners were marked-up with the fluorescent markers to track motion of the vacuum cleaner relative to the task, their hand, arm, shoulders and back position.

Figure 16: Close-up of had set-up for laboratory experiments, laboratory set-up for hoovering under a chair, motion capture analysis

From this technique were able to understand the different actions of the cleaners undertaking these series of tasks and look at the forces in their hands whilst undertaking this task.

Conclusions

The results from the experiments have only been briefly presented here since the emphasis of this paper is how the experiences of Rahayu working as a cleaner helped in production of a series of experiments. The key insights were:

- hoovering whilst thought of as an easy task, rapidly creates discomfort in the back, shoulder and hand. Hence it was decided to concentrate initially on this task for our experiments.
- differing hoovering tasks create varying levels of discomfort. Interestingly, hoovering in a corner ranks highly for this which we did not expect or originally consider. Also fatigue plays its part, cleaning a bare carpet is relatively easy but becomes uncomfortable if a large area is to be cleaned. Hence a series of tasks were used to replicate the *in situ* environment.
- posture in relation to the task, repetitiveness and hand size all play a part in the increase in force in the hand leading to discomfort. Hence we measured participant height, hand size and repeated each experiment several times before taking a capture.

A major benefit of this experiential approach is the personalization of the issue it becomes a 'real' problem as opposed to someone else's that we are trying to understand. This is important in both enabling us to understand the issues around our research but enables us to discuss these issues with a greater deal of depth, we actually understand the problem. It is not interpreted and filtered in some way. As a researcher one of the most shocking elements to come out of the diary was how quickly Rahayu became ill and had to have to take time off work due to pains in her hand.
A further interesting advantage was the ease of getting volunteers to come to our laboratory and undertake the tasks asked of them. Nobody from Rahayu's cleaning team refused to take part in the survey and further, all the studies were conducted with a great deal of warmth and humour making the studies enjoyable and setting the volunteers at ease. Similarly all participants were happy to come back for further studies on mopping and wiping that are currently being undertaken.
It is worth noting in the preparation of this paper that Rahayu took a photograph of her hands as she was determined to show how her hands had become swollen and scarred from undertaking these cleaning tasks (the scarring comes from a reaction to the latex gloves she used), to that end it is shown below:

Figure 17: Rahayu's Right Hand

Finally, the authors believe that most importantly in 'embedding' herself as a cleaner we discovered how serious this issue actually is. There are as stated previously studies on vibration white finger and heavy (predominantly male) work such as construction, but little in the field of cleaning activities. The authors feel that this paper shows that it is time to change.

Retail Design and the Visually Impaired: A Needs Assessment

Hong Yu, Ryerson University, Canada, hongyu@ryerson.ca

Sandra Tullio-Pow, Ryerson University, Canada

Abstract

This study represents a first attempt to investigate the need for universal retail design in Canada. Specifically, the research objectives were to expand understanding of the unique challenge of visual impairment and the shopping experience of visually impaired consumers, and to identify gaps in retail design in order to better serve the visually impaired community.

The researchers conducted three focus group interviews with a total of 17 informants recruited by an independent consultant who was affiliated with a visually impaired advocacy organization in the Greater Toronto Area in Ontario, Canada. Data were transcribed and then analyzed using QSR NVivo 8.

Findings suggest that mobility is the biggest daily challenge facing visually impaired consumers. Retail shopping involves significant effort at every step of the process for visually impaired shoppers, including getting into the store; judging product quality; distinguishing colour; reading labels, store signage, and receipts; negotiating store layout and fitting rooms; dealing with store lighting; and interacting with sales associates. This paper identifies visually impaired shoppers' needs for universal retail design, discusses implications, and makes recommendations to policy makers and industry practitioners in the defined fields.

Introduction

Vision loss is a detrimental effect of aging that impacts physical, social, and psychological aspects of people's lives (Moore & Miller, 2003; Pelletier, Thomas, & Shaw 2009). Approximately 3.6 million Canadians are diagnosed with disabilities, including 648,000 people with visual impairment or blindness, many of whom are elderly (Government of Canada, 2004). In the U.S., more than 3 million Americans over age 40 live with blindness and low vision (National Eye Institute [NEI], 2004, 2008). Without a doubt, the prevalence of eye disease increases with age; the American cohort with blindness or low vision may reach 5.5 million by 2020 (NEI, 2004).

Using North American criteria, blindness is defined as the maximal visual acuity in the better eye being equal or less than 20/200, while low vision is classified as maximal visual acuity in one eye equal or less than 20/40 (Maberley et al., 2006). It is important to note that only a small fraction of the Canadian population is blind; the majority of visually impaired persons live with low vision (Maberley et al., 2006). As a rule, most people adjust reluctantly to predictable changes in vision as they enter middle age: they purchase reading glasses to compensate for the inability to focus on small print, need increased light levels for improved contrast perception, and find it more difficult to drive at night due to hindered glare recovery from oncoming headlights (Carter, 1994). However, with advancing age, other serious forms of eye disease and vision loss may occur, including macular degeneration, which typically impacts central vision; cataracts, which manifest as reduced glare recovery and decreased visual acuity; glaucoma, which initially presents as a loss in peripheral vision; and diabetic retinopathy, whose symptoms include overall decreases in visual acuity, colour perception, and the ability to adapt from dark to light (Castor & Carter, 1995; The Eye Diseases Prevalence Research Group, 2004; Rosenberg & Sperazza, 2008). Some of these symptoms may be improved with surgery or medication (Pelletier et al., 2009) and resulting vision loss may be offset by using handheld magnifiers, specialized glasses with tinted filters to reduce glare, large print computer software, voice synthesizers, and audio books or other talking devices (Castor & Carter, 1995).

Loss of vision correlates to reduced quality of life (Allen, 1989; Jackson, 2006; Misajon et al., 2005; Moore et al., 2003; Pelletier et al., 2009). Persons with visual impairment have an increased risk of falls and associated injuries (e.g., hip fractures), medication mistakes, social isolation, and depression (Carter, 1994; Jackson, 2006; Pelletier et al., 2009). These issues have critical significance now that our society includes more than 4.6 million Canadians over the age of 65 (Statistics Canada, 2009).

Traditional design processes for products and the retail environment focus primarily on the mainstream market, with little attention to the needs of aging baby boomers and the disabled community (Coleman, 2001; Kaufman-Scarborough, 1999). As people are living longer (Statistics Canada, 2007) and more people are living with some type of disability (Government of Canada, 1981), incorporating universal design principles into design practice has become increasingly necessary. Universal Design (sometimes referred to as Inclusive or Accessible Design) is defined as “the design of all products and environments to be usable by people of all ages and abilities to the greatest extent possible” (Story, 2001, p. 10.3). Ron Mace is accredited as the originator of the term “universal design” (Ostroff, Limont, & Hunter, 2002). As a polio survivor, he was confined to a wheelchair from the age of 9 onward, the challenges he faced inspired him to become an architect and an advocate for accessible design which he believed was critical to independent living (Ostroff et al., 2002). Market accessibility is one of the key principles of Universal Design (The Center for Universal Design, 2010) and forms the core justification of this study.

Over the last 25 years, society has become more aware of the barriers facing people with special needs. For example, since the federal government published its *Obstacles: Report of the Special Committee on the Disabled and the Handicapped*, municipal building codes now require ramps and elevators for improved accessibility to public buildings (Government of Canada, 1981). More recently, the provincial government introduced the *Accessibility for Ontarians with Disabilities Act*, *2005*, which promotes barrier-free living (Government of Ontario, 2005). Nevertheless, persons with visual impairment are significantly limited in their abilities to travel alone and unaided (Golledge, 1993). Moreover, as Kaufman-Scarborough (1999) pointed out, truly inclusive shopping access requires more than merely widening the doors; it is only “achievable through a balancing of legally required architectural attributes, moderated by adjustments in terms of actual merchandise, displays, and specific store environment created by each retailer” (p. 505). In this sense, retail design should be looked at from a “servicescape” perspective (Bitner, 1992) which considers the store’s physical surroundings as a holistic element underpinning both the customer’s and the store employee’s experience. Inclusive design sends positive messages to disabled people, messages which tell them “you are important,” “we want you here,” and “welcome” (Napolitano, 1995, p. 33).

Literature Review

Environmental psychology theories recognize the impact of the retail environment on shoppers. Two paradigms may be applied to explain and organize shoppers' emotional, cognitive, and behavioural responses to the retail surroundings they encounter. Mehrabian and Russell's (1974) emotion-cognition-behaviour paradigm is considered classic but has faced challenges in recent years. This theory posits that emotions are antecedents of cognition, which in turn lead to two contrasting forms of behaviour: approach and avoidance (Donovan & Rossiter, 1982). Approach involves a desire to stay, explore, and affiliate, while avoidance comprises the opposite behaviours. An alternate theory states that cognition elicits emotion (Lazarus, 1991). In other words, upon entering a given environment, a person first evaluates the external and internal cues in terms of his or her own experience and goals; once such an appraisal is made, an emotion will result (Lazarus, 1991). The cognition-emotion theory has received empirical support in retail atmospherics (Baker, Grewal, & Parasuraman, 1994; Chebat & Michon, 2003) and serves as an overarching conceptual framework for the current study.

The retail environment is an important factor in consumers' evaluation of the products and services offered, because shoppers may assign aesthetic and instrumental values to the formal, expressive, and symbolic qualities of store environments (Fiore & Ogle, 2000). Therefore, a retail environment may influence consumers' inferences about merchandise, service quality, and store image (Baker et al., 1994). A number of studies suggest that ambient and social cues are significant atmospheric elements that influence consumers' affective states in store environments and impact their shopping and purchasing behaviour (Baker, Levy, & Grewal, 1992; Bellizzi, Crowley, & Hasty, 1983). Ambient cues refer to physical and auditory aspects of store environments, such as lighting, music, colour, and display, whereas social cues correspond to factors such as the number and friendliness of employees.

Beyond the impact of a retail store's physical environment on shopper behaviours and perceptions of merchandise and services, perception may also be internalized and influence shoppers' self-perception. This is true for sighted and visually impaired shoppers alike, but is more significant for visually impaired people due to the unique challenges they face in their daily lives. Symbolic interaction theory addresses how individuals come to understand their world and the process of developing this understanding (Solomon, 1983), and is used as another point of departure for this study's data analysis. The theory assumes that people interpret the actions of others and respond accordingly (Solomon, 1983). The process of interpretation involves the use of symbols which can be traced to shoppers' perceptions of how they interact with the retail environment they encounter. According to Blumer (1969), symbolic interactionism is based on three fundamental premises. First, human beings respond to things (e.g. encounters with others) according to the meanings that the things have for them. Second, the meanings of such things are derived from the social interaction that one has with one's fellows. Third, these meanings are handled in, and modified through, an interpretive process that a person uses when dealing with the things he or she encounters. Therefore, meaning is central to people's actions; it is socially constructed and derived by people as they interact (Blumer, 1969).

Symbolic interaction theory can be used to analyze visually impaired shoppers' interaction with store design as well as store employees. The symbolic messages visually impaired shoppers receive from their shopping experience may form their perception of how retailers view them (or do not view them) as valuable customers, and this perception may in turn positively or negatively impact such shoppers' self-perception. In addition, visually impaired shoppers may respond to the retail environment based on the interpretation of their experience. This psychological impact is an important aspect of quality of life among the visually impaired; therefore, it deserves serious attention among the public, and in particular policy makers and industry practitioners in the defined field.

The selection and purchase of clothing by visually impaired people has been the subject of research studies in Hong Kong, the United Kingdom, and the United States (Bradley, Hopkins, & Bailey, 2000; Frency, 2000; Kaufman, 2000). Difficulties reported include inadequate sales service, poorly communicated clothing details and pricing information, as well as awkward store navigation when compared to sighted cohorts. There clearly was a dearth of information related to the visually impaired experience within the Canadian apparel market.

Consequently, this study represents a first attempt to investigate the need for universal retail design in Canada. Specifically, the research objectives were to expand understanding of the unique challenge of visual impairment and the shopping experience of visually impaired consumers, and to identify gaps in retail design in order to better serve the visually impaired community by making recommendations to policy makers and the industry practitioners in the defined fields.

Research Method

Data Collection

Three focus group interviews were conducted with a total of 17 informants recruited by an independent consultant who was affiliated with a visually impaired advocacy organization in the Greater Toronto Area in Ontario, Canada. Each focus group consisted of 5-7 informants and interviews were held at office boardrooms close to the participants' residences. The focus group sessions were facilitated by one of the researchers and audio recorded.

Focus Group Questions and Informants

The open-ended questions focused on how visual impairment impacted daily life as well as problems encountered with clothing and shopping. Demographic information was collected via a questionnaire. Each focus group session lasted approximately 90 minutes. The audio-recorded data were later transcribed and analyzed using QSR NVivo 8.

The focus group participants were about equal in gender representation (8 women, 9 men), the majority (58.8%) were between 41-60 years of age, and 64.7% lived with a partner, relatives, or friends. Most of the informants (88.2%) had obtained a high school diploma and 52.9% had earned postsecondary degrees, including 11.8% with a graduate degree. About 82.4% were unemployed, and the majority (58.8%) had an annual income of less than $20,000 (see Table 1 for more detailed demographic information).

Findings and Discussions

The Unique Challenge of Visual Impairment

All informants reported that mobility was the biggest daily challenge they faced. Because they were not able to drive and depended primarily on public transportation for moving around, the range of places they could go and stores they could shop in was limited. One informant's comments described this typical situation of being visually impaired:

> Well, it's mobility. I think that about all of us at some point have lost our [driver's] license. You live a lot happier life with that concept of being able to go to the front door and hop in the car and drive down the street. It takes a long time, I think, to put that urge away, I guess, and then you have to figure out all sorts of alternatives to achieve that same goal…and to try not to get the feeling of being marginalized out of the main stream….So…you sort of feel that you could do pretty much what you did before if you could get there.

Shopping Experience of the Visually Impaired

In addition to mobility challenges, going shopping involved much more significant effort at every step of the process for the visually impaired; as one informant told us, simply finding the entrance is an arduous task:

> The experience is…you know, like, losing part of my sight. Now it's really hard for me to take the city bus; walking a distance, I can walk, but the thing is, it's getting from the bus stop to the store, especially if there's some construction there, you know [XX mall] where they change everything around, so it's like, where do we go? You don't know where you're supposed to stop the bus…and it's more extra walk too, because you know I have to get off at the light, and so now you don't know if you should walk left or right…for an opening to where you want to go [in the mall].

Due to visual impairment, the informants reported that they lost confidence in their ability to evaluate apparel quality and distinguish colour effectively, and to read labels, store signage, and receipts. However, these are all important factors of a satisfactory shopping experience and outcome. One male informant illustrated this scenario about judging quality:

> I went to [X store] last year for my winter boots. I found these great Velcro strap boots. They were great, but they were not leather. I've worn them right out. But when I was in Winnipeg in December I saw the very same boot in leather in [XX store]. Twenty bucks for one pair, eighty bucks for the other. Now, I probably would have seen that the twenty-dollar pair really wasn't that good, like, you can't really see inside and see what kind of stitching, and you know, the quality, like, well let's feel it, you know? And all that stuff looks good when it's brand new right? But give it a couple weeks and snow and rain and da da da.

Regarding colour, most informants described an inability to distinguish like shades of colour. They often felt embarrassed for wearing clothes, socks, and shoes that didn't coordinate. With this in mind, they depended on other sighted shopping companions or store associates for assistance. Challenges with reading labels and tags are prevalent among the informants due to small fonts, limited colour contrast between the text and background, and location of the label–tag information.

> Those tags are so small…you have to go and ask for the price after [asking for the sizes], but just to find the size you want, that's tough, because the numbers are so small.
>
> Yeah and they're always in amongst the other print too, you can't make them out.
>
> You know, to buy a shirt, you can't see [the tags]. Some days I might be able to hold it in the right spot and see that it says medium or large; other days, you know it gets so frustrating, I can't see it.
>
> The care labels, not only are they small, but being colour coded you can't always tell exactly what each thing is meant for. 'Cause sometimes they have them in yellow, red, or green. 'Cause sometimes I have trouble with the reds and greens. And sometimes just the printing isn't always very clear. You can usually make out where it's made, but the rest of it is very small.

Regarding store signage, informants indicated that letter size, font type, and sign colour, content, and location all presented them with barriers for a smooth shopping experience:

> I hate italicized. You know, like they'll do the script where it's all fancy and stuff. It might look pretty, but to us, just simple plain blacks, like Arial or something like that is clearer for us than the other types of print.

> It's even the location of the signage; if it's too high up you can't see it. But each one of us are probably different heights, so if you walk into a store and it's at my eye level then I'll see it but if it's higher or lower I won't.
>
> [In some stores, the signs will] be 8½ by 11 and the letters will be an inch, inch and a half, so those are pretty good, they'll say what it is, like men's sportswear or something like that. But if you go in …[other stores], there are no signs that say what it is, you pretty much have to look at it and say those are trousers on the shelf, I suppose, or shirts, whatever. You pretty much have to see the item to know what it is, as opposed to the sign.

Paying for purchases also created stress for the visually impaired. The issues ranged from an inability to read the receipt, to handling cash and using debit or credit cards. The informants discussed various experiences with checkout procedures:

> I favour going with cash now. Because…you just give the money and they give you the change. As opposed to if you go credit card…that process of signing is, could be a challenge….Often they'll put that thing down on the table and you'll have to find the line, to [sign]…so my signature has become very brief now, just an "R" and some squiggles. Probably not on the line. Like, if I work hard or bring the bifocals down and get within range I can see the line, but that's a stressful situation, you know; it's stressful when you have seven people behind you or whatever….We complained about receipts that are really faint, but that's the one thing that I think should be really dark and bold, there should be a huge X that's about half inch, for everybody, and then you can see at three feet without bifocals, you can see the X, and sign next to it.

A number of informants described their concerns about not being able to see the information on sales receipts. They worried that incorrect charges (e.g., due to cashier error or a discrepancy between the price tag and actual pricing in the checkout system) may have been posted on their purchase. Because they would be unaware of this at the time of purchase, travelling back to the store at a later date to get the problem corrected would require considerable additional effort.

Using cash may not be an ideal option, either, as one informant commented:

> If you use cash, the only drawback is, and you've probably all have this experience, it happens more in [XX] but it could happen anywhere, where they put the bills on your palm and they balance the coin on top of that? If you make a false move then the coin is all over the place.

With touch screen debit card machines, the informants found punching in their personal identification number (PIN) to be particularly problematic:

> The worst problem I just had the other day at a store, and I had to just leave…my order and leave the store, because they had a debit machine, a touch screen. I can't use that. On the Interac machine, okay, I can feel the buttons. And if worse comes to worst, once I punch my code in, I can ask the [cashier], "can you just press chequing for me?" 'Cause sometimes the machines…are all different…Then I push okay, then I cover it and I can feel the buttons. Then I punch in my code, then I push okay, and my order's fine. [With the touch screen machine], I didn't know there was anything on screen. I had to just say no, I had to walk out of the store.

Due to mobility challenges, visually impaired shoppers often need assistance from family members whom they shop with, as well as from store associates, especially when shopping alone. However, the informants' experiences of interacting with store employees have not been, to a large extent, satisfactory. The issues focused on the following aspects: store employees' lack of knowledge of the store and merchandise; insensitivity toward the unique needs of the visually impaired shoppers; and perceived reluctance to accommodate visually impaired customers. These issues were illustrated through the following scenarios:

> I was in [X store] a couple weeks ago…and they had pop on sale. So, I told [the store associate], "I need…two cases Diet Pepsi, and two cases Coke Zero." The guy comes up and is like, "is this what you want?" It's a bottle of pop! I said, "no. I want the twelve, two twelve-packs." So he comes back and goes, "do you want six bottles of this and six of this?" I'm like, "no!"….So he comes back and he's got the little…bottles. And he's like, "is it these ones?" I'm like, "no. It's in a box. It's square. There's twelve cans in there, and it says 'Diet Pepsi.'"

> I have a sister that's totally blind, went to the restaurant….We had a waiter there that she was, you know, trying to talk, and my sister, you know she wasn't paying attention to her. And so…I told the waitress that she's totally blind. So now that she knows that she's totally blind, she was almost eating the food for her. And she's talking louder too.

> Well, a lot of it is, what I think it is…a fear on the part of people working in the stores, and a lack of education. They don't know to come forward if they're afraid. I have enough sight, sometimes I almost feel like they duck behind a counter so they don't have to serve you….[The fear] is we're going to ask them for more help than they're prepared to give. Or they're going to expend far too much time for far too little return.

Experiences in the fitting room are also worth noting. The issues identified included seating, paint colour for walls, as well as lighting. Due to mobility and low vision challenges, visually impaired shoppers must engage in a complicated multistep process in the change room before even trying on any clothing: closing the door; feeling around to find hooks for a cane, purse, or coat; feeling around to find a seat because vision loss always results in reduced ability in maintaining balance; and looking for a mirror. If a change room is painted a dark colour and has poor lighting, these first steps become a daunting task.

Issues related to store lighting were most frequently mentioned among the study informants. As a large percentage of visually impaired people have problems with light adaptation, the issues identified included lighting contrast in different areas in a store, with lighting being too dark or too bright. Our informants gave us the following vivid illustrations of the light adaptation problem:

> For a lifetime I've had to make these trade-offs….If I know I'm going to go into a place, I wear sunglasses for a bit before, so I'm kind of half dark-adapted before I get in. And then…I'll take my sunglasses off and I'll have a chance of sort of seeing…into the shadows a bit more. So if you…go back to the retail example, if you're walking around the store and there's…a big bright light down on an arrow on the floor, and you're in the bright light, and then you walk out of the arrow and you're in the shadows. And your eyes are going as far as the function of adapting to the light, they're going up and down, they're working hard to try to get…[but they] can't come back…instantly.

> [I don't like the skylight in the malls because] when you have bright sunlight and you come in and then you have the glare in your eye and you can't see, or you get shadows from displays that are in the mall concourse.

> I find if you're under the pot light exactly, yes you might have good light, but the minute you are off of it then you have light and shadow. And that can really throw you. So as much as I really don't like fluorescent, it maybe gives you a better uniform type of light. But you don't want it too bright.

> A lot of the times if you walk into a place they've got the white walls, white floors, white ceilings, fluorescent lights; it just tends to make everything blend together too much, and it makes it way too bright, so then everything goes all wishy-washy and you're squinting trying to see what's around.

Conclusion and Recommendations

Environmental psychology literature suggests that retail atmospherics make a significant impact on shoppers' perception and shopping behaviour (Baker et al., 1992; Bellizzi et al., 1983; Chebat & Michon, 2003). This seems to be the case among visually impaired shoppers in our focus groups. Due to the unique challenges of this consumer group, their needs within the retail environment are well defined, but different than the needs of persons with other disabilities (Baker, Stephens, & Hill, 2002). Providing proper accommodation to this unique consumer group not only conforms to universal design principles, but also improves quality of life for the visually impaired. Symbolic interaction theory states that individuals interpret the symbolic meaning they receive from the people and environment they encounter, internalize it, and respond accordingly. Therefore, when the retail environment is designed with reasonable consideration of the disabled community's needs, it may send a signal to this market segment that conveys how retailers, commercial real estate developers, and society at large value them. Based on our focus group study, we identified the following needs and make the recommendations set forth below.

Store Environment

Store layout should be straightforward and logical. Because of mobility challenges, most of the visually impaired informants found it stressful to navigate through stores in which the division of departments is not intuitive and clearly labelled. For example, in some stores, boys' clothing is adjacent to the men's department, which may cause visually impaired shoppers to inadvertently cross into the different clothing section and purchase a wrong-sized item. Aisles should be wide and without obstruction. Though most of the visually impaired shoppers are not in wheelchairs, their vision loss is a significant impediment for moving around freely in a store. Narrow aisles or aisles containing display fixtures or protruding merchandise may pose potential tripping hazards for these shoppers and cause damage and bodily injury.

Signage is critical to help visually impaired shoppers better navigate through a store. It is recommended that signs use large fonts and regular-styled letters, and incorporate strong colour contrast between the letters and background (flashy digital signs and fluorescent colours should be avoided). In addition, clear signage to indicate what merchandise is on the shelf is helpful for this group of consumers. Alternatively, a hand-held scanner that can read (and announce with audio cues) the signs and tags would be especially beneficial.

Checkout procedures should be streamlined with the visually impaired consumers in mind. In particular, "checkout stress" for this group of consumers would be lessened through the use of receipts with a large font and a bold signature line; the proper handling of change by the cashier; the provision of user-friendly debit card machines for the visually impaired; and possibly an audio-enhanced checkout system that announces the price and quantity of merchandise being scanned.

For visually impaired shoppers, the preferred store lighting is uniform, fluorescent lighting that is not too bright. Lighting should be designed as an integral component of the overall store environment. Specifically, there should be colour contrast between general store lighting and walls, floors, and shelves. Using carpets in merchandising areas and tile in walkways helps define different functions within the store and provides some directional clues for the visually impaired.

Service Personnel

Store associates should be available and committed to assisting visually impaired customers. They need to be knowledgeable about merchandise within the store and receive training on the unique needs of this consumer segment and on how to provide appropriate assistance in a sensible way. They are the frontline people who interact with the shoppers directly and the symbolic message they send plays a critical role in shopping satisfaction among visually impaired customers.

Limitations and Future Research

The findings of this study are based on three focus group interviews conducted with selected members of a visually impaired advocacy organization in the Greater Toronto Area in Ontario, Canada. While these initial data provide valuable insights, inclusion of a diverse population would provide richer understanding. For future studies, systematic sampling is recommended for a more complete understanding of needs among the visually impaired community in Canada.

Additionally, how the retail shopping experience influences visually impaired shoppers' quality of life and self-perception might be another area that merits in-depth investigation. Providing appropriate accommodation for the visually impaired and other disabled communities requires collective efforts from the whole society, especially policy makers and industry practitioners in retail, commercial real estate development, design, and related fields. Future research should look into this dynamic system and explore retail universal design concept from diverse perspectives.

Table 1 Demographics of the Informants

Age	**No. Informants**
Younger than 18 years of age	0
19 - 40 years of age	2
41 - 50 years of age	5

Author Biography

Hong Yu

Hong Yu is an Associate Professor in the Ted Rogers School of Retail Management at Ryerson University in Canada. Dr. Yu specializes in researching the interaction between retail environment and consumers in a cultural context. Her main domains are in shopping experience and behaviours of diverse consumer segments in various retail venues and effective marketing strategies for different retail channels. She's been interviewed and invited to speak at conferences on the topics and also provided training sessions for retail design practitioners.

Sandra Tullio-Pow

Sandra Tullio-Pow is an Associate Professor in the School of Fashion at Ryerson University. She has designed women's sportswear and bridal wear as well as the official maternity uniform for the Royal Canadian Mounted Police. She is a consultant to various policing agencies on uniform design and garment specifications. Recent research with Princess Margaret Hospital produced a Canadian and U.S. design patent for a modular bag with therapeutic arm rest. Her passion is improving the quality of life for those with special needs by engineering clothing that combines both function and fashion.

Approaching Product Subjective Sustainability: Comparative Study on Evolution of Users' *Kansei* during Lifetime of their Mobile Phones between Iran and Japan

Hiroyuki Aoki, Chiba University, Japan

Abstract

Most of the scholar works about Sustainable Design treat of the objective side of product sustainability, whereas its subjective side has not been observed adequately. A sustainable product should be able to last in its expected lifetime not only objectively but subjectively. The main focus of design researches concerning the subjective issues of sustainability is on 'lifetime optimization of products'. Focusing on the subjective side of product sustainability, here the concept of 'Product Subjective Sustainability' is proposed to specifically indicate 'the emotional, affective and/or aesthetical capability of a product for satisfyingly and pleasantly lasting during its expected long/short lifetime'. However, such a concept may generally encompass all possible subjective effects of the product on sustainability values. This research basically aims to clarify 'Product Subjective Sustainability' experientially. As *Kansei* embraces much wider subjective issues of product than emotion, this study is based on *Kansei* Engineering approach. Here, a comparative and analytical study is done on the evolution of users' *Kansei* toward their personal product during its entire lifecycle in two different contexts, Iran and Japan. The product lifecycle from user perspective is divided into three stages including purchasing or choosing, keeping or using and replacing or throwing away the product. The assigned personal product for this comparative analysis is mobile phone which is an approximately short-lived product. Thus, two groups of Iranian and Japanese subjects are investigated about their senses, feelings and/or emotions (ie *Kansei*) regarding their mobile phone during each of its lifecycle stages. After extracting the patterns of evolution of their *Kansei* and thence drawing the trends of subjective sustainability of mobile phone in Iran and Japan, the resulted patterns and trends would be compared.

Keywords

Product Subjective Sustainability; Psychological Lifetime; *Kansei* Evolution; Attachment; Mobile Phone; Context.

The importance of subjective aspects of sustainability has been reinforced within some scientific debates almost from the first stages of emerge of the concept of sustainable development (Douven, Nijkamp, & Scholten, 1995; Ierland, Straaten, & Vollebergh, 2001). Some researchers argue that sustainable development is an inherently subjective concept (Kemp, & Martens, 2007). However, most studies about sustainability, especially in the last decade, have focused on its objective side, whereas its subjective aspects have not been observed adequately (Hart, 1994; Paddison, Money, Lever, & Lever, 1995). The key challenge of "subjective environmental aspects of products and processes" has been discussed in design research since the last decade (Hoffman, 1997). As design touches human multilaterally, the given importance to the subjective issues of sustainability within the design researches – for instance about sustainable lifestyle and socio-ethical values – is increasing theoretically and empirically (Childs, Agouridas, Barnes, & Henson, 2006). Practically, the main focus of design researches concerning the subjective issues of sustainability is on 'lifetime optimization of products' (Nes, & Cramer, 2003). Emphasizing "the main challenge in design for longevity lies in achieving an enduring satisfaction with the product, rather than only meeting the momentary desires of today", Nes and Cramer (2005), on the basis of the results of analysis of the factors influencing the users' decision for product replacement, propose five design strategies for product longevity including: design for reliability and robustness; design for repair and maintenance; design for upgradeability; design for product attachment and design for variability. Among these five strategies 'product attachment' seems to be the most directly-related one to product psychological or subjective lifetime. 'Product attachment' simply is defined as "the emotional bond experienced with a product" (Schifferstein, Mugge, & Hekkert , 2004). Many design researchers argue that extending the psychological life span of durables as well as increasing the degree of consumer-product attachment could be instrumental to reduce the demand for scarce resources and the rate of solid waste disposal and may contribute to a more sustainable society (Mugge, Schifferstein, & Schoormans, 2004; Hinte, 1997; Govers, & Mugge, 2004). The strategy to enhance product attachment is however the most uncertain in actually enhancing longevity. As this strategy is based on the fact that the disposal of products is made harder when one feels attached to the product, it brings so many questionable points and challenges implying that it should be well considered and applied delicately (Nes, & Cramer, 2005). A product, even a very personal one like mobile phone, could be emotionally pleasurable, aesthetically appealing and/or functionally comfortable during its expected short/long lifespan while there might not be any strong user-product-attachment. Moreover, durability of users' satisfaction and emotional pleasure regarding a product and its appeal may not necessarily eventuate to attachment. In fact, user-product-attachment is one of the product subjective issues including the user's total attitude, feeling, affection, emotion and/or appreciation, which could be called *Kansei*, about a product (Childs, Agouridas, Barnes, & Henson, 2006; Schütte, Eklund, Ishihara, & Nagamachi, 2007). Keeping the above mentions as the background and aiming to analytically expand 'product subjective sustainability', this paper presents the process and results of a comparative study done on the evolution of users' *Kansei* toward their mobile phone during its entire lifecycle between two different contexts, Iran and Japan.

Approach

Conceptualization

Considering the above mentioned points and challenges concerning product attachment and also according to the authors' findings within the last researches (Zafarmand, Tauchi, Terauchi, Kubo, & Aoki, 2009a,b), it seems that product attachment is just one of the effective means that can be used for extending or optimizing the psychological lifespan or subjective lifetime of products, while there are some other effective means in this regard. Thus, there is a room for an open concept or wide expression to comprehensively encompass product subjective issues contributing to the products pleasurable longevity when considering product sustainability.

The term 'subjective sustainability', as a versatile and wide concept, has been used in the literatures of various fields, such as Social Sciences (Becker, & Jahn, 1999), Public Policy (Tierney, 2003), Forest Management (Raison, Brown, & Flinn, 2001), Urban Planning (Hart, 1994; Paddison, Money, & Lever 1995; Castello, 2006) and Package Design (Salazar, 2008). 'Subjective sustainability' in terms of Social Sciences generally is the matter of the social and cultural issues of sustainable development (Becker, & Jahn, 1999) and in Urban Studies specifically is about "rising real incomes, adjusted market frameworks and changing consumer preferences interact to moderate resource inputs while raising GNP" (Hart, 1994; Paddison, Money, & Lever, 1995). According to Haie (2006), subjective sustainability criteria should be approached through subjective judgments, subjective classifications and subjective conclusions. Nevertheless, the definite territory of 'subjective sustainability' has not been identified clearly and expanded well within the literatures.

In this research "a product's capability of being pleasing, appealing and satisfyingly lasting during its expected long/short lifetime" is called 'Product Subjective Sustainability' (PSjS). The word 'sustainability' in this concept is to imply not only a fair durability but the imperative application of such durability in terms of product sustainability. However, such a concept could be expanded to generally embrace all subjective issues of product reflecting/effecting/affecting sustainability values.

Experimental Framework and Purpose

To experientially expand PSjS, we have carried out a comparative analysis on the evolution of Japanese and Iranian users' *Kansei* toward a product in its entire lifecycle. For covering all subjective issues, this analysis is on the basis of *Kansei* Engineering approach (Schütte, Eklund, Ishihara, & Nagamachi, 2007). Here, the entire lifecycle of product from user perspective is divided into three main stages including: Purchase (P); Keep/Use (KU); and end or Replace (R). The specified product type for this analytical study is Mobile Phone, since its subjective issues are more considerable than the other kinds of product due to the users' very close/personal relation with it despite being a short-lived product (Zafarmand, Sugiyama, Watanabe, & Ono, 2006a,b). User's emotional attachment to mobile phone – rather than the other kinds of product – is also reflected in numerous scholarly works (Vincent, 2006; Vincent, 2005; Wehmeyer, 2007; Wehmeyer, 2008).

Furthermore, there is the highly effects of context on the form-structural patterns of aesthetic boredom and consequently aesthetic durability of mobile phone (Zafarmand, Sugiyama, Watanabe, & Ono, 2007). In fact these two phenomena affect product psychological lifetime while being included in the subjective issues of product. Within the authors' last researches with the same theme and approach just a limited number of Japanese students were investigated. To find out the effects of contextual differences on PSjS, here a considerable number of mobile phone users living in two quite different contexts are investigated. The major processed output of investigation would the *Kansei* descriptive items regarding each lifecycle stage of the subjects' mobile phones, the items and subjects groupings and thereupon the various patterns of the evolution of the subjects' *Kansei* regarding their mobile phone during its lifecycle. Finally, as the main outcome of this study, the major trends of PSjS would be drawn on the basis of the results.

Outline and Method

This comparative study has been performed within three main steps. In the first step, two groups of Iranian and Japanese subjects are investigated through the definite and extensive-descriptive questionnaire. The second step is the process and analysis of the data derived from the questionnaire by using KJ Method, Descriptive Statistics, Quantification Theory Type III (QT3) and Cluster Analysis. Last, as the third step, the results of analysis are interpreted and put in discussion.

All of the subjects are selected randomly. The Japanese subjects ranging from 15 to 24 years, 31% female and 69% male in total, consist of 32 students of Chiba University and 17 high school students living in Chiba. The Iranian subjects ranging from 16 to 28 years, 77% female and 23% male in total, consist of 50 university students – of University of Tehran, Iran University of Science and Technology and Shiraz University – and 21 high school students living in Shiraz. They are investigated about: a brief history of their used/replaced mobile phones; their reasons for replacing mobile phone; the level of dis/satisfaction of their current mobile phones; and their feeling, emotion, image and/or attitude – namely *Kansei* – regarding their mobile phones in each of the three lifecycle stages of P, KU and R separately into three different questions.

The *Kansei* descriptive words responded by the subjects are summarized through KJ Method. Then the subjects' responded items in all three lifecycle stages are processed altogether by using QT3. To identify the *Kansei* items' grouping and also the subjects' grouping on the basis of their *Kansei* regarding their mobile phones in the three lifecycle stages, the method of Cluster analysis is used. On the basis of the axis dimensions as the output of QT3, all of the subjects' *Kansei* statuses in the three lifecycle stages of their mobile phones are put in the 3-dimensional spaces. As the following formulation shows, if the distance of a subject's *Kansei* status (S_i) in two different lifecycle stages, for example P and R, was higher than the addition of Average distance and Standard Deviation (Av.+SD), that is considered important case regarding the shift between those two stages.

$Dist\ S_{iPR}$ = *Distance of* S_i *in P and R lifecycle stages*

$$Dist\ S_{iPR} = \sqrt{(X\ S_{iP} - X\ S_{iR})^2 + (Y\ S_{iP} - Y\ S_{iR})^2 + (Z\ S_{iP} - Z\ S_{iR})^2}$$

If $Dist\ S_{iPR} > Av.+SD$, S_{iPR} *Importance = 1*

If $Dist\ S_{iPR} < Av.+SD$, S_{iPR} *Importance = 0*

The various patterns of the subjects' *Kansei* evolution are then extracted from the positions of the highlighted important cases in terms of the resulted groupings in each lifecycle stage. Then, according to the positions of extracted patterns in the areas of the resulted 3-dimensional spaces, the major trends of PSjS are drawn. Finally, the major trends and patterns of PSjS extracted from Iranian and Japanese subjects' responses are compared.

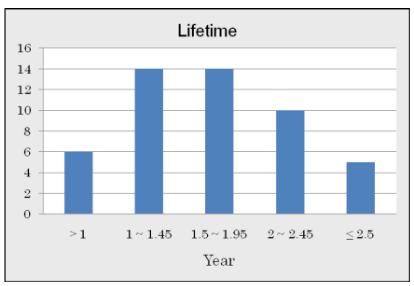
Results

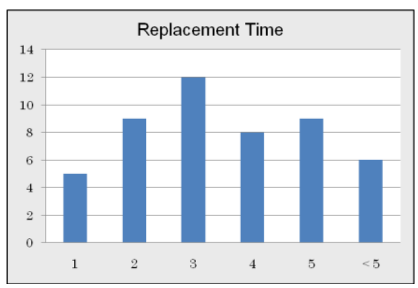
Replacement Circumstances

The general results of investigating the Japanese and Iranian subjects regarding mobile phone replacement are as follows. Indifferently, a Japanese subject and an Iranian one have already used respectively '3.6' and '2.4' mobile phones (Av.MP) from '5.37' and '3.75' years ago. The average lifetimes of mobile phone used by the Japanese and Iranian subjects are respectively '1.59' and '1.88' years. Besides, just 65% of the Japanese subjects are satisfied with their current mobile phone and 80% of them like it. But 85% of the Iranian subjects are satisfied with their current mobile phone while 80% of them like it. For more easily comparison, the above mentioned results are presented in Table 1. The histograms of Japanese and Iranian subjects' mobile phone lifetimes and replacement times are also shown respectively in Figures 1, 2, 3 and 4.

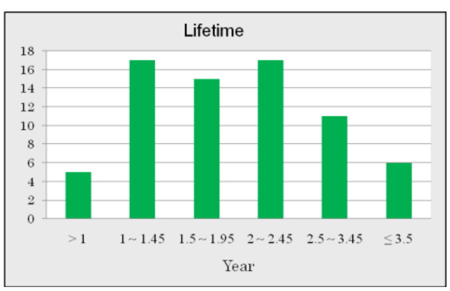
Subjects	Tot No.	Av.MP used	Start of use	Av. Lifetime	Satisfied with current MP	Like current MP
Japanese	49	3.6	5.37 *yrs ago*	1.59 *yrs*	65%	80%
Iranian	71	2.4	3.75 *yrs ago*	1.88 *yrs*	85%	80%

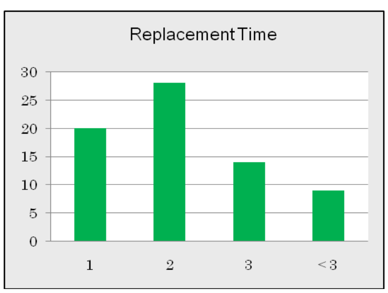
Table 1 Comparison of mobile phone replacement circumstances between Iran and Japan





Figures 1 & 2 Histograms of Japanese subjects' mobile phone lifetime and replacement time





Figures 3 & 4 Histograms of Iranian subjects' mobile phone lifetime and replacement time

The Japanese subjects' reasons for replacing mobile phone are summarized into 11 items including Boring, Broken, Defect, Form, Found Favorite, Lost, Novelty, Oldness, Price, Service and Tattered. The ones of Iranian subjects' are also summarized into 18 items including Boring, Broken, Defect, Facilities, Fashion, Form, Gift, Individuality, Interest, Lost, Novelty, Oldness, Performance, Physics, Price, Quality, Service and Variety. To distinguish the most ongoing and frequent reasons and compare them between the Japanese and Iranian subjects, the reasons are sorted followed by their frequency into the bar-graphs shown in Figures 5 and 6. As it can be seen, the most ongoing and frequent reasons are respectively Defect, Oldness, Novelty and Broken in the context of Japanese subjects and Facilities, Defect, Broken and Form in the context of Iranian subjects.

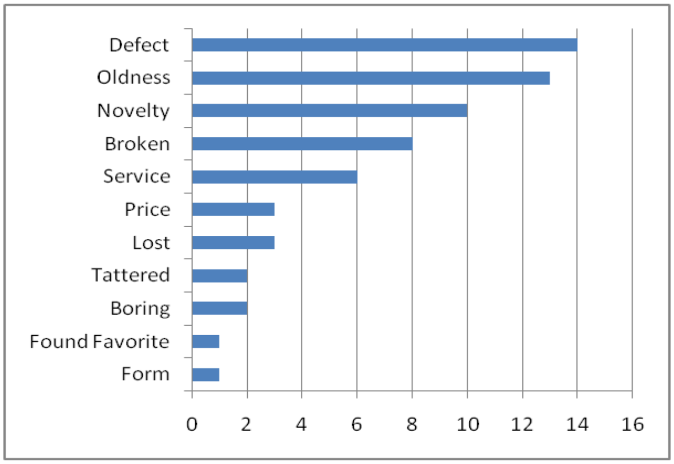


Figure 5 The Japanese subjects' main reasons for replacing mobile phone

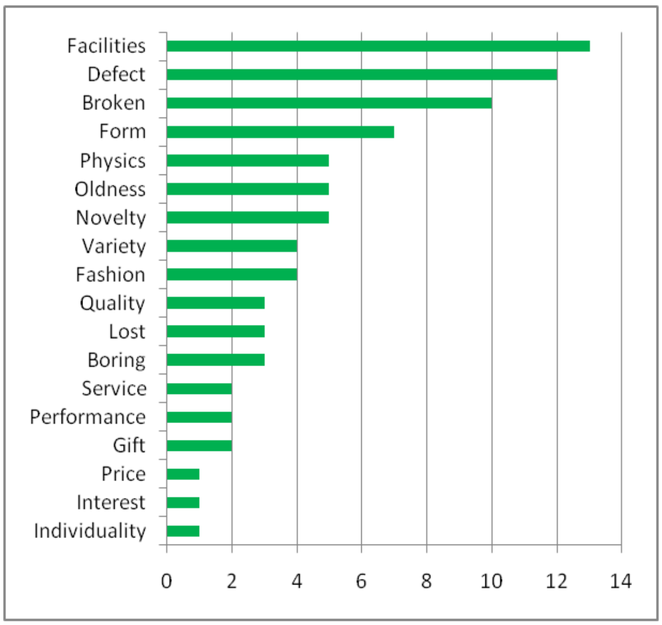

Figure 6 The Iranian subjects' main reasons for replacing mobile phone

Derived Kansei Items Groupings

In total, 626 Japanese *Kansei* keywords (including 136 ones for R stage, 278 ones for P stage and 212 ones for KU stage) and 635 Persian ones (including 190 ones for R stage, 224 ones for P stage and 219 ones for KU stage) are derived respectively from the Japanese and Iranian subjects' responses regarding their *Kansei*, emotion or feeling about their mobile phone in its different lifecycle stages. These two groups of keywords are separately summarized into 41 and 42 *Kansei* items or descriptive words through KJ Method. The Japanese and Iranian subjects' responded data about their *Kansei* regarding all of the three lifecycle stages of their mobile phones are separately adapted to these 41 and 42 *Kansei* items and processed by using QT3 and Cluster

Analysis. The overall output distributions of the *Kansei* items in the lifecycle stages of mobile phone regarding each country's subjects are shown into X-Y and X-Z graphs in Figures 7 and 8.

The chosen cut-off lines for the clustering algorithms have yielded five clusters marked from *C.1* to *C.5* in the X-Y graph and eight clusters marked from *G.1* to *G.8* in the X-Z one regarding the Japanese subjects (Fig. 7), and six clusters marked from *Ci.1* to *Ci.6* in the X-Y graph and six clusters marked from *Gi.1* to *Gi.6* in the X-Z one regarding the Iranian subjects (Fig. 8). This choice of cut-off is carefully made in order to arrive at the most meaningful groupings for understanding of the relationship between various *Kansei* items. The lists of *Kansei* items, their output dimensions in X, Y and Z axis, their belonging clusters in X-Y and X-Z graphs and their frequencies in each lifecycle stage according to the Japanese and Iranian subjects' responses are presented in Tables 2 and 3. To illustrate the lifecycle stage (P, KU or R) each item associates with rather than the other stages, the different point shapes and colors are used in the graphs. This suggested association is decided on the basis of the higher frequencies of each item in the lifecycle stages highlighted in Tables 2 and 3.

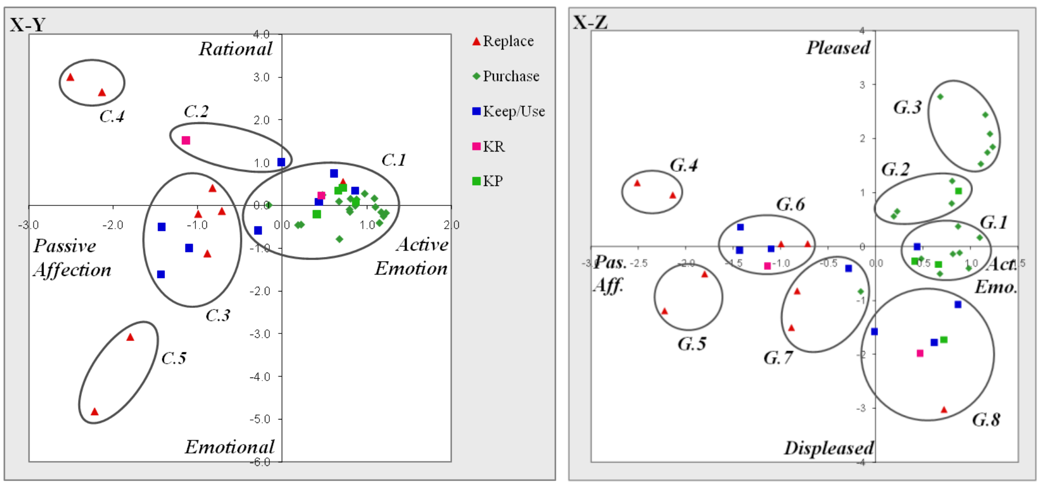

Figure 7 Distributions and groupings of 41 *Kansei* items in X-Y and X-Z graphs of Japanese subjects

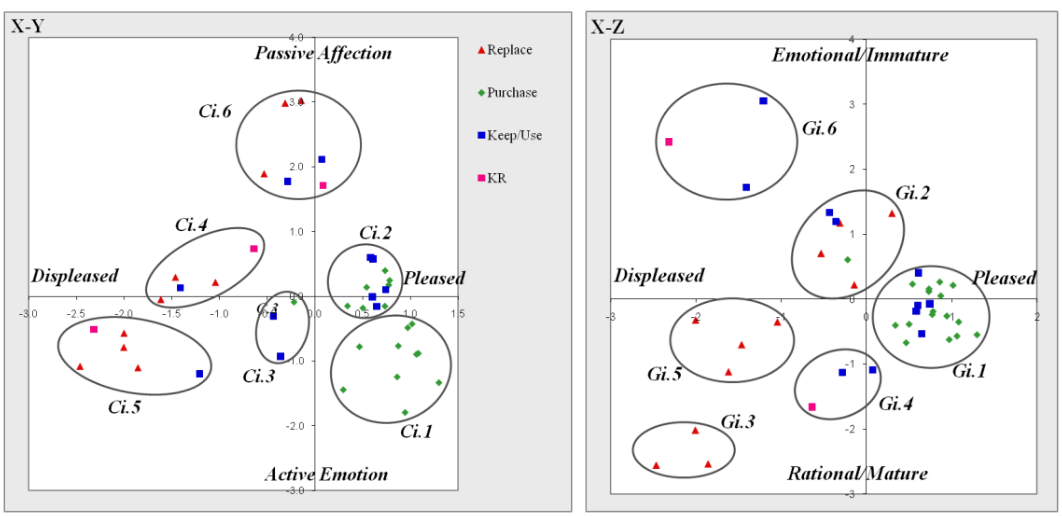

Figure 8 Distributions and groupings of 42 *Kansei* items in X-Y and X-Z graphs of Iranian subjects

In the graphs relevant to the Japanese subjects (Fig. 7), the directions of the three axis of X, Y and Z are respectively named as '*Passive Affection - Active Emotion*' (*Pas.Aff - Act.Emo*), '*Emotional - Rational*' (*Emo - Rat*) and '*Displeased - Pleased*' (*Disp - Ples*). The clusters *C.1* to *C.5* can be characterized respectively as Gratification/Concerns, Old, Enduring, Ally and Lonely. Similarly, clusters *G.1* to *G.8* can be characterized respectively as Practical Concerns, Pleasant, Joy/Fresh, Ally, Lonely, Attached, Undergone and Dissatisfied. As it can be seen, the items having more association with the lifecycle stage of P and R are located respectively in the right and left sides of the graphs.

In the graphs relevant to the Iranian subjects (Fig. 8), the directions of the three axis of X, Y and Z are respectively named: '*Displeased - Pleased*'; '*Active Emotion - Passive Affection*'; and '*Rational/Mature – Emotional/Immature*' (*Rat/Ma – Emo/Im*). The clusters *Ci.1* to *Ci.6* can be characterized respectively as Joy/Fresh, Satisfaction, Concerns, Dissatisfaction, Displeasure and Attachment. The clusters *Gi.1* to *Gi.6* can be also characterized as Joy/Fresh, Affected, Riddance, Ally, Displeasure and Boring. Similarly, the items having more association with the lifecycle stage of P and R are located respectively in the right and left sides of the graphs. All of the above given names are decided on the basis of the context and distribution of the *Kansei* items in the graphs.

Table 3 *Kansei* items and their dimensions, belonging clusters and frequencies relevant to Iranian subjects

Subjects' Groupings and Kansei Statuses in Lifecycle Stages

In order to delineate the subjects' *Kansei* statuses concerning their mobile phone during its P, KU and R lifecycle stages, the resulted graphs of distribution of the Japanese and Iranian subjects in X-Y and X-Z axis are shown in Figures 9 and 10. These distribution graphs and the ones of *Kansei* items grouping (Figures 7 and 8) are built on the basis of the 'sample score' and 'category score' of the same output of QT3 analysis on the same input data derived from each country's subjects, and hence can be overlapped. The same names are therefore given to the directions of X, Y and Z axis in both sets of distribution graphs. The purposely chosen cut-off lines for clustering within the resulted X-Y and X-Z dimensions have yielded respectively five clusters marked from *A* to *E* and five clusters marked from *F* to *J* in the graphs relevant to Japanese subjects, and five clusters marked from *Ai* to *Ei* and five clusters marked from *Fi* to *Ji* in the graphs relevant to Iranian subjects.

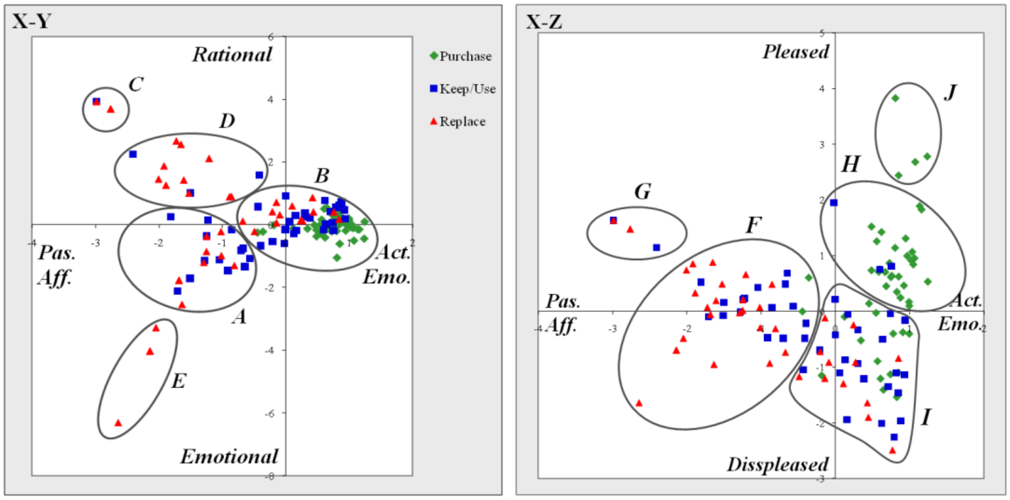

Figure 9 Distribution and groupings of Japanese subjects' *Kansei* status in the lifecycle stages of their mobile phones

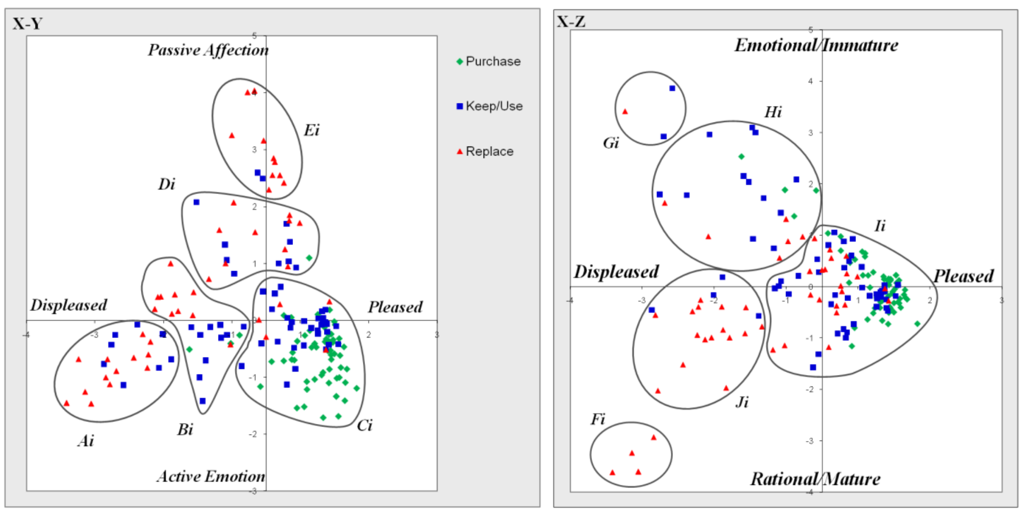

Figure 10 Distribution and groupings of Iranian subjects' *Kansei* status in the lifecycle stages of their mobile phones

According to the *Kansei* items responded by majority of the subjects belonging to each cluster highlighted in Tables 2 and 3, the following appropriate names can be given to the clusters to express each cluster's exceptional characteristic. Regarding the graphs relevant to Japanese subjects (Fig 9), the given names to clusters *A* to *E* are: Attached; Gratification/Concerns; Gratitude; Ally; and Lonely. Clusters *F* to *J* are also named as Attached/Lonely, Gratitude, Pleasant, Dissatisfied/Concerned, and Joy/Fresh. Regarding the graphs relevant to Iranian subjects (Fig 10), clusters *Ai* to *Ei* are named as Bored/Displeased, Concerned, Joy/Pleased, Attached and Affected, while clusters *Fi* to *Ji* are named as Ridded, Bored, Detached, Joy/Pleased and Dislike/Bothered.

In these graphs (Figs 9 and 10) each point represents a subject's *Kansei* status in each of the three lifecycle stages, which are discernible by three different colors and shapes in the graphs. The subjects' *Kansei* statuses in P stage are almost located in the left side of the graphs. The resulted clusters indicate each subject's *Kansei* statuses in the three lifecycle stages of his/her mobile phone.

Patterns of Subjects' Kansei Evolutions

In order to distinguish the various patterns of the subjects' *Kansei* evolution during the three lifecycle stages of their mobile phones, the clusters to which each subject belongs in each lifecycle stage (presented in Tables 4 and 5) are used as indicators for sorting the subjects into various types.

	QT3 output X, Y and Z in lifecycle stages									Dist. of 2 stages			Importance			Belonging clusters

Table 5 Dimension, distance, importance and clusters of Iranian subjects' *Kansei* in the lifecycle stages

As each subject's *Kansei* status in the three lifecycle stages is quantifiably represented by three points specified by X, Y and Z dimensions, the distance between these points indicates the level of the subject's *Kansei* changes during the stages. Accordingly, the higher distance than 'Av.+SD' is considered important while indicating a drastic change of a subject's *Kansei* status during two lifecycle stages. The resulted Average distances, SD and the addition of these two parameters relevant to the Japanese subjects are respectively 2.27, 1.45 and 3.72 (Av.+ SD=2.27+1.45=3.72). The ones relevant to the Iranian subjects are also 2.23, 1.58 and 3.81 (Av.+ SD=2.23+1.58=3.81). As the result, the important cases of the Japanese and Iranian subjects' *Kansei* evolution during the lifecycle stages of their mobile phones being identified through their belonging X-Y and X-Z clusters in each stage are also highlighted respectively in Tables 4 and 5.

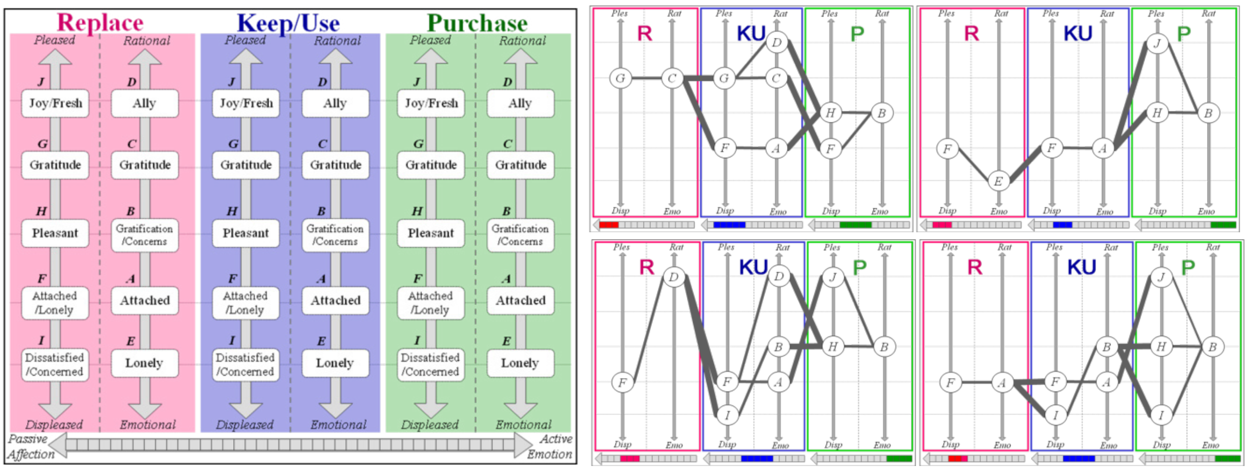

Figure 11 Important patterns of *Kansei* evolution extracted from Japanese subjects' responses

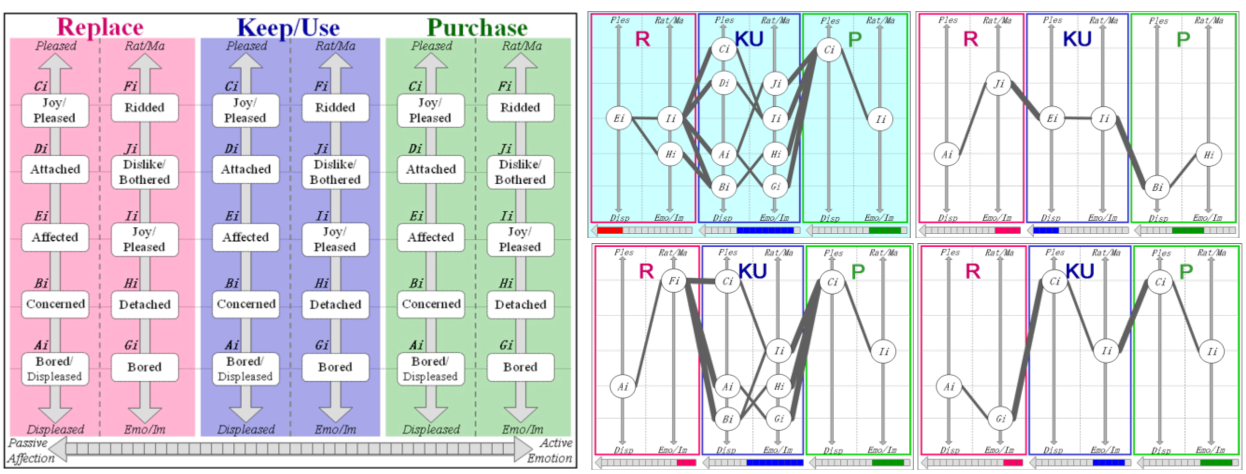

Figure 12 Important patterns of *Kansei* evolution extracted from Iranian subjects' responses

On the basis of the similarity of the clusters belonging to the important cases in R stage, namely the eventuation of their *Kansei* evolutions, these cases could be set into four main classes regarding each country's subjects. The resulted classes of the extracted patterns of the Japanese and Iranian subjects' *Kansei* evolutions during the lifecycle stages of their mobile phones are visualized into two diagrams respectively shown in Figures 11 and 12. The colored part in the scaled arrow located below each stage in the diagramed classes is to indicate the position of the ongoing clusters in that stage beside '*Passive Affection - Active Emotion*' directions. As there is a reversely similarity between the axis directions in the distribution graphs derived from the Japanese and Iranian subjects' responses, the axis (X-Y-Z) directions order relevant to the Japanese subjects is considered as the base in the format of diagrams. Accordingly, in the diagram relevant to Iranian subjects (Fig. 12), the axis directions are adapted to the same order as Japanese subjects' one to be more easily comparable. As the result, the eventual *Kansei* statuses in all four classes of the patterns extracted from the Japanese subjects' responses are good or positive, whereas such statuses in the classes extracted from the Iranian ones are almost negative. However, just in one class relevant to the Iranian subjects, which is highlighted in Figure 12, there is a low degree of positivity namely eventual affective relation.

Interpretation and Discussion

Iran and Japan have two quite different contexts of mobile phone market. In Japan, the presented mobile phone devices are almost the regionally localized product designed specifically for Japanese users while the carriers are offering the very advanced and wide services. But the presented mobile phone devices in Iran almost belong to the global market. The Iranian mobile phone users are bereft of so many services such as internet, online search and navigation. Comparing with last 5 years, the number of mobile phone users is drastically increased in Iran. Nowadays the Iranian students almost have their own mobile phone, whereas 5 years ago only less than half of them had it (Zafarmand, Sugiyama, Watanabe, & Ono, 2006b).

As the general results of investigation show, mobile phone is approximately a short-lived product in both countries. However, its lifetime is actually a little longer in Iran than Japan. Considering the contextual differences between Iran and Japan from socio-cultural, economic and industrialization points of view, the Japanese subjects' backgrounds and experiences in mobile phone use and replacement are naturally higher than the Iranian subjects. But mobile phone replacement reasons in Iran are more various than in Japan; seemingly the more standardized individuals belonging to a more industrialized country. In both countries, the similar top/main reasons for replacing mobile phone including 'defect', 'broken' and 'oldness' are almost actual, rational or somehow objective. Nevertheless, for the Japanese users 'novelty' and 'service' and for the Iranian users 'facilities', and 'form' are also among the top main reasons of replacement. Majority of both countries' subjects are satisfied with and interested in their current mobile phones. However, in Japan the percentage of those being satisfied is lower than of those liking their current mobile phones, but in Iran vice versa.

The *Kansei* items derived from the investigations of the Japanese and Iranian subjects despite of having some similarity are not the same. This point emphasizes the highly effect of context socio-culturally and linguistically on a user's *Kansei* about a product and his/her responded words in this regard. As the distribution graphs of the items (Figures 7 and 8) show, the main axis (X) directions relevant to the Japanese and Iranian subjects, which generally identify the most ongoing reciprocal trend of the items derived from each context, are not the same. The one relevant to the Japanese subjects is 'Active Emotion - Passive Affection', whereas the one relevant to the Iranian subjects being 'Displeased - Pleased'. Furthermore, numerous clusters of the items are located near the directions of 'Passive Affection' in the graphs relevant to Japanese subjects and of 'Displeased' in the ones relevant to Iranian subjects.

A pattern of *Kansei* evolution eventuating in a cluster of *Kansei* items with a positive *Kansei* status indicates a state of PSjS. As all of the classes of the patterns of *Kansei* evolution extracted from the Japanese subjects' responses have eventuated in the positive statuses, there is seemingly a tangible state of PSjS in mobile phone market of Japan. Unlikely, most of the classes of the patterns of *Kansei* evolution extracted from the Iranian subjects' responses have eventuated in the negative statuses. Therefore, it seems that product subjective un-sustainability is an ongoing issue in mobile phone market of Iran. Nevertheless, there is a low or potential degree of PSjS in one of the classes relevant to Iranian subjects.

Combining the X-Y and X-Z clusters of the subjects' *Kansei* status in R stage regarding the resulted classes of the important patterns of the subjects' *Kansei* evolution, on the one hand, there are four main trends of PSjS being ongoing in mobile phone market of Japan. The first one identified by clusters *A* and *F* characterized as Attached and Attached/Lonely can be called <u>Affectional Attachment</u>. The second one identified by clusters *C* and *G* both characterized as Gratitude can be called <u>Gratification</u>. The third one identified by clusters *D* and *F* characterized as Ally and Attached/Lonely can be called <u>Rational/Associational Attachment</u>. And the last one identified by clusters *E* and *F* characterized as Lonely and Attached/Lonely can be called

Emotional Attachment. The above-mentioned three kinds of attachment imply that there is a clear demarcation between various kinds of relationship, which could be in affective, collaborative and/or emotive way between a user and his/her object as well as human, and the consequent attachments in Japan.

On the other hand, there are three main trends of product subjective un-sustainability occurring in mobile phone market of Iran. The first one identified by clusters *Ai* and *Fi* characterized as Bored/Displeased and Ridded can be called Affectional Detachment. The second one identified by clusters *Ai* and *Gi* characterized as Bored/Displeased and Bored can be called Boredom or Emotional Detachment. The third one identified by clusters *Ai* and *Ji* characterized as Bored/Displeased and Dislike/Bothered can be called Emotional Objection/Dissatisfaction. However, there is also a potential trend of PSjS in Iran. This potential trend can be identified by cluster *Ei* characterized as Affected in R stage followed by clusters *Ci* or *Di* and *Ii* characterized as Joy/Pleased or Attached and Joy/Pleased in KU stage. As this trend involves a degree of affective, emotive and/or associative relation with mobile phone at the same time, it can be called generally Psychological Attachment. Therefore, unlike the Japanese subjects, the Iranian subjects' responses have not indicated a clear demarcation of the various kinds of affective, collaborative and/or emotive relationship with their mobile phones and the consequent psychological attachment. Such a point reemphasizes the highly effect of context on PSjS.

Conclusion

The actual lifetime of Mobile phone, as an approximately short-lived product, is not the same in different contexts. The majority of Iranian users cannot afford to quickly replace their mobile phone, even though they don't like it. Despite of the longer actual lifetime of mobile phone in Iran than Japan, product subjective un-sustainability is seemingly an ongoing and egregious problem in mobile phone market of Iran. This point led us to conclude that PSjS is not necessarily analogous to a longer lifetime of product. Product subjective un-sustainability at least has three main trends including: Affectional Detachment; Boredom or Emotional Detachment; and Emotional Objection or Dissatisfaction. On the other hand, PSjS has at least four major trends including three different kinds of attachment and a state of gratification. Attachment, as the most important trend of PSjS, may appear into the following levels: deep, permanent, passive or affective; partnership, association or collaborative; and shallow, temporary, active or emotive. Besides, the trend of gratification indicates a good utility of mobile phone and at the same time cherishing it as an important and valuable object. In order to extend the subjective lifetime of mobile phone various design solutions or means being fit to the above-mentioned trends of PSjS should be applied. According to the findings of this research, PSjS in fact is not necessarily the issue of a constant *Knasei* toward a product. Rather, it would be the result of various emotions, feelings or moods, etc regarding a product and their evolution while being mostly good or pleasant or dynamically positive and becoming mature alongside the product's expected lifespan being over.

Authors Biography

Seyed Javad Zafarmand

Postdoctoral researcher awarded by Japan Society for the Promotion of Science (JSPS) and the former Assistant Professor of Industrial Design Dept of University of Tehran. He received BA and MA in Industrial Design from University of Tehran, Iran, and PhD in Design Science from Chiba University, Japan.

Takatoshi Tauchi

Master of Arts and Assistant Professor of Design Morphology, Design Science Div, Graduate School of Engineering, Chiba University, Japan.

Fumio Terauchi

Doctor of Engineering and Associate Professor of Materials Planning, Design Science Div, Graduate School of Engineering, Chiba University, Japan.

Mitsunori Kubo

Doctor of Engineering; Professor of Design Morphology, Graduate School of Engineering, Chiba University, Japan; and President of Design Science Div of Chiba University.

Hiroyuki Aoki

Doctor of Engineering; Professor of Materials Planning, Design Science Div, Graduate School of Engineering, Chiba University, Japan; and President of Japanese Society for Science of Design (JSSD). This research is done under his leadership and supervision.

Dealing with the human-centered approach within HCI projects

Mithra Zahedi, University of Montreal, Canada, mithra.zahedi@gmail.com

Giovanni de Paoli, University of Montreal

Abstract

Our interactions with objects or/and systems through digital screens are constantly increasing. Industry and information technology have more and more ambition toward offering new functions and interactions through these computerized systems. At the same time as the complexity of these systems is escalating, the complexity in designing them also grows. While user-centered approaches and usability in the area of human-computer interfaces (HCI) have been thoroughly researched for more than a decade now, we still encounter regularly unsatisfying interfaces. It is generally recognized that the design of HCI within multidisciplinary teams brings better answers to users. However as design practitioners, we see the inadequacy when it comes to working with other disciplines, at the conceptual level, and in creating shared understanding and new knowledge regarding user-centeredness. The paper explains what factors contribute to user-centered design and how we can see the inadequacy within multidisciplinary teams. Aiming to create the conditions for knowledge sharing and emergence of innovative and sustainable solutions, we propose a model called environment for reflective collaboration that encourages interdisciplinary attitude and allows for achieving joint reflective practice. Both seem necessary for dealing with the complexity of HCI. In this model, design is used as a method to understand people. Applying this design process in the early stages of a project provides the needed structure for collaboration. We explain the model as used in a real project, and we explain how a project-grounded approach helped the team bridge theory and practice.

Keywords

User-centered design; HCI; Interdisciplinary; Project-grounded approach.

As users of a variety of digital devices, we are witnessing an ongoing development of human-computer interfaces (HCI). While digital technologies are transforming lives, each one of us can recall occasional dissatisfaction. User-centered approaches and usability have been thoroughly researched in the area of HCI. Also it is known that it is crucial to develop HCI within a multidisciplinary team (Dourish, 2004; Löwgren & Stolterman, 2004; Preece, Rogers, & Sharp, 2002). However as design practitioners, we encounter conflicting situations: within multidisciplinary teams, members have difficulty in agreeing on the needs and motivations of the user, on usability issues, and on creating shared understanding.

It is generally accepted that unsuccessful design is a direct result of an inadequate approach at the conceptual level, and in many cases, the inadequate approach is caused by problems of communication and understanding among team members (Carrara, Fioravanti, & Nanni, 2009; Kleinsmann, Valkenburg, & Buijs, 2007). In our practice, we have witnessed that HCI specialists (who, in many cases, are computer scientists) and designers have a different understanding about users' interests and needs as well as usability. We have also noticed that HCI specialists and other participants of these multidisciplinary teams are mainly concerned with their own expertise, making it very difficult to consider the end user.

In this context, how can we create the conditions for a variety of contributing experts to go beyond their individual knowledge, thereby enriching their reflections in order to efficiently collaborate within a human-centered design? The idea is that their enriched knowledge will then contribute to a more successful design, and to the development of the project in a timely and more economically efficient manner.

What contributes to user-centered design?

Early interfaces were technology-centered, made by engineers in order to be used by experts like themselves (Carroll, 2000; Linard, 2001). In the beginning, as the computer's time was more expensive than people's time, efforts were focused on making more efficient computers rather than making them more usable for users (Dourish, 2004). With early software interfaces, in the 1950s and 1960s, the communication with computers was by code, based on the mathematical model of computers (Boyarski & Buchanan, 1994). During the 1970s, communications were cognitively based, which means they were based on task requirements (Linard, 1998). It was only later, around 1983, when the Internet appeared that we started seeing interfaces based on users' needs, related to the context of use, and activity of the user as Mark Weiser mentioned in1988 (Weiser & Brown, 1996): "The important waves of technological change are those that fundamentally alter the place of technology in our lives. What matters is not technology itself, but its relationship to us". Yet human-computer interfaces are still mostly developed with a technology-centered approach (Carroll, 2000; Dourish, 2004; Linard, 2001).

With the development of information technology, an interest in the active user and in activity theory also grew. The designers of human computer interfaces (HCI) found themselves confronted with new demands of users, which were created by the evolution in Information Technology (IT), and by the lack of performance of the classic engineering-type interfaces (Linard, 1998; Norman, 1988; Winograd & Flores, 1986).

The fast development of information technology, along with users asking for an easier and more efficient interface, contributed to the creation of a new design domain called 'interactivity design', which is defined as "The shaping of use-oriented qualities of a digital artifact for one or more clients" (Löwgren & Stolterman, 2004). This new domain combined interests form many disciplines including business, technology and engineering, psychology, interaction, design, media and culture. It became clearer that interactivity design was about humans and the way humans understand information technology.

With the technological advancement of HCI, the disciplines of ergonomics and cognitive psychology became highly involved in studying users' needs and performance with the use of interface and interactive devices, which contributed to the move away from technology-centered design and to the shift to a focus on the human being. The following definition by Boyarski & Buchanon (2000) shows the focus on users: interactivity design is: "the synthesis of many traditional and new elements of design thinking, leading to products that provide intelligent and emotionally satisfying experiences serving a wide variety of human needs."

Inadequacies

With the growing number of non-specialist users of computers and interactive devices, around 1995, companies started to see the need to better understand users. They brought together project teams composed of a variety of people with different expertise. However, as Preece et al. (2002) mention, the communication and collaboration between the team is not easy. "The more people there are with different backgrounds in a design team, the more difficult it can be to communicate and progress forward the designs being generated." The reason seems to be that people from different backgrounds have different perspectives and different ways of talking about things; what is valued by one person maybe of no interest to another; the lack of a common language creates confusion and becomes the source of disinterest and dissatisfaction regarding the exchange of ideas. Communication and collaboration become almost impossible. This communication difficulty is similar to what we have experienced on many occasions throughout our practice.

To better serve users, a number of researchers have suggested new ways and techniques for a user-centered design. However, in our practice we have remarked that it is difficult to use those techniques thoroughly within a multidisciplinary team. The encountered difficulties are, in most cases, that team members fail to see the advantages of using such new ways and that they are not committed to user-centered approaches. In this situation, it seems essential that we need to create a situation where sharing knowledge among team members becomes natural and easy.

Aims

In HCI projects, to increase the efficiency of the user's experience, project members should consider the user in all phases of the design process, from the early stages of a project (Carroll, 2000). In addition, it is well accepted that the design of any interactive system is a multidisciplinary activity (Löwgren & Stolterman, 2004). We find essential to consider the following four factors: the uniqueness of each project, the continuous change of user needs, the rapid development of information technology, and that we are dealing with complex and messy situations. We believe that to design with usability and sustainability in mind, the multidisciplinary project team needs to, not only consider these four critical factors, but also understand the relationship between them.

An efficient communication seems to let us deal with these factors. However, searching for effective ways of communication between disciplines has been a concern for researchers, trying to find a new language that could go beyond the subjects of individual specialists: a language that could be understood by all would allow for the exchange of knowledge and design outside the boundaries of individual disciplines.

As a team, we need fluid communication between disciplines and exchange of knowledge, which means to move toward interdisciplinarity. According to Morin (1994), the interdisciplinary approach supports dialogue and the exchange of knowledge, analysis, and methods between two or more disciplines. It also implies interaction and a mutual enrichment between specialists. By agreeing on the needs and motivations of the user, by sharing knowledge and by constructing new knowledge, the team can become committed to each other and to interdisciplinarity.

Design activity in HCI

With a particular focus on the design of interactive devices, researchers in this field generally accept that 'design' is not something that can be narrowly defined. In that respect, of main concern to the HCI community is user-centeredness and the various approaches and techniques offered. Carroll (2000) recommends the scenario-based design method, which he defines as follows: "scenarios are concrete stories about use". Referring to Schön, he says, "scenarios evoke reflection-in-action".

From a cognitive point of view, Visser (2006) mentions that design, in the context of HCI, has specific characteristics that distinguish it from other cognitive activities. She explains that design takes different forms depending on its main purpose. For her, from the perspective of computer science and cognitive design research, design can be characterized as a problem solving activity with the following aspects: that design problems are ill-defined problems (or in Simon's terms, ill-structured); design problems are complex and cannot be decomposed into independent sub-problems; design problems have several acceptable solutions, which are more or less satisfying; analysis of the problem and elaboration of the solution are not two consecutive stages, rather they progress in parallel; for their activities, designers cannot rely on a pre-existing plan: they need to use opportunities related to different design situations; and, designers reuse knowledge from previous design projects.

Although the above list does not mention the multidisciplinary aspect of design activity and all issues related to collaboration leading to design solutions, the author also explains that design always requires the integration of information, knowledge and competencies from several domains.

The activity of design, as Boyarski (1998) brought up, is also practiced by other disciplines that include engineering, computer science, and information technology. In that respect, today partnering with these disciplines is common practice. However, communication between various disciplines is still problematic. The question remains how design activity can lead to a better exchange of information and construction of new knowledge for the project?

In project situations, although the team shares the overall objective, each team member has a particular goal towards which her/his effort and focus is directed. Team members' interests may even be in conflict in some situations. Nevertheless, when the issue is designing HCI, it is fundamental that all disciplines exercise and integrate a user-centered approach in every aspects of the project. This idea has been gaining acceptance by many researchers. User-centeredness cannot simply be a tag phrase used in a general sense in discussions; rather it must be applied to achieve specific concrete goals. Consequently, adherence and engagement of all team members to the approach is needed. This means bringing team members together to work constructively and efficiently, with common understanding of goals. For Boyarski (1998), there is need for an ‘interdisciplinary attitude’, by which he means “integrating approaches from other disciplines, allowing ‘multiple sighting’ on a problem”. This suggests that all team members should participate in the design and should think about collaboration and sharing knowledge as an important element for the development of new ideas, processes, and working relationships. It means that each team member could engage thoroughly in the project, to propose solutions which cross boundaries in such a way that others not only understand, but also to which they can adjust their own solutions accordingly.

Research methodology

The research has been developed in the context of a professional design project in order to understand what really happens during the process of collaboration. The focus of the research was on the design approach and on the interaction between experts and non-experts participating in the design of a website interface.

As designer-researcher, we wanted to know what discussions and activities were fruitful or fruitless; what approaches were acceptable by all and carried out successfully or unacceptable and abandoned; in meetings, what motivated the collaborators to participate fully and in a constructive way or what made them become passive; and, what tools were helpful for demonstrating and understanding the complexity of the project (including design process and collaboration). The design research method, ‘Project-grounded research’ (Findeli, 1998, 2004) was privileged for this study. This kind of research, first called ‘Research through design’ by Frayling (1993), is about developing knowledge and theory related to design activity by going through a real design project. It conciliates theory and practice. In other words, conducting research and constructing knowledge become part of the design project.

This approach allows the development of our project towards the two poles ‘research through design’ and ‘design through research’ as Jonas mentions (2006, 2007). In recent years, this type of research has become a method also privileged among some researchers in HCI (for example, for Zimmerman and Forlizzi 2008, Löwgren 2004, and Fallman 2008). Fallman (2008) also brings up the two concepts: ‘research-oriented design’ to describe the user-centered design approach generally applied in HCI practice, and the concept of ‘design-oriented research’ “where research is the area and design the means”. In other words, by involving design activities in the research process, new knowledge is produced. Löwgren and Nagai (2008) talks about practice-based research and asks if we can construct knowledge about a phenomenon by designing for it. For Zimmerman and Forlizzi (2008), the research through design approach offers several benefits that compliment HCI research such as addressing wicked problems and allowing an “ongoing dialogue on what a preferred state should be”.

This research approach can deal with ‘wicked’ problems (Rittel & Webber, 1973), contrary to techniques of science and engineering, which deal with ‘tame’ problems. Alexander, Simon, and other thinkers also pointed out this distinction between design and science as we can see in the following well known quotes: “Scientists try to identify the components of existing structures, designers try to shape the components of new structures.” (Alexander, 1964) and “The natural sciences are concerned with how things are… design on the other hand is concerned with how things ought to be.” (Simon, 1996).

It is common practice today to bring together a multidisciplinary team, in a virtual or face-to-face setting, for solving various parts of the problems related to a design project. However, team members often have difficulties with sharing knowledge. They each have their own knowledge, operating procedures, their own ways in which they communicate about the design, and how they make representations of their ideas (Klinsmann et al., 2007).

Design activity, therefore, should take into account all contributing disciplines but also all human factors related to cognition, social and cultural influences. As Boyarski mentioned, (1998) “without primary consideration for the people using the artifacts we design, and the context for their use, –in short, the entire experience of use– we relegate design to a marginal and self-serving activity.” In HCI, this concern for the user is what distinguishes design disciplines from computer science and also from other ‘problem owners’ (for example, managers and clients).

Design model

Based on *interdisciplinary attitude* and *joint reflective practice* we introduced a design model (figure 1) geared to facilitate collaboration and knowledge sharing among team members of a complex project, while positioning the user at the center of the design process. The model, *environment for reflective collaboration*, allows for the construction of collective knowledge, which will be achieved by collaborative learning opportunities that combine theoretical and practical aspects.

a. the *interdisciplinary attitude* will allow openness to other perspectives and a willingness to share information. It means shared commitment, acceptance of approaches from other disciplines, and looking at the problem from various perspectives (Boyarski 1998). For us, the interdisciplinary attitude is the mind-set that encourages an informal teaching and learning dynamic. Once the information is contextualized (for the project at hand), it will be easier for all team members to understand diverse perspectives and to see the relevance of diverging viewpoints. To achieve good understanding as a team, the individual team members need to interact with others, and through a continuous process of learning each other's roles, responsibilities, priorities and practices, they will become aware of diverse aspects of the task (Gero & Kannengiesser, 2003). This process will encourage the team to adopt an attitude of critical thinking. As the team members become more familiar with the situation and with each other, interaction and collaboration become natural. We expect that through the commitment to an interdisciplinary attitude, the team will become more engaged in all aspects of the project.

b. through *joint reflective practice*, we bring together diverse knowledge and skills, allowing the team to notice interconnected problems, construct new knowledge, and to formulate the situation differently. HCI design situations are complex and problems are interconnected. The complexity is increasing continuously as we have to design for very diverse end-users of technology. So the design tasks require the confluence of a variety of expertise. As more people become involved in the design process, we also see more value conflicts. Schön (1983) emphasizes the "complexity, uncertainty, instability, uniqueness, and the value conflicts" of situations of professional practice and explains that these situations are not problems to be solved. They are problematic situations, which are uncertain and unclear, but they need to be understood. As reflective practice is associated with learning from experience, it will allow the team to change its perspective, gain new knowledge, and challenge the concepts and theories by which they make sense of knowledge. As a consequence of joint reflective practice, a project-specific team will bridge different understandings and through intense team interaction will produce new knowledge to deal with uncertainty.

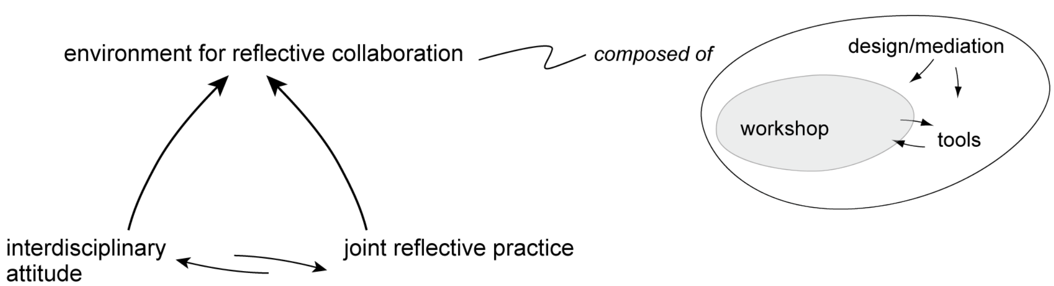

Figure 1: ERC, based on interdisciplinary attitude and joint reflective practice

Both the interdisciplinary and the reflective attitudes are essential for linking the knowledge of an individual team member to others in order to stimulate emergence of team expertise. We support this process with our proposed model *environment for reflective collaboration* (ERC). The model has the following objectives:

- to encourage contact between actors
- to incite knowledge sharing and develop a holistic vision
- to encourage critical thinking and direct feedback
- to reach consensus
- to make resources readily accessible to all at the opportune moment, and
- to advance the project in an efficient manner, on time, and while respecting the process

This model allows for collaborative learning opportunities that combine theoretical and practical aspects. It is composed of the following three elements:

- An intensive workshop to encourage joint reflective practice and collaboration, composed of a series of activities organized at the onset of the project
- Tools to support knowledge sharing and team performance (i.e. visual representation of processes, systems like wikis for contribution and access to information, etc.)
- Design as a method to facilitate collaboration and understanding between people

The workshop, the tools and the designer in the role of facilitator –to apply design as a method–, are strongly related.

The research was carried out through a real design project of a complex website for Princeton University. The design project became our field of research. This means that the theory was situated in the project and its implication on practice was directly observable. As we become more engaged with the project and the research, new questions emerged and modified the research throughout the project.

The client approached us to redesign a website. The existing one was designed a short time before this intervention, however it had technical flaws which seemed to be the single reason for the client's request to redesign. A careful analysis of the website made it clear that it was designed following the administrative structure of the institution and very elaborated visual elements were used to make the website attractive to users. Although most content was valid for reuse, the site had several shortcomings from a user point of view, including deficiencies for those who had to feed the site and keep it updated. These people, (who are another type of users), were not computer specialists. They were office staff members who had the responsibility of updating the site daily. They were also in direct contact with end users of the site and received regular feedback. A functional site was urgently needed to serve both groups, but very limited time was available for redesign and development of the website. However, the time constraint in this case was of help; the client accepted to make everyone involved in the project available for the redesign and the development of the site. The availability of these people for a set period of time was the needed condition for applying the mentioned design model through which, we aimed to translate disciplinary collaboration into new knowledge construction, useful for the purpose of the project.

A project team composed of eleven persons including office staff members, content experts, higher management, web programmers, and a designer was created. However, in most activities the workshop functioned with 6 or 7 team members. Based on the previous analysis of the project (i.e. through the design brief, meeting with project owners, research), its estimated complexity, and the knowledge about the team, the workshop was planned for 6 days.

The collaborative design process started with the intensive workshop. All project members were invited to engage in the predesigned activities in order to achieve the mentioned objectives.

We prepared a set of activities (e.g. creating personas, writing use scenarios) to support the collaboration during the workshop and planned to facilitate its progress. Visual representations of design and development process were shared with the team. Also the team developed a web-based system for gathering information about the project, which could be accessed when needed. As the main goal of the intensive design workshop was to redefine the information architecture of the site with a user-centered approach, it was clear that a common understanding of users' interests and needs was essential. The team participated in all activities and design activity became a method for better collaboration.

Discussion about the process helped the team to share information and develop a common understanding; it also helped them to realize the complexity of the project. The team worked together in redefining the objectives and priorities of the site and the methods to achieve them. They used their personas and use scenarios to structure the information architecture of the site, and to plan future steps. The team's focus remained on the users as it can be seen in the following anecdote regarding personas: After brainstorming, 5 sets of characteristics were defined. The team created silhouette-shaped cardboards for each persona, marked their characteristics on the cardboards, added a face and gave a name to each of them. During most activities and discussions, the cardboard silhouettes were placed on the table as if they were also assisting the meetings. In a few occasions while the team was working on the information architecture of the site, a team member (one of the office staff members) suddenly made comments on behalf of those personas and suggested a different solution.

We carried out the following roles: first as designer, we analyzed the project and designed, not the project, but the ERC (the workshop, the activities, the tools). Then as a mediator, we ran the workshop (created the activities and brought the team together to collaborate, made a synthesis of each step of collaboration, modified activities to fit the on-going project development, and supported the team to reach consensus). Finally, we worked on the actual project. Our research activity continued during the workshop: as designer-researcher we needed to learn from the situation in hand, to evaluate the actions and adjust new ones.

The principal expected results of the workshop were: better definition of the project where parameters and priorities were clarified, access to new knowledge, user-centeredness, and higher level of collaboration among the team. These elements led to a faster process for design and development and a more sustainable end-result focused on users.

Through the project-grounded research it became clear that the designer-researcher need to have an overall familiarity with the variety of disciplines involved in the project and be able to see the complexity of the situation rapidly. The research also showed how design could actively modify the project members' visions in order to promote the exchange of knowledge, while ensuring that the design activity remains concentrated on the user.

We noticed two main difficulties: 1. some specialized vocabularies, which were not understood by all team members, made participating in the discussion difficult. 2. some information and shared knowledge came at a wrong time, or with too much details when the team was not yet ready for it. Although later in the process the information was essential, at the time it created confusion and changed the focus of the collaboration. It became clear that because of the uniqueness of each project, adequate activities and tools needed to be designed for each situation. Examples of these tools are: visual representations of processes, systems for contribution and access to information (such as wikis), and tools for project coordinating (such as Basecamp), which give access to the on-going and growing knowledge of the project and which help its management.

Through this model, we sought to build the particular sense and the know-how for the project, to enrich and harmonize the understanding of the users' needs and motivations, and to create conditions for interdisciplinary exchange. We noticed that the dynamic and the productivity of the ERC depend not only on how the workshop plays out, but also upon the effectiveness of the designer/mediator to facilitate the events and to prepare and adjust the tools.

By achieving an interdisciplinary attitude along with a joint reflective practice, it became possible to encourage the design team, in the early stage of the project, to approach the design problem with a research stance, while keeping their focus on the end-users.

Conclusion

Applied to the mentioned project, the ERC model showed how the intensive collaboration of the team at the very early stage of the project, coupled with the mediation of the designer, directed the project toward a human centered design, reduced significantly the development time, and added value to the project by becoming a sustainable design.

We wish to turn back to the purpose of design research as explained earlier. The outcome of design research should satisfy the design research community, design practice community, and design education community. Clearly for each of these communities, the produced knowledge may have different value and relevance (Findeli, 2008). In other words, at this point, we are interested in the produced theoretical knowledge for the research, and the applicable knowledge for the practice.

The aim of the inquiry was to explore the design activity in the area of HCI and to develop a new methodological model intended to assist multidisciplinary teams designing thoroughly user-centered interfaces. This knowledge would be useful for a practitioners' community. It became clear that achieving this goal might only be possible by engaging all project team members in a joint reflective practice in the early phase of design. The joint reflective practice would lead to enhancing the shared understanding of the project, in clarifying the problematic, and in making the knowledge that is retained among stakeholders accessible to all. Finally, it stands to reason that only by bringing different and controversial viewpoints together does the framing and resolution of such complex design problems become possible. This is to say, by creating an environment that empowers the team to adopt an interdisciplinary attitude, new ideas for solving problems emerge.

However the activities geared to support the interdisciplinary attitude, as well as the joint reflective practice, which are the foundations of our suggested model, need to be designed and facilitated. For us, the designer should ensure this facilitation for a number of reasons that are related to her/his expertise as a designer. These include, among others: she/he is trained to develop a holistic view of the situation despite it's wickedness and fuzziness, has skills to diagnose problem areas, can communicate visually, can rapidly develop mockups and prototypes that would be used as tools for helping teams exchange ideas, and (referring to Cross, 1993, 2001), has a 'designerly' way of thinking, knowing and acting (referring to the specific tacit know-how of a designer). The designer needs to be trained for this new role that we call designer-mediator. Therefore it becomes important to consider the outcomes of research in design education. Additional knowledge and a set of new skills will be required: for example, to enable the designer to organize and run the environment, to facilitate the interactions among the team, to facilitate the achievement of the needed attitude, to keep the team focused on the goals, to create a synergy, to mediate the informal situation of learning and teaching, and so on.

Our next step is to present the model to three practitioners for peer review and validation. We will create a short questionnaire to verify if they deal with similar frameworks. Then we will discuss the process in detail to see if the model fits in their practice and if so, what makes the model sustainable in their practice. As raised by Manzini (2008) the transition toward sustainability is by "a radical change in ways of being and doing."

Author Biography

Mithra Zahedi

Currently Mithra is a visiting assistant professor at the School of Architecture & Design at the Lebanese American University. Prior to this she was a lecturer at the School of Industrial Design at the University of Montreal for eight years. Mithra holds a Masters of Science in Educational Technology, preceded by her study in Industrial design at La Cambre Brussels. Before her work as a researcher, Mithra worked as a design consultant for more than 15 years, focusing on human-centered product and communication systems in the IT industry and in educational institutions. Her focus is to make communication more effective through its visual, ergonomic, and graphic aspects. In her current research her main interest is in team interaction and support for design activities in a multidisciplinary group. Mithra is a member of GRCAO. She is currently a Ph.D. candidate.

Manon Guité

Manon Guite is an associate professor at the School of Architecture at the University of Montreal. She is currently Vice-Dean of Academic Affairs in the Faculty of Environmental Design and also project director of the new Digital Learning Environment, ENA, at the University of Montreal. Specializing in 3D modeling, Manon focuses on the multiple changes induced by the use of digital technology in professional practice and architectural education. Her recent studies have focused on the design of digital technologies, project conception of which the project memory is considered in terms of a collection of the interactive designer's experience. As a member of GRCAO, Manon's research focuses on methods for learning and strategies for teaching architectural design, specifically ways integrate, organize, and describe the processes and skills of architecture.

Giovanni De Paoli

Giovanni De Paoli is a professor at the School of Architecture at the University of Montreal and holds a doctorate in Computer Science and Architecture, and a Ph.D. in Architecture from l'École Polytechnique de Turin. Giovanni was responsible for the Computer Aided Design & Modeling option of the MA program in Architecture. He is currently Dean of the Faculty of Environmental Design at the University of Montreal. As a member and fellow of the Royal Architectural Institute in Canada, he works actively in the areas of climate and building physics and device design for digital 3D modeling. A member of GRCAO (Research Group Computer Aided Design), Giovanni is participating in several research projects with the support of major funding partners. For a number of years, Giovanni De Paoli has presented numerous articles and research results at major international symposia in the field of digital architecture.

Inspiring from the Works of Other Architects in Reinforcing Students' Creativity

Seyyed Mohammad Hossein Zakeri (PhD candidate) Department of Architecture, University of Tehran, Iran
Email: hossein.zakeri@gmail.com

Abstract

The present article investigates "the role of influences of other architects' works" as a learning tool in order to improve the creativity of the architecture students. Firstly, the definition of creativity is discussed and then the view points of creativity in the sphere of architecture follows. Secondly, a model is presented on the need of the presence of creativity in the deep layers of a creative architectural work. In the presented model, the need of the element of creativity, at least in three major phases in the deep layers of an architectural work, will be explained.
Afterwards, the concern of "influences of other architects' works" is discussed by considering two main states of conscious and subconscious forms and then the article concludes that unlike the orthodox view point of some architecture teachers who believe that "influences of other architects' works" blocks the innovative architectural ideas, it can play a major role in at least two stages of the presented model of creativity and increases the possibility of reaching creative solutions by the architecture students.
As a supplementary, and to clarify the point that the treatment of teachers for the so-called influences has to change as students' cognitions of architectural works change, the concept of "cognition " itself will be discussed.
It must be mentioned that in some cases, the author has made use of polls containing the views of both the teacher and the student about the case study. These polls were answered by 10 architecture teachers of Tehran University and Shiraz University of Iran who had a broad experience in teaching the architecture material and also 40 students who were recently graduated from the colleges.

Keywords: creativity, architecture education, precedent-based design, cognition, the process of architectural design

In the present time, through a day by day progress in public media and information technologies like satellite TVs and the Internet, the subconscious influences on students made by other architects' work – either local or international – has been a challenging issue in Iranian architecture colleges. Sadly, by following orthodox view points, not only have problems been doubled but the quality of architectural education has also been challenged for the worse. As it may be expected, the side effects of this educational problem have affected the architectural businesses and have resulted in low-level imitations which have degrade and threaten Iran's contemporary architecture. (Zakeri, 2007, p107)

It seems obvious that a good resolution for this issue in architectural colleges, both fundamental and wise, must be investigated thoroughly. A good solution not only answers the questions of students and teachers when they face the issue, but at a higher level will suggest solutions in a wise, true, and constituent way for what that many professionals believe is threatening Iran's contemporary architecture system.

Due to the above challenges, the need for a deeper and more thorough investigation of the "influences of other architects' works" has to be clarified. The main purpose of this research is to measure how the subconscious influence of other architects' works, that results in blind imitations in architectural practices, where no teacher can review the works and turn it to a chance for creative inspiration that might create a better architectural education.

The need and importance of the issue

In the current conditions imposed by globalization and the everyday progression of information technologies like satellite TVs and the Internet, the process of familiarization and collecting information about architectural works for the architect–has achieved a new form and speed. If in the past this process was subject to voyages and personal encounters, or information being obtained from the books that were published *after* an architectural landmark was born, then today we clearly see that even before a project starts, architectural images are easily available both from the media or the Internet for the public to see. Such incomplete visions which often have immediate influence on the young minds of architecture students has caused very unfavorable effects on the quality of education in most architectural colleges of many developing countries such as Iran in the last decades. On one hand the youthful architecture students believe that they belong to modern times and have a burning desire to see the works of so-called avant-garde architects and look forward to seeing as many as works as they can from the media. On the other hand a lot of architecture teachers, due to their personal rules of creativity development, do not like what happens to their students. They think it may lead to blind imitation which is harmful for Iranian traditional architecture. They may suggest that students should be allowed a free and open-ended regime in which free expression is encouraged.

Figure 1 compares the interest in using internet to see the works of western pioneer architects, both for the teachers and the students. The figure partly shows the doubts and disagreements of many teachers regarding the issue. In the same time, most of the students showed interests to the issue indeed.

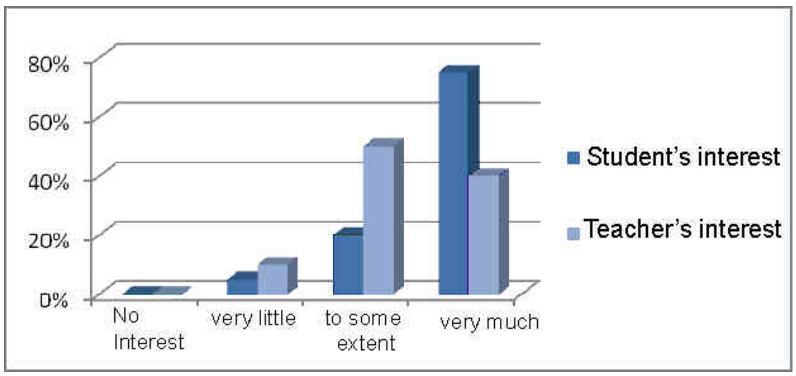

Figure1) Source: author

The point which underlines the issue of influence from outside sources the most are the statistical results which emerged from the answers of the newly graduated students when questioned about their use of other architects' works in their university projects. It is interesting that 83% of them confessed that they had had this experience before (figure 2) and even more interesting is that 70% of these people preferred to hide the issue from their respective teachers and only 30% of them - because of the special educational system of the teacher and aware of his agreement - told their teachers that the project had direct influences from the outside. Because some teachers believes that students have to solve real-world problems and they should pay attention to the acquisition of knowledge by visiting other architects works so their students feel free to be honest with them. But most of teachers do not want to accept the statistical results and try to limit their students.

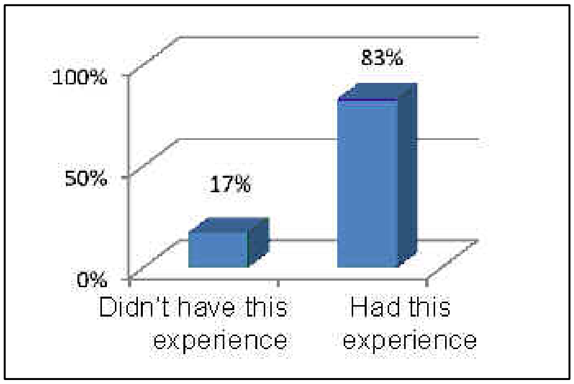

Figure2) Source: author

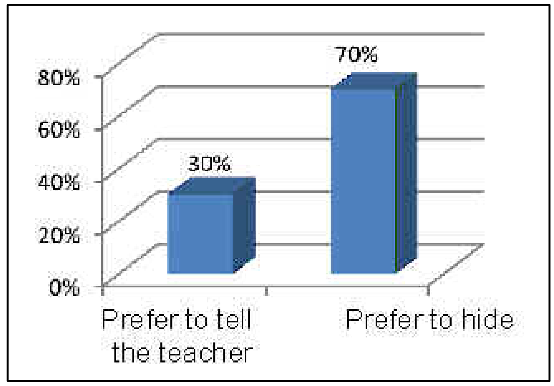

Figure3) Source: author

These results show that nowadays it is nonsense to discuss whether students are 'allowed' to be influenced by other architects or not. Whether we like it or not, many students are, and if they feel insecure with their teacher they will hide the issue from him/her (it is very natural that no teacher can claim that s/he knows every single architectural work on the planet). Unsurprisingly, 60% of the teachers said that they cannot completely recognize the possible outside influences on their students' works.

So, it would be better that in such situations, instead of disagreements or rows, we look for a solution not only to neutralize the threats on the quality of architectural education and the creativity of the students, but with the aid of good management of this issue we can also turn it into a chance and use it as a learning tool to develop the creativity of students.

Now the questions arise. Is it possible to use the influence of other architects' works as a learning tool to develop the creativity of architecture students or not? If the answer is in the positive, how can it be done? And at every stage of education, and according to the students' cognition, how it can be managed in the best way? To answer these questions, firstly we have to clarify a definition of creativity to know its origins, and to define what in particular ' creativity in architecture' means so that we can suggest methods to deploy the influences of other architects' works as a learning tool to develop the students' creativity.

Creativity and finding its roots in the history of art and aesthetics

Dr Shahram Pazouki believes the first person to talk about creativity in the history of art was Leonardo da Vinci. Before him, the only thing that mattered was mimesis not creation. The artist was someone who was subject to be an explorer instead of a creator. Da Vinci said for the first time that "the artist has to create instead of to imitate." From this time on, little by little, the focus on "subject" began. (Pazouki, 2005, p97)

On the other hand, one can say that subjectivity of creation began in harmony with the introduction of the modern philosophy by Descartes. In 18th century, when for the first time the term fine arts was introduced, art began to detach itself from industry, and 'creativity' began to show itself. In modern philosophy, creation stood facing the ancient concept of mimesis. When the arts, became subjective, then creativity in the arts found its meaning. In mimesis, the artist has an eye on the world where in the modern era, the artist looks inside himself instead. This landmark concept built by Descartes was then completed by Kant. In his *Critique of Pure Reason* he wrote that "the aping imitation must be substituted by creativity. If the arts want not to be imitative, they have to rely on the human subject. It means that they have to be the creatures of the human mind and for this genius must be developed."(Kant, 2001, p 188)

It is the case that artistic creativity which we talk about it today with ease, has been never discussed in some eras when the concept of creation was restricted to the High Almighty himself. Terms like 'creation', 'taste', and 'influence' are the fruits of modern thought and known only since Descartes introduced subjectivity into philosophical terminology. But today, creativity is a keyword in clarifying the process of design and creative education. Re-understanding and defining the word creativity can shed some light on its role in the process of designing. The famous Persian writer Ali Akbar Dehkhoda defined 'creative' as a noun for the Almighty and 'creativity' as something which can result in innovative forms. Omar Farouq defines creativity as a unique answer, both better and more suitable, to a problem. The "Advanced Dictionary of Psychology of Knowledge" defines creativity as "the power to find unordinary and high quality solutions for problems." According to the above, a creative person is someone who faces the data that every one of us may face, in a new way. (Mahdavinejad, 2005, p.58)

Creativity in architecture

After World War II, social scientists and engineers both concluded that for more optimization and productivity, creativity must be introduced in business and to do this, much discussion took place. During that time there were two viewpoints regarding creativity. One framed creativity as science and believed that it could lead human kind to progress and the other did not tolerate any scientific aspect and framed it through a totally metaphysical approach. Architects did not take part in the on creativity in the mid 50's where poets, writers, painters, sculptors, scientists, social scientists, and psychologists were the main discussants. Thus, most of the work done in this sphere has not been especially related to architecture and the relationship between the two is not worthy of note. (Antoniadis, 2004, p37)

Most of the theory available on creativity is either purely scientific or purely artistic. Alvar Alto, observed that architecture is a vast and multi-dimensional system that if we want to be creative in it, then we have to have a hand in a number of fields – some pure artistic and some pure scientific (like technology, structure, material, and equipment) and some professional – and be creative in such fields.

If we want to categorize the view points of architects and architecture theorists about creativity in architecture then we can establish two main categories:

1- The first group knows creativity as a sacred gift and prefers not to speak about it at all. Architects like Luis Sullivan, Frank Lloyd Wright, Alvar Alto, and Le Corbusier are in this group. As an example Frank Lloyd Wright defined the creative imagination as "the humanistic light in the human kind" and identified creative entities as they were related to gods. (Antoniadis, 2004, p39) According to Frank Lloyd Wright, Alvar Alto, and Le Corbusier, imagination and creativity is sacred and is clouded in metaphysics. Now it is obvious that why these giants disagreed with psychological research that tried to outline scientific formulas for their sacred imagination and creativity.

2- In the second group, people like Brian Lawson, Barnes Wallis, and Santiago Calatrava can be seen as the defenders of creativity as a learnable skill. They identify the creativity in architecture as a fine search of problems of design on one hand, and finding the precise, suitable, and even unique solutions for such problems on the other. Barnes Wallis said once that "I never had a novel idea. My deeds were just solutions." Santiago Calatrava known as a creative architect says that "all my projects were answers to specific problems." (Lawson, 2005, p176)

Today the second group has won the public’s interest. If we accept the second viewpoint then more or less we agree that creativity in architecture is something that can be taught and has a direct relationship with the process of researching the problem and the procedures for its solution and we do not have to meditate to find an answer from the heavens. To put it simply, in this model of creativity, the general conditions for one to create a work is that the first step is to discover the designing challenges with precision and then find precise answers for the problems.

The term ‘creativity in architecture’ like any other, has both a surface and a depth. The surface itself is not enough to be explored. What we see as a creative architectural work is, in fact, the surface of the phenomenon which has been manifested as a solution. By having an eye on ‘man's need’ as the main cause of the formation of any architectural work, a creative solution follows when ‘design problems’ are included in them. In the next step, the architect enters as the subject and through the use of ‘design tactics’ searches for a solution of the given problems.

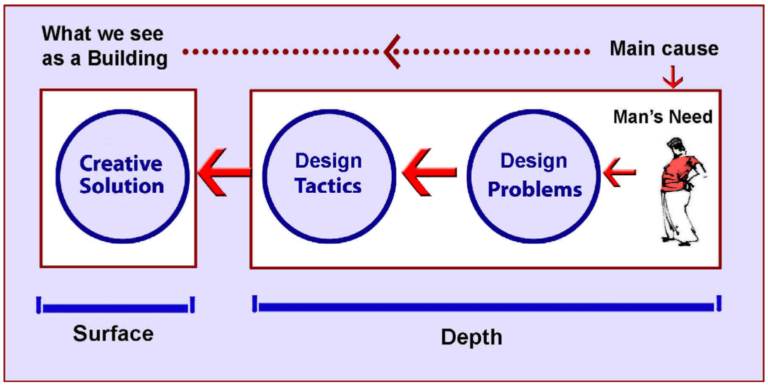

Figure4) Source: author

Thus the first stage, which has a vital importance, is to search and to identify problems which many have debated. Books like *"Problem Seeking*" by William Pena, and *"How Designers Think?*" by Brian Lawson, can be counted here. In my experience, Lawson's is one of the best and most comprehensive models of a variety of many designing problems **(Figure 5).**

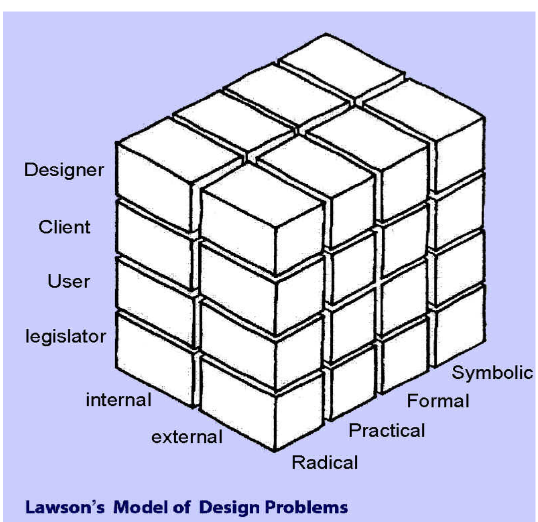

Figure 5) a model of design problems. (Source: Lawson: 2005)

For example, in figure 5, the group of people who can be counted as the origin of the problem seeking process can be categorized in four different subsets, the designer, the client, the user and the legislator. With more precise and detailed identification of internal or external problems – which an architect feels necessary for his project – the possibility of reaching a creative solution will be higher.

But this stage of problem identification itself cannot guarantee creativity. The next important step which has to be studied in depth is what is known as design tactics which are adopted to reach a creative solution. Tactics like Generation of alternatives, parallel lines of thoughts, or telling a story, can lead to a solution for the problems (Lawson, 2005, p212). By the use of different tactics one can find a number of solutions for any given problem. This is because the complexity of the designing process "can be divided, like any other problem, into smaller parts and by solving the problem parts one by one, then the general solution will be in hand." (Mahmoudi, 1999, p77)

After the stage of problem seeking and using design tactics, in the next step we must assign priorities, and also analyse and synthesize the differing solutions of the different problems to reach a final solution. A final solution usually takes shape by choosing from present solutions, or it can be a hybrid of them all.

Whilst creativity is also present at two previous stages, both in problem seeking and design tactics, it has to be said that in the final solution phase (see *Prioritization and final Analysis and Synthesis* in figure 6) that it reaches its peak.

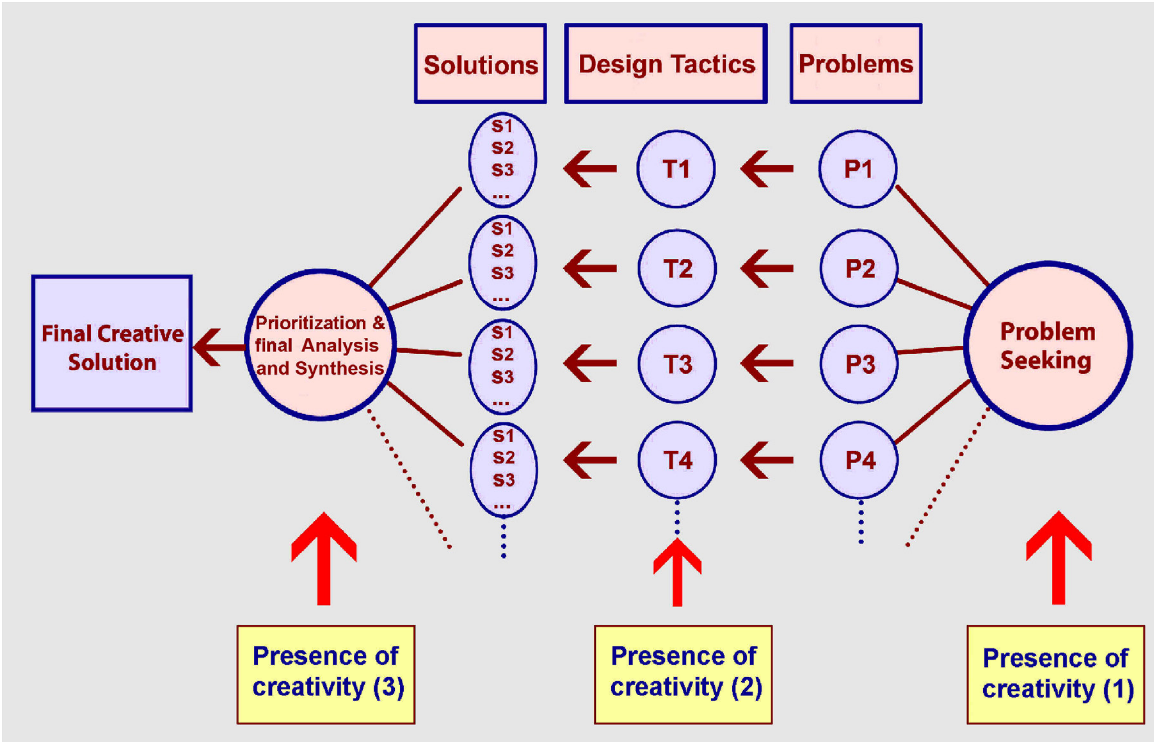

Figure 6) a simplified model which shows the importance of presence of creativity in the deeper layers of a creative architectural work. (Source: author)

By making use of the model of creativity presented a critique of many so-called ‘creative’ architectural works is made possible. For example; in critiquing the measure of creativity used in the design of The Guggenheim Museum in Bilbao by Frank Gehry we have to note the problems which arose in the problem seeking phase. We have to see whether he was creative in the problem seeking phase or not. Then it’s the tactics turn, and finally the final solution that he presented. For example we may find that in the case of the form of the building used to solve the problem of "attracting tourists to an abandoned city" the project has to have a high level of creativity, but in many other aspects we may see nothing. For example in the case of construction's cost to solve the problem of "inexpensive building" as a practical issue, the project has no particular creative solution.

The role of the influences of other architects' works in reinforcing creativity

The main issue of this paper is to determine at what level students must be familiar with previously made designs in order to develop their creativity.

In particular an issue here is the extent to which we should make design students aware of previous design work. One school of thought may suggest that students should be allowed a free and open-ended regime in which free expression is encouraged. Another might argue that designers have to solve real-world problems and they should pay attention to the acquisition of knowledge and experience. (Lawson, 2005, p155). In this field it is necessary to be familiar with Hertzberger (1991), Laxton (1969) and Kneller (1965) who salute the second school.

In his *Lessons for Students in Architecture,* Hertzberger wrote that:

> Everything that is absorbed and registered in your mind adds to the collection of ideas stored in the memory: a sort of library that you can consult whenever a problem arises. So, essentially the more you have seen, experienced and absorbed, the more points of reference you will have to help you decide which direction to take: your frame of reference expands.
>
> (Hertzberger 1991)

A study of design education in schools (Laxton 1969), concluded that children cannot expect to be truly creative without a reservoir of experience.

Kneller also clarifies, when he talks about creativity, that:

> "One of the paradoxes of creativity is that, in order to think originally, we must familiarise ourselves with the ideas of others . . . These ideas can then form a springboard from which the creator’s ideas can be launched. "
>
> (Kneller 1965)

Now the point of my argument is that the influences of other architects' works can be categorized into two main parts; which are conscious and subconscious influences. By this I mean if the student has used the solutions of other architects to solve design problems consciously or whether his own subjective experience, subconsciously and without his awareness, helped him to find the solutions.

A close relative to the phrase ‘subconscious influence’ is the term ‘schema’ in Gestalt psychology. Schema was firstly used by Bartlett who defined it as "the representative of an ordered and active set of past time experiences which is used for organizing and explanation of the future phenomena" (Lawson, 1384, p157). Gestalt psychologists paid specific attention to the way that the image of the outside world is represented inside mind. The Schema itself can be regarded as a form of subjective image of the individual's mind.

One cannot deny the role of schemas in creativity and the process of creative design as it has a direct relationship with the architect's experiences. The architects, consciously or subconsciously, makes use of their own experiences when they design a work.

As mentioned before the point at issue was, and is, the conscious influence from other architects' works on the architecture student. As I have previously observed a majority of the teachers are against this kind of influence and they see the inspiration of other architectural works as a blockage to the students' brilliant and creative ideas. On the other hand, according to the polls' results, most of the students, found these influences useful in development of their creativity though (figure 7). It has to be mentioned that the teachers' views differ depending at which level of the designing process the students are on. (figure 8).

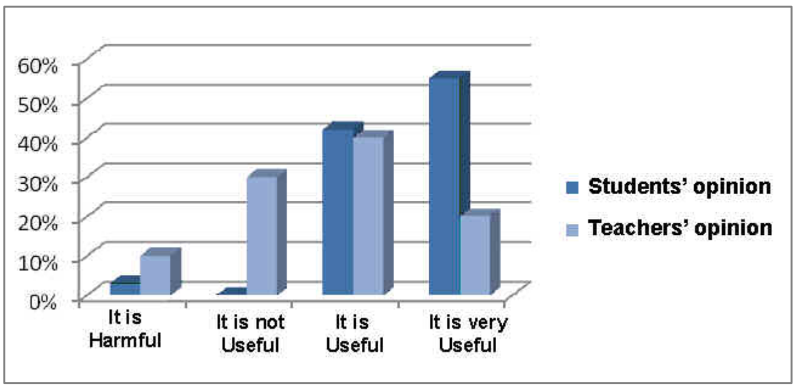

Figure7) Source: author

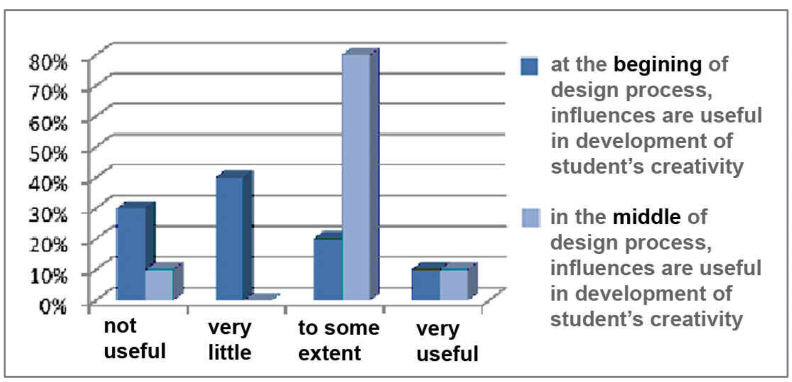

Figure8) Source: author

To briefly return to figure 6, it is clear that if the students use their inspiration based on other architects' works fairly, and if teachers manage and control this procedure, then no harm can be attributed to it and instead it can be used to improve the students' creative spirit. By looking at the model, which described the need for creativity in the deeper layers of a creative architectural work, we can find that inspiration from, and evaluations of, other architects' works can invoke feedback in the students' minds which can be useful in at least two stages of the model presented to improve students' creativity.

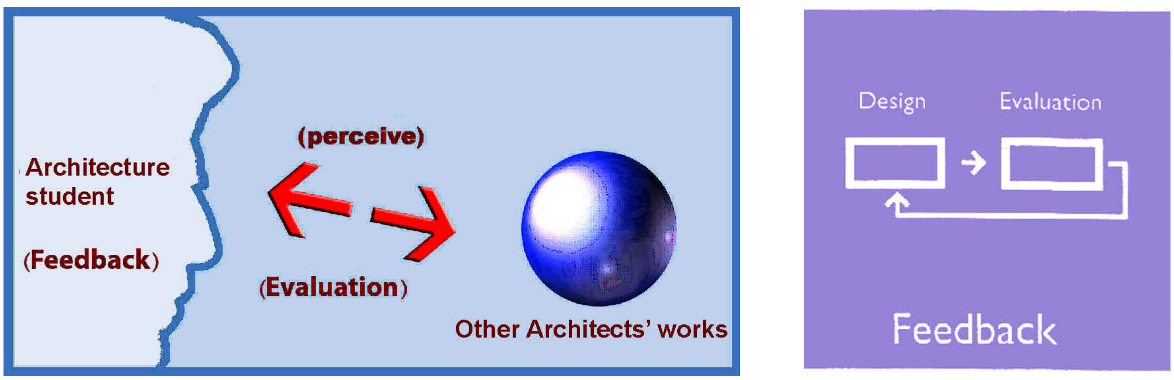

Figure9) Now by a look at the model, which described the need of creativity in the deeper layers of a creative architecture work, we can find that inspirations and evaluations of other architects' works can invoke feedbacks in the students' minds which at least can be useful in two stages of the presented model in the figure 6 to improve students' creativity.

Source: right side: Pena 2001, left side: Author inspired by The Three Worlds by Popper.

1. In 'problem seeking', these feedbacks, inspired by other architects' works in the primary stages of designing, can be very useful for the students. This can be used for example, to discover the problems which might be unknown to the other architects or it can lead to wrongly diagnosed problems by other architects or even answered incorrectly. Because precise problem seeking is a priority in reaching a creative solution, then such inspiration can play a major role in increasing the possibility of reaching a creative solution.
2 In 'design tactics', together with 'Analysis and Synthesis' creativity evoked by inspiration, can be identified as a useful tactic that leads to improvement.

So, if the model presented in figure 6 is accepted, one can hardly reject the role of influences of other architects' works in the primary or middle stages of designing process. Alternatively, if students face their teachers' orthodox views, they prefer to find a way out of the complex problems' labyrinth by use of other architects' works; there is the possibility of choosing a wrong method, for this pseudo-solution increases and may lead to blind imitations.

The students' way of cognition in leading their way of inspiration is important

Many theories have been developed to describe the types of cognition and their importance in problem identification and their respected solutions. In problem seeking and the design process, the Gestalt school has the upper hand in this kind of treatment for design problems. The Gestalt stresses cognition and as a result underlines the importance of thought.

The cognition factors of human thought have to do with becoming aware of and understanding classes of objects or ideas. This analytic ability to classify and recognise is of the utmost importance in everyday thought. For example, it would not be possible to study the differences between the structural systems employed in Romanesque and Gothic churches unless one could first recognise and classify such buildings. Guilford (1956) believes there are three ways of developing such a class system depending on whether the figural, structural, or conceptual content is used. Thus one might recognise a class by its figural properties. Children may initially recognise all four-legged animals as cows and only later look for further detail such as horns or tails. The second system of class recognition, by structural content, requires some functional relationship to exist between class members such as in the ‘complete the series of symbols’ type of IQ test question. Finally, one might recognise a class conceptually, such as architects or lawyers as being a group of people having passed certain examinations. For Guilford, then, these cognition factors influence our ability to define and understand problems whether they are to do with the appearance, function or meaning of objects. As Guilford (1967) himself points out, problems of figural and structural types abound in design and the ability to discriminate figural and structural classes is likely to be important to the designer. (Lawson, 2005, p 139)

The questions that future research can build on includes whether the understanding of the student of other architects' works remain unchanged in the university and after graduation, or whether the influence of such works on students depends on their ways of perceiving them? Is it possible to deploy an educational strategy to change the students' way of cognition, and use inspiration as a positive learning tool?

Comprehensive answers demand comprehensive future research, but as-is we can say that the student’s way of cognition, from the day s/he enters the university to the day s/he leaves the campus, can alter from figural to structural and in the end lead to conceptual cognition. As an example new students may understand an architectural work as figural, because at this level they cannot recognize the quality of the works, or are unable to distinguish between the different forms of the buildings, and their comments on the works may not stand that much above what ordinary people may say. Step by step, depending on their courage and courses they may pass, they begin to get familiar with different architecture schools and obtain some structural cognition and by discovering the 'hidden' ideas and theories behind the physical structures they step into a conceptual cognition of architectural work. One cannot precisely assign a cognition level to a given study period for a particular student. The students' cognition will change through factors like; how and what s/he studies or the circumstances that s/he grew up in. A first year student may have some structural or conceptual cognition where a fourth year student may have become stuck in figural cognition. What is clear is that figural cognition always appears during the college period. How it appears and by how much depends on the availability of other forms of cognition developing inside the student.

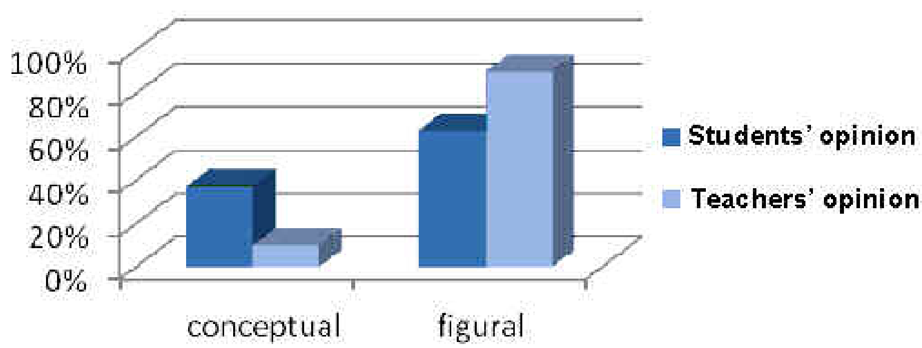

Figure10) Source: author

At each level of their development the student, either consciously or sub-consciously, may be under the influence of architectural works. By combining this influence with conscious thinking strategies like adaptation, imitation, inspiration, and developing critical thought and definitions and basic practices of creativity, we can suggest a theoretical model for creative inspiration. Using this model, we can change the three forms of student cognition, use it to improve the students' creativity and turn a perceived threat into a big chance.

Conclusion

We have seen so far that if we consider creativity as a layered phenomenon, to have a creative work on the surface needs problem seeking and design tactics in its layered depths.

Thus, there is no need to reject influences or inspirations from other architects' works as threatening according to our orthodox views. It can be used creatively through good management in the deeper layers of creating an architectural work. The role of influence can be highlighted in the problem seeking and design tactics layers which are the most basic and deepest layers in the making of a creative work. However, as mentioned earlier, an attempt to monitor the changes in the student's cognitions of architectural works, as an introduction to inspiration or influences, must be included.

So it is now clear that student's conscious inspirations or influences from other architects' works which can lead to blind imitation without a good management or by enforcing the orthodox views and threaten the architectural education, can be turned to a chance by a bit of care and attention and it can be used as a learning tool to improve the students' creativity.

Integral design method in the context of conceptual sustainable building design

Wim Zeiler, Technische Universiteit Eindhoven, Netherlands, w.zeiler@bwk.tue.nl
Perica Savanović, Technische Universiteit Eindhoven, SBR Rotterdam
Duncan Harkness, Technische Universiteit Eindhoven

Abstract

Global warming, shortage of fossil fuel and rising energy prices are endangering humanity. The built environment is responsible for a large part of the energy use and waste production. Traditional building design approaches essentially lead to redesign and optimization, whereas to meet the unique challenges for sustainability in the present day built environment, we need to go further and generate new concepts and knowledge that represent the necessary conditions to arrive at new sustainable design solutions.

This research set out to develop a method to create a more integral process that would create the opportunity to introduce a greater variety and amount of design knowledge from the outset of the conceptual design phase. The approach was tested by using series of workshops in which more than 100 experienced professionals participated. The Integral Design method [ID-method] developed here, given the right cultural environment, may in time lead to the generation of new building concepts that will allow us the opportunity to move beyond redesign and optimization. The necessity of concept creation is shown by C-K theory that defines design as the interplay between two interdependent spaces, knowledge space K and concept space C, which allows us to conceive of the possibility to transform the building design team's knowledge into new concepts.

Keywords

Integral Design, morphological overview, C-K theory, workshops

Many factors influence the sustainability of the built environment, however, man-made climate change and the measures that are needed to counteract such change seem to be by far the main problems of our time. To understand the impact of building design on the environment, recent research has shown that 40% of the total energy output of The Netherlands is consumed by the built environment, and this figure rises to 70% when social services such as healthcare are included [Uitdenbogerd 2007]. The fact that these rather worrying figures are the result of current building design approaches underlines the need for new, creative approaches that can achieve better results.

Therefore there is a clear necessity to better integrate comfort and sustainable energy systems in buildings [Opstelten et al 2007]. It is our belief that this can best be achieved by rejecting current design practice, and by organising relevant disciplines into functional, mutlidiscplinary design teams.The unsatisfactory cooperation between building design disciplines has resulted in calls for better organization of the design process [Friedl 2000, Wichers Hoeth and Fleuren 2001]. These calls gain more importance when we consider the increased complexity in current design processes arising from, amongst other things, growing sustainability demands. In this context, traditional approaches to organize and plan these complex processes may no longer suffice [Van Aken 2005]. First and foremost, a method needs to be developed to allow other, largely engineering, building disciplines to be integrated into the design process from the outset in a meaningful way. This re-evaluation of the design process and the individual disciplines within it should facilitate the inclusion of all relevant team members at the outset and give proper recognition to the influence their knowledge and input has on the final design. The standpoint in this research is that a more integral process will not only improve the design process, it will also create the opportunity to introduce a greater variety and amount of design knowledge from the outset of the conceptual design phase.

Methodology

In the early sixties design became an international concern. In the United Kingdom the Feilden Report concluded that design was of paramount importance and asked for more effective design management, more attention to customer requirements and asked for more cooperation in design teams [Blessing 1994]. The origins of new design methods in the 1960s were based on the application of 'scientific' methods derived from operational research methods and management decision-making techniques in the 1950s [Cross 2007]. However, in the 1970s came the rejection of design methodology by even some of the founding fathers themselves, such as Alexander and Jones. Fundamental issues were raised and design problems were characterized as 'wicked' problems, un-amenable to the techniques of science and engineering. This resulted in a proposal for a new generation of methods by Horst Rittel, moving away from attempts to optimize and towards recognition of satisfactory or appropriate solutions [Simon 1969]. In the 1980s engineering design methodology of the systematic variety developed strongly. A series of books on engineering design methods began to appear; Hubka [1980], Pahl and Beitz [1984], Cross [1984] and French [1985]. In fact, after the risen doubts of the 1970s, the 1980s saw a period of substantial revival and consolidation of design research. Since then there was a period of expansion through the 1990s right up to day: design as a coherent discipline of study was definitely established in its own right [Cross 2007]. Still there is no clear picture [Horváth 2004, Bayazit 2004] and many models of designing exist [Wynn & Clarkson 2005, Pahl et al. 2006, Howard et al 2008].

Even though design undoubtedly includes stretches of 'normal' ill-structured problem solving [Dorst and Rooyakkers 2006] any model or description method that tries to reduce design to ill-structured problem solving is bound to miss important aspects of the design activity [Hatchuel 2002]. Recognizing the fact that design is not a scientific or merely a problem solving activity, we wondered if any of the existing and largely neglected prescriptive design methods could help us to understand design by using them for research, rather than [as originally intended] for design activities. The motivation behind this idea was that, being developed on the basis of a scientific approach to designing, these prescriptive design methods 'automatically' meet the requirements for being methodical – one of the key characteristics of valid design research [Cross 2002]. We choose Methodical Design as developed by van den Kroonenberg as a starting point, as it is based on a synthesis of the German and Anglo-American design models of the mid seventies and using the analogy with Systems theory [Zeiler and Savanovic 2009b]. Within Methodical Design the design process is thought of as a chain of activities, which starts with an abstract problem and results in a concrete solution [Blessing 1994].

Morphological overviews within Integral Design

Starting from the prescriptive model of Methodical design a method was developed to articulate the relationship between the role of a designer as descriptor or observer within the design team and to reflect on the process [Zeiler and Savanovic 2009a, 2009b]. Methodical design was chosen as a starting point of development because it has exceptional characteristics [Blessing 1994]. The Integral Design model, an adapted model of Methodical Design, allows various design complexity to be separately discussed and generated [sub] solutions to be transparently presented.

A distinguishing feature of Integral Design is the intensive use of morphological charts to support design activities in the design process. Morphological charts were first used by Zwicky [Zwicky 1948]. By using morphological charts each discipline can look for all the necessary functions and aspects decomposed from the program of demands. All of the design team members have to come up with their interpretation and possible solutions to the design task. On the vertical axis of the morphological chart the required functions, sub-functions or aspects are recorded. The purpose of the vertical list is to try to establish those essential functions or aspects that must be incorporated in the product, or that the design has to fulfil. These are expressed in rather abstract terms of product requirements or functions. On the horizontal axis possible sub-solutions for these functions or aspects are given. The morphological chart gives an overview of aspect elements or sub-solutions that can be combined together to form overall solution proposals, see Fig. 1 combinations A, B and C. The proposals can be presented to the client and discussed. After which a decision can be made to proceed further or to do a backward iteration step in the design process.

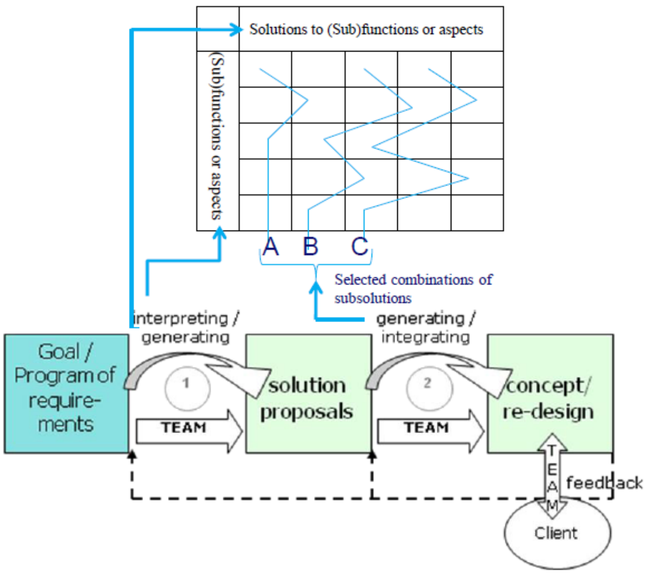

Figure 1: Program of demands as input for the morphological chart, sub functions on the vertical axis, the possible solutions as combinations of elements on the horizontal rows of the matrix. There is a possibility for feedback by the client as well as possible backward iteration loops.

As the morphological chart allows every designer to immediately see the results, they can discuss aspects that are unclear to them. The morphological charts made by each individual designer can be combined into a [team] morphological overview. The whole process is done in two steps: first the functions and aspects are discussed and then the possible related solutions see Fig. 2.

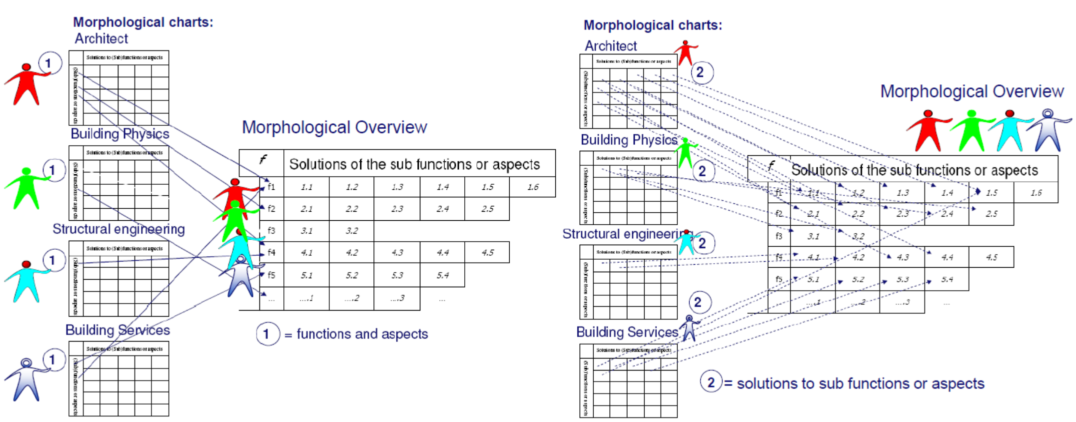

Figure 2: Building the morphological overview; Step 1; The Morphological overviews show the agreed functions and aspects [1] of the different morphological charts. Step 2: The Morphological Overview with the agreed on sub solutions [2] from the separate morphological charts

A morphological overview is generated [see Fig. 2] by combining the different morphological charts made by each discipline after discussion on and the selection of functions and aspects of importance for the specific design. Such a morphologic overview can be used by the designers to reflect on the results during the different design process stages. The advantage of this approach is that the discussion begins after the preparation of the individual morphological charts. As each designer uses his own interpretation and representation, in relation with his specific discipline based knowledge and experience, this gives an overview of different interpretations of the design brief resulting in a domain specific morphological chart from each design team member. In sum, this approach allows a greater freedom of mind of the individual designers and results in more creativity in interpretation of the design problem and generation of part solutions from the different disciplines. Morphological charts play a central role in facilitating the visualization of solution alternatives. Although the use of functional description and morphological charts is common practice in mechanical engineering design, there is scant evidence of their use outside of engineering or in a multi-disciplinary context. Within the approach described here, the possible input of 'soft' aspects adds a new dimension to the strict functional approach of a traditional morphological chart.

C-K theory

Pragmatic views of design as well as existing design theories [Yoshikawa 1981, Suh 1990, Gero 1996, Braha and Reich 2003] define design as a [dynamic] mapping process between required functions and selected structures [Hatchuel and Weil 2008]. Hatchuel and Weil argue that dynamic mapping is not sufficient to describe the generation of new objects and new knowledge, which, according to them, are distinctive features of design. Their statement that "there is no design if there are no concepts" [Hatchuel and Weil 2003, p.5] underpins the logic of C-K theory and of the present research. Generally speaking, design thinking is a creative process based around the transformation of needs into solutions. In this process existing knowledge and information about the actual needs of the principle forms the basis to work from. This often has to be transformed into new unknown concepts if solutions based on existing knowledge are not adequate. So, in this case, we have to develop from the known the unknown. As such we can make the distinction between the known [knowledge] and the unknown [concepts]. This distinction determines the core propositions of C-K theory [Hatchuel and Weil 2007].

Assuming that design thinking is related to design knowledge, and that knowledge is often something implicit, the definition of design by C-K theory [Hatchuel and Weil 2009] allowed us to approach design concepts as indicators of design thinking. C-K theory defines design as the interplay between two interdependent spaces having different structures and logics. This process generates the co-expansion of two spaces, space of concepts C and space of knowledge K. Within this research, in the case of a multidisciplinary building design team, the available knowledge within this team represents space K. Since C-K theory defines a piece of knowledge as a "proposition with a logical status for the designer or the person receiving the design" [Hatchuel and Weil 2002, p.11], all explicit representations of a design team's knowledge are considered to form part of space K. The overview of this knowledge is captured using morphological design tools. From the perspective of C-K theory, the initial object-design-knowledge that participants bring into design team defines space K. From here, two types of synthesis are possible: either the representations are combined, using the K→K operator, or are transformed, using the K→C operator, see Fig. 3. In this thesis the former possibility is explained as leading to 'redesigns' [RE], while the latter leads to 'integral design concepts' [ID]. Ultimately, evaluation of RE-design can only result in the same object-design-knowledge, while from ID-concepts new object-design-knowledge can be created.

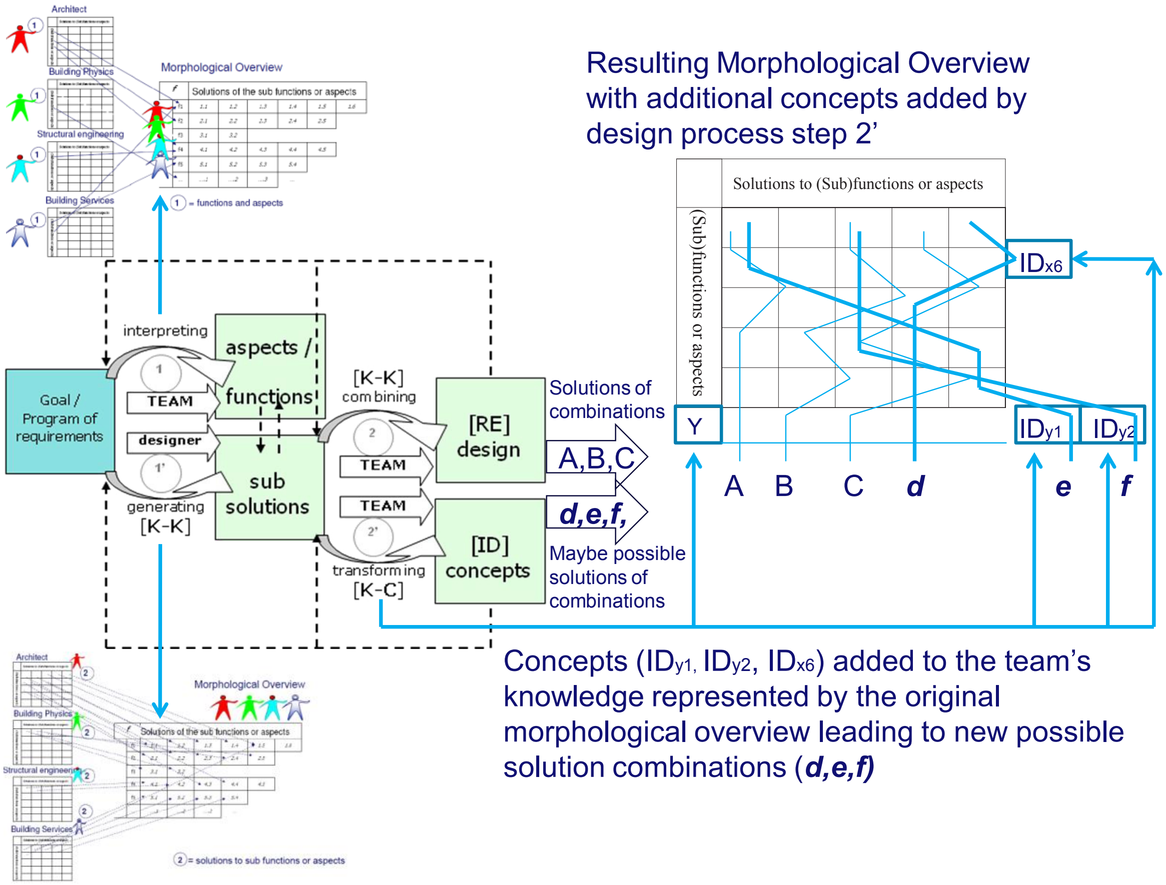

Figure 3: Integral Design model with C-K transformations, leading to solution of combinations [A,B,C] and leading to maybe possible solution concept combinations [***d,e,f***]

Within the ID approach, after the first step of generating discipline specific morphological charts and discussing the results as a team, the individual charts and combined into one morphological overview containing all of the useful sub solutions from the individual team members. The next step is for the team to take the knowledge and ideas from the overview and translate it into a proposed design solution. This step can take two forms:

I. design team combining sub solutions into RE-designs,
II. design team transforming object-design-knowledge into ID-concepts.

The ID-model wishes to force the focus on the distinction between redesign [K-K] and concept generation [K-C]. The elements ID_{x6}, ID_{y1} and ID_{y2} represent conceptual sub solutions as a result of the concept generation K-C, see Fig. 3. This distinction is crucial since, we firmly believe, that the development of new concepts is essential if we would like to generate creative sustainable solutions to the highly complex contemporary design problems that our societies face. In this research the main area of interest lies in the conceptual phase of the design process. In essence, in the current research ID-concepts are seen as essential for the creation of new, innovative building designs, which increase the possibility to ultimately realise sustainable building solutions. Perhaps more importantly, ID-concepts represent the potential for the definition of new object design knowledge, which can then be exploited to solve future design problems.

Experiments: Workshops for professionals

To test our approach of the morphological overviews and to determine if the approach led to positive effects for the professionals, we arranged workshops as part of a training program for professional architects and consulting engineers [structural engineers, building services engineers and building physics engineers]. On average these participants had 12 years of professional experience. An essential element of the workshop, besides some introductory lectures, was the design cases, on the basis of which the design teams worked and presented their ideas/design at the end of each session to the whole group. These design exercises were derived from real practice projects and as such were as close to professional practice as possible. Using workshops in which experienced professionals participated, a workable method was arrived at through iterative improvement of four key elements: design team, design model, design tool and design setting. The iterative development of the method results from housing the research within the Design Research Methodology framework [Blessing and Chakrabarti 2009]. In the current configuration [Fig. 4] stepwise changes to the traditional building design process type, in which the architect starts the process and the other designers join in later in the process, are introduced in the set up of the design sessions. Starting with the traditional sequential approach during the first two design sessions on day 1, which provide reference values for the effectiveness of the method [amount of integral design concepts], the perceived "integral approach" is reached through phased introduction of two major changes: first all disciplines start working simultaneously within a design team setting from the very beginning of the conceptual design phase and secondly the integral design model / morphological overviews are applied.

The second set up of the design sessions allowed simultaneous involvement of all design disciplines on a design task, which aimed to increase the amount of considered design functions/aspects. Additional application of morphological overviews during the set up of the third design session demonstrated the effect of transparent structuring of design functions/aspects on the amount of generated [sub] solution proposals. Additionally, the third setting provided the possibility of one full learning cycle regarding the use of morphological overviews so to correctly study in the fourth setting this process intervention of introducing the use of morphological overviews. All sessions were videotaped and additionally photographs were taken every ten minutes. The end presentations and all used material, sketches etc. were also photographed.

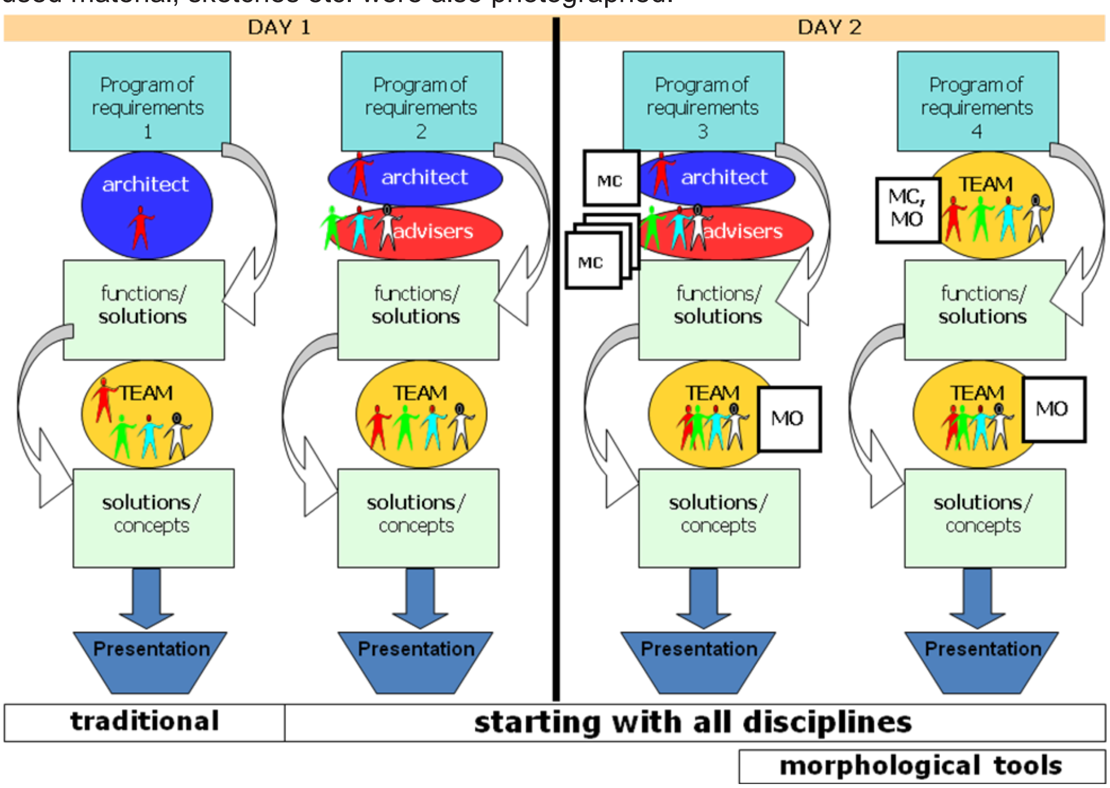

Figure 4: Workshops series 4 & 5, four different design set ups of participants and with or without Morphologic Overviews [MO] during the four design sessions within two days

Analysis I

The first goal of our research is to integrate engineering disciplines into a team design process and to share their knowledge at the outset of the conceptual design process. Therefore is it necessary to observe the actions by the participants during the conceptual design tasks. By this point in the research various observation methods and tools had been used Savanovic 2009]. Essentially, what was needed was a categorisation based only on functions/design aspects and solutions. Indeed, these are the things that participants needed to make explicit during the workshops. The idea appealed that the proposed design tool to structure these elements might just as well be used as a research tool to categorize them. Another advantage of using this tool is that it removes the need for live observation, which in early workshop set-ups had received consistently negative feedback from the participants and had also not yielded desirable results. For the sake of clarity, the tool in question is a morphological overview.

Here only a brief selection of all the results is given. The focus here is on the comparison of setting 1 session 2 [traditional building design setting] with that of setting 2 session 2 [where all disciplines work with the same information] and setting 4 [integral design setting with support of the morphological overview as design tool]. As an example only the process steps of one design team [group 1] is presented, as the process went similar for the other groups.

The compilation of the design team was such that only the architect was part of group 1 in all settings, the other members changed each time. More information and results are presented in Savanovic [2009].

Overall Workshop configuration of the workshops held in February 2008, is presented in table 1.

Duration	two days
Design sessions	4
Duration design sessions	2x2x120min [total 480 minutes]
Design task	Day 1 'parasite' & 'office'; Day 2 'renovation' & 'school'
Number of participants	19 in total, [day 1 – 18, day 2 – 16] 14 same for all four tasks
Architects	5
Building physics con.	4
Building services con.	7
Structural engineers	3
Observations by	Questionnaires, Photographs, Videos, all produced material collected

Table 1: Final two-day BNA-ONRI workshop

1st design setting, 'parasite' design task

Design session I: only architects, working individually - 5 architects

Design session II: team setting - 5 design teams

In design setting 1 each team was given the same design task: to design a 'parasite' structure to be placed on the building that the workshop was taking place in. For full description of the design task see Savanovic [2009]. All teams proceeded with the task in the same way. Initially, in the first design session, which lasted approximately 30 minutes, the architect worked alone on the design. Basically, this was done to mirror the status quo in which the architect is responsible for the original design, which is then presented to engineering disciplines. Following this, the other engineering disciplines of the design team joined the architect in order to discuss the proposed design. In this sense, the design team members of the engineering disciplines adopted the reactive role that is the norm in the status quo, and gave their reactions to different aspect of the design proposal. On the basis of these reactions the architect made adjustments to his original design. These adjustments led to improvements of the design.

In order to demonstrate what occurred in design setting 1, the work and analysis of one team is presented below, while the work of the other four teams can be found in Savanovic [2009]. After the initial design session I, in which the architect worked alone, all team members met in design session

II, to discuss the design. Here, the architect led the discussion. He did so by first explaining the considerations he took into account while working on his design. Through analysis of the session, these considerations were recorded in the Table 2 below. The analysis of each team's work started with the translation of the architect's explanation of the initial proposal at the beginning of second design session is into a table of aspects and sub solutions. This resulting sequential list is then structured in the architect's morphological chart. Then, on the basis of a review of the videotaped session,a table of aspects and sub solutions considered by the design team is structured in the design team's morphological overview. Design team 1 consisted of: architect [A], building physics consultant [BP], building services consultant [BS], and structural engineer [SE] [4 members from 4 disciplines].

Time (design session II)	Who	Aspect or sub solution	Description	Text/sketch or verbally
00h04min	A	Aspect (1)	Form	Text (session I)
00h04min	A	Aspect (2)	Materialisation	Text (session I)
00h04min	A	Sub solution (1-1, 2-1)	Contrasting to the existing building	Text (session I)
00h04min	A	Sub solution (2-2, 3-1)	Wood	Text (session I)
00h05min	A	Sub solution (2-3)	Open structure	Text (session I)
00h05min	A	Aspect (3)	Sustainability	Text (session I)
00h05min	A	Sub solution (4-1)	On (the existing building)	Text (session I)
00h05min	A	Sub solution (4-2)	Against (the existing building)	Text (session I)
00h05min	A	Sub solution (4-3)	Loose (from to the existing building)	Text (session I)
00h06min	A	Sub solution (4-4)	In the middle (of existing building)	Text (session I)
00h06min	A	Solution!	'Roof' on the existing roof…	Sketch (session I)
00h09min	A	Solution!	Loose, vertical spiral addition…	Sketch (session I)

Table 2: Aspects and [sub] solutions as explained by architect 1 to design team 1 [session II]

In order to allow comparison between different design teams and settings, these tables were reconfigured into the form of morphological overviews. The analytically derived morphological overview of team 1 is presented in Fig. 5. The aspects/functions and sub solutions originally brought to the table by the architect can be found as {A} in Fig. 6. After the discussion with the designer of other disciplines the team decided to work on different functions leading to the morphological overview of Fig. 6, which represents the final result of the design session.

Design aspects/ functions:	**Sub solutions:**			
(1) Form {A}	(1-1) Contrasting {A}			
(2) Materialisation {A}	(2-1) Contrasting {A}	(2-2) Wood {A}	(2-3) Open structure {A}	
(3) Sustainability {A}	(3-1) Wood {A}			
(4) [positioning]	(4-1) On {A}	(4-2) Against {A}	(4-3) Loose {A}	(4-4) In the middle {A}

Figure 5: Architect's morphological chart

Design aspects/ functions:	**Sub solutions:**			
(3) Sustainability{A}	(3-1) Wood {A}	(3-2) Heat pump {BP}	(3-3) Natural ventilation {BP}	
(4-1) On [positioning]	(4-1-1) 90° over the ex. building, on own legs {BP}	(4-1-2) 35-meter beams {SE}	(4-1-3) In line and partly over the ex. Building {BP}	(4-1-4) V-shaped columns {A/SE}
(5) Demountable {SE}	(5-1) flexible, prefab system {SE}	(5-2) plug'n'play building services {Team}		
(6) [Entrance]	(6-1) Independent {A}	(6-2) Extend existing entrance {A}		
(7) Flexibility {BS}	(7-1) Theatre at the end {A}	(7-2) entrance on west side {BP}		
(8) Orientation, sun {BP}	(8-1) roof wider than floor {A}			

Figure 6: Design team's morphological overview

2nd design setting, 'zero energy office' design task
Design session I all disciplines separately:
5 architects
3 building physics consultants
7 building services consultants
3 structural engineers
Design session II team setting: 5 design teams.

The analysis of the second design sessions of the second workshop design setting is based on videotaped design team activities. The resulting table of aspects and sub solutions considered by design teams during session II is structured into the design team's morphological overview. The goal of setting two was to make minimal changes to the status quo and measure the effect on the design process and the final product. To reach this goal at the beginning of the design process in design session 1 all disciplines were asked to respond to the design brief, as opposed to only the architect in the previous setting. In practice the participants worked together with members of the other teams from the same discipline. In effect, this led to the creation of four mono-disciplinary teams. All of these teams ended up with one finished product. The individual disciplines took this product back to the multidisciplinary team. These discipline-based responses were then brought to a team discussion in design session two. How much of this product was used in the multidisciplinary team and in what way was down to the representative of each discipline. The logic for following this procedure was to see if asking all disciplines to work on the task from the outset had any effect on the amount of aspects/functions and sub solutions that were generated by design teams during design session II. The analysis of the team work of design team 1 in design session II is shown in Fig. 7. Design team 1 consisted of: A, BP and BS: 3 members from 3 disciplines.

Design aspects/ functions:	**Sub solutions:**			
(1) Keep sun out {A}	(1-1) Trees {BP}	(1-2) Overhangs with PV panel{BS}	(1-3) reflective glazing{BP}	
(2) Light {BP}	(2-1) High-frequency lighting {BP}	(2-2) Solar tubes {A}		
(3) Heating {BS}	(3-1) office to storehouse {BP}	(3-2) TES {BP}	(3-3) sedum roof {BS}	
(4) [cooling]	(4-1) Adiabatic cooling {BS}	(4-2) Night ventilation {BS}	(4-3) air intake underground {A}	(4-4) In the middle {A}
(5)Electricity {A}	(5-1) Wind turbin{BS}			

Figure 7: Design team 1 morphological chart

In order to determine the effect of the set-up of setting two it must be compared to setting one. The main point of interest is to assess whether requiring individual disciplines to consider the task from the outset had any effect on the number of sub solutions generated when the individuals came together as a multi-disciplinary team. The comparison is presented below: table 3 contains the aspects and sub solutions generated by each individual team in setting I; table 4 contains the aspects and sub solutions from each individual team in setting II.

	Team 1	Team 2	Team 3	Team 4	Team 5	Average
No. of aspects	5	7	2	5	7	5.2
No. of sub solutions	13	16	12	16	17	14.8

Table 3: Aspects addressed and [sub] solutions produced by design teams [setting I]

	Team 1	Team 2	Team 3	Team 4	Team 5	Average
No. of aspects	5	2	3	3	3	3.2
No. of sub solutions	13	5	7	8	7	8.0

Table 4: Aspects addressed and [sub] solutions produced by design teams [setting II]

As can be seen from the table, contrary to what one might have expected, the intervention of introducing other disciplines into the design process from the outset did not result in the generation of a greater number of aspects and sub solutions. On the contrary, in setting two fewer aspects and sub solutions were generated than in setting 1, which was meant to represent the status quo.

3th design setting, 'renovation' design task

Team setting for both design sessions: 5 design teams.

Design setting 3 represented a learning-by-doing opportunity for the individual disciplines and the design teams. The ideal outcome would be that each team could clearly demonstrate successful use of the design tools during the design process. However, as a key part of learning is feedback, after the teams completed tasks set in setting 3, time was given to compare and appraise the teams' work and to answer any questions that arose. The results of this learning session are discussed in Savanovic [2009] but are not relevant in the context of this article.

4th design setting, 'school' design task

Team setting for both design sessions: 5 design teams

Design setting 4 represents the very last stage in the cycle of research in this research project. All of the individual interventions that were used in the earlier research stages are combined so that in setting 4 the ID-method can be tested. To be explicit, the elements that have been combined are: design team, design model, design tool and design setting. The analysis of the fourth workshop design setting, in which 5 design teams participated, of team 1 is here presented. Design team 1 consisted of: A, BS, SE: 3 members from 3 disciplines. In this setting, all of the design teams' proposed sub solutions were recorded directly on morphological overviews, see Fig. 8.

Design aspects/ functions:	Sub solutions:					
(1) Sustainability {Team}	(1-1) 'green' façade {A}	(1-2) PV/T shadings {BS}	(1-3) 'buffering' for humidity {A}	(1-4) roof garden {BS/A}		
(2) child-friendly, healthy {Team}	(2-1) Scale, identity {A}	(2-2) natural materials {BS/A}	(2-3) structure, protection {A}	(2-4) open façade, windows {A}		
(3) Natural ventilation {Team}	(3-1) HOLCOM ventilation {BS}	(3-2) higher classrooms {BS}	(3-3) walls for ventilation {BS}	(3-4) building orientation {BS}		
(4) Energy sustainability {Team}	(4-1) photo-voltaic thermal	(4-2) adiabatic cooling {Brief}	(4-3) air-inlet via underground {BS}	(4-4) CHP for winter {BS}	(4-5) floor heating {A/BS}	(4-6) sprinkler comb. cooling {A}
(5) Flexibility {Team}	(5-1) Columns {SE}	(5-2) Walls {SE}	(5-3) C/W Combination {Team}	(5-4) System plafond {A}	(5-5) 'Clear' plafond {A}	(5-6) HOLCOM floor {A}

Figure 8: Design team 1 morphological overview [design setting 4]

To conclude this section comparison is made between settings 1 and 4, and the research questions that were stated for setting 4 are answered. Table 5 contains information on the number of aspects and sub solutions generated by the teams in the setting four.

	Team 1	Team 2	Team 3	Team 4	Team 5	Average
No. of aspects	5	11	11	5	10	8.4
No. of sub solutions	24	26	39	20	46	31.0

Table 5: Aspects addressed and [sub] solutions produced by design teams [setting IV]

Result I: The use of the design tools and the team approach confirmed that goal was was realised

The comparison of design setting 1 and 2 presents the effect of introducing all the different designers from the start without using support. This led to a decrease of the number of aspects and subsolutions, indicating a less effective design process.
From the analysis of the workshops it could be concluded that the solution space, resulting from the number of functions and aspects considered, was significantly increased by applying the Morphological Overviews. A good example of this increase can be seen from the results from session 1 [without morphological charts and morphological overview] compared with the results of session 4 [with use of morphological charts and morphological overview]. Figure 9 clearly show that, as expected, more aspects and sub solutions were generated in setting 4 than in any previous setting 1 and 2. The increase of the number of considered functions and aspects leads to a larger number of partial solutions, which implies an increased problem-solution space, defined as the number of aspects times the number of solutions, see Fig. 9.

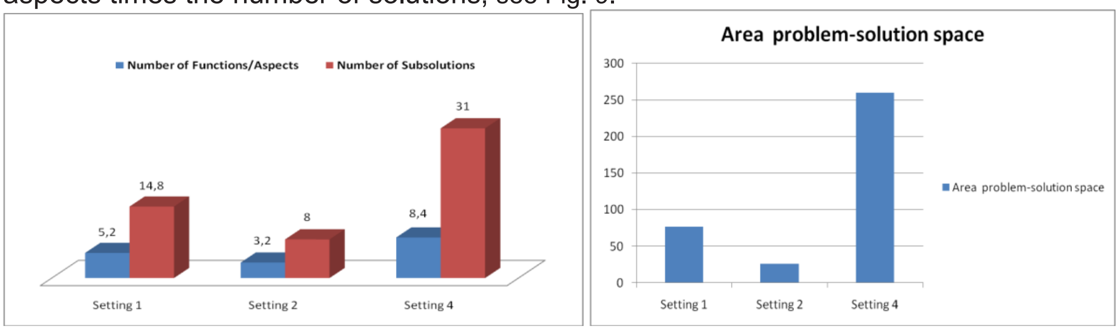

Figure 9: Comparison of the number of aspects/functions and the number of partial solutions being generated by the design teams in design session 1 & 4 and as an overall indication the 'problem-solution' area

Result II: Transformation of initial design knowledge to concepts

The results of analyzing the transformation of initial design knowledge into design concepts with the help of morphological charts and morphological overview showed that the Integral Design method did prove successful in facilitating the inclusion of engineering knowledge from the outset of the conceptual design phase. This in itself rendered the design process more efficient as it removed an unnecessary iteration, that is, the architect beginning the design task on his own before receiving input from engineering disciplines. However, what the disciplines within design teams ended up doing in many instances amounted to no more than seeking to fit solutions to design tasks. In essence, the design teams' approaches could best be categorised as 'integrated' rather than the desired 'integral' design, leading to redesigns [RE] rather than the desired integral design concepts [IDC]. This research therefore cannot claim to have realised the aim of using the ID-method to arrive at integral design concepts.

Conclusions and further research

The ID(Integral Design)-model is relevant to demonstrate the need for the explication of individual disciplines' object-design-knowledge. Additionally, the model can focus design teams on this object-knowledge in order to encourage the creation of ID-concepts. Although object-design representations can be driven by individual interpretations of the design task, in order to arrive at integral design concepts it is necessary that at a certain point the team agrees on design aspects / functions.

The main characteristic of the ID-method is the use of design teams' object-design-knowledge as 'building blocks' for either redesign [RE] or integral design concepts [ID]. The clear distinction between the two, redesign and design concepts, is only possible by using C-K theory. Building object-design-knowledge is discipline based, and to get an overview of the knowledge needed to produce a sustainable building concept in a specific context implies a team design approach as the first prerequisite. Research has shown that a highly promising way to get different disciplines truly working together is in a face-to-face setting [Abadi 2005, Emmitt and Gorse 2007]. Our experiences through the workshops and the feedback from the participants confirmed this. In addition, creating a workshop environment allowed professionals to work openly and freely, without the burdens that a laboratory setting bring with it.

The results showed that the ID-method did prove successful in facilitating the inclusion of engineering knowledge from the outset of the conceptual design phase. This in itself rendered the design process more efficient as it removed an unnecessary iteration, that is, the architect beginning the design task on his own before receiving input from engineering disciplines. However, what the disciplines within design teams ended up doing in many instances amounted to no more than seeking to fit solutions to design tasks. In essence, the design teams' approaches could best be categorised as 'integrated' rather than the desired 'integral' design. This research therefore cannot claim to have realised the aim of using the ID-method to arrive at integral design concepts. Nonetheless, the ID-method represents a set of necessary conditions for the creation of integral design concepts. More importantly, reflected by the expressed satisfaction of the majority of the participants, the ID-method represents an important step in what is argued as a necessary change in current building design practice.

In the next stage of the research the use of so called C-constructs will be investigated to stimulate the creation of new concepts. These C-constructs, sometimes called C-projectors, are used by Hatchuel and Weil in their KCP [Knowledge-Concepts-Proposition] workshops [Hatchuel et al 2009] to stimulate the forcing of concepts. The KCP workshops were held in different companies in France and more recently in Volvo in Sweden [Elmquist en Segrestin 2008, 2009]. The use of C-constructs could lead to increased effectivness of the Integral design workshop, and especially to an increase of the solution space by stimulation the transformations of K-C and C-K. In this research morphological analysis combined with the C-K [Concept-Knowledge] theory was used to explain the different design steps that take place in the conceptual design phase. Further research will start with a different approach for the analysis of the two final workshops series. A literature study will be done to determine analysis methods for conceptual design sessions: especially methods from linguistics and argumentation theory [Stumpf and McDonnell 2002, Dong 2007, Dong 2009]. Based on this analysis a new support tool will be developed and tested in new workshops series.

Author Biography

Wim Zeiler

Professor Building Services unit Building Physics and Systems at the Department of Architecture Building and Planning, Technsice Universiteit Eindhoven, Netherlands. His current research is on Integral Design and Renewable Energy applications in the Built Environment.

Perica Savanović

PhD on Integral Design and architect. Working at SBR Foundation Building Research as project manager Integral Design.

Duncan Harkness

PhD researcher at the Department of Architecture Building and Planning, Technische Universiteit Eindhoven, Netherlands. He has a background in argumentation theory.
