EDITORIAL

Welcome to the proceedings of the 2010 conference of the Design Research Society hosted by Université de Montréal, Canada.

The international biennial conference of the DRS is held during even numbered years in various countries around the world. The most recent conferences have been held in London, Melbourne, Lisbon, Sheffield, and now Montréal. We are most grateful to the hosts of this year's conference for the hard work they have put in since the early discussions some two years ago.

By close agreement, DRS biennial conferences alternate with the biennial conferences of the International Association of Societies of Design Research which are held in odd numbered years, thus consistently ensuring that a world class general design research conference is held somewhere in the world each year as a service to the international design research community.

Organisation of the DRS biennial conferences is taken very seriously. Host institutions and their organising teams are often new to the special demands of DRS conferences, though the collective experience of the Society is provided to organisers as published guidelines, and members of the Society assist organisers as advisors, reviewers and sometimes convenors of focused strands of presentations.

One firm principle of these DRS conferences which has been honed over several events, is to ensure the highest standards of selection of papers that will be presented at the event and subsequently published in the proceedings. This principle is important for two reasons. Firstly, delegates tell us that they prefer to attend conferences where only the strongest research is presented that is appropriate to the audience, is communicated clearly, and demonstrates research that has reached a stage where there are findings worthy of transmission. Secondly, as the oldest learned society of its kind, the DRS believes that the interests of the community of scholars - including early career researchers and doctoral research students - are best served by adequate screening of submissions to include only work that is demonstrably robust research worthy of publication.

Review of proposals is overseen by a small internationally based Review Committee comprising several skilled reviewers, which is appointed by the DRS. This committee is chaired by a member of the DRS Council and operates independently of the host organisers. In this way, the focus is rightly on academic judgement of the research.

All reviews are double blind - that is where the reviewer and the author are unknown to each other. We rely heavily upon independent reviewers who have either been invited due to their previous good record of conducting reviews, or who have volunteered and been vetted for the purpose. Reviews were conducted by 209 reviewers plus the committees. Each full paper was read by at least two independent reviewers as well as at least one member of the Review Committee.

The quality of peer review is of course only as good as the judgements that reviewers make. Reviewers may have varying levels of expertise. Some are expert in certain closely focused topics, others may have a more encompassing view of research beyond their deeper expertise. We are fortunate to count among our reviewers for this conference some of the most prominent scholars globally. Where possible, we have matched reviewers' expertise closely to the topic of the paper. Reviewers are also expected to provide feedback to authors for improvement of their paper, or to justify their decisions.

DRS considers that maintaining a high standard of acceptance to its conferences both sets a benchmark for peer review of research papers, and attempts to provide a solid body of work to which future scholars, including research students, may refer.

DRS conferences attract many more proposals than organisers can accommodate. In our experience about one third of initial proposals make it through to the final publication. In other words, about two thirds of applications are rejected either at the proposal stage or after submitting a full paper. In rounded figures, the total of initial proposals for this conference numbered 600, from which 380 authors were asked to submit full papers for a second round of reviews. 250 full papers were received. Following final judgements, 150 papers were selected for presentation at the conference and for subsequent publication in the proceedings, thus giving an exceptional ratio from initial submission to presented paper of about 4:1. In this sense, DRS conferences are nearer to a good journal review process than many other conferences in our field.

The working language of DRS conferences is English. On this occasion, being located in a French speaking country, we optionally invited papers in French. These were reviewed by a Francophone team, and the results calibrated with the main review. The papers are published in the proceedings in their original language, though French presentations at the conference have the benefit of simultaneous translation into English.

The programme of presentations is rich and extensive, with discussions ranging across various practices which cover the recurring topics of our field of design research. Parallel sessions provide strands that run throughout the conference programme. Here we find many strands that seem common to these kinds of events such as: methods for design and research; reflective practice; interaction; user centred and participatory designing; and many others. Also, newer strands are appearing representing perhaps current or emerging concerns such as: design and society; creativity; sustainable design; and growing work across or between disciplines. In addition there are specially convened strands that address issues arising from DRS special interest groups, for example well-being, pedagogy, and experiential knowledge.

I would like to take this opportunity to thank our host organisers, the large body of reviewers based around the world, my colleagues on the Review Committee, and advisors who have been instrumental in bringing together a collection of papers clearly demonstrating the health of research in our community at this time.

We hope that you enjoy the conference, and that these proceedings provide valuable reading for you, your colleagues, and your students.

The Role of Interaction Design in Information and Communication Technologies Embedded Product Development Activity

Canan Akoglu, Yildiz Technical University, Istanbul, Turkey, cakoglu@gmail.com

Alpay Er, Istanbul Technical University**,** Istanbul, Turkey, alpayer@itu.edu.tr

Abstract

This paper describes the role of interaction design in information and communication technologies (ICT) embedded product design and development activity. Besides presenting the relationship between industrial design and interaction design in the same activity, it also re-defines this relationship in terms of roles in ICT embedded product development activity.

This research has been accomplished by having an extensive interdisciplinary literature review, a series of interviews and also a case study based on a specific product's development process. The series of interviews have been conducted face to face in USA with professionals from 5 different industrial design and interaction design based consulting firms such as IDEO, Cooper Interaction, Smart Design, Swim Interaction Design Studio and LUNAR Design. The next step of the field research has been a case study based on gathering information of a spesific product through secondary sources and then conducting in-depth interviews with designers, who have worked in that product's development process, from different professions.

Major conclusions of the research include as follows: Being a younger discipline relative to industrial design, the role of interaction design in ICT embedded product development activity has the similarities to that of industrial design in the same activity. The most extensive collaboration between industrial design and interaction design is seen at *Planning* and *Concept Design* phases in ICT embedded product development activity. As the products become more complex in terms of interactions, interaction designers will gradually need to manage the design teams. There will be a need for a new sub-field of interaction design which is supposed to emerge as interaction design management. Comparing with industrial design, interaction design is foreseen to have a wider activity area in *Planning, Concept Development* and *System Level Design* phases of ICT embedded product development activity. As interactions with products become more and more immaterial, be a new actor from service design is supposed to have a role in ICT embedded product development activity.

Keywords

interaction design; industrial design; information and communication technologies; role of the designer; product development activity.

Penetration of information and communication technologies (ICT) in daily life has been causing changes in products. When the intensive use of ICT in different sectors is taken into consideration, it becomes inevitable to say that this subject is even transforming design processes.

Industrial design, as a professional practice, has been influenced by different dynamics such as the development of information and communication technologies, changes in products, changes in the way users interact with products, emergence of different disciplines in product design and development activity, changes in the focus points of product design and development activity throughout its short history.

In a context where products become more complex and where the competition in ICT embedded product development activity increases day by day, interaction design discipline comes into question. Alike Industrial Revolution has led up to the emergence of industrial design, the development of digital technology, especially of ICT and its use has caused the emergence of interaction design.

Throughout 20th century, while the interaction between users and products has been material, along with beginning of the design of ICT embedded products, materiality has been giving its place to immateriality in terms of interaction. This change has led to the emergence of new roles and professions in product development activities (Margolin, 1998; Buchanan, 2001; Forlizzi and Batterbee, 2004; Zimmerman, et al., 2004). One of these roles, accepted to design of the dialogue between users and products by a general definition, is interaction design (Smith, 2004; Moggridge 2006; Cooper, et al., 2007; Kolko, 2007). The profession which provides users interact with a product or system in a short span of time, continuity of interaction, decrease the period of first experience and provide less complexity but more satisfaction is considered to be interaction design (Smith, 2004; Zanini, 2004; Moggridge, 2006).

The Role of the Designer in Product Development Activity

Even though there are not specific periodical distinctions, it has been determined that there have been changes ranging from the definition of design to its role in product development activities. Especially in terms of industrial design, it is determined products and product development processes have concentrated on different focuses (Sparke et al, 1997; Vertelney and Booker, 1990; Cagan and Vogel, 2002; Heskett, 1980; 2002; Er, 2007).

Both designing and production activities have been under the responsibility of craftsmen who had the roles of designers before the Industrial Revolution (Heskett, 1980; Vertelney and Booker, 1990; Rothstein, 1999; Dreyfuss, 2003; Cagan and Vogel, 2002).

With Industrial Revolution taking out design and production from one person's responsibility, products have no more been designed and mass produced for only one but wide range of users (Heskett, 1980; 2002; Buchanan, 2001; Cagan and Vogel, 2002). In this period, the role industrial designer had been limited to design of the skin, or in other terms form (Loewy, 1979; Heskett, 1980; Dreyfuss, 2003).

Beginning to take place in early phases of product development processes caused designers participate also in user research studies (Kelly and Peters, 2001; Press and Cooper, 2003; Brown, 2005). Previously working with user and market data which marketing professionals put forward, designers have begun to collaborate with social science professionals such as human factors specialists and with people from other professions; then they needed to have information on cognitive and psychological factors in order to understand user needs and preferences. It is possible to assume that this situation accords with the factors such as understanding users, designing products or services for as many as users that underlie interaction design. Looking from the perspective of different dynamics, it is possible to say that not only ICT, but also the changes in social and economical structures will contribute to the critical roles of both industrial design and interaction design in product development activities.

Interaction Design

Interaction, which naturally exists from the presence of human beings, is taken into consideration as a profession in product development activities in this study. As Cooper et al (2007) and Smith (2004) states, interaction design is a new discipline that utilizes methods and techniques from existing disciplines.

It is determined that the development of ICT, especially the Internet, decrease in hardware dimensions, changes in products, user numbers and profiles, user-product interactions, changes in software and service development activities and the graphic user interfaces have appeared in the emergence of interaction design.

It is possible to assume that interaction design attempts to makes the interaction that is becoming more complex and more immaterial be understandable, useful, usable and desirable for users. While industrial design concentrates on the form and function of a product traditionally, interaction design concentrates both on how users interact with ICT embedded products, softwares and services and on how information can be exchanged.

Alike industrial designers design products for different uses with the contribution of mechanical technology, interaction designers define and design the dialogue between users and products, services and systems (Smith, 2004; Kolko, 2007). This similarity between industrial design and interaction design indicates that both of these professions interwine each other in terms of role sharing in product development activities. On the other hand, this similarity can be seen as an indication for potential changes in role sharing in product development activities.

Methodology

In this study an extensive literature review, including various disciplines, a series of interviews and a case study has been held.

“The role of interaction design in ICT embedded product development activity” being as the basic research interest of this study is a very new and limited field in terms of product development activity in Turkey. Therefore interviews have been conducted face to face in USA with key professionals from leading industrial design and interaction design based consultancies, that have pioneer work in the mentioned area internationally, such as IDEO, Cooper Interaction, Smart Design, Swim Interaction Design Studio and LUNAR Design. The interviewers were Bill Moggridge (IDEO), David Cronin (Cooper Interaction), Gitta Salomon (SWIM Interaction Design Studio), John Edson (LUNAR Design), Sheila Foley (Smart Design, SF Office). In this phase of field research, the definitions and design and development processes of those mentioned consultancies were examined.

The second phase of the field research has been planned as a case study based on a representative product’s literature review and interviews with professionals from different disciplines on its design and development process. After product selection criterion was prepared, it has been corresponded with firms such as Apple, Nokia and LUNAR Design. At the end of this correspondence, the case study was held on a product called Pasco Spark which has been recently designed by LUNAR Design and planned to be shipped in August 2008. Interviews of this case study were held with specialists from different professions who have worked in Pasco Spark’s design and development process through the Internet.

Findings of Interviews

Interaction designers of interviewers accept industrial designers as professionals who design product’s form and its mechanical interaction with users and who has knowledge on production and materials. On the other hand, industrial designers see interaction designers as professionals who design product’s digital interaction with users. Behavior has been stated to be the common point in both of these definitions.

Although interaction design has been considered to take part from the first step of product development activity as a common aspect of interviewers, it has been determined that there are different approaches in the related sector.

During the interviews except from IDEO, it is determined that there are significant phases in which interaction design and industrial design collaborate in the rest of the interviewer firms design and development process. When the design and development processes of the firms have been examined, interaction design based consultancies stated that some of industrial design based consultancies contacted with them to work together after having fundamental design decisions, even after defining the product's form. Interviewers emphasized that this situation has negative effects on final product's success and innovation (Cronin, 2005; Moggridge, 2005; Salomon, 2005).

When industrial design and interaction design processes in ICT embedded product development activities are considered, it is possible to assume that the fuzzy front end of product development is the process where the most collaboration and corporation between interaction designers and industrial designers takes place. It is examined that when design concept has been being generated, roles of industrial designers and interaction designers on creating the form of the product and the location, form, color and material of physical controls which users interact with, has been indefinite.

Although there has been a common viewpoint that traditional product design and development process has been supposed to continue, it has been stated that there would be changes in ICT embedded product development activities. On the other hand, it is determined as a common approach that there would be changes in terms of new material uses and production technologies.

Case Study Findings

Pasco Spark which was designed by LUNAR Design has been the product of the case study. It is a product used for education that enables students aged between 12-16 years old explore the world and make discoveries in basic sciences both inside and outside the classroom. The interviews of the case study were held with project manager, interaction designers, industrial design lead and user researchers who worked throughout Pasco Spark's design and development process in LUNAR Design.

As well as having a role as interaction designers, the interaction designers also had roles as project manager and user researchers in Pasco Spark's development process (Author, 2009). It is determined that the reason one of the interaction designers took part as the project manager besides being an interaction designer has been because of the complexity in Pasco Spark's functionality and content. LUNAR's design and development process consists of 3 main phases including sub-phases: vision, magic (the design phase) and reality (Anderson, 2008; Lebas, 2008). Although the sub-phases seem to be similar, it is determined that there are differences in terms of the content proposed and the techniques used by industrial design and interaction design (Author, 2009). During the vision phase while the design and development team concentrate on user research studies, it is observed that interaction designers focus on researching user mental models and processes. On the contrary, it is determined that industrial designers research ergonomic considerations of users and competing products in the market. When the time spent on user research is considered, it is examined that industrial designers pass over to other phases in a shorter time than interaction designers. Thus it is determined that industrial designers have already created general qualities and form alternatives about product when interaction designers just begin creating concepts.

In Pasco Spark's development activity, the phase during which collaboration and corporation between industrial design and interaction design take place is determined to be concept generation. During this phase there is information needed to be exchanged between industrial designers and interaction designers; that is to say, there are sub-phases in which both designers are dependant to each other (Author, 2009): interaction designers need to get information about the screen dimensions in which the content and interaction is supposed to be embedded from industrial designers. Thus the dimensions of the product affect the dimension and resolution of the screen and those are the factors which affect the quality and quantity of information and the interface that are supposed be embedded in the product. But at this point, it is foreseen that not only industrial designers but also interaction designers might propose the mentioned dimension information. Although this information is directly dealed with the product's form and is supposed to be within the role of industrial designers, it can be accepted as type of information in terms of product's content and its dialogue with users at the same time. On the other hand, the prototypes concerning the use of both the digital content and physical content are supposed to be compatible with each other and constitute an entirety. Because of these reasons industrial designers and interaction designers are needed to work dependant to each other.

Conclusions

This study attempts to define the role of interaction design in ICT embedded product development activity, to re-define its relationship with industrial design within the same process. According to these mentioned aims, the results of this research are explained below.

Development of Interaction Design

Being a younger discipline relevant to industrial design, the role of interaction design in ICT embedded product development activity has similarities with the changes industrial design's role in product development process (Author, 2009). Alike industrial designers being included into the development team after basic design decisions have been determined, interaction designers have had the similar experience. Also, alike industrial designers have been accepted to be who only design the form, interaction designers have been seen professionals who only design the graphical user interfaces. This belief and approach is still been observed in the sector. Although there are exceptional approaches are determined in literature review and interviews which constitutes the first phase of field research, it appears that interaction design has been involved in the development process after Planning and Concept Generation phases. On the other hand, it is determined that interaction designers both work as user researchers and project managers in the case study. Although the second phase of the field research has been conducted as a single case study, the above mentioned development shows that interaction design will gradually continue to have a wider role in ICT embedded product development activities.

Additionally, ICT embedded products are becoming more and more multifunctional and the behavior of such products are provided by dynamic interfaces instead of static ones. In this situation, it can be accepted that the products are becoming "boxes" that shelter the hardware and functions in terms of physical considerations. This determination also shows that interaction design has begun to have a wider role than industrial design has in ICT embedded product development activities.

The contents and functions of products becoming more and more dynamic causes the interaction shift from material qualities towards immaterial qualities. The said interaction moving toward immateriality is supposed to cause the emergence of another new actor on service design in ICT embedded product development activities.

The Relationship Between Industrial Design and Interaction Design in ICT Embedded Product Development Activity

It is essential for interaction design and industrial design to be in corporation and collaboration in ICT embedded product development activities. Although this situation has come forward in the literature review, it is determined that the said necessity is taken into consideration in the sector except for the leading design consultancies. The findings of interviews which consist the first phase of field research, support the literature review. As a matter of fact, design consultancies in which there are no in-house interaction designers, outsource interaction design at the end of Concept *Generation* and *System Level Design* phases. This situation which is supported by both literature review and interview findings is in contradiction with case study findings.

</table>

It is considered that industrial designers and interaction designers collaborate and cooperate starting from first step of the development process which is the *Planning* phase. The reason of this contradiction might be the 3 years time period between interviews and the case study and also the rapid developments in this field. Another finding that supports the mentioned development is that in-house interaction designers began to work in LUNAR Design, one of the product design consultancies which interviews were conducted within this period of time.

Table 1 shows that there are common factors that both industrial designers and interaction designers focus in terms of design processes. Thus these common factors, which did not come out in literature review but in interviews, constitute the steps that interaction design and industrial design are dependant to each other in ICT embedded product development activities. Although both industrial designers and interaction designers have been considered to propose alternatives about the mentioned common factors in the case study, it is seen that industrial designers' information is still needed (Author, 2009). Yet determination of ergonomic factors and form creation are still in the profession of industrial designers. In the case study although two design professions seem to propose alternatives about the screen dimension of the product, it is believed that interaction designers should be responsible because of designing the information and the functions embedded in that screen. Although both of the design professions seem to propose alternatives for affordances, it should be accepted as a problem to collaborate and cooperate. As a matter of fact, these relationships are being solved by using users' hands instead of other physical controls such as a mouse, handle etc. This situation is gradually shifting interaction design into its individual area from being dependant to industrial design profession. Affordance which is located under the user title also is moving into the profession of industrial design.

Redefining the Roles in ICT Embedded Product Development Activity

The subjects which were supposed to be solved collaboratively and cooperatively by industrial design and interaction design in ICT embedded product development activities have begun to move towards to the responsibility of interaction design profession (Author, 2009). Because the physical controls that take place in user product interaction have been gradually disappearing,

Disappearance of physical controls that take place in user product interactions shows that the activity area of interaction design will be wider and wider in ICT embedded product development activity. This extension points out that interaction design profession will have a leading role on the process and design management comparing with industrial design.

In Table 2 the roles of industrial design and interaction design are redefined in ICT embedded product development activity: in *Planning* phase, both industrial designers and interaction designers have active roles in identifying user needs and preferences, company and market needs. But at this point, as interaction designers focus on especially user mental models and processes, their role in user research studies have dominancy than that of industrial designers. At the end of *Planning* phase, both industrial designers and interaction designers have roles in creating concept, use and context scenarios. These steps in *Concept Development* phase are the ones which collaboration and cooperation are seen the most between industrial designers and interaction designers. Thus in *Concept Development* phase, the basic design decisions are taken. Due to the basic design decisions, both design professions create alternatives for the project. These alternatives are tested by gathering the mockups generated by industrial designers and paper prototypes generated by interaction designers. Both design professions generally work in their teams in *System Level Design* phase. At this point, although neither of teams are totally independent to each other, it is foreseen that they frequently cooperate in order to discuss and exchange ideas. In *System Level Design* phase both industrial designers and interaction designers continue creating design alternatives. Ulrich and Eppinger (2004) shows interface issues within the scope of industrial design. But creating an interface depends on creating physical controls which are not only in responsibility of industrial designers but should be also of interaction designers.

Table 2 Redefining the roles in ICT embedded product development activities (adapted from Ulrich and Eppinger, 2004)

	Marketing	*Design* Industrial Design	*Design* Interaction Design	Manufacturing	Other
Phase 0: **Planning**	Market opportunity articulation Market segments definition	User Company Market needs Product platform and architecture New technologies assessment Persona creation	Hypothesis generation **Research** Stakeholder research User research Field research **Modeling** Persona creation Workflow generation Use scenarios generation **Requirements Definition**	Production constraints identification Supply chain strategy setting	Research: Demonstration of available technologies Finance: Providing planning goals Management: Allocation of project resources

Phase 2: **System Level Design**	Plans development for product options and extended product family Target sales price points setting	Generating alternative product architectures Choosing materials Defining major sub-systems Refining industrial design	**Design refinement** Detailed design	Suppliers identification for key components Final assembly scheme definition Target costs setting	Finance: Make-buy analysis Service: Identification of service issues
Phase 3: **Detail Design**	Marketing plan development	Defining part geometry Choosing materials Assigning tolerances Completing industrial design control documentation		Piece-part production definition Tooling design Quality assurance definition Procurement of long-lead tooling	

disappearing as might be observed in ICT embedded products in the market. Consequently, industrial designers will gradually leave their roles in this subject to interaction designers. In this case, it is possible to foresee that interaction design profession will play role more and more in this mentioned step.

Starting from the above evaluations, it is possible to say that interaction design will have a wider activity area in Planning, Concept Development and System Level Design phases comparing with that of industrial design.

According to the results of this study, there are differences in terms of methods, techniques and design language in approaching the design problem and understanding users between industrial designers and interaction designers. Conducting more case studies regarding this result might contribute to affect and develop thriving techniques, design and representation languages.

The results of this study foresee that interaction design will gradually play a wider role in design and process management in ICT embedded product development activity. Hence a conducting a research in the near future on interaction design management might contribute to both interaction design profession and ICT embedded product development activity.

Canan Akoglu

PhD, Research Fellow in Department of Architecture, Computational Design Unit at Yildiz Technical University, Istanbul. Dr. Canan Akoglu holds a PhD in industrial Design and interaction design from the Department of Industrial Product Design at Istanbul Technical University (ITU). Dr. Akoglu has a masters degree in interactive media design specializing on human-computer interaction and usability evaluation tests. Her research interests include interaction design, design process, collaboration, research methods and techniques for innovative product development process.

Alpay Er

PhD FDRS, Head of the Department of Industrial Product Design at *Istanbul Technical University* (ITU). Studied industrial design at METU in Turkey, Professor Alpay Er received his PhD from the *Manchester Metropolitan University* in the UK.. He is an International Council Member of the *Design Research Society* (DRS) since 2002, and a Fellow of DRS since 2006. His main research interests include design management and strategy, industrial design in emerging economies, design education, and government design polices.

A Survey of Definition and its Role in Strengthening Design Theory

Robert Andruchow, University of Alberta, Canada

Abstract

This paper argues that an essential task for managing complexity in design is clarification of key terms within the field, and most importantly the term that defines the field itself: Design. This position rests on the argument that theory—a key tool for managing complexity in design—is weakened by ambiguous terminology, and crucially, ambiguity of the word *design*. Although it has been well documented that design is a highly ambiguous term and that this is problematic for the field as a whole, many designers are resigned to this fact since it is unclear how one can resolve differences of opinion about what such a central and sensitive term means. This paper argues, though, that once designers have a better understanding of the process of definition—a process that has its own complexities—they might see the benefit of trying to define design and other key terms. To this end, this paper provides an overview of definition, borrowing largely from philosophy, which includes a survey of the types and methods of definition and issues related to each. It will also explore methods and criteria by which one can evaluate various competing definitions. From this survey, I propose that designers use a stipulative and pragmatic approach to definition outlined by Edward Schiappa (2003). Schiappa's approach is useful because of these two key underlying assumptions: first, defining design (and related terms) is not a search for the record of past usage but an act to persuade others of how to use the word in the future, therefore the person defining must provide a compelling argument for why others' usage should be modified; second, defining design is not a search for the 'true' or 'real' meaning of a word but instead a goal-oriented process and, therefore, dependent on the context and purpose of those defining the word.

Keywords

design; complexity; definition; terminology; concept analysis; philosophy; language; ambiguity

Design research, education and practice have all faced greater complexity as the field has grown and matured over the past several decades (Buchanan, 1992; Meurer, 1999). This added complexity comes from several sources, including:

- A growing emphasis on *research and methods* in design, borrowing largely from more established disciplines such as psychology, sociology, anthropology, marketing and engineering (Meurer, 1999; Frascara, Meurer, Toorn, Winkler, 1997).
- A greater awareness in the business community (and to some extent the general public) that design plays a *central role in product and service development*. Thus, designers have seen their roles expand from stylist to “strategic consultant” (J. O'Grady, K. O'Grady, 2006, p. 10-11).
- A recent *expansion of new media and technology*, such as the Internet, social

networking and mobile computers/phones in which a designer can deliver a message or product through.

- A greater emphasis on *social responsibility, ethics and environmental stewardship*, requiring the designer to have a more informed view of the socio-political context in which their design will exist (Frascara et al, 1997; Papanek, 1975).

With each of these sources, theory is a critical tool for the designer. Theory helps designers understand this complexity and more importantly explain how it will impact their design problems and solutions. Epistemological theories are required so a designer can explain when to use qualitative or quantitative *research methods*. Helping a client determine long-term communication and marketing *strategies* requires theories about how they will impact product sales. Choosing a *medium or technology* in which to deliver a message requires theories of communications and semiotics to understand how it may be affected and interpreted. Lastly, all design solutions affect the *socio-political and environmental* contexts they are placed within, requiring the designer to have a world-view or ethos based on theories about politics and the environment. In each of these examples, the designer's understanding of the theories being applied have a direct impact on the design solution. For simple design projects, one does not have to be explicit about how their theories impact their design solution and can rely on intuition; but for more complex projects, a designer will be expected (most likely by their client) to explain why a certain world-view or method is used.

Building design theory

This brief examination brings us to two crucial points: first, theory is becoming more vital for design practitioners as their practice becomes more complex; second, as the examples provided above show, many of the required theories originate in other disciplines: sociology, psychology, political science, marketing, communication studies, etc. This second point leads us to a new source of complexity in design: the state of design research and how it informs design practice.

For this, I turn to two papers: “Language definition and its role in developing a design discourse” by Sharon Poggenpohl, Praima Chayutsahakij and Chujit Jeamsinkul (2004); and, “Constructing a coherent body of theory about designing and designs” by Terence Love (2002). These papers are relevant to the discussion about complexity in design because they both present a summary of the state of design research and they both argue that design must develop its own research discourse rather than rely on other disciplines to strengthen its theoretical development. According to Love (2002), there is growing interest “in the development of a unified body of knowledge and theory about designing and designs” (p. 345). This interest is shared by Poggenpohl, Chayutsahakij and Jeamsinkul (2004), who argue that design research and practice would be well served to have its own “core knowledge” which would lead to the development of “an intelligent discourse” (p. 588).

While Love (2001) believes creating a more unified body of theory is gaining interest among design researchers, it has “not yet emerged in spite of extensive research undertaken over several decades, across several hundred domains of practice, and from a wide variety of perspectives” (p. 345). Both list several key reasons for this lack of emergence. According to Poggenpohl, Chayutsahakij and Jeamsinkul (2004) there is a range of “stronger, weaker, or virtually nonexistent discourse traditions” in different sub-disciplines in design (p. 588). Overall, “[d]esign does not have a strong tradition of reflective or critical writing, perhaps because much design knowledge is tacit and formalizing this knowledge through language is difficult" (Poggenpohl, Chayutsahakij, Jeamsinkul, 2004, p. 588). This is because discourse is "dominated by trade magazines that follow trend and fashion in practice" (Poggenpohl, Chayutsahakij, Jeamsinkul, 2004, p. 588). While Love (2002) does not evaluate the quality of research in design, he does emphasize that it is often "tied" to the subdomain it was created within (p. 346). So, even if we found strong research within a subdomain, according to Love, it is not or cannot be shared with the other subdomains in design. For Love (2002), this inability to share research between subdomains feeds into what he sees as a fundamental reason design has not seen a unified body of theory emerge: "a lack of philosophical foundations" (p. 346). These foundations include: agreement upon "core concepts and terminology" in design to clarify "the scope, bounds and foci of fields of research and theory-making about designing and designs"; greater investigation into epistemological, ontological issues in design; and lastly, better "integration" of design theory and "other bodies of knowledge" (Love, 2002, p. 346).

Poggenpohl, Chayutsahakij and Jeamsinkul acknowledge there are critics of the creation of a unified body of theory. They argue these critics disagree because "design is necessarily a synthetic discipline" and, therefore, can rely upon research from research-based disciplines such as "human-computer interaction or social science" (Poggenpohl, Chayutsahakij, Jeamsinkul, 2004, 589). While they agree that design is a synthetic discipline, they disagree that this means it cannot have its own internal discourse. More importantly, they argue "a lack of a specific design discourse with ongoing development, argument, criticism, research findings, etc. hampers development of design as a discipline and prevents design from contributing its knowledge more broadly" (p. 589).

Strengthening design theory through definition

Clearly, the task of unifying design theory has its own complexities—both in defending the endeavor and in the foundational goals necessary to complete it—but as argued above, if design practice seeks to manage complexity, it must do so with a body of theory and knowledge of its own. To minimize the complexity in this task, the remainder of this paper will investigate the first philosophic goal that both papers argue for: "clarifying definitions of core concepts" (Love, 2002, p. 346).

One could argue that this is a primary philosophic goal since one's definition of design will inform the next two goals: epistemology and integration with other disciplines. This is a point not lost on Poggenpohl, Chayutsahakij and Jeamsinkul (2004), who see the task of definition as central, impacting design in mundane yet highly practical ways, from effective "tagging" of research (p. 579), to wider foundational implications such as: "how the design profession envisions itself—as a craft or a discipline; how curricular programs in design need to change or not based on its accepted definition; what other disciplines can hope to learn from design and its research; how design research can improve knowledge and performance in design practice" (p. 590).

While the following exploration of definition will be relevant to all core concepts in design, this paper will focus on the term that defines the field itself: design. Focusing on the definition of design is valuable not just because of the reasons listed above and the obvious fact that it names the field as a whole, but because it is also a highly ambiguous term. According to Love (2002), design has "different meanings in different domains, [is] used in different ways by researchers in the same domain, and [is] found in the literature referring to concepts at different levels of abstraction" (p. 347). This ambiguity results in theories and research where accounts of design are "contradictory," causing confusion about which findings are actually applicable from one domain to another (Love, 2002, p. 347).

While there are a myriad of reasons for this range of opinion, two are particularly significant: the dramatic change in the field of design in the last one-hundred years; and, the ambiguity of the word itself. First, the practice of design has seen dramatic change in the last one-hundred (or more) years—from an applied art at Bauhaus in the 1920s, to an attempt at an applied science at Ulm in the 1960s. Even the last thirty years has seen a shift from a more scientific approach to design to a more generalized notion of design that is not necessarily scientific, but understood as a type of planning (Buchanan, 2001). The second significant reason for this ambiguity is the many overlapping meanings of the word design itself. Design has a range of meanings from the abstract to the specific. To demonstrate how confusing using the word design can get, John Heskett (2001) provides the following sentence:

> *Design is when designers design a design to produce a design* (p. 18).

He then explains how all four uses of design are each a different sense of the word:

> The first usage is as a noun, connoting the field of design as a whole in a very general manner, as in the phrase: “Design is important to national economic competitiveness.” The second usage is as a verb, meaning the action or thought involved in the act of designing. The third also is a noun; this time connoting a plan or intention. Finally, the fourth usage again is a noun, this time meaning the finished product. All the usages have very different meanings, yet even people professionally involved in design continually slip between them, seamlessly moving from one meaning to another without distinction (Heskett, 2001, p. 18).

Few other disciplines are the victim of such a high number of multiple meanings or polysemy. While almost all words in our language are polysemic, design is particularly polysemous, and to make matters worse, the many meanings are very closely related. A very common error is to equate the noun design, used to describe the discipline or field of practice (ie. “architecture is a subdomain of design”), with the more general verb design, used to describe planning or scheming (ie. “that football play was by design”) (Bamford, 1990, p. 6).

This ambiguity begs the first question when defining design: which sense of the word are we using to define the *discipline*? Or, is it even one of the definitions given in Heskett's quote? If it is another definition, how does one formulate a new definition? How does one develop arguments for a definition and how are these arguments evaluated? As these questions suggest, the process of defining design is complicated. The difficulty for designers is they lack the philosophical background to navigate these questions, which according to Richard Buchanan (2001), is the source of the discipline's difficulty with definition:

> Efforts to establish a new field of learning require a definition of the field, and design is no exception. Unfortunately, our community has often foundered on the problem of definition. The literature is filled with contrasting and sometimes contradictory definitions of design, and efforts to define design have often led to acrimony. […] There has been an unfortunate misunderstanding about the nature and use of definitions, and this has caused our discussions to become unproductive and wasteful of time and energy (p. 8).

Some may argue that definition should be left for philosophers due to its complexity but the following quote from Schiappa (2003) reminds us of the central role designers must play in defining design: “definitions put into practice a special sort of social knowledge—a shared understanding among people about themselves, the objects of their world, and how they ought to use language” (p. 3). As designers, we maintain this shared knowledge through communities of research and practice, making us experts on how to define our world. So, if designers must play a central role in definition, we must clarify the process itself to make it more productive for designers.

A survey of definition

Outside of philosophy and law, definitions are normally quite mundane since the majority of the time we have strong tacit agreements about the words we use in conversation. Edward Schiappa (2003)—the central author used for this summary on definition—notes that definition as a method is not even required for good communication since a shared vocabulary is learned through a variety of social contexts that are far less formal (p. 28). Definition, though, is far from mundane when the use or application of a term is disputed or has large ramifications, for example, in legal or academic communities (Schiappa, 2003, p. 33). Philosopher Trudy Govier (2005) says the following about definitions:

> We look for a definition when we see a claim or argument that is unclear or hard to understand, or when a practical problem whose solution depends on our having an explicit definition. At such points, we begin to wonder what certain important words mean and it makes sense to look for definitions. (p. 95)

The tradition of definition started two thousand years ago with Socrates. As a philosopher, Socrates was interested in seeking and building knowledge, as opposed to opinion, about the natural, psychological and political world. He was interested in an important test of knowledge: the determination of the "essential" nature of concepts, such as "justice" and "courage" (Schiappa, 2003, p. 22). Aristotle continued this tradition with the development of the "standard definitional form involving genus and difference," which bears resemblance to methods used by Socrates and Plato (Schiappa, 2003, p. 23). The genus would establish what *similarities* the thing being defined had to other things, and the difference would be identified through *attributes* which differentiated it from other things within the genus. For example: "A chair is a piece of furniture (genus) used for sitting (attribute)" (Schiappa, 2003, p. 25). This approach has proved so effective that two thousand years later, the creators of the Oxford English Dictionary used it to clarify terms:

> There are rules—a word (to take a noun as an example) must first be defined according to the class of things to which it belongs (mammal, quadruped), and then differentiated from other members of that class (bovine, female). (Winchester, 1998, p. 150)

The longevity and effectiveness of Aristotle's method stems from the fact that he had gained insight into basic functioning of the brain that only recently, through psychology and biology, has been provided a scientific basis. Schiappa (2003) explains the scientific basis for the genus-species method of definition as follows: "[M]uch remains unknown about how the human brain processes sensations ... [f]or present purposes, the most important theory is that our sensory-perceptual activity *forms* experiences through a process of abstraction and categorization" (p. 13) He then links this process to evolution by quoting child psychologist Bowermann: "[t]he grouping of discriminably different stimuli into categories on the basis of shared features is an adaptive way of dealing with what would otherwise be an overwhelming array of unique experiences." (Bowerman, 1976, 105-6). In child psychology, this discrimination process is known as developing "similarity/difference relationships" or "SDRs" (p. 17-18).

For Aristotle, this method of definition was particularly important for knowledge-building because it allowed one to develop principles based on the categorization and listing of essential attributes. For example, one could start the process of defining design by first establishing the genus which it could belong to: “discipline.” A by-product of this first step is also clarifying which sense of the word we are defining; in other words, we are trying to define “design as a discipline.” Because “discipline” is a broad genus, the next step would be to determine if a further sub-categorization might be useful. For example, we could divide the disciplines into knowledge disciplines and applied disciplines. Now we have a narrower genus for design: “applied discipline.” A final step would be to differentiate design from the many species within applied discipline, so one could say design is a combined applied art and social science. Thus, we differentiate design from engineering which is the application of the physical sciences. While the example definition we ended up with is not important to analyze, what is important is to see how this process has given us useful attributes that could form principles of design. So, if one sees design as part applied art and part applied social science, one could develop the following principles:

- A design researcher could argue that the epistemological foundations of design ought to balance the subjectivity of aesthetic choices of fine arts with the objectivity of empirical science.
- A design educator could argue that design education must include a foundation in the fine arts and the social sciences.
- A design practitioner could argue to clients that the effectiveness of their design is based upon the satisfaction of both aesthetic and social scientific criteria.

While this example was quite brief and far from exhaustive, it demonstrates the usefulness of the genus/species (or similarity/difference) method of definition. Today, this method of definition is still important for philosophers and, as mentioned, lexicographers. But, other fields such as law and linguistics also use or study definition, which has led to the creation of various *types* of definition, each geared towards a particular purpose. The following is a survey of the three main types:

- An “*ostensive* definition” is one used to describe a thing that can be pointed to, and particularly useful for things that are difficult to explain using words, such as colour but not good for explaining abstract or complex phenomena (Govier, 2005, p. 96).
- A “*lexical* definition” tries to list and describe all common usages of a term (Govier, 2005, p. 96); These are the definitions you would find in a dictionary. This method often uses the etymology (study of the history of words and how their form and meaning have changed over time) to inform the definition of the word being defined.
- A “*stipulative* definition” states what a term ought to mean, and may be adopted as a lexical definition if widely used (Govier, 2005, p. 99). The notion of “ought” is crucial here because it implies stipulative definition is a persuasive act. That is, one must provide reasons to its listeners as to why they should change their usage of the term.

In relation to defining design, each type of definition has varying levels of use value. Ostensive definition is the least useful type because, as discussed above, it does not explain abstract terms very well; one cannot develop a foundation for a discipline by just pointing to a set of objects. Theory requires an articulation of definition that can be scrutinized through written or spoken language. That said, through the process of articulating a definition of design, it is highly useful to point to examples that are the product of design. This is especially important for when explaining a definition to a design audience that largely learns through visualization.

Lexical definition is valuable but, again, limited. In defining the discipline of design, if one simply referred to a dictionary, which of the twelve or so definitions provided does one use to define the discipline? Even if the dictionary provides a definition explicitly for the discipline, we then need to ask whether the definition is appropriate. For choosing one of the lexical definitions and in determining appropriateness of the definition chosen, one needs a justification or reasons. In other words, there is an element of persuasion involved through articulation, but not based on past usage of the word design, but rather on conceptual and pragmatic grounds. Arguing for a definition in this way means you are now using a stipulative definition.

In fact, this is the limitation of Poggenpohl, Chayutsahakij and Jeamsinkul's approach to definition in their paper. A large focus of the paper is on the organizational aspect of definition—that is, the problem of gathering thousands of word uses and definitions to be used in a design dictionary and then using this dictionary to help stabilize language used in design discourse (Poggenpohl, Chayutsahakij, Jeamsinkul, 2004, p. 582). Their emphasis on the organizational aspect of creating a dictionary demonstrates a possible misunderstanding regarding the types of definition. While collecting lexical definitions and creating a dictionary can serve a purpose within a community, it will not help one through the process of selecting and evaluating one dominant definition (or set of definitions) that a whole research community ought to use. This selection and evaluation process is primary and is where difficult theoretical debates about appropriateness and efficacy take place. According to Govier, dictionary definitions do not suffice for complex or abstract concepts where “fundamental” issues of “theory and value are involved” (Govier, 2005, p. 97). Therefore, if ostensive and lexical definitions cannot resolve the definition of design, stipulative definition seems to be the most appropriate type. Before a final conclusion is drawn, a full exploration of stipulative definition is required.

Exploring stipulative definition

Within stipulative definition, there are two important epistemological debates about *approach* that impact the method we will use: the essentialism vs. anti-essentialism debate and the real vs. nominal definition debate. In exploring these debates I will also introduce Edward Schiappa's approach since it is particularly useful for the definition of design.

An essentialist approach assumes one can define the essential features of a thing such that these features are universally true, with no exceptions. The essential features are also known as the necessary and sufficient conditions. For example, the necessary and sufficient conditions for being a bachelor are being “male” and “unmarried.” Being male and unmarried are sufficient because we don't need additional conditions for a person to be considered a bachelor and they are necessary because every bachelor is married and male. Opposed to this essentialist view, are the anti-essentialists of which there are several flavors. The most famous is Ludwig Wittgenstein's theory of family resemblances, which assumes that words such as “game” and “art” do not have such universally true features but rather a patchwork of related resemblances that may or may not fit to each application (Weitz, 2007, p. 190). In the case of defining design, the essentialism debate is very important, since “design” falls into the same category of ambiguous terms as “game” and “art.” One could argue that the elusive nature of the term and inability of the community to come to a shared definition is proof that a finite set of necessary and sufficient conditions does not exist. On the other hand, if we take a pragmatic approach to defining design, one could argue for the essentialist approach based on its utility. That is, creating a set of conditions for what constitutes design is useful because it allows the community to develop principles for the discipline, differentiate design from other disciplines, etc. While it is outside the scope of this paper to fully explore all of the arguments within these debates, the salient point is to know they exist. For purposes of this paper, I will use the essentialist position based on the utilitarian grounds.

The second key debate within stipulative definition is between those that consider definition to be “real” or “nominal.” For Plato, a “real” definition was a search for the Ideal Form, that is, a definition that describes the “true” and “universal” nature of a term (Schiappa, 2003, p. 36). This view depends on “metaphysical absolutism: the belief that things have independent, “objective” structures of essences that are knowable “in themselves” (Schiappa, 2003, p. 36; quoting Barnes, p. 79-83). While this approach may seem appropriate when trying to define physical phenomena like “tree” or “planet” which necessarily involves identification of properties that are *objectively* perceived, the approach quickly becomes complicated when defining social or metaphysical concepts like “justice” and “good.” What are the essential characteristics of “justice” that we can objectively perceive? Even with the definition of “tree,” a real definition is problematic because it is unclear how one can determine which characteristics are objectively essential. According to Schiappa, the essence of a thing depends on one's interest/context, therefore, one cannot search for the “absolute” essence of a thing. For example, a lumberjack may define a tree with an emphasis on characteristics that allow him to distinguish trees from things he cannot chop down, while a chemical engineer may define trees according to its molecular makeup. In other words, “[a] thing-as-experienced may have as many essences as we have interests” (Schiappa, 2003, p. 41). Based on this major critique, philosopher Richard Robinson, along with most modern philosophers, objects to the notion of “real” definitions because they are “at best a mistake and at worst a lie” (Schiappa, 2003, p. 48; Robinson, 1950, p. 170). Robinson uses the word lie because a real definition gives the “false impression” that definition is a matter of correcting “knowledge of facts” rather than a process of isolating characteristics that are relevant to a given purpose (Schiappa, 2003, p. 48; Robinson, 1950, p. 170). To resolve this confusion, Robinson and Schiappa argue that all definitions should be viewed as nominal—that is, arbitrary yet dependent on context. For Schiappa, one way of resolving this confusion is to rephrase the definitional question:

> Instead of posing the questions in the time-honored manner of “What is X?” ..., I suggest that we reformulate the matter as “How ought we use the word X?” given our particular reasons for defining X. Specifically, I advocate that we think of one appropriate form of definition as “X counts as Y in context C.” (p. xi)

Reformulating the question in this way does three very important things. First, the use of “ought” rather than “is” makes it clear that definition is a matter of persuading others to adopt a new usage of a word rather than a search for the essence of a thing. Second, clarifying that we are defining a word within a specific “context” makes clear to those engaged in the discussion that context matters, both in terms of how the definition is formulated but also in how it is evaluated. Thirdly, notion of “we” emphasizes the very social nature of the process of definition.

Although stipulative definition is persuasive in nature, this does not mean the process must be a one-way argument where the definer proposes a definition of design and the audience simply agrees or disagrees. If we return to the ancient Greeks, a key aspect of their process of definition was coming to a shared understanding of more than just the term being defined. This dialectical process is illustrated through Plato's dialogues where an interlocutor leads a discussion with one or more people. The discussion often revolves around clarifying important moral concepts such as “justice” and “the good” (Schiappa, 2003, 31). The role of the interlocutor is to help the discussants clarify their often tacit and vague notions of the concepts in question. Definitions are proposed and through scrutiny in the form of argument and examples, the interlocutor shows the discussants that their tacit notions require adjustment. This adjustment leads to a new definition which then bears more scrutiny. Much of the discussion involves clarifying not just the one term in question but a whole constellation of related terms. Discussion usually opens with a great deal of disagreement and confusion, but through the course of clarifying what each discussant means when using each related term, disagreement often turns to understanding (or, at least, an understanding of the complexity of what at first seems simple). This back-and-forth, give-and-take process is called dialectic. Poggenpohl, Chayutsahakij and Jeamsinkul (2004) note that the process of dialectic can be difficult in written form:

> Speech is less calculated and more spontaneous with the speaker observing (or listening) whether the response from an audience demonstrates understanding. There is a turn taking that allows repair and clarification. In contrast, writing is discontinuous; misunderstanding may reveal itself only over time and through response (p. 583-584).

Dialectic is not only significant here for its relationship to Poggenpohl, Chayutsahakij and Jeamsinkul's description of oral speech acts, but more importantly, it points to a method to be used for not only forming a definition but also achieving consensus among a group of users.

A second point regarding the social nature of definition, actually directs us back to lexical definition and the role it plays in conjunction with stipulative definition. One of the traps of stipulative definition is that it cannot simply ignore conventions of language users when making a stipulation. Ignoring convention is called the “Humpty Dumpty theory of definition”, which comes from Lewis Carrol's *Alice in Wonderland*, where Humpty-Dumpty “says that he can make words mean whatever he wants them to mean” (Govier, 2005, p. 99). Although it is certainly possible for one to define words however one wants, the value of doing so is very limited, since one will have no way of sharing this knowledge with others. Govier (2005) explains: “If a person defines words arbitrarily with no attention to public conventions, other people will not understand them and the *words will have no use”* (p. 100). She continues by reminding us of a fundamental value of words in language:

> Words in a language are public instruments for communication in that language, and a stipulative definition is useful only if it sets out predictable and comprehensible standards of use that are workable for the purpose at hand. (Govier, 2005, p. 100)

Seeing words as public instruments is valuable because all the reasons given for defining design at the start of this paper revolved around a community of language users: designers. Since one cannot define design in a bubble, lexical definitions or a record of previous usage must be a type of definition employed (although not central).

While this summary covers the key debates regarding definition, it is by no means exhaustive. The most important point this summary can demonstrate is that definition is full of complexities. Due to the great difference in purpose of and method used between a) type of definition, and b) definitional approach, it is essential that prior to all formal discussions about definition, discussants state their purpose and approach upfront. If this is not done and discussants jump straight into the process of definition with no knowledge of these dilemmas, it is likely that these dilemmas will cause great confusion and even great conflict about the proposed definitions without the discussants understanding that their differences lay in more fundamental issues than a simple difference of opinion regarding proposed definitions.

Based on the summary above, I propose that designers approach definition from a pragmatic perspective, seeing definition as a proposal for new usage that must be negotiated by designers according to the purposes of definition that they collectively determine. This community of designers could be small (a school faculty determining a definition or vision of design for curriculum development) or large, in the case outlined by Love, Poggenpohl, Chayutsahakij and Jeamsinkul (determining a common usage for a community of researchers). This approach assumes that definition is nominal and, therefore, avoids metaphysical dilemmas about the “true” or “real” nature of design, and instead evaluates proposed definitions based upon practical ends, such as the development of clear connections between other disciplines. Within this approach, several methods can be employed to form and then evaluate the definition. The species/genus method of definition is valuable for differentiating design from other activities and then establishing logical consistency between a constellation of terms required to understand the phenomenon of design. The etymological method helps provide an understanding of how and why the word has changed. The lexical method is used to avoid humpty-dumptyism that increases the chances others will take up the novel definition. Finally, the ostensive method can help one illustrate one's definition by pointing to examples.

Future directions

“What is design?” As this paper demonstrates, this question is highly complex. It is fraught with as many linguistic and theoretical difficulties as the age-old philosophical question: “What is art?” But, due to its relatively recent emergence as a discipline and limited discourse, there is only a fraction of the literature. This confusion poses problems for the teaching of design and for the sharing of knowledge about design. In fact, the ambiguity is so great, some argue that one cannot even call design a discipline; and as long as design remains as ambiguous as it is today, creating a body of theory unique to it will prove very elusive and, without which, complexity will be even more difficult to manage.

While Love, Poggenpohl, Chayutsahakij and Jeamsinkul make strong arguments for the need to build stronger philosophic foundations in design and, specifically, clarification of key terms through definition, these are only four voices. There are others who have written on this same issue (Buchanan, 2001; Bamford, 1990; Friedman, 2003; Galle, 2008; Owen, 1998) but the list is short and little progress has been made in the last ten years. Hence, there is still a need for greater research into establishing reasons for why focusing on the process of definition is *valuable* for design researchers, practitioners and educators. Many designers simply don't think a general definition of design is attainable even in small contexts (let alone the larger community as a whole) and even worse, they do not see the process of definition as being beneficial. Hopefully, through this paper and similar efforts by others, we can generate a greater, more informed and productive debate about the definition and foundations of design and how this impacts the research, teaching and practice of design.

His company focuses on enabling social, political and environmental groups build capacity and create political and social change through an integration of new (web, social networking) and traditional media (print, advertising). Robert also teaches design fundamentals, design theory, design research and interactive design as a part-time instructor at the University of

Alberta, Canada. He is currently finishing his Masters of Design in Visual Communication Design.

Interaction Designers' Conceptions of Design Quality for Interactive Artifacts

Mattias Arvola, Linköping University and Södertörn University, Sweden, mattias.arvola@liu.se

Abstract

It is important to be aware of different ways of seeing design quality of interactive artifacts in order to appreciate the various aspects of a design, but how do professional interaction designers understand design quality? In theory, one way of approaching design quality of interactive artifacts has been the Vitruvian principles of commodity, firmness and delight, originally created for architecture. Such frameworks are, however, seldom directly employed in practice. This paper investigates what conceptions professional interaction designers have of design quality for interactive artifacts. Interviews were conducted with ten designers. The analysis disclosed four conceptions concerning: (a) Constraints & contexts, (b) motivations & purposes, (c) use-qualities of functions & content, and (d) experiential qualities of form & behaviour. An awareness of these conceptions may facilitate the appreciation for different aspects and opportunities in a design situation.

Keywords

interaction design; design quality; use-qualities; conceptions, user experience.

Interaction design has many fields of origin that potentially have different design ideals. This means that there is a complexity in the criteria and values that shape an interactive artifact. So what do professional interaction designers really mean when they say that an interactive artifact is an example of good or bad design? It is likely that different designers have quite different conceptions of what good design really is? It is important for researchers, students, professional designers, critics and managers in interaction design to be aware of different ways of seeing design quality of interactive artifacts in order to appreciate the various aspects of a design. Alternative perspectives can open up for reflection, learning, and change, but the lack of such awareness may obscure design opportunities (Hult, Irestig & Lundberg, 2006). The conception of design quality among interaction designers is the problem area of this paper, but first a few words on the notion of interaction design.

In their design effort, interaction designers focus on interaction with artifacts and experiences of interactive artifacts. Bill Moggridge and Bill Verplank coined the term interaction design in the late 1980s to describe their work at the intersection of industrial design, information design, graphics, human factors, and computer science. Moggridge (2007) pictured a creative and imaginative design discipline working with software, designing behaviours, animations, sounds, and shapes. Like industrial design the new design discipline would focus on qualitative values. It would start with the needs and desires of people who would use a product or service, and aim towards designs that would give aesthetic pleasure, lasting satisfaction and enjoyment. Verplank summarizes his view on the interaction designer's job by answering the three questions; how you "do", "feel" and "know" (Moggridge, 2007). Interaction design does, however, not only involve shaping conditions for the interaction between people and artifacts. It also involves shaping conditions for the interaction between people by means of artifacts (Arvola, 2005; Buchanan, 2001; Hernwall & Arvola, 2008). This points towards understanding interaction as conversation, which is a more complex process than the feedback loop used in Verplank's do, feel, and know questions (Dubberly, Pangaro, & Haque, 2009). The word interaction in human-computer interaction design, can be defined as a mutually and reciprocally performed action between several parties in close contact, where at least one party is human and at least one is computer-based (Arvola, 2005). This gives a background to interaction design, before returning to the issue of design quality in this field.

Design Quality

A multifaceted approach to design quality has been used in architecture since Antiquity, when Vitruvius described the virtues of a building in the terms utilitas, firmitas, and venustas. An often-used translation of those terms is commodity, firmness and delight. The same framework is still used today as in for example the Design Quality Indicator—DQI (Gann, Salter & Whyte, 2003)—where the three Vitruvian principles have been given a modern day interpretation in a conceptual framework consisting of three aspects: Function (use, access and space of a building), Build Quality (performance, engineering systems and construction), and Impact (form, materials, internal environment, urban and social integration, identity and character). DQI is pictured as a pyramid with sides representing function, build quality and impact. The form of a pyramid highlights the multifaceted nature of design quality. Gann et al. (2003) give the example of lighting in a building, which has a functional quality of providing a bright and accessible work area, but also has an impact on the pleasure and wellbeing in use of the building.

The Vitruvian principles have also been introduced in interaction design theory by Ehn and Löwgren (1997) who defined a framework for quality-in-use of interactive artifacts. Their interpretation of the Vitruvian includes structural aspects assessed from, a constructional quality perspective, functional aspects assessed from an ethical quality perspective, and formal aspects assessed from an aesthetic quality perspective.

Dahlbom and Mathiassen (1993) have introduced a similar framework for quality of IT-artifacts. Their work is built on the design movement of the Swedish functionalists during the first half of the 20th century (Paulsson & Paulsson, 1956). Their framework includes four quality aspects for evaluating technical artifacts: functionality, for evaluating practical use; aesthetics for evaluating looks and experiences; symbolism, for evaluating social use, what it means to us and signals to others; and politics for evaluating wider effects on peoples' lives, including power relations, coercions, and liberties supported and encouraged by the artifact. The political aspect is also closely related to ethical issues concerning what practices and behaviours are supported and required from users.

These theoretical frameworks for design quality have also been used in combination (Arvola, 2005, 2007; Johansson & Arvola, 2007), but they are still theory; the question here is instead how practicing interaction designers conceptualize design quality.

Conceptions

The units of analysis in this paper are conceptions of quality that interaction designers have. A 'conception' is a specific way "in which people understand a particular phenomenon or aspect of the world around them" (Marton & Pong, 2005, p. 335). Conceptions are represented by qualitatively different meanings or 'categories of description' of the phenomenon. A 'conception' has in earlier research also been called 'ways of conceptualizing', 'ways of experiencing', 'ways of understanding' 'ways of apprehending' and 'ways of seeing' (Marton & Pong, 2005). Conceptions are also structurally linked to each other in what is called an 'outcome space' that describes logical relations (often hierarchically inclusive) between different ways of seeing a phenomenon.

The aim of this study is to explore the range of different ways of conceptualizing design quality among professional interaction designers. The result will be an analysis of categories of description and a clarification of structural relationships between these categories.

When describing designers' ways of conceptualizing quality one can distinguish between structural and referential aspects of experience (Marton & Booth, 1997). Structural aspects refer to the discernment of the whole from the context and discernment of the parts and their relationships within the whole. Referential aspects of experience refer to identification of what something is; the assignment of meaning.

Another distinction, used in phenomenology, is between an external and an internal horizon of experience (Marton & Booth, 1997). The external horizon of experience is that which surrounds the phenomenon experienced including its contours. The internal horizon of experience is the parts and their relationships, together with the contours of the phenomenon.

The research question for this study is: What are the conceptions interaction designers have of design quality in relation to interactive artifacts? The theoretical framework for design quality and conceptions forms the background to the study. Next, the method for answering this research question is presented.

Method

Semi-structured interviews were conducted with ten professional interaction designers. Interviews were recorded and transcribed into a verbatim transcript, which was analyzed using qualitative content analysis.

Participants

Ten interaction designers (four female and six male), with four to thirteen years of work experience, participated in the study. Two participants were based in Finland and eight were based in Sweden. The designers in Sweden had an educational background in cognitive science and human-computer interaction with a profile in interaction design. One of the designers in Finland was originally from Spain, but had lived in Finland for eleven years. He had an educational background in business and new media with a design angle. The other designer in Finland described himself as a media artist and designer, and had an educational background in photography and installation art. The different areas that the participants worked in covered government websites, intranets, office applications, electronic medical record software, air traffic management software, concept design for future home communication, ambient media, interactive exhibitions, and mobile television applications. Participants worked as freelance designers, at small and medium-sized usability and design consultancies, and as in-house designers at software companies.

Data Collection

The interviews were semi-structured and ranged from 45 minutes to 1 hour 40 minutes. Five of the interviews were conducted face to face and five were conducted over distance via video calls. Three interviews were audio recorded and seven interviews were also video recorded. The two interviews conducted in Finland were made by one interviewer, and another interviewer made the interviews in Sweden. The interview guide was revised after the first two interviews. It focused on the participants' workplace, role, projects, background, views on design quality, and design processes. All taped material from the interviews was transcribed and partly normalized to a written form. Names of clients were removed from the transcripts.

Procedure of Analysis

The procedure of analysis in this study builds on Graneheim's and Lundman's (2004) review of the methodological literature on qualitative content analysis.

The interviews were read through and listened to several times to obtain a sense of the whole. Overarching content areas in the interview text was then identified. Sections concerning design quality were extracted and brought together into one text. The extracted text was divided into meaning units that subsequently were condensed. The condensed meaning units were abstracted and labelled with a code. The various codes were compared based on differences and similarities and sorted into 19 sub-categories and 7 categories, which constitute the manifest content. The tentative categories were discussed by a group of researchers and revised. What differed between the researchers were assessments about sub-categories, and the wording of specific codes and categories. Reflection and discussion resulted in agreement about how to order the codes. Finally, the underlying meaning, that is, the latent content, of the categories was formulated into themes.

The empirically driven qualitative content analysis was followed by a more theoretical analysis. The relations between categories of description were analyzed in more detail to map out the space of different ways of seeing design quality of interactive artifacts. The theoretical concepts of referential aspects, structural aspects, internal horizon and external horizon were used in this analysis to clarify the structure of that space.

Results

Two overarching themes emerged in the analysis: Getting the right design and getting the design right. As a side note, the two themes also form the title of a paper on usability testing of alternative design solutions by Tohidi, Buxton, Baecker and Sellen (2006), as well as the subtitle of the book Sketching User Experiences by Buxton (2007). The different conceptions are presented in Table 1.

Theme	Conception of Design Quality of Interactive Artifacts as:
Getting the right design	A: Managing constraints on the interactive artifact
	B: Delivering a motivated interactive artifact
Getting the design right	C: Creating opportunities for usage of the interactive artifact and its contents and functions
	D: Creating opportunities for experiences of the interactive artifact and its form and behaviour

Table 1 Conceptions of design quality of interactive artifacts grouped around the two themes The right design and The design right

Conceptions A and B concerns getting the right design in relation to constraints and motivations, while conceptions C and D concerns getting the design of functions, content, form and behavior right. Getting the right design answers the question of why a design should be developed. Getting the design right answers how the design should be composed.

Conception A: Design Quality as Managing Constraints on the Interactive Artifact

Design quality can be seen as adapting to the conditions of a design project. An example is provided below:

I sometimes feel that you may have focused a bit more on this like ideal design on what you would have wanted to do if all preconditions where there, like time and opportunities, and no, for example, particular tool is chosen and so on. Such fixed parameters, you just have to take them into account because they're not gonna change during the project you do. (Interview 9, Row 118, translated from Swedish)

In the example above it is highlighted that it is one thing to have high standards and high ideals, but quite another to reach those ideals under the constraints of a particular project. The design quality of a product or service can therefore be seen in the light of the conditions under which it was produced.

Participants noted that a design project is performed in relation to technical conditions of what can or cannot be done within given financial constraints. The design project is often scoped in relation to already made decisions regarding technical platforms, or there might already be, for instance, a publishing system in place to which the design of a website needs to adapt. In such cases there must be a technical fit between the design and the existing technical context. Design projects are also performed in relation to organizational conditions of issues like roles and power structures that one cannot change and must adhere to.

The focus, when viewing design quality this way, is on the preconditions and the context of the design project; factors that are external to the interactive artifact as such.

Conception B: Design Quality as Delivering a Motivated Interactive Artifact

Design quality can be seen as delivering an interactive artifact motivated by different stakeholders. An example is provided below:

Yeah, well that is a question of design quality then. What is, what is good quality in… a design, a product that you have participated in developing then, service. And now you come back to you know why did we build this in the first place, who are, what needs have we really been trying to satisfy. Both for users and customers and the organization as such. And that is of course, that is the answer to the question somehow. (Interview 3, Row 214.b, translated from Swedish)

In this example the participant returns to the question of why something was built in relation to latent needs of users, customers and organizations. The basis for design quality can thus be seen as whether an interactive artifact meets its purposes or not, given that the design fits the already existing technical and organizational contexts. The interactive artifact needs to have values in use for the people and the organizations it concerns. Values in use, exemplified by participants, may be to contribute to experiences, effectiveness and business utility.

A design can communicate a business strategy or contribute to strategic ways of working. A focus on experience and beauty, which is a higher standard than mere elegance, can also be part of the purpose of the interactive artifact in relation to a business strategy.

A focus on usefulness as an overarching goal is a more instrumental view than user experience. This view indicates efficiency in the organization, effects before form, design solutions that are sustainable over time, and meeting the user, customer and business needs behind the design brief.

Related to the purpose of the design are the intended and unintended effects of the design and the ethical consequences of those effects. The purpose of interaction design can also be to create new conditions for a strategic way of working, by supporting a particular way of using the interactive artifact in a specific situation.

The focus in this conception of design quality is on the motivations that drive people and businesses.

Conception C: Design Quality as Creating Opportunities for Usage of the Interactive Artifact and its Contents and Functions

Design quality can be seen as concerning the use of content and functions of the interactive artifact. An example is provided below:

Good design, it has to... fulfil a few requirements, it has to be something that fulfils the main objective of being something that is useful, you know? … So that people can really use it … in the most efficient and simple way. (Interview 1, Row 90–95)

In this example the participant started out in Conception B with ”something that is useful” and then specified that to something that people can use in an efficient and simple way. The things that are used are functions and content of the interactive artifact. The use of the functions and contents of an interactive artifact must also be safe.

The focus in this conception of design quality is on qualities of the interactive artifact in use.

Conception D: Design Quality as Creating Opportunities for Experiences of the Interactive Artifact and its Form and Behaviour

Design quality can be seen as concerning experiences of form and behaviour of the interactive artifact. An example is provided below:

*On a personal level I think it’s easy to talk about good and bad design insofar that a solution is kind of obviously elegant, right. That it is simple, it’s clear, you have taken away lots of fuss that makes it easier to zoom through it, or it’s cool, it has cool interaction, it’s, it’s kind of modern at the forefront of what’s currently considered good interaction design. And form. (*Interview 3, Row 214.b, translated from Swedish)

In the example above, the same participant as in the example from Conception B, continues to describe his way of conceptualizing design quality by covering Conception C in terms of simple and clear usage, but he also covers the area of elegance and cool, modern or even interesting form. The form (including interactive form – i.e. behaviour) of the interactive artifact can accordingly also be the basis for design quality. It should ideally be interesting and modern, even though this may be an issue open to interpretation and taste.

Beside from interesting, the form and behaviour should as indicated by the example above, also be elegant in its simplicity and clarity. In this way of seeing design quality, beautiful form and behaviour follows function, and the aesthetics are contrasted to the practical.

The focus in this conception of design quality is on experiential qualities of the interactive artifact.

Space of Conceptions for Design Quality of the Interactive Artifact

The outcome space of design quality can be summarized as in Table 2.

Conception	Referential aspects	Structural aspects	Horizon
A	Design quality as managing constraints on the interactive artifact.	Focuses on preconditions and contexts of the design project.	External
B	Design quality as delivering a motivated interactive artifact.	Focuses on the purpose of the interactive artifact and how it meets the motivations that people and businesses have.	External, Internal
C	Design quality as creating opportunities for usage of the interactive artifact and its contents and functions.	Focuses on the use of the interactive artifact, and its functions and contents, and the qualities displayed in that use.	Internal
D	Design quality as creating opportunities for experiences of the interactive artifact and its form and behaviour.	Focuses on the experience of the form and behaviour of the interactive artifact, the qualities of the experience, and the constituents of the form language.	Internal

Table 2 Conceptions of design quality of the interactive artifact

In Table 2, the referential aspects refer to the meaning of design quality. The structural aspects refer to the discernment of the whole phenomenon, and its parts. In Conception A the whole is the design project; in B it is the people and the business; in C it is the use of the interactive artifact; and in D it is the experience of the interactive artifact. The parts discerned are preconditions and contexts in A, the purpose, motivations and goals in B, and qualities, functions and contents in C, and qualities, form, behaviour and form language in D.

The external horizon of design quality of the interactive artifact is the constraints for the design project in the specific situation that the designers find themselves in. The internal horizon, i.e. the parts and their relationships, of design quality of the interactive artifact consists of motivations and purposes, functions and content, behaviour and form.

The relations between the conceptions of design quality as well-designed interactive artifact can be represented as a logically inclusive structure in an outcome space. This is depicted in Figure 1, and it also illustrates the internal horizon (B, C and D), and the external horizon (A and B). B belongs to both the internal and the external horizon of experience, by forming the contours of the phenomenon, since the purpose belongs to the interactive artifact while the stakeholders' motivations belong to the context.

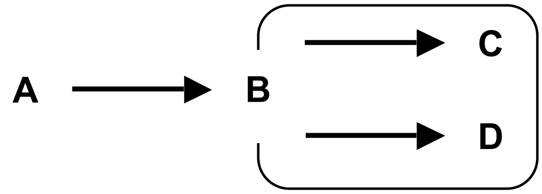

Figure 1 The hierarchy of logical relationships between conceptions of design quality of the interactive artifact

The figure means that Conception B is implied by Conception A since the conditions of the design project form the backdrop for the purpose of the interactive artifact. Conception B implies both Conception C and D in that the contents and functions, and their form and behaviour are means that contribute to the purpose, which is to deliver an interactive artifact that meets stakeholders' motivations and fit the context.

Discussion

The results can be interpreted using the theoretical frameworks for design quality presented in the introduction. Such an interpretation is depicted in Table 3.

Conception		Design quality aspects
A	Design quality as managing constraints on the interactive artifact.	Structural, ethical, political.
B	Design quality as delivering a motivated interactive artifact.	Functional, aesthetic, ethical.
C	Design quality as creating opportunities for usage of the interactive artifact and its contents and functions.	Primarily functional, secondarily symbolical.
D	Design quality as creating opportunities for experiences of the interactive artifact and its form and behaviour.	Primarily aesthetic, secondarily symbolical.

Table 3 Relations between interaction designers' conceptions of design quality and design quality aspects derived from the theoretical framework

Conception A: Design quality as managing constraints on the interactive artifact, has to do with what can and cannot be done in terms of technical and organizational structure. It also has to do with political and ethical issues related to power structures. This conception belongs to the external horizon of design quality for the interaction designers, and is thus something they experience as framing but not something that is focal for them.

Conception B: Design quality as delivering a motivated interactive artifact, has to do with the purpose of the design and the motives of the stakeholders. It is about delivering value in use of the artifact, whether it is functional usefulness and strategic ways of working for users or organizations, or aesthetic experience.

Conception C: Design quality as creating opportunities for usage of the interactive artifact and its contents and functions, has primarily a functional dimension in simple efficient ways of using an artifact. In simplicity there are also symbolic or communicational dimensions since functions and contents need to be presented in a clear and efficient way.

Conception D: Design quality as creating opportunities for experiences of the interactive artifact and its form and behaviour, has primarily an aesthetic dimension in elegant behaviour and form. It is also concerned with a symbolic dimension in creating interesting experiences.

The results indicate accordingly that the participants conceptualized symbolic, social and communicational aspects as secondary to, or at least not separate from, functional and aesthetic dimensions. The functional also seems to come before the aesthetic. Both these aspects are conceived as instrumental to the purpose.

No interaction designer had only one conception of design quality. In fact, in order to discern qualities of a phenomenon (such as an interactive artifact) one needs to experience variation in that which is discerned (Marton & Booth, 1997). One way to achieve variation of experiences is to actively shift conceptions (Hult, Irestig & Lundberg, 2006). Both Gann et al. (2003) and Ehn & Löwgren (1997) indicate this when arguing that a specific feature or quality does not belong to only one quality aspect. Participants in this study constantly moved between conceptions in their reasoning.

Verplank has three questions an interaction design has to answer (Moggridge, 2007): How do you do, know, and feel? An interaction designer does, however, not directly shape how people do, know and feel. He or she can only indirectly affect these issues. So what is it interaction designers do shape directly? It has been argued that it is the conditions for interaction that are shaped (Arvola, 2005; Hernwall & Arvola, 2008). Although not the focus for this study, the results indicates that shaping these conditions includes deciding the form and behaviour at the surface of the interactive artifact, and deciding the functions and content at its core, in relation to contextually dependent purposes and motives for users and businesses.

When interpreting the results of this study some caution is called for. The interview material analyzed here has to do with how interaction designers talk about design quality in general. It is not connected to specific design projects, and it is not situated in design action. An analysis of project specific quality judgements, or situated quality judgements may show that they in reality reason differently from how they say they reason. Future research will have to tell.

The results do not represent the full range of possible ways of conceptualizing design quality for this group at this time. Such a study would not be possible to conduct. All participants were from Sweden and Finland, and most of them had an educational background in cognitive science and human-computer interaction with an interaction design profile. Another sample may disclose other ways of seeing design quality in interaction design.

Design quality is always a topic for discussion in the design community, but do we talk about the same thing? The results would be interesting to contrast with the conceptions human factors specialists, industrial designers, graphic designers, and engineering designers have. Or why not game designers or artists in interactive art?

At face value, the results may seem equally applicable to industrial designers or graphical designers as to interaction designers. If we, however, look at the results more closely we see issues like supporting specific ways of working and interacting among users in organizations, and we find issues about behaviour, and combinations of content and functions of interactive artifacts that are typical to the interaction design discipline.

Conclusions

Four different conceptions that interaction designers have about design quality for interactive artifacts were identified, and they can be expressed in a condensed form as: (a) Constraints & contexts, (b) motivations & purposes, (c) use-qualities of functions & content, and (d) experiential qualities of form & behaviour. An awareness of these conceptions may facilitate researchers, students, practitioners, critics, and managers of interaction design in their appreciation of different aspects and opportunities of a design situation.

Author Biography

Mattias Arvola

An interaction design researcher and lecturer with a Ph. D. in cognitive systems from Linköping University in Sweden. His background is in cognitive science in a combination with training in interaction design. His research is primarily in human-computer interaction and social computing, with a focus is on methods like sketching, enactments, patterns, personas and scenarios. Another strand of the research is the role of assessment and appreciation in design considerations, and models of user experience, use-quality, and usability.

Émergences du design et complexité sémantique des sextoys

Résumé

L'exposition « Love design », en 2009, et notamment le *8ème ciel* de Matali Crasset, manifeste l'intérêt du design pour l'érotisme et les sextoys. Nous traiterons ici des glissements sémantiques opérés ces dernières années dans le monde des objets à usage sexuel. Le phallus, devenu un artefact hypertechnologique ou bien un objet habillé d'une iconographie issue d'un bestiaire, évince le registre pornographique au profit d'une apparence ludique ou raffinée. Les sextoys mettent donc en lumière la complexité sémantique à l'œuvre dans la construction d'un nouveau champ de pratiques afin de faire accéder le produit à l'univers commun. A travers cet objet d'étude, le design est interrogé dans une démarche à double tranchant. L'élaboration d'une cohérence sémantique repositionne le discours des sextoys mais elle se limite souvent à l'iconographie et à la technique en quête d'efficacité. Dès lors, le design, vecteur de cohérence sémantique au sein de ce terrain hétérogène émergent, reste en deçà de ses capacités à construire des scénarii complexes des diverses pratiques sexuelles.

Abstract

The exhibition « Love design », in 2009, and in particular the *8ème ciel* of Matali Crasset, shows the interest of design for the eroticism and the sextoys. We deal with semantic movements operated these last years in the world of objects with sexual usage. The phallus, become a hypertechnological artefact or an object dressed in an existent iconography of a bestiary, ousts from the pornographic reference in benefit of a funny or refined appearance. Sextoys highlights therefore semantic complexity in the structure of the new practice's reference in order to democratize the product. About this research, the design is asked in a double-edged approach. The structure of a semantic coherence redirect the speech about sextoys but it often limits itself in the iconography and in the technological in search of efficiency. From then, the design, vector of semantic coherence within this emergent heterogeneous subject, stays on this side of its capacities to construct complex screen play of various sexual practices.

Keywords

Design and sex; sextoys and society; perception/cognition of sextoys; design of sextoys for well being; sex efficiency; sexual practice and creativity.

Nous avons observé depuis le début des années 2000, l'apparition de sextoys dans les vitrines des centres villes en Europe et en Amérique du Nord, des sextoys ludiques, colorés ou encore élégants et raffinés qui s'éloignent de l'univers pornographique. L'émergence de ces sextoys dans les love-shops sous entend un nouveau niveau de visibilité sociale important. Ces sextoys, expression que l'on pourrait traduire par « jouets sexuels » ou plutôt jouets érotiques, constituent l'objet de notre étude au titre de territoire d'un design émergeant. Notre approche traite d'une étude contextuelle en France, susceptible d'être vérifiée dans les pays occidentaux. Le basculement stylistique de ces sextoys fait état d'un rhizome sémantique complexe, c'est-à-dire qu'il utilise des unités esthétiques permettant d'opérer des glissements du point de vue de sa lisibilité, de la cible visée et par là-même, de l'univers social dans lequel il fonctionne. L'émergence de ce nouveau marché associé à de nouvelles cibles et usages constitue un observatoire privilégié pour comprendre l'apparition et les implications du design au sein même des complexités qui articulent de nouveaux usages à la société, de nouvelles entreprises à leurs clients et de nouveaux produits aux cultures établies. Ce terrain est en fait relativement vaste et nous présenterons ici l'élaboration de notre projet d'étude et les premières conclusions observées. Cette étude est un travail de recherche en cours par le regard croisé de chercheurs en science de l'Art, en design et en sémiotique, nous proposons une première analyse du terrain qui vise à mettre en place et à structurer un projet de recherche plus vaste, interrogeant la part du design dans ces pratiques sexuelles intégrant l'artefact.

Le développement des sextoys nous semble relatif à une évolution du terrain des pratiques sexuelles et de la société avant d'être un phénomène lié au design. Ce serait parce que des initiatives concrètes disparates des distributeurs et des usagers sont apparues que les sextoys ont connu un renouveau. Ils sont en effet, les héritiers des traditionnels godemichés issus de pratiques ancestrales et vibromasseurs mis au point au XIXème siècle dans le milieu médical. Longtemps cantonné à l'univers des sex-shops, ils sortent aujourd'hui de cet univers déclassé et jugé socialement vulgaire pour intégrer au même titre que les pratiques qui y sont associées une nouvelle norme sexuelle. Pour les promoteurs des sextoys, la revalorisation des produits a nécessité une redéfinition des codes sémantiques associés aux produits qui correspond au passage d'un paradigme négatif à un paradigme positif que nous montrerons plus loin. Comment un tel glissement catégoriel s'est-il opéré ? Que nous apprend ce glissement sémantique sur l'évolution des valeurs associées à ces produits ? Quel est le rôle du design dans l'élaboration de cette nouvelle sémantique ? De plus, ce type de jouet sexuel excluant le corps de l'autre au sein d'une pratique autonome où le complétant au sein d'une pratique partagée, nous conduit à se demander ce qu'il reste de l'amour et du sexe quand cela ne fonctionne pas. La contre-performance peut-elle être entendue comme un ressort créatif du sexe ? En d'autres termes, et à une plus large échelle, le design cherchant systématiquement à proposer des solutions performantes, ne conduit-il pas dans le cas du sexe et peut-être à une plus large échelle à un épuisement des ressources créatives de l'humain ainsi qu'à une standardisation du plaisir sexuel ? Ces questions concernant la créativité de l'usager montrent la portée des enjeux que constituent l'implication du design dans les plaisirs sexuels.
Notre étude portera dans un premier temps sur le rôle du design en tant que vecteur corrélatif de la complexité sémantique associée aux produits. Nous nous aiderons pour cela des conclusions actuelles de certains sociologues comme Coulmont et Bozon ainsi que d'une approche intuitive du terrain étudié. Du point de vue du design, la complexité sémantique repose à la fois sur la technique, la manipulation, la sensorialité et l'image du produit ainsi que sur tout le discours et la rhétorique « marketing » qui l'entourent. Au sein de cet ensemble de valeurs (technique, usage, esthétique, sociologique) que l'objet intègre, chacune est porteuse de sens. Ce qui fait design en l'objet constituerait entre autres choses, l'unification de cette complexité sémantique. Il nous semble que dans le cas des sextoys, la complexité des sens construits et portés par l'objet est renforcée par le modèle intime et relationnel des usages au sein duquel il s'inscrit. Dans notre enquête de terrain, nous avons observé à quel point ses produits, même possédant une forte valeur d'image, semblent fortement tributaires des discours qui en font la promotion, organisés par les médias, par les vendeurs, ou encore par les témoignages organisés au sein de cercles de femmes tenus à domicile ou dans les boutiques spécialisées. De l'objet aux espaces de distribution, en passant par le packaging et les discours médiatiques (séries TV, etc.), nous avons affaire à un processus global de transformation, duquel il serait vain d'isoler la dimension « objet » comme dimension autonome et lieu du design. Ici, il s'agit plutôt d'une économie générale en

mutation, dont le design est vraisemblablement un instrument privilégié. L'intérêt de cette étude est de pouvoir observer ces phénomènes en direct et peut-être d'entrevoir à terme, et à titre d'anticipation prospective, les futures transformations possibles en matière design de sextoys.
Du point de vue de la méthode et de l'échantillonnage de l'objet d'étude, l'offre en matière de sextoys « nouvelle génération » est très étendue et elle est structurée en catégories variables selon les marques, et plus ou moins cohérentes selon le critère catégoriel considéré : genre d'objet (boules, godes, anneaux, etc. objets inédits), cibles (H/F, Homo/hétéro, âge, secteur (luxe/...), valeurs (ludique, technique, performant, « hardcore », aventurier, familier, etc). La définition d'un corpus d'étude étendu présentait donc des difficultés objectives, et à ce stade (inchoatif) de notre travail de recherche. A titre d'entrée en matière, et de manière plutôt intuitive et phénoménologique, nous avons simplement choisi des objets présentant des « saillances fortes » et des niveaux de « présence » élevés ; objets auxquels nous avons conféré une valeur d'échantillons-types pour commencer notre étude. Ainsi, notre étude se limitera ici à un échantillonnage choisi de vibromasseurs. Il est question d'étudier le degré d'esthétisme, de performance et la valeur sémantique observable dans cet ensemble d'objets afin de comprendre les glissements sémantiques sur plusieurs niveaux. Dans un deuxième temps de l'étude, nous projetons de vérifier cette analyse en évaluant la perception des potentiels usagers mais aussi des utilisateurs afin de repérer précisément les valeurs et les parcours sémantiques en jeu, ainsi que les modes subjectifs d'appréhension de ces valeurs chez les utilisateurs (féminins et masculins) de ces objets de désir. Un différenciateur sémantique soumis à un panel d'utilisateurs et de non-utilisateurs permettra d'évaluer la perception et les usages des sextoys étudiés ici.
Enfin, cette nouvelle génération de sextoys, nous semble démonstrative de l'irruption du design au service du développement de nouvelles pratiques du sexe récréationnel. Cela nous invite à nous poser la question suivante, à partir de quand, de quels phénomènes peut-on estimer qu'il y a émergence et développement d'un design au sens d'un projet cohérent. Quels sont les données et les éléments qui vont nous permettre d'évaluer l'apparition ou non de celui-ci ? Y a-t-il différents types de design ou, différents degrés d'application du design détectables au sein de ces émergences ?

Notre hypothèse est que le design est un outil d'intégration de la complexité. Lorsque de nouveaux usages ou besoins, apparaissent ou se répandent, le design intègre les complexités des nouvelles significations pour construire une forme de cohérence sémantique au sein de l'environnement quotidien. Outre le plan s*émantique,* le design apparaîtrait ici en tant que vecteur corrélatif entre les sphères marketing, social, sémantique et stylistique. L'émergence d'une nouvelle génération de sextoys est l'occasion pour nous d'observer comment et sous quelles formes le design apparaît au sein d'un terrain hétérogène en recherche de lisibilité. Dans un premier temps, nous traiterons des mutations sociales actuelles liées aux sextoys afin de contextualiser l'émergence d'un design dans une seconde partie. Cette étude sera enfin approfondie par l'analyse de plusieurs cas. L'élaboration de ces glissements sémantiques nous conduira aussi à pointer les limites d'une quête d'efficacité.

Mutations sociales

En 2001, Elisabeth Bernstein « évoquait le déplacement de certaines conceptions de l'intimité sexuelle, d'un modèle relationnel vers un modèle « récreational » (Coulmont, 2007 : 231). L'évolution des modèles relationnels de la sexualité serait partie prenante du développement des sextoys. Ce déplacement des valeurs a permis l'apparition de ces nouveaux produits destinés à compléter les pratiques récréationnelles et ludiques du sexe qui devient un loisir comme un autre. Il s'agit en fait d'une redéfinition sémantique d'appareils déjà existants comme le godemiché et le vibromasseur opérant un déplacement sémantique des codes de la pornographie vers ceux de l'érotisme, du sexy, du ludique et du bien-être.

Dans son ouvrage *Sex-shops : Une histoire française*, Baptiste Coulmont explique que la manifestation de ce glissement sémantique est d'abord apparue avec un nouveau type de magasins qui se démarquaient des sex-shops en s'installant hors des quartiers chauds associés à la pornographie, dans des rues plus passantes et jugées moins vulgaires. Dans ces magasins, explique-t-il « les gadgets sont présentés en terme de « récréation ». Attwood souligne donc le rapprochement constant des vibromasseurs avec les jouets et surtout les vêtements, ainsi que l'éviction des formes visuelles de la pornographie » (Coulmont, 2007 : 232). Celle-ci est rejetée « vers le sale, le malsain, l'atteinte à la dignité humaine et [l'objectif devient] d'élever l'objet sexy vers le sain, le beau, l'éthique. Les promoteurs des sextoys sont donc des producteurs de normes sexuelles. » (Coulmont, 2007 : 237) Ces « love-shops » ou « sexy-stores » par le nouveau nom qu'ils se donnent, montrent bien que le développement de ces nouveaux produits est dans un premier temps fondé sur une redéfinition sémantique du discours sur l'objet. L'élaboration de ce nouveau discours vise essentiellement la valorisation de nouvelles pratiques sexuelles récréatives s'opposant à la pornographie, jugée vulgaire, et s'intègrent selon leurs promoteurs à une sexualité positive : c'est-à-dire « en couple, à la maison, hétérosexuelle, stable ». Si le sociologue B. Coulmont juge que le sextoy fait entrer la sexualité « normale » dans « une zone contestée ni entièrement reléguée dans le pathologique, ni entièrement acceptée » (Coulmont, 2007 : 231) la journaliste Elisabeth Weissman, quant à elle, considère qu'en « massifiant [la production du sextoy], en le médiatisant, en le commercialisant, en le banalisant ainsi, le marché a même réussi ce tour de passe-passe : faire perdre au gode son pouvoir transgressif » (Weissman, 2008 : 108). Nous le voyons, les sextoys ont ouvert une brèche dans les usages sexuels acceptés comme norme et continuent à poser question à la société et aux consommateurs. Beaucoup de choses semblent à inventer et notamment le sens de ces pratiques à l'heure où il incombe « aux sujets […] d'établir la signification de leur conduite sexuelle et d'en résoudre les contradictions. » (Bozon, 2009 : 112). Un vaste réseau sémantique est donc encore à établir pour répondre aux diverses significations que l'utilisateur de sextoy peut donner à ses conduites sexuelles, variables selon les situations.

L'émergence d'un design

Conscients des mutations actuelles, les revendeurs n'hésitent pas à ré-emballer les produits pour valoriser une image sensuelle et sensible de la femme à l'aide par exemple, de papiers de soie et de plumes. Ceci dans le but d'évincer l'image de la femme présentée sur les emballages d'origine, jugée dégradante car pornographique. Ce nouveau discours donne un autre rôle à la femme qui n'apparaît plus comme le réceptacle des fantasmes masculins mais devient maîtresse de son propre plaisir et de son bien-être. Ce déplacement sémantique du « sex » vers le « love » et le « sexy » correspond donc à la définition d'une nouvelle cible largement plus féminine, - B. Coulmont parle d'un « processus de féminisation pluriel » (Coulmont, 2007 : 232) - sensible à des valeurs comme l'humour, la sensualité et le beau, sensible à la mode et au design. Les sextoys sont aujourd'hui vendus comme de véritables accessoires de mode, présentés dans des emballages à jour des nouvelles tendances et des magasins décorés avec goût dans des tons allant du pourpre au rose bonbon. Le design de ces magasins est souvent proche de celui du magasin de lingerie, ou d'accessoires de mode et de décoration. Les vibromasseurs sont couramment présentés en position verticale qui leur procure une visibilité attractive. Regroupés par types ou par marque, ils sont exposés comme des objets possédant une certaine aura proche de celle du bijou ou parfois de l'objet d'art. Cette mise en scène fait partie du processus de transformation entre les champs sémantiques que nous avons évoqué.

De manière générale, les sextoys s'émancipent des représentations mimétiques du membre masculin et deviennent de véritables entités indépendantes, des corpuscules aux déclinaisons figuratives variables. Si dans les années 70, l'imitation du membre masculin a pu être un canon érotique, aujourd'hui il semble que les critères ont évolué et s'appliquent à des registres formels variés. Dès lors, le sextoy s'éloigne des représentations mimétiques et revendique une part d'artifice. Cela le rapproche des conduites sexuelles actuelles caractérisées par ce que Lasch appelle « the flight from feeling », c'est-à-dire « la fuite devant le sentiment » (Lasch, 1979 : 61). Selon cette idée, les émotions sont jugées dangereuses, voire même embarrassantes, elles sont en effet susceptibles d'altérer l'équilibre intérieur de l'individu. L'exemple de la série *Sex and the City* est illustratif de ces comportements. Cette série américaine traite du sexe selon le point de vue de quatre copines, sans aucun tabou. Elles expérimentent la vie, le sexe, les hommes, les sextoys. Leurs conversations tournent autour de leur rendez-vous manqué, de la taille des pénis de leurs amants ou encore de leurs ex-petits amis. Ces filles trentenaires, représentent le désengagement émotionnel, elles prônent la liberté et exaltent la relation amicale. La protection est de rigueur dans cet individualisme qui conduit à consommer l'individu et à le réduire à un objet de plaisir. Lipovetsky précise que « c'est moins la fuite devant le sentiment qui caractérise notre temps, que la fuite devant les signes de la sentimentalité (Lipovetsky, 1983 : 111). » Au-delà d'une réduction artificielle de l'autre, c'est l'usager lui-même qui se trouve également privé de sa dimension d'auteur-créateur. En effet, lorsque la personne détourne des produits du quotidien pour satisfaire ses plaisirs sensoriels et sexuels (plume, bougie, concombre etc.), il interprète le monde en en proposant une lecture personnelle (décodage sémantique), en cohérence avec son propre système de valeurs en perpétuelle évolution. Les sextoys le privent de cette lecture singulière par laquelle il affirme son individualité. Les sextoys, fixent et figent les figures sémantiques du sexe au sein desquelles l'usager est réduit à un choix nécessairement limité, qui risquent à terme de standardiser les valeurs personnelles de la sexualité. La dimension humaine n'est pas prise en compte, à travers les sextoys, même la morphologie organique de l'autre est évincée. Cette consommation du plaisir par le truchement d'un artefact sans référence directe au corps d'autrui conduit à considérer le sextoy comme une entité à part entière. Le sextoy étant présenté comme un acteur permettant de relancer ou d'agrémenter la libido du couple apparaît comme un tiers, au sein même du couple. D'ailleurs, le love-store *Les passages du désir* (Fig. 1 et 2) dans le marais à Paris se revendique déjà comme un promoteur du « développement durable du couple ». Pour le sociologue Serge Chaumier, « c'est l'intervention ou la menace du tiers qui relance la mécanique de la passion amoureuse » (Chaumier, 2004 : 25). Son essai sur le nouvel ordre amoureux, n'est pas sans intérêt pour notre étude puisqu'il explique que « le retour du refoulé semble particulièrement s'exprimer dans le domaine de l'érotisme, présent dans de nombreuses créations culturelles. L'inflation des productions érotiques n'est pas sans lien avec l'idéal d'autosuffisance du couple ni sans effet sur la régression progressive de l'adultère comme façon d'extérioriser ses pulsions. (Chaumier, 2004 : 30) » L'érotisation des marchandises constituerait un exutoire à l'extériorisation des pulsions. Les sextoys issus d'une stratégie intégrant le design possèdent à la fois le statut d'objet de mode désirable et d'objet associé au sexe, ils sont probablement le type de biens répondant le mieux à cet assouvissement d'autosuffisance du couple ou de l'individu, ils évoluent donc dans un moment propice à leur développement. Si le glissement sémantique et l'évolution des pratiques se sont d'abord produits de manière diffuse dans la société, le design est intervenu sur ce nouveau terrain de consommation et a permis à de nouvelles marques de se développer avec des concepts originaux. Au sein de ces pratiques émergentes, le design semble avoir favorisé l'intégration des complexités sémantiques en jeu à travers les sextoys en proposant une cohérence plus lisible entre les marques, les gammes, les packagings, les produits et leurs lieux de distribution (magasins et sites web).

Figure 1 et 2 Le love-shop « Les passages du désir », Paris

Etude de produits

Pour débuter notre étude de terrain, nous avons opté pour une approche intuitive et effectué une sélection après une large observation des produits via les magasins et les sites internet. Nous avons choisi un échantillonnage de travail afin de refléter la diversité des univers de gammes proposées en vibromasseurs, selon les marques. Une méthode de travail empirique s'est imposée pour appréhender cet univers. Nous nous sommes rendues aux réunions du soir proposées dans les love-shops. Exclusivement réservées aux filles, la potentielle acheteuse est dorlotée avec champagne et petits fours. Nous intégrions dès lors un univers féminin, convivial chic et presque secret à l'abri des hommes. Après avoir détendu l'atmosphère, la vendeuse nous explique à quoi servent et comment utiliser ces vibromasseurs ou ces stimulateurs clitoridiens. A l'écoute, les jeunes femmes manipulent, touchent la matière, appréhendent le lisse, le doux. Elles évaluent les degrés d'intensité de vibration sur le bout du nez ou sur le ventre, elles testent les mouvements rotatifs, le nombre de mouvements différents et les créativités interactives possibles. Au final, ces réunions et la plupart des visites opérées dans les love-shops, ont rendu compte d'une nécessité de pratiquer, de toucher, de prendre connaissance de ces objets et des performances offertes. Nous avons également questionné les vendeurs et les attachés de presse afin de mieux connaître leurs buts et leur type de clientèle. Les registres formels, esthétiques et techniques repérés dans ces love-shops présentent un ensemble cohérent, une unité qui coordonne leur discours.

Nous résumons ici les résultats de nos observations en nous concentrant sur les cas les plus parlants.

Figure 3 En dessous, le Magic Rabbit

Le *Magic Rabbit* (édition internationale, Fig. 3), le *Vibro chenille* (un modèle représentatif de la gamme de vibromasseurs de la marque *Fun Factory* (Allemagne), Fig. 4) et le vibromasseur *Iris* de la marque *Lelo* (Suède, Fig. 5, 6 & 7). Notre méthode consiste à s'appuyer sur les conclusions actuelles de la sociologie pour situer les nouvelles valeurs véhiculées par ces produits puis à repérer les discours spécifiques de chaque marque pour comprendre comment le design les a fait évoluer. Nous repérerons donc au moins deux niveaux de valeurs dans les discours : le premier, générique, est celui qui permet de faire glisser ces produits de l'image pornographique vers l'image d'un paradigme positif ; le second niveau, plus spécifique, concerne les valeurs propres à chaque marque. Celles-ci constituent en effet des discours distincts contribuant à enrichir par différenciation et segmentation, le discours de ces nouveaux produits. Un autre niveau questionne les valeurs de la discipline du design, celui de la technicité et de l'optimisation des performances orgasmiques en un clic, au risque de négliger les scenarii créatifs des usagers.

Le *Magic Rabbit* est reconnu comme l'un des must du genre. Popularisé au début des années 2000 par la série *Sex and the City*, ce modèle est fabriqué en Chine, et distribué dans plusieurs pays sous des marques différentes. Il est pourtant issu des pratiques sexuelles établies au Japon où les sextoys sont répandus depuis longtemps et leur usage très courant. Le *Rabbit* est un produit misant principalement sur la technique au service de l'orgasme. Il assure à la fois une stimulation clitoridienne et vaginale à l'aide de deux moteurs qui actionnent indépendamment la vibration du stimulateur clitoridien et la rotation des billes de la partie phallique. L'iconographie employée dans le produit semble ambiguë. L'ensemble paraît peu cohérent car les stylisations figuratives mixent des représentations à la fois humaines et animales avec des degrés d'abstraction différents. Cela s'explique en partie par le fait que la représentation mimétique du phallus est prohibée au Japon. Les producteurs du *Rabbit*, ont donc dû « habiller » l'appareil d'une iconographie suggestive non mimétique. Le petit personnage figuré peut apparaître anecdotique et renvoyer l'appareil au rang du gadget. Néanmoins dans la culture nippone il symbolise la Déesse Kanon, déesse de l'amour et de la compassion présente depuis de siècles sur les godemichés et les vibromasseurs japonais. Le cas du *Rabbit* est intéressant, il est typique des gadgets vendus depuis plusieurs années dans les sex-shops et gagne aujourd'hui les *love-shops*. Il fait partie des appareils souvent ré-emballés ou présentés hors de leur emballage trop connoté. De plus, le *Rabbit* montre une incohérence entre l'emballage, le produit et son mode de distribution. Comparé à certains de ses actuels concurrents, le *Rabbit* conserve l'image du gadget valorisant la partie technique de l'appareil grâce à la transparence du plastique coloré employé. La transparence offre la possibilité de voir les billes rotatives et axe le produit sur la qualité de la performance obtenue.

Figure 4 A gauche, le Vibro Chenille, Fun Factory

Le *Vibro Chenille* de *Fun Factory* quant à lui, apparaît ludique, ses codes formels sont amusants et doux. L'objet tente de séduire un vaste public féminin sur les terrains du plaisir lié à une hygiène sexuelle et non plus uniquement à une masturbation. C'est un objet de détente. Évinçant toute ressemblance marquée avec l'imitation du membre masculin, cet appareil n'apparaît plus comme un membre tronqué, mais bien comme un personnage ou une figurine intègre et autonome. Cette impression d'autonomie est renforcée par l'emploi des piles, l'objet n'est alors quasiment plus perçu comme dépendant de l'univers artificiel auquel il appartient. L'identification du produit au petit animal représenté est plus aisée, elle relie l'objet au monde du vivant auquel nous appartenons. La référence animalière et ludique procure également au produit une aura transgressive tout en restant dans le domaine de l'acceptable grâce à l'humour. L'objet conserve donc l'attrait de la transgression tout en restant dans le domaine du familier. Cette petite figurine animalière apparaît tel un habillage illustratif favorisant la dédramatisation du jouet érotique et le plaçant sur un niveau récréationnel et relationnel. Cela peut sembler paradoxal, mais la figurine favorise sans doute une approche relationnelle à l'objet qui, dans son autonomie, peut devenir un petit être de plaisir à part entière. L'effort de *Fun Factory* a essentiellement porté sur une redéfinition stylistique du sextoy visant à intégrer un nouveau discours dans le dessin même des produits. La cohérence stylistique entretenue entre les produits, les gammes et leurs environnements a contribué à plus de cohérence entre la sémantique du produit et l'usager. La marque communique également sur les progrès apportés par le design en termes d'ergonomie, de matériaux (introduction du silicone), de techniques et de manipulation. Néanmoins l'évolution la plus visible et la plus marquante pour l'usager est avant toute une stylisation ludique du produit. Pourtant, même si cette stylisation formelle peut apparaître comme le ré-habillage d'un objet technique déjà existant, elle constitue en soi une étape importante destinée à marquer un changement notable dans les pratiques courantes et ses effets vont au-delà d'une stylisation purement décorative. L'encodage esthétique des nouvelles valeurs sémantiques associées aux pratiques du sexe permet de développer une familiarité avec l'objet technique grâce à une valorisation de l'usager face à un produit qui sollicite son sens de l'humour. Les aspects relationnels des pratiques sexuelles, grâce à la figure rassurante de l'animal et à l'autonomie formelle et technique de l'objet déplacent ce modèle relationnel du partenaire vers l'objet, qui devient lui-même un partenaire familier. L'acceptation des appareils à forte valeur technique semble passer par une apparence anthropomorphe ou zoomorphe. La figure familière est alors garante de sympathie tandis que des morphologies plus abstraites véhiculent un sentiment d'angoisse (Mori, 1970).

Par ailleurs, le design apparaît ici comme un outil permettant de faire passer une pratique déclassée dans le champ du familier. Nous pouvons parler de design, car l'effort de redéfinition stylistique est bien motivé par une stratégie globale destinée à optimiser l'entrée en relation entre de nouveaux produits et de nouveaux usagers. À ce stade le design apparaît encore essentiellement consacré à l'encodage de nouvelles valeurs sémantiques dans l'habillage formel du produit destiné à la construction d'une cohérence lisible permettant au produit de se démarquer des anciennes générations de sextoys.

Figure 5,6 & 7 Modèles Iris(au dessus) et Gigi de Lelo

La marque *Lelo*, enfin, fait partie des nouvelles marques qui proposent des produits spécifiques à la clientèle des love-shops. Elle propose des appareils jouant sur le registre de l'évocation formelle abstraite. Ses produits sont visuellement lisses et clos dans une coque bicolore qui sépare l'interface de commande de *l'interface de plaisir*. Le lisse, le blanc, l'épuration, la sobriété et l'élégance de ces courbes le positionne à la fois du côté des objets haut de gamme et raffinés. L'épuration lui octroie un mystère symbolique, il semble être un concentré technologique tout en manifestant une simplicité extérieure. Il intègre l'esthétique épurée des téléphones cellulaires tactiles comme *l'Iphone*, le *Corby* de Samsung, le *Viewty* de LG, mais aussi d'un raffinement très féminin, proche de la lingerie féminine de par ces couleurs et sa prestance. Tout comme les téléphones portables, l'*Iris* fonctionne avec une batterie rechargeable sur le secteur. Sur le site internet de la marque l'appareil est représenté par des vues en image de synthèse renforçant son lien avec les produits technologiques. Curieusement, la référence au téléphone portable nous ramène encore à un modèle relationnel et récréationnel qui participe à un phénomène de familiarisation avec l'objet technique. Ici l'objet est peut-être plus conçu comme une interface de mise en relation plutôt que comme une entité figurative autonome comme peut l'être le *Vibro Chenille*.

Malgré une morphologie abstraite, les produits de la marque Lelo, sont également exposés sur des fonds suggérant l'univers associé aux produits. Ainsi, les vibromasseurs pour femme, sont-ils présentés sur fond de dentèle chic et sexy, le fond de satin noir souligne le modèle luxe en plaqué or. Cela nous permet de penser que la marque élabore un discours visuel autour de ses produits pour construire une identité lisible. L'épuration formelle des appareils ne suffit donc pas à rendre lisible l'identité du produit. Cette présentation ajoute un ensemble de références à la sensorialité qui complète le discours du produit. Ici, le design apparait comme un vecteur d'organisation et d'intégration de la complexité sémantique au sein du produit et de son environnement de distribution et d'usage. Comme pour le modèle de *Fun Factory*, *l'Iris* manifeste une cohérence entre le produit et ses environnements issus d'une stratégie intégrant le design à plusieurs niveaux.

Les deux derniers exemples montrent une cohérence sémantique entre l'usage, la technique, l'image et l'environnement du produit, il se construit un discours sémantique sur deux niveaux. Le premier consiste en effet en une stratégie de valorisation du produit qui passe d'abord par l'image et la stylisation du produit, dans le but d'associer le produit à des valeurs positives. La référence à la figure animale ou au téléphone portable semble indiquer une stratégie visant à rendre les vibromasseurs familiers en réduisant, voire en supprimant la barrière existante entre des appareils d'usages courants. La suppression de cette barrière est non seulement garante d'une facilitation de l'usage de ces produits, car ils empruntent des interfaces de commande communs à d'autres appareils électriques, mais elle agit aussi sur une déculpabilisation de l'acte d'achat. Le second niveau sémantique de ces produits, montre les positionnements différents qu'ont choisis les marques. Il désigne des stratégies de familiarisation opérant sur des cibles différentes et révèle un marché lisible ou la complexité peut être lue par les utilisateurs comme une variété d'offres et de possibles. A ce niveau là, le design apparaît comme un vecteur structurant la variété afin de la rendre lisible. Il devient un outil de facilitation de l'usage grâce à l'intégration structurée d'une complexité sémantique assurant la lisibilité du discours de l'objet au détriment parfois de la lisibilité de l'usage. La conception des deux derniers exemples exprime une forte orientation stylistique. Il est clair que cet effort paraît nécessaire pour affirmer la nouvelle rhétorique identitaire des sextoys. Du point de vue de l'analyse, même si les objets sextoys constituent un point d'entrée sur le phénomène étudié, il est difficile de distinguer clairement les niveaux de l'objet, de la pratique (de ses styles), et du marché. L'une des hypothèses interprétatives consiste à affirmer que les configurations repérées sur les objets, notamment au niveau thématique et figuratif, configurations qui peuvent être premièrement perçues comme de simples variations stylistiques, assument en réalité une fonction rhétorique qui s'explique par l'état du marché et les intentions d'en modifier les équilibres de la part des promoteurs des sextoys, principalement des marques.

Figure 8 Delight, Fun Factory

Nous avons par ailleurs remarqué d'autres produits annonçant une implication plus marquée du design dans la conception de nouveaux usages. Le *Delight* de *Fun Factory* ou les *masseurs sensuels* de *Philips* proposent des formes aux ergonomies originales, renouvelant la typologie du vibromasseur et suggérant d'autres manières de les utiliser. Nous pourrions y voir alors, un troisième niveau où le design comprend une intégration sémantique beaucoup plus synthétique de l'ergonomie, de l'esthétique et de la technique.

Conclusion

Il est probable que cette nouvelle génération de sextoys ait été rendue possible grâce au travail stylistique que nous avons décrit et qui a rendu lisible le changement de paradigme de ces appareils. L'analyse que nous venons de mener semble montrer plusieurs mouvements de la relation entre design et complexité sémantique. Un premier mouvement de contraction et de synthétisation des tendances sociales émergentes dans l'élaboration d'une stylisation nouvelle. Un second mouvement semble alors rendu possible, celui de la construction d'une diversité structurée et lisible pour l'usager.

Dans notre étude nous avons montré un processus de familiarisation grâce au discours visuel de l'objet, or il nous est apparu simultanément une difficulté de lecture de l'usage et des emplois de ces produits. Cela est confirmé par l'organisation des réunions organisées par les magasins de sextoys. Par ailleurs, dans les perspectives de cette recherche, il apparaît essentiel de développer une étude de la sémantique de l'usage. En outre, nous souhaitons évaluer la lisibilité des usages auprès de panel par le biais d'enquêtes de perception. De ce point de vue, les sextoys sont des objets qui engagent le rapport à notre propre intimité, que cette intimité soit partagée ou non.

Au-delà d'un remodelage stylistique et sémantique, le design met en scène une cohérence déplaçant ces objets pornographiques vers une dimension sensuelle et féminine. Ce glissement n'est pas sans limiter ces artefacts du sexe à une question technique qui tourne autour de problèmes de dimension, de diamètre ou de vitesse. Au final, plusieurs aspects du design sont évincés dans le cas des sextoys à l'heure actuelle. En se concentrant sur la notion de performance, le sextoy évince l'imaginaire, la place de l'expérience et du développement de scénarii liés au plaisir et aux émotions. Notre étude ne se borne pas à une réflexion d'ordre stylistique, elle dénonce les limites actuelles du marché des sextoys. Nous ne pouvions pas faire l'économie des rapports de complexité entre des niveaux de lecture différents. Il s'agit maintenant de savoir si ces objets pourraient mettre en route une créativité originale de l'usager. Cela nous conduira à interroger les limites de la notion de performance et d'efficacité fonctionnelle qui constituent souvent des objectifs fondamentaux du projet. Serait-il souhaitable dans le design de sextoys, d'impliquer la contreperformance du produit comme ressort d'un plaisir intégrant la créativité des usagers ? Par ailleurs, un projet de design global pourrait prendre en considération de manière plus vaste les ambiances, les scénarii et les expériences sensorielles liées au plaisir. Cette recherche pointe une difficulté quant à des définitions objectives ou standardisées du plaisir, elle révise les définitions usuelles du design comme recherche optimale et efficace d'une réponse à un besoin.

Sustainable collaborative services on the digital platform: Definition and application

Joon Sang Baek, Politecnico di Milano, INDACO, Italy, joonsbaek@gmail.com[1]

Abstract

Information communication technologies (ICT) have emerged as an enabling solution that facilitates grassroots social innovations. Among them are collaborative services in which the final users collaborate to provide solutions to their unmet social needs. These alternative solutions aggregate to result in radical innovations towards a sustainable society (Meroni ed., 2006). Examples of collaborative services on the digital platform include Hitchhikers, a service created by hitchhikers to connect people with empty seats in their cars and people in need of a ride, thus allowing them to meet new people and reducing carbon footprint; Vicini Vicini, a service that aims to strengthen social fabric in Rome by helping people to organize parties with neighbors; Peladeiros, a service in Brazil that helps people to organize soccer matches; GROFUN, a service organized by people in Bristol to promote urban gardening, share the produce and dine together.

We introduce the notion of collaborative service and showcase the examples of collaborative services supported by ICT, mainly web-based. The cases studies reveal that collaborative services have a common structural system and that they can be classified into seven categories based on their meta-function. Collaborative services produce two elements – a solution and a social network. Based on theories of social network analysis, we argue that the two elements influence the formation of each other, i.e., a solution generates a social network as a byproduct and the social network in turn become a medium to diffuse innovations and creates opportunities to start new collaborations and that this virtuous cycle is amplified by ICT.

Keywords

social innovation; sustainability; service design; information communication technologies (ict); social network.

Social innovation is moving from the margins to the mainstream with the launch of President Obama's new Office of Social Innovation and a new push in Europe from President Barroso to link innovation strategy to social goals (The Young Foundation, 2009). However, this is not because social innovations have suddenly grown in number. What has changed is people's attitude. They have become more conscious of alternative and sustainable solutions due to the failing system of the current paradigm. At the same time, technologies that can democratize and accelerate innovation have diffused to our everyday life. These two conditions create a favourable condition to diffuse social innovation with an urgent need for designers to participate. One possible role of designers is to facilitate the on-going transition by creating conditions for people to use creativity and innovate at the local scale and that of design researchers is to provide designers with a theoretical ground by understanding the environment in which collaborative services are created, developed and replicated and supporting them with appropriate methodologies.

This research discusses issues on design for social innovation and sustainability which specializes in service design for social innovation at the grassroots level and sustainability. Social innovation is defined as "innovative activities and services that are motivated by the goal of meeting a social need and that are predominantly developed and diffused through organisations whose primary

---

purposes are social" (Young Foundation, 2006). Design for social innovation and sustainability is a domain of design that deals with services for people whose social needs are not met and their relation to sustainability. A role of a design researcher in this field is to understand the phenomenon of social innovation at the grassroots level in various contexts, identify its relation to sustainability and to design conditions that empowers people to use their creativity to ideate, implement and disseminate the solutions for their needs as Manzini claims, transition towards sustainability is a social learning process that requires active involvement of social constituents (Manzini in Meroni ed., 2007). How social innovation at the grassroots level contributes to sustainability is not discussed exhaustively here but it can be stated in summary that the radical innovations of local systems, i.e. discontinuities with regard to a given context, that challenge traditional ways of doing things introduce a set of new, very different and intrinsically more sustainable ones and that these micro-transformations become the groundwork for great systemic change (Manzini in Meroni ed., 2007).

With this in background, a series of projects have been conducted to collect the cases of social innovation at the grassroots level around different parts of the world. In 2006, the cases of so-called creative communities were collected in Europe (Meroni ed., 2007). Creative communities are groups of people who creatively solved social problems around them rather than complying with existing solutions that were proven to be ineffective. Similar research was conducted in developing contexts such as China, Brazil and India (Manzini & Jègou, 2007) and finally in Africa (work in progress). Although these cases consist of a wide range of ideas from diverse cultural and technological contexts, they share one thing in common in that they are social services in which the final users collaborate to produce solutions to a wide range of social needs that have failed to be met by existing solutions. For this reason, they are called collaborative services and the people who designed them are called collaborative organizations (Jègou & Manzini, 2008).

Collaborative service is distinguished from other services in that it requires relational qualities as a prerequisite to function. Relational qualities as the expressions of the "genuine dialogue" established between the participants of collaborative service and include trust, intimacy, friendship and a common identity (Cipolla, 2007). Figure 1 is a matrix that illustrates where collaborative service is positioned in relation to other services.

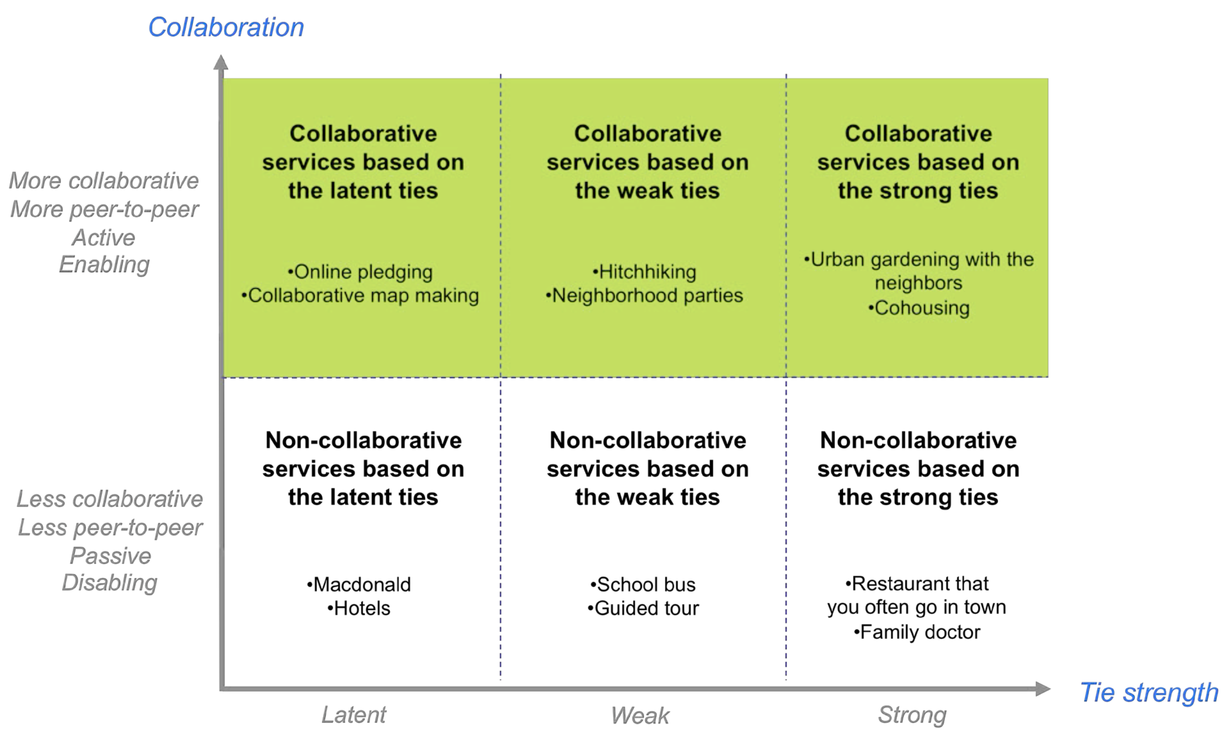

Figure 1. Positioning of collaborative services

1. Collaborative services on the digital platform

In recent years, peer-to-peer and collaborative production has emerged as a powerful trend in the digital, networked industries. Just to mention a few, Wikipedia, an archive of distributed knowledge; Google and Amazon which provide a peer-to-peer platform for sharing information and trading products; various open-source software projects based on Creative Commons licenses. Exhibiting characteristics of anti-rivalry and inclusiveness (Cooper, 2005), collaborative production in digital world is distinguished from traditional ways of production in the market economy in that it is more democratic in political aspect and more efficient in economical aspect (Benkler, 2006). They are examples of socio-technological innovation that are changing our ways of production and living and show possibilities that technologies, especially ICT, can be used an enabling solution to promote social innovation at the grassroots level.

Collaborative service shares several aspects in common with digital collaborative production. Both of them require collaboration rather than competition, inclusiveness rather than exclusiveness and are based on a platform that is decentralized rather than centralized. They also aim to improve the quality of the commons rather than privatized goods. Digital collaborative production aims to expand the repository of digital commons that are mainly information whereas the latter focuses on improving social commons such as relational qualities and social network. In addition, collaborative service and digital collaborative production can supplement each other when they are combined and produce a synergy effect. Firstly, when digital, networked platform is applied to collaborative service, it can increase the accessibility and replicability of the given service, making it available to people of wider social and economical status. Secondly, it can enhance communication between stakeholders within a service and between similar services, thereby strengthening the social fabric and making a service more resilient. Finally, advanced ICT, collective knowledge and innovative business models in open networked platform can reduce the technological, bureaucratic and economical burden of creating and supplying a service respectively.

As the first step to understand how collaborative organizations use ICT to improve their services, case studies of collaborative services on the digital platform were conducted.

2. Research method and the result

Case studies consist of two stages: in the first stage, 30 cases were selected from different parts of the world and analyzed using so-called a ‘light format’. The aim of the light analysis is to obtain basic information – both qualitative and quantitative - of the cases in order to understand and affirm the phenomenon. In the second stage, 10 cases were selected from the 30 cases for in-depth analysis in order to understand how ICT facilitate the diffusion of collaborative services.

In order to select the cases that satisfy our definition of collaborative service, over 100 cases were reviewed using the following criteria:

1. A service uses ICT to promote itself and enhance communication within community.
2. A service involves collaboration in physical and/or digital spaces.
3. A service is designed and provided by users with an intention to satisfy their unmet social needs.

In addition to these criteria, factors such as the service area, age of service, organizational size, aim and type of the services were taken into consideration to give diversity to the cases. The result is the 30 cases in table 1.

Case	Form	Service area	Origin	Since	Size
Hitchhikers	Enabling solution	Mainly Europe	The Netherlands	1999	Unknown
Hope institute	Enabling solution	South Korea	South Korea	2006	3365 ideas
Peladeiros	Enabling solution	Brazil	Brazil	2001	32250 users
Vicini vicini	Enabling	Rome, Italy	Italy	1999	Not known

	solution				
Green map	Enabling solution	Worldwide	US	1995	400 cities, 51 countries
Open green map	Enabling solution	Worldwide	US	2008	+ 4000 sites
Grofun	Collaborative service	Bristol, UK	UK	2007	10 people
Couch surfing	Enabling solution	Worldwide	US	2004	+ 950000 users
Meetup	Enabling solution	Worldwide	US	2001	4700000 users
Pledgebank	Enabling solution	UK and 12 other countries	UK	2005	91625 users
Katrinalist.net	Enabling solution	US	US	2005	4000 users
Shelfari	Enabling solution	Worldwide	US	2006	Six digits (confidential)
Bookcrossing	Enabling solution	Worldwide	US	2001	740000 users
Mapo dure	Platform	South Korea	South Korea	1997	+ 2500 members
Activmob	Enabling solution	Kent, UK	UK	2008	+ 20 mobs
Aka aki	Enabling solution	Germany	Germany	2008	1494926 encounters
Carrotmob	Enabling solution	US	US	2008	Not yet launched
Economia solidale	Enabling solution	Italy	Italy	1994	4736 users
No 10 Petitions	Enabling solution	UK	UK	2006	+ 5000000 participants
FixMyStreet	Enabling solution	UK	UK	Unknown	31628 problems reported
WiserEarth	Enabling solution	Worldwide		2007	Unknown
Solidarius	Enabling solution	Brazil	Brazil	2008	22319 users
mySociety.org	Platform	Worldwide	UK	2003	1000 users
Sistema FBES	Enabling solution	Brazil	Brazil	Unknown	Unknown
RED Open Health Project	Enabling solution	UK	UK	2004	509 users
Diabetics' meetup	Collaborative service	US	US	2009	55 users
Zero relativo	Enabling solution	Italy	Italy	2006	217 users
Timebanks	Platform	Worldwide	US	1980's	Unknown

Table 1 Case list (data accessed February 26, 2009)

3. Discussion

Despite the diversity in nature and context of the cases, several patterns were identified. Firstly, the cases could be categorized into 7 types according to their meta-function. Secondly, all the collaborative services have a commons structural model and thridly, they produce two essential elements. Finally, ICT contributes to facilitating the production of the two elements.

3.1. A typology of collaborative service on the digital platform.

Each case has a specific function that is performed in a form of a service (e.g. to purchase high-quality agricultural produces directly from the local producers, to exchange used books). These functions can be grouped into what we call meta-goals. Based on these meta-goals, the 30 cases were categorized into 7 types:

Producer/consumer network. In this typology, producers and consumers pursue mutual benefits by establishing a direct network. It is often found in the food industry where producers and consumers create networks to solve problems caused by long supply chains such carbon emission and degeneration of local food industries and to promote critical and responsible consumption.

e.g.) Mapo Dure, a food cooperative in Mapo district of Seoul, South Korea; GAS (Gruppi di Aquisto Solidale), a food purchasing group in Italy; Solidarius and Sistema FBES (Fórum Brasileiro de Economia Solidária) both of which are digital platforms to promote solidarity economy in Brazil.

Figure 2. GAS, the solidarity purchasing groups and the GAS website (http://www.economia-solidale.org/)

Mapping diffused information. In this typology, users collaborate to map diffused locational information.

e.g.) Green Map and Open Green Map which aim to create a global map of sustainable sites and events through grassroots collaboration; FixMyStreet, an open-source project that reports, views, or discusses local problems like graffiti, fly tipping, broken paving slabs, or street lighting which can then be solved by the local councils.

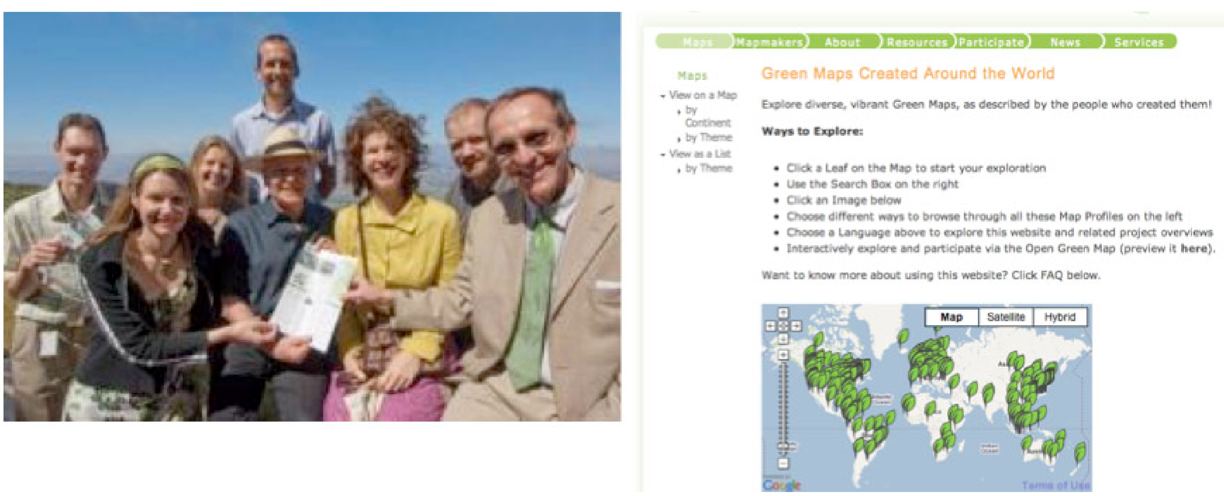

Figure 3. Green Map makers and the Green Map website (http://www.greenmap.org)

Aggregate social action. In this typology, people act together and use their collective power to achieve certain social goals.

e.g.) Pledgebank, a website that enables people to achieve their goals by asking other people to do the same; No 10 petition, an e-petition solution in UK that delivers people's petitions to the Prime Minister; Carrot mob, a network of consumers who buy products in a form of a mob in order to reward businesses who are making the most socially responsible decisions. Its goal is to leverages consumer power to make the most socially-responsible business practices also the most profitable choices.

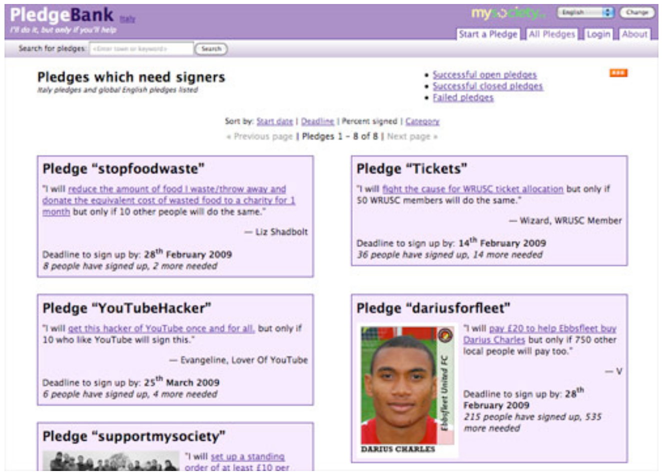

Figure 4. The Pledgebank website (http://www.pledgebank.com)

Creating a network for social conviviality. In this typology, the primary goal is to improve social conviviality by forming and reinforcing a social network. Users are often from the same locality and interact face-to-face and virtually on a regular basis.

e.g.) Meetup, an enabling solution that allows people to form a network of local groups hosts numerous collaborative services, i.e., individual meetups. Among them ones that are organized by users in a specific region for socialization such as Milano meetup; Peladeiros is a solution in Brazil that helps people organize soccer matches; Vicini Vicini is a service initiated by the Municipality of Rome to promote social conviviality of the community. It provides people with tools to organize neighboring parties.

Figure 5. Peladeiros users and the Peladeiros website (http://www.peladeiro.com.br)

Mutual support circle. In this typology, users provide mutual support to one another in order to solve problems that they have in common.

e.g.) Open Health project by the Design Council of UK intends to empower patients of chronic disease and their family members to support themselves and those who have the same problem. One result of this project is Activmob, a service organized by people in Kent to do physical activities together.

Figure 6. A Local Vocals Singing Group mob and the activmob website (http://www.activmob.com/)

Competences, time and products exchange. In this typology, people collaborate through the exchange of competences, time and products.

e.g.) Time bank, a reciprocal service exchange based on a time-based currency in which community members exchange their time to satisfy their needs. Zero Relativo, an online bartering system in Italy which allows people to exchange secondhand products.

Figure 7. The Zerorelativo website (http://www.zerorelativo.it)

Products, places and knowledge sharing. In this typology, people collaborate through sharing products, places and knowledge.

e.g.) Hitchhikers, an online service that connects people in need of rides and people who have empty seats in their cars; Couch surfing, a global initiative of sharing couches between travelers while exchanging different cultures and creating social network; Bookcrossing, a global book sharing scheme in which one leaves a book in a public place to be picked up and read by others, who then do likewise.

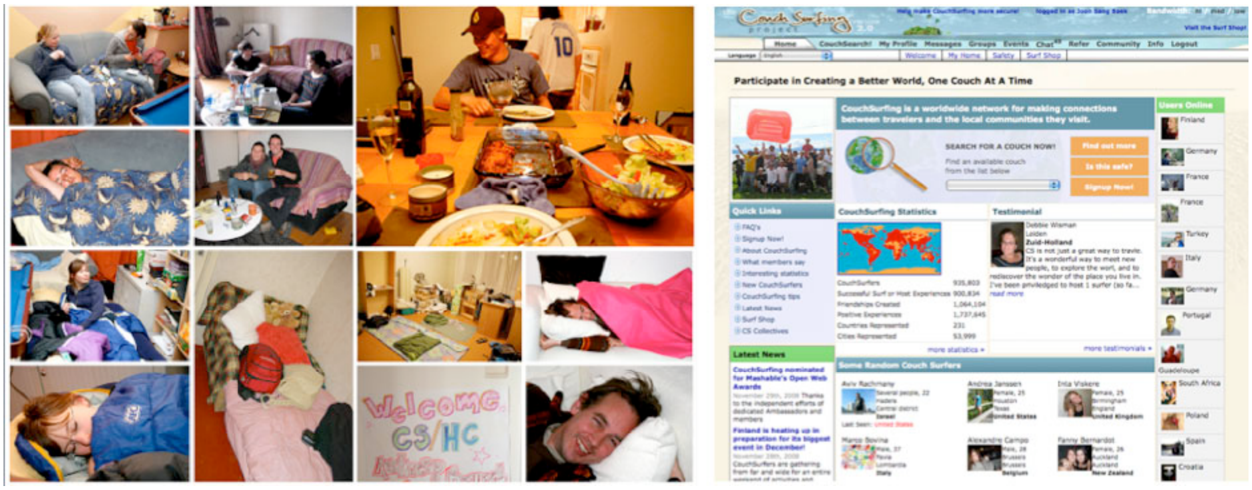

Figure 8. Couch surfers and the Couch Surfing website (http://www.couchsurfing.org)

3.2. The structural system of collaborative service on the digital platform.

In defining collaborative services on the digital platform, there was a hypothetic idea of what it requires to be formed (3 criteria for selecting the cases). The result of case studies clarified this hypothesis and confirmed that all the cases exhibit a common characteristic regarding the environment in which it is formed and develops. The structural system of collaborative service on the digital platform consists of 3 elements: an event, a collaborative service and an enabling solution (Figure 9).

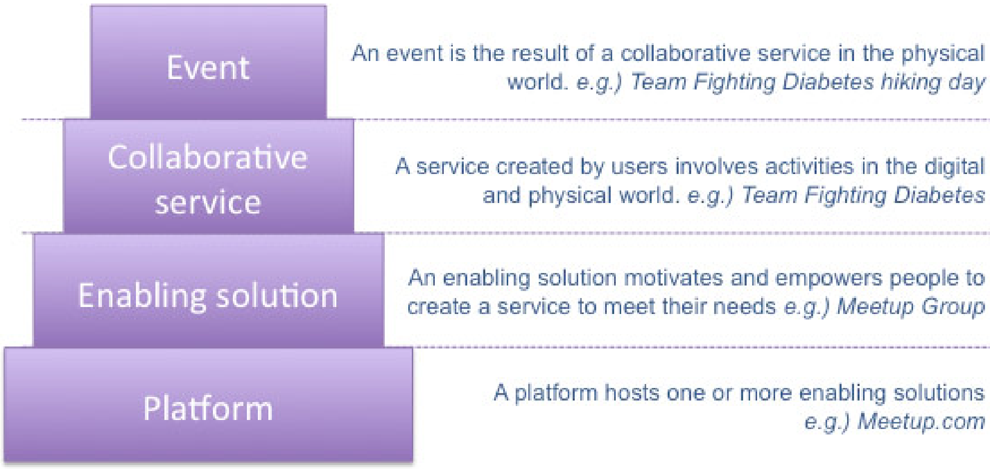

Figure 9. The structural system of collaborative service on the digital platform

1. *A platform.* A platform is a base of the structure that hosts one or more enabling solutions. It may not exists in some cases where there is only one collaborative service. An example is a social networking service called Meetup.com that supports organization of local groups across the world (figure 10).

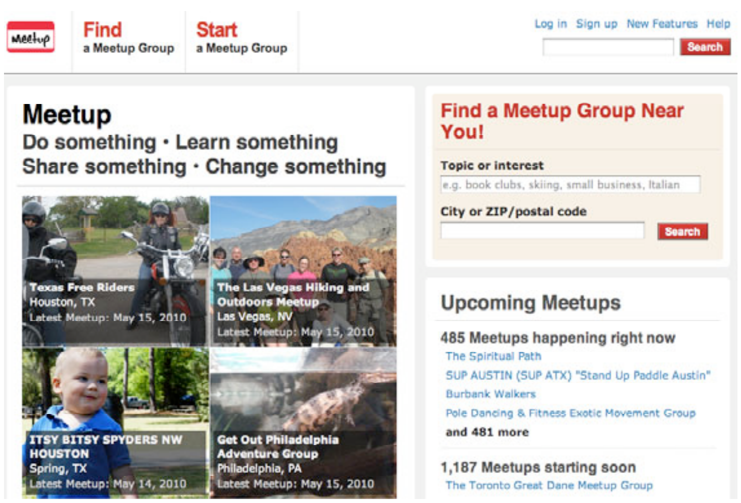

Figure 10. Meetup.com is a digital platform that hosts diverse Meetup Groups (http://www.meetup.com)

2. *An enabling solution*. An enabling solution is a system of products, services and communications that empower people to collaborate to meet their needs and to diffuse their solutions. Democratization of ICT provides people with a variety of effective tools to organize, manage and participate in collaborative services more efficiently than ever. Figure 11 is the homepage of Team Fighting Diabetes Meetup Group. Meetup.com provides groups with a set of tools that support group activities.

Figure 11. Team Fighting Diabetes Meetup Group homepage (http://www.fightingdiabetes.org/)

3. *A collaborative service*. On top of the enabling solution lies a collaborative service created and accessed by users. In Meetup.com, there are tens of thousands of collaborative organizations in places around the world (figure 12).

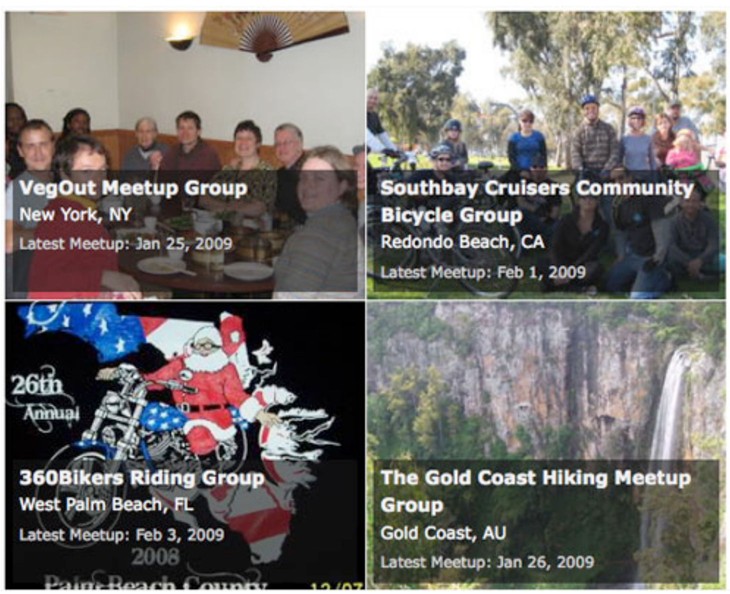

Figure 12. Collaborative services in Meetup.com (http://www.meetup.com)

4. *An event.* An event is the result of a collaborative service in the physical and digital world. An event may vary in the size of participants, the degree of interaction and the knowledge or physical assets required by the participants (e.g. a large smart mob vs. two people sharing couches). These variables need to be considered when designing a collaborative service and an enabling solution. Figure 13 illustrates a scene from a hiking day organized by Team Fighting Diabetes Group where the members – diabetics and their families – exercise together and promote a healthy lifestyle.

Figure 13. Team Fighting Diabetes' hiking day (http://www.fightingdiabetes.org/)

3.3. ICT and the dual dimension of collaborative service

Collaborative service by definition has a dual dimension of production: the first dimension is the production of a solution, i.e., a service that meets the social needs of users. Because this is the main goal of a collaborative service and the outcome is visible and measurable, current service design tools are dedicated to this dimension, i.e., how to design a solution that effectively solves the existing social problems.

However, we also look at the other dimension, the production of social network. Social network is crucial to the existence of a collaborative service. As Cipolla (2007) claimed, a collaborative service requires relational qualities as a prerequisite and if this service manages to be scaled up or replicated, the existing relations among users are reinforced and new relations are formed in the process of collaboration. These relations in turn become a ground for new collaborations and, as it will be discussed, contribute to the diffusion of social innovations (or solutions). In short, the production of a service and a social network is mutually beneficial and creates a virtuous cycle. Furthermore, we argue that the production of the two elements can be amplified by ICT (figure 14).

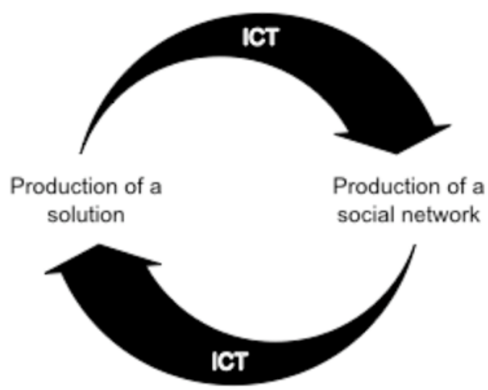

Figure 14. Production of a solution and a social network in a virtuous circle and its amplification through ICT

ICT and the production of a solution. The degree to which each case of collaborative service makes use of ICT varies from a simple mailing list to a highly customized database. However, in all of them, ICT plays a role of "democratizing innovation" (Hippel, 2005). It has introduced novel ways of production based on peer-to-peer relation that are more democratic in political aspect and more efficient in economical aspect than the traditional mode of production (Benkler, 2006). The case studies revealed that collaborative services on the digital platform benefit from ICT mainly by:

- Sharing and creating the Creative Commons. Many examples in our case studies have been developed using open source code or solutions that are free for non-commercial uses, thereby reducing the cost and more importantly allowing others to replicate their initiatives. These cases include No 10 Petitions, FixMyStreet, Pledgebank and Open Green Map.

- Improving productivity and efficiency of communication. In the cases of Meetup and WiserEarth, organizing a face-to-face meeting has become easier than ever thanks to a set of digital tools such as social networking service, calendar, blog and RSS. Carrotmob, a so-called flash mob[2], uses ICT to organize collective social actions. In Green Map Service, users have collaborated to create maps of over 400 cities from 55 countries since 1995 and with the launch of Open Green Map in 2008, a mashup version of Green Map, more than 4000 sites have been created in less than one year (counted in December 2008).

- Lowering the threshold of participation. As much as the creation of a collaborative service has become easy, so has been the participation and withdrawal. This contributed to lowering the psychological pressure put upon users and gave users more freedom. This consequently eliminated barriers that kept people from participating in collaborative services such as economic burden, dedication of time and effort to the service.

- Motivating people to collaborate. Some cases employ incentive mechanisms used in a crowd-sourced system in order to motivate people to participate and collaborate. Pledgebank, a website where people publicize their pledges and ask others to join, shows the number of people who have joined the registered pledges, thus creating a bandwagon effect to attract people to participate.

ICT and the production of a social network. As ICT facilitates the production of solutions, at the same time it reinforces the social network of engaged communities and creates new ones, mainly what is known as weak personal ties. The importance of weak ties was first recognized by sociologist Granovetter in his work 'The strength of weak ties' (1973). In this work, he claimed that personal ties can be categorized into strong, weak and absent. The tie strength can be measured in terms of a combination of the amount of time, the emotional intensity, the intimacy (mutual confiding), and the reciprocal services which characterize the tie. Strong ties arguably takes decades to be formed and are observed in intimate relations such as families and cliques. On the other hand, weak ties take relatively shorter time to be formed and are observed among friends, colleagues and acquaintances.

According to Granovetter (1973), information tends to remain isolated in a group formed by strong ties whereas it tends to diffuse through weak ties. It is because people connected through strong ties share a large part of their social network and therefore tend to form an isolated group. In such a group, information is likely to be self-contained and inaccessible by those outside the group. On the other hand, people with many weak ties often play a role of bridges that connect groups and it is through these bridges that information, including difficult innovations, diffuses. As a result, the social network of an organization whose members are connected mainly through weak ties forms an open network where information is widely shared among the members while an organization whose dominant ties are strong turns into fragmented cliques (Granovetter 1983).

The case studies show that both weak ties and strong ties are essential to collaborative services and that they play different roles (Baek 2009): The strong ties exist mainly in a community where collaboration initiated and was incubated. A collaborative service is initiated by a group of people who share the same value and are often tied in strong ties. They are usually friends, families or long-time neighbors. They are the ones who maintain the core values of a service and incubate the service until it becomes ready to diffuse. On the other hand, the weak ties maintain a collaborative organization open and allow its innovation to diffuse and replicate. As the innovation diffuses through the weak ties, the collaborative organization develops from a closed group into a network and the impact of innovation is amplified. Once the innovation is adopted to a new context (through weak ties), it requires strong ties between the adopters and the whole process repeats. In short, the diffusion of collaborative services is an iterative process where the generation and incubation of an innovation are mainly achieved through strong ties and the development and the diffusion are achieved through weak ties.

[2] A flash mob is a large group of people who assemble suddenly in a public place, perform an unusual and pointless act for a brief time, then quickly disperse. (The Concise Oxford Dictionary, 2004)

3.4. The role of ICT in design process

In design for social innovation and sustainability, the aim of design activities is to foster grassroots social innovations and facilitate their diffusion so as to increase the impact on society and ultimately to trigger a systemic transformation towards sustainability. One approach to do this is by designing enabling solutions, a system of products, services and communications that empowers people to collaborate and innovate to meet their own social needs. The role of ICT in this context is to be a building block of this system. In other words, ICT can be a tool to design a favorable environment for individuals and communities to collaborate and innovate. Then it is absolutely necessary to understand how the technologies can be used most effectively under which circumstances. The role of ICT in designing collaborative services can be threefold: to diffuse information such as innovative ideas, to connect people and to improve the functionality of services. Identification of these roles leads to providing designers with guidance to use ICT to design a product service system that reinforces a sense of community among users, allows people to get connected to those who share the same values and interests and thus to diffuse their innovative ideas to outside their community.

4. Conclusion and future work

In this paper, we introduce the notion of collaborative services, an example of grassroots social innovations, and show how ICT can support their implementation and diffusion using case studies and literature studies. Despite an effort to cover the cases from diverse contexts, this research does not comprehensively explore the ubiquitous phenomenon. Neither does it contain an application of the findings to a design project. Instead, this research identifies the characteristics of collaborative services on the digital platform and the role of ICT in design process. It is a preliminary step to design a digital platform that supports grassroots collaborations for sustainability and improve the social network of engaged communities.

The future works will include an investigation of the roles of ICT in a more specific context, sustainable food production and consumption and applying the findings to a design project, more specifically, to develope a digital platform that supports various initiatives related to this topic. The project is called ‘Feed Milan (in Italian, Nutrire Milano)’ project[3] and it aims to build a sustainable food network in Milan and its peripheral rural area called the Agricultural Park South of Milan in collaboration with Slow Food and the University of Gastronomy.

Author Biography

Joon Sang Baek

Ph.D. candidate at Politecnico di Milano. He works at the research unit of Design and Innovation for Sustainability in the department of Industrial Design. His research focuses on supporting grassroots social innovations using service design and ICT. Before coming to Politecnico, he worked as an interaction designer at Samsung Mobile.

Ezio Manzini

Professor of Design at Politecnico di Milano, Honorary Doctor at The New School of New York (2006) and at the Goldsmiths College of London (2008) and honorary professor at the Glasgow School of Art (2009). Presently, his main interests are towards design for social innovation and, in particular, towards the promotion of DESIS, an international network on Design for Social Innovation and Sustainability (http://www.desis-network.org)

Francesca Rizzo

A researcher at Politecnico di Milano, Department of Industrial Design. She got the PhD in Telematics and Information society at University of Siena in 2003. She taught for many years Human Computer Interaction and Interaction Design at University of Siena and at Politecnico of Milan. Her fields of interest are User Centered design (UCD), user studies and usability of interactive products. Currently her research activity is focused on co-design as a new creative technique to engage end users in design process and on service design as an emergent field of application of knowledge developed under the umbrella of interaction design.

A competitive game-based method for brainstorming and evaluating early stage design ideas in terms of their likelihood of success in the marketplace

Professor Tom Barker, University of Technology Sydney

Abstract

This paper considers a game-based method for the early evaluation of design ideas in terms of the likelihood of success of the designs in the marketplace. The method was developed in the format of a multiplayer competitive team game for up to 120 participants. Known as the Marketplace Casino, it has been applied in both design education and industry. The paper reviews the evolution of the game with international play testing and refinement involving over 400 participants in Europe (UK), Asia-Pacific (Japan, Korea, China, Australia), and Africa (Ghana).

The research innovation discussed in this paper relates to the combination of game play and brainstorming with a real world simulation component for evaluation, aimed at improving both the quality and ranking of outputs. The research draws on game theory, game typologies, and game research and development methods using play testing and iteration that are comprehensively described in “Rules of Play” (Salen, 2004). Effective brainstorming principles are well practised and described (Osborn, 1963) as are case studies in design brainstorming (Kelley, 2001), along with pitfalls (Sutton, 1996).

Bringing a contemporary design to market can be complex and expensive. Techniques that improve the likelihood of success in the marketplace can potentially reduce the associated risk and cost. The aim of the Marketplace Casino is to link creative ideas generation to a marketplace evaluation through a simplified model (the “game”) of a complex situation (the “reality”). The format is based on play specifically to enable a non-threatening and exploratory environment for participants.

The development of the game-based Marketplace Casino has focussed on product design and service design outputs. The author also considers its possible application to other disciplines in which creative output has to compete in the marketplace.

Keywords

Design management and strategy; brainstorming; design enterprise; design evaluation; game play; design; marketplace simulation; design methodology

The evaluation of early stage or concept design ideas in terms of likely success in the marketplace can be an elusive and risky process. When designs are at a very preliminary stage, much of the data that could be used when evaluating a more developed design is yet to be generated. For businesses, this uncertainty of information equates to risk: the risk of investing in products or services that may fail in the marketplace. This paper discusses a game-based method, called the Marketplace Casino, that has been developed to assist in the early stage evaluation of products and services in the marketplace context.

Aim

Bringing a contemporary design to market can be complex and expensive. Techniques that improve the likelihood of success in the marketplace can potentially reduce the associated risk and cost. The aim of the Marketplace Casino is to link creative ideas generation to a marketplace evaluation through a simplified model (the “game”) of a complex situation (the “reality”). The format is based on play specifically to enable a non-threatening and exploratory environment for participants.

Issues

The research innovation discussed in this paper relates to the combination of game play and brainstorming with a real world evaluation component, aimed at improving both the quality and ranking of outputs. Game theory, game typologies, and game research and development methods using play testing and iteration are comprehensively described in “Rules of Play” (Salen, 2004). This book was influential on the game designers’ approach, in particular play testing and iteration.

In developing a game simulator, a key challenge for the research was how to take a complex real world situation and simplify this into a reduced set of “features” with core rules that could still result in a complex and relevant process and outputs.

Effective brainstorming principles are well described (Osborn, 1963) and these were reviewed by the author, and a number tried in advance of the Marketplace Casino development work. Brainstorming case studies in design (Kelley, 2001) were also reviewed, along with pitfalls (Sutton, 1996). Sutton in fact questions the value of brainstorming compared with individuals working on ideas in isolation.

From the review of other brainstorming methods, the development of the Marketplace Casino aimed to address a collective of issues that have previously been difficult to capture in their entirety in brainstorming for early stage design evaluation. The range of issues that the game was intended to reflect and incorporate were:-

- The competitive element between newly launched products and services
- The ranking of ideas in a hierarchy that indicates likelihood of market success
- The random intervention of significant events, known as Force Majeure, that upset market conditions
- The use of a simplified set of assessment criteria for ideas
- Briefing starting points that were inspirational but not constraining
- The use of a consumer panel to influence idea evaluation
- A gaming technique that was both easy to learn and entertaining
- Self-documenting output

The innovation of the Marketplace Casino is in the combination of these elements into a single ideas generation and evaluation method.

Context for play

Donald Winnicott perceived creativity to be a thing in itself that is present in all individuals and expressed through play. “..in play, and perhaps only in playing, the child or adult is free to be creative, and to use the whole personality, and it is only in being creative that the individual discovers the self..” (Winnicott, 1971). Winnicott believed creativity gave a person's life meaning. The use of play with adults, that is playing with ideas, and imagination add to one's creativity. He described Transitional Space as the space situated between the inner and outer reality, between subjectivity and objectivity. In the organization, transitional space refers to a situation where past and future are present at the same time; it is a transition, it is not 'real' yet. Fantasy and creativity are central in this space and the aim is to prepare for the future.

In terms of the psychology of play and environment a game essentially creates a small world for the players – a safe world in which the rules are known but the outcomes uncertain. The ontological framework that sets up the rules within the game enables the complex systems of ideas to interact and provides the dynamic and didactic impetus for the players. The players learn to decode the frameworks and forms that underpin the games as they play them, essential to understand in our quest to "win", which is what makes them so useful as Learning Tools.

Conceptual framework

The game methodology and mechanics described by the paper evolved from investigating ways to facilitate the forms that groups of creative people employ to achieve outcomes. The particular processes, resources, cycles and sequences of events used by a group to achieve an objective, carry the *imprimatur* of that group's success. What may appear as chaotic to an outsider, may contain extremely complex codes of behaviours, and a culture which mark the success of one group against another. Consider the unique *modus operandi* that distinguish one leading design studio from another, or what the Italians term *sopra la bottega*, the "all hands on deck" atmosphere of creativity that pervades the small family factory above the store.

The research context relates to these forms (processes, resources cycles, sequences, cultures) and in particular those that govern the successful development of creative ideas. The research interest is in mapping these forms and synthesising them sufficiently to create games that seek to teach, simulate and generate the complexity of successful early stage design.

Kokotovich (2008) points out that the problem with treating design as a game per se is that there are few rules in design. The author's approach is to propose the framing of a game as just one element *within* the design process. Hence, a simplified and restricted rule-based component is possible that aims to enhance the overall freedom of the design process. Additionally, the game milieu, taken as a group exercise, aims to benefit the personal pattern of experience of the individual designers (Harfield, 2007), in both a professional context and an educational environment – reflecting the value of group working in design (Barlex & Rutland, 2008).

Value in the marketplace is qualitative and quantitative, so a system was required that considered both of these. For the distillation of value into simplified but highly focused elements, the game designer Jameson drew on a method developed through his marketing consultancy, known as the Jameson Criteria.

Research Method

The early evaluation of design ideas was developed in the format of a multiplayer competitive team game for up to 120 participants. Known as the Marketplace Casino, it has been applied in both design education and industry.

The game development was initiated with a games brainstorming activity between the two creative practitioners: their backgrounds were a designer and educator (the author of this paper), and a marketing expert. Through a series of workshops, the game designers roughed out a gaming process that reflected their combined experience of designing and marketing commercial products and services. The rough games were mocked up with physical components and then a further series of workshops was undertaken with a number of play testers, typically 4-6 in a session. The gaming rules were refined as a result and the game was given its first full play with 64 people drawn from a range of disciplines in the design and creative industries, including: product design, retail, marketing, innovation investors, management. Following this large scale test of the Marketplace Casino, which lasted around 3 hours, the rules were adjusted to improve playability.

The game design team was expanded in 2007 when a creative industries expert joined the developers, and with this contribution Version Two became the definitive version for subsequent extensive use.

From 2005-2009, the game received international play testing 400 participants in Europe (UK), Asia-Pacific (Japan, Korea, China, Australia), and Africa (Ghana). The aim was to expose the system to many cultures and players, while documenting the outputs and evaluating these with the help of a multidisciplinary group of experts.

Participant feedback was also collected in various ways, for example: through interviews, discussions and feedback forms.

The game rules

Introduction

The Marketplace Casino is all about creating great ideas that can succeed in the marketplace. But unlike conventional brainstorming, the Marketplace Casino also selects the best ideas. The game is competitive and it is about survival of the fittest ideas. The Jameson Criteria are used as the basis for judging success. These are: better, more, cheaper and wow!

To generate ideas, the game has over 60 briefs that are dealt out to teams. These are deliberately vague but also interesting and often humorous puns. A selection of the briefs is: the 7 year niche; buy 1 pay for 2; the divine right of ultimate selfishness; supersize me; million dollar baby food; a funeral service to die for; senior moments; an inconvenient truth; times squared; the pleasure principle; eclectacity; patients is a virtue; truth or dare; property is theft.

The game is for 8-120 players - the system becomes unwieldy beyond that. These rules give a “knockout” format for 24 players, which can be adjusted.

Key gaming elements

- JAMESON CRITERIA TOKENS (round poker chips are used): Blue = Better; Red = More; Green = Cheaper; White = Wow!
- CONSUMER PANELS (4 people at a table): Will make your idea live or die
- FORCE MAJEURE (cards): Can upset even the most winning ideas

Rounds

- Practice Round: the game begins with 4 gaming tables. 3 teams (each team has 2 people) sit at each table. Each team is numbered (team 1 to team 12). The practice round is for everybody to get to know the rules.
- Round 1: as per the practice round, the game begins with 4 gaming tables. 3 teams (each team has 2 people) sit at each table. Team numbers can very a little and do not have to match between teams, eg: 1-3 people is fine in a team]

- Round 2: the winning teams from each table then join one of two new gaming tables. For this round, there are just two teams per table.
- Round 3: the two winning teams from each table then join a single gaming table for the final round.

Order of play in each round

Each team starts with six white tokens in front of their marketplace casino placemat.

A briefing card is dealt to each table face down. This card has the brief from which the ideas have to be generated.

The card is turned over and the teams have 5 minutes to come up with their idea. The idea must be a product or a service that responds to the brief. Each team must write their idea on a blank card as a sentence or a couple of sentences. The teams also write their team number on the card.

Each team the nominates a member who takes the idea to a consumer panel to make the pitch. The pitch lasts for 1 minute. During the pitch, the panel are not allowed to ask any questions. The consumer panel will form a view about how good the idea is. The panel marks the idea on the basis of the Jameson Criteria to compare the idea with competition in the marketplace:-

- Better: it is simply a better product
- More: the consumer gets more functionality or more of it
- Cheaper: it costs less
- Wow! It is unique, instantly desired and creates an impulse to buy and own

The consumer panel will award up to 5 tokens of each colour at the end of the pitch. The team member returns to their team with these tokens and now goes head to head in the marketplace with their gamble.

Tokens are placed by each team without the other teams seeing where they go or how many there are. The coloured tokens have to be placed on their respective positions on the team placemat. The white tokens can go on any position.

When the tokens have been placed, one person from each table goes to visit the Force Majeure facilitator to have a go on the computer fruit machine. If a strawberry, cherry, or pear shows up on any of the fruit reels then a Force Majeure card is given out for each fruit type (if a particular fruit shows up more than once then only one card for that fruit is given out). Fruit types are as follows: Strawberry = Better; Cherry = more; Pear = Cheaper.

Any Force Majeure cards are taken back to the gaming table and turned over. They will affect the tokens of every team at the table (they may be increased or decreased, or moved around).

The tokens of each team are then revealed. If a team has a bigger pile of tokens in a particular placemat position than the other teams, then the other teams have their tokens in that placemat position removed.

The winning team at a given table has the most tokens remaining on their placemat. The winning team then returns their tokens and goes through to the next round.

If there is a tie with the number of tokens then more than one team can go through to the next round. If it is the final round, the teams become joint winners.

Results

In addition to the individual documented ideas resulting from the game, the outputs from the game play were sorted via the knock-out selection process into a hierarchy of ideas. In each game these outputs were reviewed by expert facilitators to see if the selection hierarchy was credible. Additionally, in cases where there was a known standard of the designers that produced the ideas, the quality of each designer was reviewed against how well they did in the games.

The facilitators included a mixture of disciplines typically with 10-20 years of experience in their respective fields. The disciplines were drawn from industrial design, marketing, design management and innovation design.

The outputs were also reviewed by pseudo clients in the situations where these were involved. Pseudo clients were leaders from collaborating businesses or institutions - government or academic.

The outputs from the game play were split reasonably equally between ideas for artefacts and ideas for services. Some ideas (around 25%) incorporated a combination of both artefacts and services.

The ideas were often lateral and insightful. A characteristic of many design proposals was an element of humour, both in the way the teams presented and in the ideas themselves.

The collection of ideas from the game play over several years has been extensive. Some examples include: a new movie format called Hollywood 2.0 in which audience individuals can participate as actors on screen; a funeral service that you can enjoy well in advance of your own death; an honest promotion system for affordable products rated as worse, worser, worst; an instant $100 home; new no-effort dieting products; a boy band pop competition for the homeless; fashion that comes in tin cans; a loan system for artworks at home; tradable religious components to bring together faiths.

Participant feedback was almost wholly positive and varied to an extent between stakeholders – players, reviewers and clients. Positive comments reported as feedback by stakeholders were: good to have the link between brainstorming and marketplace factors; encouraged lateral thinking; good collaborative and competitive mix; entertaining and enjoyable; good for networking with participants; best ideas tended to go forward each round; caused the participants to think more about the market when designing. Negative comments were that the practice rounds were generally very chaotic as people struggled to assimilate the rules in advance of playing the game; apart from a few people joining the consumer panel, those who were knocked out early only had a subsequent role as an audience to the game.

The principle game plays carried out were: 2005 in the UK at the ICA with professional design practitioners (64 players); 2006 in Thailand with TCDC and professional young designers (30 players); 2006 in the UK with student designers from Royal College of Art (30 players); 2007 in Korea, with student designers from IDAS (120 players); 2007 in China, with student designers from Tsinghua (60 players); 2008 in Japan, with student designers from Tsukuba (60 players); 2008 in Australia, with professional design practitioners (30 players); 2009 in Africa, with student designers from KNUST (60 players).

In many cases, the game play was part of a collaboration between participants from institutions in different countries. For example, Figure 1 shows the game being played by graduate students in 2009, in a collaboration between two academic institutions: Royal College of Art in the UK and KNUST in Ghana.

Figure 1. Marketplace Casino being played in Ghana, Africa, 2009. Top row: participants at the gaming tables, engaged in a knock out tournament. Bottom row: consumer panels deliberate on how many tokens to award pitching designers, based on the Jameson Criteria assessment.

Discussion

The absolute quantitative measurement of the success of the Marketplace Casino in selecting the best design ideas for development was not possible without subsequently developing the ideas and launching them into the marketplace. Even if this had taken place, the establishment of similar conditions for each idea would be very challenging – and the random “Force Majeure” aspect would demand a very large product sample. Hence, the value of the game as a tool could only be ascertained from the responses of stakeholders: players, expert reviewers and clients. These stakeholders were very positive about the game value and relevance.

The slightly humorous, puzzling and provocative nature of the briefing cards was an important benefit, particularly in encouraging participants to relax and be creative.

Generally, in situations where the game was played by design students, more talented students did in fact achieve better results in the game, getting closer to the final round. Of course, game mechanics such as Force Majeure and the quality of opponents on a given gaming table made it impossible for the best designers to win consistently. This is just as in the real world.

There was interesting feedback for the game in Ghana, Africa. This was a collaboration between local design students at the KNUST University and UK graduate design students. The Ghanaian students had no prior teaching exposure relating to design markets. The feedback from many of the Ghanaians was that the game had provided them with a lot of valuable insights that would influence their design thinking in this context for the future.

The consumer panel was an important key to real world simulation. The consumer panel was a “focus group” but with the important distinction of being comprised of both general consumers formed from several of the early drop-outs from the game, and experts drawn from the game’s facilitators. Additionally, the award of tokens for the value argued during the 1 minute pitch was a collective decision made by the focus group. This helped to smooth extreme responses from individuals.

It was clear that on infrequent occasions the Force Majeure element of the game eliminated strong ideas which would otherwise have come first in a given round.

This became a salutary lesson in the uncontrolled events that occur within a marketplace and the outcomes were taken in good humour by the participants.

Although development of the game-based Marketplace Casino has focussed on product design and service design outputs, the game mechanics have potential application to other disciplines in which creative output has to compete in the marketplace. The Marketplace Casino is currently not a generic brainstorming method tool like the IDEO Method Cards (IDEO, 2003). By being specific in it's play mechanics context, the Marketplace Casino offers the advantages of a being a real world simulation. To use the game in a different discipline, the briefing cards would need to be customised. This approach was tested successfully to some extent when the game was used in Korea with briefing cards that were localised to Korean culture. Adapting the cards to other disciplines could be of interest.

Conclusions

The Marketplace Casino introduced participants to market factors when generating and prioritising design ideas. The competitive element and the resulting single "winner takes all" game play mechanism proved extremely motivating to the participants and it also had the advantage of sorting ideas out into a hierarchy of likely success in the market. The Force Majeure element provided a sobering element to the mix: that events beyond the control of design, marketing or business will always maintain risk and uncertainty in the face of planning.

The game format encouraged playfulness and this was reflected in the humour of many of the design ideas, even though they were still often very practical.

In undertaking further development of the Marketplace Casino, there are several options that the system would benefit from:-

- Incorporating more real world elements into the game play and additional detail into the existing elements
- Running the tool over an extended period of time within a product or services development department of a commercial business for the creation of a range of products, and benchmarking the success of those products against those generated by other means.
- Establishing an annual league competition between participating academic institutions as part of their design teaching programs (this could possibly be run online).

For real world use, the author concludes that it would be appropriate for the Marketplace Casino to be used as one of several techniques in a commercial context. The game offers complementary outputs to other brainstorming and selection methods. The tool also has some value for use in design education, as well as introducing businesses to design and its benefits.

Facilitators and participants felt that the game produced more diverse, richer, and better concepts when compared with the approach of individuals working alone on creating ideas (Sutton, 1996), although this was a qualitative assessment that was not tested through experiment.

The Marketplace Casino game was able to take a complex real world situation and simplify this into a reduced set of features with core rules. The game resulted in a useful competitive creative process and generator of design outputs, ranked with consideration for market factors. The game can be a useful addition to the range of brainstorming techniques currently available, addressing a suite of criteria that are not dealt with collectively other methods.

The impact of modular product design on innovation compared with design from first principles

Tom Barker, University of Technology Sydney, Australia

Vasilije Kokotovich, University of Technology Sydney, Australia

Abstract

The research looks at whether modular design methods can compromise innovation when compared with design from first principles. The questions that the authors investigated were: to what extent does modular product design restrict innovation in design? Is design from first principles a better starting point for innovation, and if this is the case, then what methods and environments facilitate design from first principles among design teams? The authors were also interested in the relationship between industry and academia when taking these differing approaches.

The authors consider design from first principles to be where there is a significant shift in a product or system which - while addressing similar societal wants, needs and desires - is not built upon nor based on previous technological modules, or on existing design paradigms. These shifts derive from “tabula rasa” design research and lateral thinking, often in combination with new technologies or innovative technological combinations. These innovations are radical as they force creative and/or technological discontinuity.

Informed by their projects with industry and academia, the researchers argue that modular-based physical products are generally more appropriate for evolutionary designs or mature products, and that a design from first principles approach is better suited to genuine innovation and step change design. However, in terms of the creative design process, a design from first principles approach can be accommodated in both modular and non-modular products or systems.

Keywords

Modular design; industrial design; design education; design innovation; design methodology

Through action-based research case studies of collaborations between industry and academia, and an industrial case study, this paper considers the pros and cons of design from first principles versus modular design for products. The differences relate to both the design methods employed and innovative outputs that result, as well as the design thinking.

Objectives

The objective of the research was to undertake and review a number of case studies to investigate the impact on innovation of modular design methods versus design from first principles methods. Another aim was to investigate the relationship between academic design teaching and industrial collaboration, and to see how the teaching process could be improved and better orientated towards practice-based requirements through one approach or the other. A final objective was to determine the extent to which process (design thinking) predetermined the format and success product outputs.

Research proposition

The framework for our work emerges from the view that the rationale for component based design is well established in manufacturing (Dahmus, 2001). Modularity can produce cost savings on tooling, assembly and maintenance, improve quality and reduce design cycles. However, this consolidation and organization can mitigate innovation (Senge, 1990) for example for 'green' auto design. This notwithstanding, the software industry has achieved phenomenal improvements in innovation, productivity and quality through the adoption of object-based modular programming over the last 25 years (Sutherland, 1999). But it is difficult to apply physical design methods that correlate with software modularity methods (Gabriel, 1998). Modular strategies appear to allow for, what may be called 'significant' improvements ; it can be argued these alone may not assist greatly in developing step change innovations.

The research proposition here is that modular design methods could compromise innovation compared with design from first principles. In this context, the research questions were: (1) to what extent does modular product design restrict innovation in design; (2) s design from first principles a better starting point for innovation, and if this is the case, then what methods and environments facilitate this among design teams? For this research, the context was design as artefact-based industrial design, conducted in teams - typically with a technological component. We present the following case studies:

- **Unilever** project which had successfully created paradigm shifts in a product range.
- **3 mobile** case study demonstrating that design from first principles is able to contribute to 3 Mobile's future phone design thinking.
- **Swarovski and Sharp solar** project that used a modular methodology coupled with a second stage using design from first principles.
- **McLaren Group** case study where they employ more subtlety to the distinction between modular design and design from first principles

The themes that resonate within these studies highlight relationships between issues and design processes as they relate to Modular design, Design from First principles, and 'Step Change' innovation. In order to contextualise these issues we first discuss what is meant by modular design and Design from First Principles.

Design Methods

Design from first Principles

The authors consider design from first principles to be where there is a significant shift in a product or system which - while addressing similar societal wants, needs and desires - is not built upon nor based on previous technological modules, or on existing design paradigms. These shifts derive from "tabula rasa" design research and lateral thinking, often in combination with new technologies or innovative technological combinations. These innovations are radical as they force creative and/or technological discontinuity, and they are similar to the discussions in the technological change literature where they address the notion of S curves and discontinuity and the importance of it (Girifalco, 1991) (Porter, 1980 and 1991).

The web has greatly helped make innovative "learning how to learn" (Senge, 1990) methods more realistic. Thomas Edison (Josephson, 1992) stated that it took 100 days to become a sufficient expert in any area to permit invention – with the internet, this was reduced dramatically. With a deep understanding of first principles and how these may be applied in alternate contexts, teams could methodically and creatively apply information. Without this, technology information did not equal technology, or for that matter new highly innovative designs (Porter, 2005).

Modular Design

Modular design can take the form of physical hardware components or software, or a mixture. This paper is not concerned with the notion of modular design that relates to the ability to add products together for consumer benefit. It is concerned with the design of products by selecting and using existing components or assemblies to build a new product. Such a product may still have original parts or the parts may be scaled to some extent physically. Components and assemblies can be manufactured in-house, or sourced from suppliers.

Modular design is considered to be fundamental to the computer industry and software in general (Clark & Baldwin, 2000). Software modularity is generally the only way of writing contemporary code - with exotic exceptions such as neural networks. The authors acknowledge the crossover influence of software systems design methods into product development (Gabriel, 1998).

There are examples of physical product manufacture where modularity has been embraced that have an evolutionary approach to new product development. One of these is the automotive industry, where the approach increasingly extends outsourcing to modular consortia (Collins & Bechler, 1998).

Research Investigation

For experimental results, the authors reviewed pedagogical and industrial projects. A number of projects undertaken by the authors were reviewed as case studies for the research. These were academic-commercial case studies and interviews. Four of these are described.

Case studies

Academic-commercial projects

The academic-commercial projects were commissioned by corporate clients and undertaken by students at the Royal College of Art, a postgraduate Masters course that takes students from a range of backgrounds: industrial design, engineering and science, materials, architecture, marketing, business. The focus of the course is collaborative working.

Unilever

This 2006 case study relates to a commission by the international food, drink and household products company Unilever. The project was for a team of 15 graduate students to come up with new formats for ice cream. Unilever is the second largest ice cream manufacturer in a global $59bn industry (Scott & Flanagan, 2007), holding 16% of the market to Nestlés 17.5%. However, most of Unilever’s market share has been through aggressively expanding through acquisition of established brands such as Ben and Jerry’s in 2000. Although this was a successful strategy, growth was not coming from in-house ice cream innovations to the extent that such a large business required. Generally, previous innovations related to maximising the variations that could be offered by existing brands and product components – the ice cream industry’s equivalent of incremental and modular design. So the project was brought to the Royal College of Art by Unilever’s R&D and marketing departments to see how design from first principles from a group of mixed discipline students could lead to innovative product concepts.

To facilitate the ideas generation, an unusually formatted brainstorming day was held which blended concept design methods with marketing aspects. Participants came from Unilever to join the graduate students. The format started without any assumptions and went back to the principles of what being an ice cream means. The session is summarised below.

- **I am an Ice Cream**

  One by one everyone describes themselves (what kind of ice cream are you...). When am I liked when am I not liked? When am I allowed, not allowed? What people like me, who doesn't? How am I different? Where am I liked where am I not liked? How am I liked how am I hated? These become some of the catalyst for 'What's the Problem'.

- **What's the Problem**

  Format: for this, once the problems are written down, sketch doodles only are made. The groups brainstorm problems by noting them down on blank cards which are then shuffled between both groups and redistributed "blind". The groups work on solutions sketching lots of possible ideas. Example: A problem is that ice cream melts in a fridge (as opposed to a freezer); so solution may include a "high temperature" ice cream (like yoghurt).

- **Speed date**

  Each group shares out the designs among the team (one idea per team member) and then these are speed date presented as 1 minute per idea one-on-one to each of the other group members. Everybody hearing an idea has to find 3 ways of improving it. These should be noted on the drawing.

- **Killer Rabbit**

  A positioning statement is made and then the groups come up with the designs backwards from this point. What would have happened in 1989 if you had been asked to design an iPod? Example: Positioning Title: Global Hypercolour; Positioning Statement: a kaleidoscopic ice cream that reflects the national colours, the time of day, or the mood of the user. How to: illustrate how it could work..

- **Run the Gauntlet and wrap up**

  Selected work is presented and discussed at a final ideas review.

The brainstorming generated a number of ideas that appealed to Unilever and these were subsequently developed by the graduate students. Although the work was confidential, it can be revealed that none of the ideas had any relation to existing ice creams on the market. Two of the ideas were taken on by Unilever for subsequently bring to the market. Unilever was delighted with the result which had successfully created paradigm shifts for their product range.

Hutchison Whampoa's 3 Mobile

In this 2007/8 case study the mobile phone company 3 Mobile, owned by Hutchison Whampoa, commissioned a group of 30 graduate design students from the Royal College of Art in London to respond to two briefs. The two briefs were: (1) design the best phone ever for today, and (2) design the best phone ever for the future. The company made losses in 2008 of HK$3.2bn on global revenues of HK$32bn, with a customer base of 19 million people worldwide (Middleton, 2008). These losses were large and the company had lost money since launching with 3G phones in 2003. When 3 Mobile briefed the graduates on this project they observed that they had launched with 3G too early for customers and with phones that were complicated and had too many features.

The purpose of coming to design graduates was to see if they could get a fresh and innovative approach to their future phones. 3 Mobile had identified the market as moving towards specialist phones which offered features related to websites, particularly social networking sites. Hence, they were looking at a Facebook phone and they had already launched a Skype phone offering free calls Skype to Skype. The approach taken by 3 Mobile prior to this graduate design commission was that early 3 Mobile products attempted to incorporate as many general purpose functions as possible.

The commission to the students was looking very much for a "design from first principles" approach. The results of the work were richly varied and the designs were of great value to 3 Mobile in terms of provoking their own design teams' thinking. Additionally, several concepts had aspects which 3 Mobile felt they could develop into real products. A question, not covered by this paper, is the extent to which outsourcing of detailed phone design impacts on 3 Mobile's product success.

This case study does demonstrate that design from first principles was able to contribute to 3 Mobile's future phone design thinking when undertaken as an academic collaboration, at least complimenting the in-house process. The award of the contract to the Royal College of Art was made at a time when 3 Mobile had moved away from the modular, scaleable feature-rich product model. Figure 1 shows some of the phone designs from the project. Note that several design anticipated subsequent commercial products: "Free Key" anticipates the Blackberry Storm with a flexible LCD button surface; the "Teiko" phone anticipate kids' phones; "Touch" the rise of gesture-based interfaces.

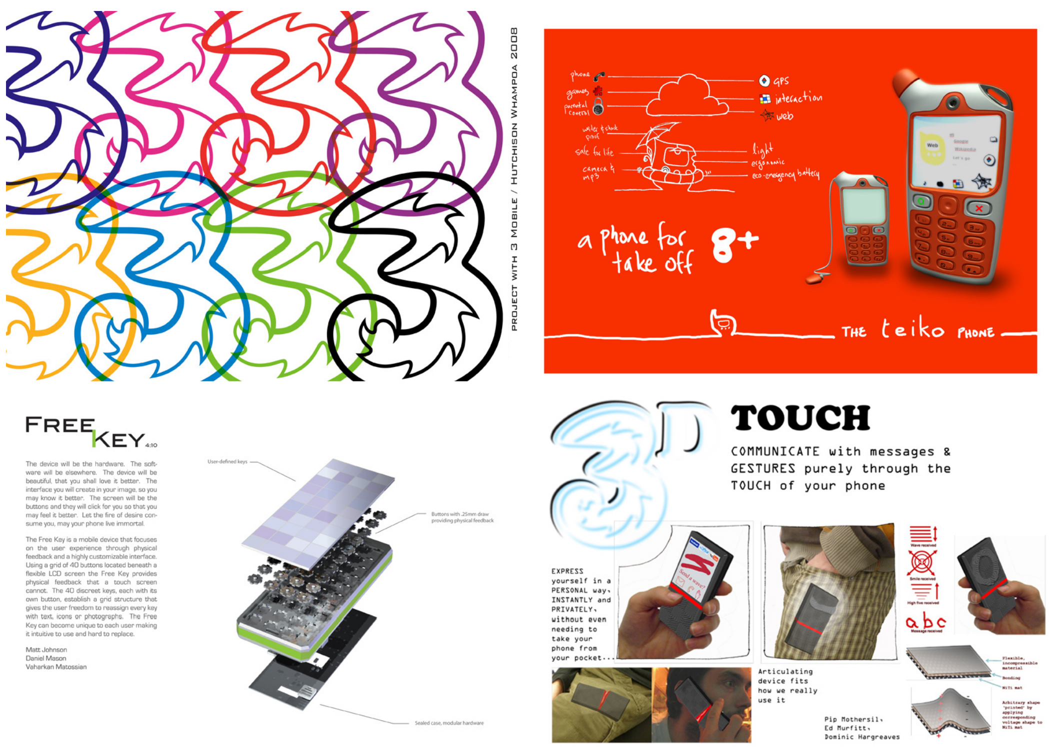

Figure 1: "design from first principle" mobile phone concepts for 3 Mobile, 2008.

Swarovski and Sharp Solar

In 2008, Swarovski Crystals sponsored this project for graduate designers at the Royal College of Art. Over 6 weeks, the project was co-run with Lovegrove R., an internationally recognised industrial designer with expertise in advanced materials and solar design, and The project received technical support, equipment and materials (photovoltaic solar panels and wafers) from Sharp Solar. The project brief is summarised below.

- *Located in the near future, and on the outskirts of a Northern European city, Sunny delight will be home to a few lucky residents who will benefit from a town that uses the very latest solar power, and related technologies, to create the world's first ever integrated zero energy housing and transportation system. It is your job as cutting-edge designers to make Sunny Delight. The challenge is to create a vision for a near future that works seamlessly in terms of both design and technology.*

For this case study, there were two distinct stage to the project. An initial stage used a modular methodology and the second stage used design from first principles. Although the two parts of the project were in response to separate parts of the brief, the graduate students were the same and it offered some comparison between the outputs offered up at each stage.

An important first stage of the project was set up as a Skunk Works (Jenkins, 2001) using working hardware components and systems, for modular systems design:

- *Design and build something interesting in 48 hours with the solar and other kits that are provided. You can make whatever you like but it needs to be an experiment from which you learn (and can tell us about) to help you understand the technologies involved.*

The second stage of the project encouraged a holistic integrated innovative approach:

- *Individual team members will each champion one or more of the Sunny Delights components to resolve in more detail: house, garden / outdoor areas, car, car port / street, marketing / services, energy system, business / economic case. It may be that your design merges or redefines these almost beyond recognition. For example, you may drive a piece of your house into work!*

Although the Skunk Works stage resulted in some very interesting working experimental design test rigs, none of them offered a real step change in innovation. The combinations of solar hardware (all using photovoltaics), sensors, mechanics, and software resulted in some interesting ideas, but the real innovation came with the second stage of the project. For the second stage, the graduate students were not asked to follow a specific methodology although they were asked to work in teams of 3-4. The students had a free hand at how to interpret the brief. Some of the project results are shown in figure 2.

Interestingly, the projects in stage two moved away from variations on use of photovoltaic solar panels for energy supply alone, and looked at comprehensive integration, as well as alternative solar energy cycles such as ammonia and hydrogen from algae. Although these stage two projects were mostly created as non-working models and animated illustrations, the science and technology research to prove feasibility was done fairly thoroughly convincingly.

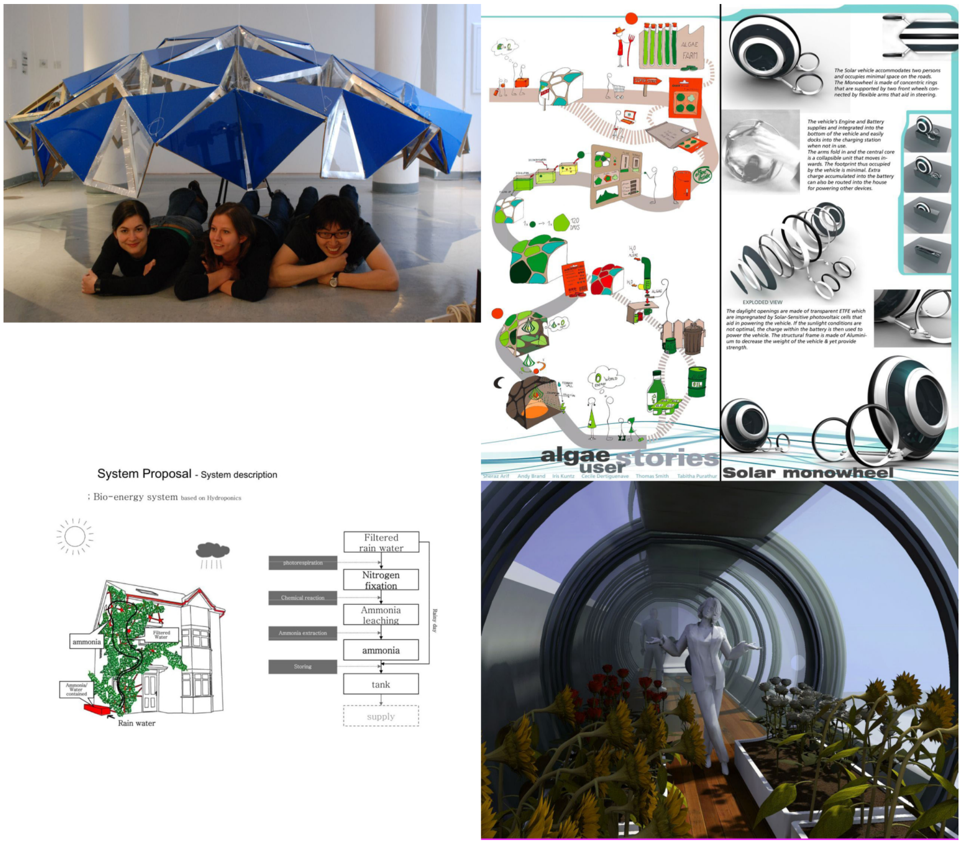

Figure 2: design proposals from ‘Sunny Delight: Solar Living’ a Swarovski / Sharp Solar project. Clockwise from the top left: a deployable solar shelter; Algae-based hydrogen solar cycle; a solar powered ‘wheel vehicle’; ammonia solar cycle; a hydroponic solar living unit.

Industry: McLaren Group

In 2009, Van Manen P. a CEO of control systems at McLaren Group the Formula 1 race team was interviewed. McLaren is currently contracted provide a modular, programmable electronic control system to all race teams in Formula 1, and this system is Van Manen’s responsibility. Previously, each race team designed and built their own control system, comprising sensors, computer and casings. Figure 3 shows the McLaren vehicle. McLaren are also contracted to develop high technology telemetry systems for other industries, including ranging public rapid transit rail systems.

Figure 3: McLaren Formula 1 racing car.

The interview with McLaren lent more subtlety to the distinction between modular design and design from first principles because, although McLaren create modular systems, their design thinking takes a more conceptual and design from first principles outlook when looking for innovation.

In the case of high technology electronics, systems are typically modular in nature, with microprocessors and other embedded circuitry forming parts of larger modular systems. The thinking required to develop these systems is far from being a simple reconfiguration exercise of mixing and matching modular sub-systems in order to develop a larger more complex system. This was evidenced in the McLaren interview. The McLaren electronics group rely on a few core guiding values for modular system design.

Firstly, in order to cope with the increasing technological changes that are advancing at an exponential rate a core understanding of the physical principles is imperative. In essence, when step change in design is required it can be argued that what is being manipulated is not mere components but the creative manipulation of divergent sometimes opposing physical principles. Secondly, McLaren's designers (ie: design students) also need to understand which are the nonnegotiable parts of design or the semi-negotiable, if they are going to develop technologies even further in innovative ways. Thirdly, McLaren regard it as important to have confidence in one's capabilities and a willingness to work together as a collective intelligence. When a high technology design team is working together they must see the relevance of what they are trying to accomplish and more often than not the divergent design specialists must communicate through a language of metaphor, where these metaphors relate to key physical principles not technological modular blocks. Fourthly, is an acceptance that what one learns today won't be the same as what is around in five years' time. But that the underlying principles - first principles - will be the same. McLaren's fifth and final value is the ability to have a vision and to develop a shared vision, because in talking about clarity of vision the ability to be agile and listen to others is key so they can operate with networking. This core principle not only relates to the physics but to the social dynamic as well.

When Van Manen is looking at a problem outside of his immediate area of expertise he will consider it in terms of metaphors. And as long as it is done with care he generally starts extending his knowledge into different applications and often new and innovative ways. It is important to understand a lot of this also comes back to the basics, because the better understanding one has of the basics, the easier it is to move between these metaphors. Because we can see the common elements and say "yes, I understand that now". For example, a bigger battery is like starting up higher on the Hill, so it will flow longer and faster and that is clear now. And so we can start building our experiences and metaphors any time.

Van Manen considers that it is important to remember a lot of the innovation that people do is building things, building business, building technologies. This comes about by being able to collaborate to understand how things fit together. There aren't that many sort of light bulb inventions, there are few inventors, there are a lot more people who can see how things/principles fit together. Therefore, reasonable working knowledge of the general way in which the world operates, physical laws, chemistry, mathematics, are all viewed as being important when involved in any sort of technological area. This notwithstanding Van Manen assumes that if he talks to anyone within his organization that they understand the basic laws of physics so he does not need to explain to them if something is heavy then it would accelerate slower if a force is applied, so just basic ground knowledge of physical principles is very important.

One of the things that Van Manen observed from working in the motorsports industry and its environment is that he is certain that one of the reasons that we have such good engineers in motorsport is they get the opportunity to design something, make it and put it into service in a time frame which is short. And every time they make something they get better and better at making things. And they increase their confidence. They know when something's not going to work. They know if they are at a dead end and have to change something. It is strongly arguable that a successful educational environment should also embed the understanding that balance between theory and praxis, between making and doing, and thinking about making and doing is necessary.

The McLaren approach is that when developing a system, whether it is a machine, a business system, or whatever, the key element is to understand what it is there for. If one is clear what is there for and what the important outcomes for it are, then this can properly frame what the important characteristics of that system are that are allowing innovation to occur, even if a design team member does not understand all of it and does not have a big picture. Once one understands what the importance is, and identifies the important characteristics of a system, that then frames whether one breaks it down and analyses it, or whether one looks at how something flows through the system. This in turn assists in innovation development.

By way of example Van Manen suggests that if we take a transmission system of a car, asking what is the reason behind having an engine and a gearbox and a differential, the reason is so that you can apply traction at the wheels. So the complex systems are there for managing the delivery of torque. Once you start thinking of that as a torque manager, then you can focus on the engine as a source of torque for the gearbox and that it controls this torque. In this conceptual model, the reason that these things interrelate is just to manage the torque running from the combustion chamber to the wheels. Via a first principles perspective, it immediately gives you a way of thinking about the system and how you exchange the torque, and then an understanding of trade-offs in terms of mechanical advantage. When thinking about a power train in that way it always come back to the core principles. A McLaren designer ends up saying “what we are interested in is this torque, and how we dealing with the torque”, as opposed to starting from a classical engineering perspective which tends to be very modular in nature.

Discussion and Conclusions

Based on the case studies, the research findings indicated that a modular approach to industrial design is generally but not exclusively more appropriate for evolutionary designs or mature products, and that a design from first principles approach is better suited to genuine innovation and step change design. The case studies indicated that, when faced with the need for step changes in innovation industry-academic collaborations could bring particular value.

The role of academia in offering a step change approach to established businesses was apparent. Many companies are better suited towards steady state and incremental design changes, so the academic partnering can give opportunities for tabula rasa design approaches, possibly even more so than design practices which will have preconceptions through practical experience. The authors found that creativity and lateral thinking were able to make up for lack of experience among graduate students, particularly when mentored by experienced facilitators from both academia and industry.

The research also highlighted difficulties and challenges presented to corporations in accommodating the culturally different approaches of design evolution and revolution within a single design environment. Another finding highlighted tensions between a culture of formalised experimentation, as opposed to a more chaotic or intuitive one, as part of an innovative creative design process. Modular design was more likely to mitigate creative leaps, but these could also be compromised by homogenous use of methodologies.

In addition to the obvious requirements of a brief and a project plan, the research found evidence that there is merit in the adoption or adaptation of design methods to use as creative scaffolding in both education and practice. These can be bespoke, such as the unusual design-marketing hybrid method used in the Unilever case study, or established systems such as TRIZ (Orloff, 2003; Savransky, 2000) which have first principles at their core.

However, as evidenced by the McLaren approach of conceptual thinking and team working, design methods are not exclusively necessary for innovation. The McLaren case study also indicates that although the division between design from first principles and modular design may be explicit in terms of physical product, the method used to design the product does not have to follow the physical outcome. In other words: a modular product can be designed from first principles. The 'aha!' innovative moment (Gardner, 1978), is an important tool also. But the authors conclude that the frequency and quality of the 'aha!' increases within catalysing design methods in conducive cultures.

Entrepreneur, designer, educator and technologist. Professor of architecture, innovation and design at University of Technology Sydney. Previously a professor at the Royal College of Art. His research activities are: creative industries; urban digital media; next generation housing. He has over 25 patents in his name relating to architecture, products, materials and processes. Working at Arup from 1990-1996, he contributed to the design of the London Eye’s capsules and boarding system. Founded b consultants in 1997, a multidisciplinary design practice based in London. Inventor of SmartSlab digital media system in 2000.

Dr. Vasilije Kokotovich

Base at the University of Technology Sydney Dr. Kokotovich has worked extensively as an Industrial Designer and Design Engineer in both the United States and Australia for ten years. Additionally, he has twenty years of teaching experience at the tertiary level. Dr. Kokotovich’s current research interests relate to Design thinking and Creativity. He has been developing an international reputation in the areas of creativity and design thinking by writing and delivering papers. The aim of his new body of research is to develop creative thinking strategies that assist in the creative resolution of design problems.

Beyond the Designers' View: How People with Autism Experience Space

Stijn Baumers, Katholieke Universiteit Leuven, Belgium, stijn.baumers@asro.kuleuven.be

Ann Heylighen, Katholieke Universiteit Leuven, Belgium

Abstract
Harnessing all different dimensions of space is an immense, if not hopeless task. Thus the design of space is challenged by a complexity of meanings. The meaning attributed to a certain physical environment depends to a large extent on the personal interpretation people attach to this environment, influenced by their personal interests, attention and perceptual possibilities, whatever the designer's line of thought that generated this built environment.

Aware of the diverse ways in which a designed environment can be received, this paper attempts to understand the built environment from another perspective. It reports on a study that starts from different people with autism spectrum conditions, throwing light on their spatial interpretation and the way they deal with the physical environment. Insights from an analysis of autobiographies of people with autism, tinged with the experiences of engaging with people with autism in different contexts, give an idea of what understanding another view on the built environment could imply.

This paper presents fragments of a particular autistic world of experience as a challenge to open our eyes. It illustrates how some people with autism place an enforced confidence in the direct perception of the built environment, and it highlights the influence of extra connotations—exceeding the directly perceptible—which are inherently connected to space in our society. In an attempt to look at the built environment from this perspective, this stance enables us to be critical of the way we—architects and designers—think about designing space and it spurs us to be alive to the multiple complexity of space.

Keywords
architectural design, autism spectrum, built environment, design thinking, interpretation of space, interaction with space

Harnessing all different dimensions of space is an immense, if not hopeless task. The wide range of meanings the built environment may have adds even further to the complexity of space. This complexity is an intriguing challenge to the design of space. A design, nourished by the architects' line of thought, finally acquires a meaning in the way people deal with it. In view of the diversity of people dealing with the built environment, this paper takes up the challenge to take another view on the built environment, in order to trigger the complexity that captivates the design process.

Architectural Design and Autism
Space is a complex idea. Through the years, all kinds of scientists made frantic efforts to grasp the entire world, aiming to set up an informational dominance over it (Thrift, 1999). Without avail, Nigel Thrift (1999) poses, because thinking about space complicates immediately. The infinite web of meanings we are living in loads even the physical space with a distribution of meanings, meaning that are continuously regenerated by people interacting with the built environment. The meaningful entities of space are interpreted by their habits of action (Määttänen, 2007). In this way, one place in natural space may well have different meanings; it may be a place for different habits and practices at the same time.

Physical space incites people to a certain way of dealing with it, it affords certain behaviours. And even the meaning of this space, the meaning of architecture, can be interpreted as an affordance, Jonathan Maier and Georges Fadel (2009) argue. In the sense of James Gibson's idea, this implies that the interaction between people and the built environment depends not only on the physical form of architectural elements, but also on the observer's past experiences, beliefs, aesthetic preferences, etc. The meaning of any architectural attribute, therefore, depends on the individual (Maier & Fadel, 2009), which complicates the built environment even more.

The idea of affordance may also mark the process of designing space, in which possible behaviour response can be anticipated (Maier & Fadel, 2009). However, designers do not only work with certain attributes or elements, related to previously defined meanings or affordances, as signs which has to be combined and recombined (Louridas, 1999). By seeing things in different ways, designers succeed in determining meanings, and organizing them in a structured whole. Designers reorganize meanings depending on the result, they redefine meanings, and in this way, designers do not only speak with their work, but they also speak through their work. Designers pour themselves into the design process, they disclose themselves through the design. The result of a design carries some part of the designer/s in it (Louridas, 1999). But whatever the considerations from which designers organize a certain environment as a structured whole, eventually, the built environment acquires a meaning through interaction with people. What is meant (or not meant) in a particular architectural setting depends on the prior experiences of the individual (Maier & Fadel, 2009), and people interpret the built environment based on their own habits of action.

Starting from a wide diversity of people, this paper investigates the interpretation of the environment and the use of space by people with conditions on the autism spectrum, shortly people with autism[1]. While neuroscientists are still looking for a biological explanation, autism is diagnosed on account of a characteristic behaviour, known as restricted and repetitive actions (Wing, 1997; Happé, 1999). Nevertheless, according to most theoretical approaches, the true essence of autism underlying this distinctive behaviour is supposed to be situated in a characteristic difference on a cognitive level (Baron-Cohen, 1995; Lawson, 2003; Noens & van Berckelaer-Onnes, 2004). Their specific 'distinct' way of perceiving and information processing causes people with autism to make sense of their surrounding world in a unique way (de Roeck, 1997), moulding the way they view, and engage with, reality (Lawson, 2003).

Both the characteristic behaviour and the particular way of sense-making of people with autism, influence their spatial experience and interaction with the physical environment. This is a central argument to confront the perspective of people with autism spectrum conditions and the design of the built environment. Gaining insight in the built environment from the perspective of people with autism, this paper aims to open up the designers' view on (designing) this environment.

Accessing Another Perspective

To get an idea of an 'other' view on the built environment, i.c. an autistic perspective, this study intended to engage extensively with people with autism in different ways. However, since impairments in social interaction and communication are considered as common characteristics of the autistic spectrum (Happé, 1999; Wing, 1997), it is not obvious to gain access to the range of thought of people with autism. This prompted us to explore other approaches. To start with, our study took advantage of the fact that some people with autism poured out their reflections on the surrounding world—including the built environment—by writing them down (Baumers & Heylighen, 2010). A number of autobiographies were selected on the dual condition of having been written by people with autism themselves and about

[1] The autism spectrum consists of divergent pervasive neuro-developmental conditions, entailing difficulties in social interaction, communication and flexible thinking or acting (Wing, 1997).

experiences of their own lives (see Sellin, 1993; Gerland, 1996; Rand, 1997; Willey, 1999). The analysis of these sources investigated the way people with autism talk about space and the importance they attach to their physical environment, as reflected in written stories.

Joining onto this earlier analysis of writings, the first author also engaged with the doings of people with autism in various settings. Associating with people with autism in three different contexts, he tried to understand their bodily interaction with the physical environment, paying attention to the way they use space, to their behaviour in relation to the built environment, and to the influence of the physical environment on their doings.
A first setting comprehended a short introductory period in the daily living environment of a young woman with autism, living in a common housing facility for people with an intellectual disability. In this house, the woman with autism was living together with seven other persons with an intellectual disability. The researcher joined the daily life in the house during one day, giving attention to the woman with autism both in the common spaces and her private room.
A second engagement occurred in a housing facility only for people with autism. For several successive days, the researcher participated the evening-activities in a house of six people, starting from the moment they came home from the workshop until the time they went to bed. During these days, the principal point of interest was the interactions in the collective places, although in personal contact with the occupants, the researcher also explored some private rooms.
A third setting considered in this paper, is the audit of a university building in which the researcher collaborated with a student with autism (Heylighen *et al.*, 2010). In close cooperation with the student, the integral accessibility of the facility was questioned. Because the audit was focused on the accessibility of the building itself, this personal interaction clearly revealed the view of the student with autism on, and his engagement with, the built environment.

In this study, we want to give depth to a few insights from the earlier study of autobiographies of people with autism by relating them to an interpretation of the observations in different settings. In this way, fragments of an autistic perspective on the built environment are sketched, as a basis for a critical reflection on our own way of thinking about the built environment.

Fragments of the Built Environment

Interpreting their Writings

The analysis of a selection of autobiographies of people with autism—shortly *auti*-biographies—revealed some characteristic aspects of an autistic view on the built environment (Baumers & Heylighen, 2010). Within the scope of this paper, we want to throw light on three of the mentioned aspects, three particularities of an autistic world of experience that were noted in the written stories of people with autism: the confidence offered by physical space, the hidden logic associated with space, and a direct and conscious way of experiencing the world.

Living in an incomprehensible world, a lot of auti-biographers push forward the physical space as a source of certainty. Physical space, presented as a fixed and self-evident feature of the environment, gives a sense of grip the authors are looking for. The physical characteristics of space, which are directly perceivable, seem to inspire more confidence than human beings. Even though some authors write that, from a physical point of view, there is no essential difference between people and objects, the meaningful world behind human beings arouses some unpredictability and uncertainty. “When I’m not concentrating on people,” Brad Rand (1997) writes, “they just look like shapes, like furniture and trees are shapes.” But Birger Sellin (1993) clearly differentiates this view: “Because of important reasons I can find safety only in things. People are incalculable and distinct monsters.”
The incalculable feeling in associating with people is also reflected in the behaviour people

with autism describe in their stories. In this way, Liane H. Willey (1999) relates she knew how to control herself, if she started to lose her bearings. “Whenever things became too fuzzy or too loud or too distracting; whenever I began to feel as though I would come unravelled, I knew I could crawl into my alcove and crunch up into it until I felt as square and symmetrical as the alcove itself.” In the alcove, she could always find herself. And just like Liane, most of the authors describe how they—faced with unsteady situations—seek comfort in reliable spaces, where they find a tangible source of peace and safety, rather than to seek comfort with other human beings.

However, even though in most stories of people with autism the physical space features as a source of grip, the built environment—brought into use in society—reveals an unpredictable side too. Each of the considered auti-biographies reports about problems experienced in dealing with the built environment, or rather ‘maladjusted’ behaviour compared to the expectations of society. Gunilla Gerland (1996) describes her struggle to interpret the built environment 'correctly', so as to be able to deal with it in an appropriate way. Musing on the way other people deal with space, she tries to explain her 'maladjusted' behaviour. “There *must* be a sign of some sort on the doors, because the others didn’t hesitate over where they should go.” Not sure to find a traceable proof of what the others seemed to see, she had a fleeting thought that “maybe the others knew automatically which lavatory they should go into, and so needed no special labels in the way I did. Perhaps they had innate abilities for knowing that kind of thing?” (Gerland, 1996) And probably, Gunilla's explanation is not that far-fetched; there may be such an invisible logic in the built environment, owing to the cultural and social connotations associated with it. Not only human beings, but also objects and the whole built environment are loaded up with additional layers of meaning which, in our society, are assumed to be inherently connected to space. Such layers of meaning cannot yet be perceived just like that.

This raises a third remarkable aspect in the stories of people with autism. In each of the auti-biographies, the authors explicitly testify to a direct and conscious way of perceiving the physical environment, in order to position themselves in the world. Gunilla Gerland (1996) describes how she, scared by the sudden sound of a moped, tries to find a way not to lose herself. “So as not to fall over or explode from inside, I would grab the fence where I was standing, pressing myself against it and holding on hard. I had to feel something that stood still, something anchored, in a world that had suddenly become totally unpredictable.” (Gerland, 1996) Clutching the rails of a fence, or crawling into an alcove under the bed, the authors succeed to come to their senses again, starting from a conscious experience of the physical environment.

Witnessing their doings

The fragments of an autistic perspective on the built environment presented above arose from an analysis of written reflections of people with autism. These fragments are reconsidered in the light of the behaviour regarding space, observed during real interactions with people with autism.

In the interaction of people with autism with space, it also dawned how the physical elements of space are able to give some grip, and even more, how the sense of grip can be qualifying to the use of space. In this respect, the first author witnessed the weekly cleaning ritual of the young woman living in a housing facility for people with an intellectual disability. After she had accurately dusted every little spot in reach, persuading herself that every object in the room was still present in the way she expected, she put the bucket with water in the middle of the corridor. A somewhat ill-chosen place, perhaps, but while completing every next stage of the cleaning plan, she had to walk conscientiously around the place where the bucket—coincidentally or not—had been arrived. A similar situation struck the researcher in the other housing facility, where the plan to play a game fell through because the playmate was not able to take the game. An ironing board, awkwardly placed in front of the cupboard, prevented him to open the cupboard. A simple object, be it a cleaning bucket or an ironing board, was standing convincingly on its own spot, exuding an immovability that was able to determine the following moves.

But the built environment contains more than only this convincing aura, as also illustrated by the use of space of people with autism in different settings. In one of the houses, the counsellors resolutely connected all activities to a particular place in the house. When one of the occupants caught the researcher red-handed in the entrance hall while he was quickly writing down a few notes, she severely reprimanded him: “Hey, without any problem, you can take a seat in the living room to write, you know!” Even in the world of the occupants, each place carried the meaning of the connected activity, and they convincingly proclaimed it to others. However, not all the meanings connected to spatial aspects in our society are as obvious. The audit of the university building in the company of a student with autism revealed that spaces and spatial elements are not always understood according to the meaning we associate with it. The student confided that the staircase of the building did not invite him to go upstairs, and the doors did not show him in a unquestionable way whether he was allowed to come in or not, even though this seemed obvious in the researcher's eyes (Heylighen *et al.*, 2010). And the other way around, when the researcher purposefully opened the dividing door to allow some circulation of air in the house of people with autism, one of the occupants abruptly closed it again. He started to pace up and down nervously, quickly looking around as if something unsuspected was on the verge to happen. The researcher understood that his intentions were probably not clear to the occupant. Only after the next day the dividing door was closed at the moment all occupants quietly had started their evening activities, it dawned that the interpretation of this spatial configuration in the occupant's world was not understood right away by the researcher either.

Finally, the interactions with people with autism also revealed an impressively attentive way of perceiving. During the exploration of the university building, the student frequently pointed at details, which passed the researcher completely: a door handle that was missing at the end of the corridor, or a tiny date indication hidden in a scutcheon next to the ceiling. But also the sounds of the wind around the building, or moving chairs a few rooms away, were details that would not have drawn the researcher’s attention. And the conscious perception of space even seemed to exceed the researcher's own capacity of experience. When in the housing facility for people with autism, after a hot summer's day, an unexpected shower of rain provided some cooling, one of the occupants positioned himself under the cupola in the center of the living room. Noticing the occupant blissfully dancing back and forth, the researcher wondered what it was that this guy experienced. Was it the image of the falling raindrops that made him that happy? Or the sound of the raindrops on the glass? A light cooling breeze slipping into the room? Perhaps the very thought of relief? Probably, space contains a lot more aspects; aspects we cannot easily get hold of, but that a particular perspective on the built environment, in this case a consciously focused—maybe hypersensitive—experience of space, can bring to light.

Facing the Complexity of Space

Each of the considered examples lay bare a particular aspect of the world of experience of people with autism. Discussing these different aspects, we do not intend to give a decision on the world of experience of people with autism. The fragments of an autistic perspective on the built environment, put forward both by the analysis of auti-biographies and by the moments of interaction, offer an occasion to reflect on our own view on the built environment and to question the 'truth' behind this view.

In the study of the world of experience of people with autism, the attention was attracted by the grip offered by physical space and the sense of certainty and confidence this can bring about. Analogously, Ruud Hendriks (1998) explains how people with autism often feel rather supported by non-humans than by humans: “The nonhuman predictable behaviour and iron regularity are thing-like traits that people can only try hard to simulate.” The predictability and regularity of the physical space even turn out to cause objects, as immovable entities, to qualify the spatial behaviour of people with autism. This notion of grip, offered by physical space in an autistic perspective on the world, can value the physical entity of objects. Even banal objects, like a cleaning bucket and an ironing board, or a small space beneath a bed, are essentially physical anchor points of the built environment, which can draw attention to what is undeniably here.

But even though the view on reality of people with autism would be focussed on those features that are given in direct experience, there is more to reality than actualities, as stated by John Lawson (2003). Emma Williams (2004) too describes how objects exist in a social world, and are an enduring source of social influence. Our world is shaped by human activity, and is full of things designed by people to be used in specific human activities by people who share a common body shape, similar needs, and a same cultural history. The same difficulties experienced by people with autism in social or interpersonal relationships constitute part of their problems in relating to objects and the built environment (Williams, 2004). Those difficulties come also to the fore in the stories and actions of people with autism, described above. They show that the additional layers of meaning, in our society inherently connected to space, follow from our own view on reality, which is no less an interpretation of this world. Which logic concludes that our own interpretation of space could be considered as being better adapted to 'reality'? Simply because it is self-evident—in accordance with our own interpretation—that a door is used to enter or exit, this layer of meaning is assumed to be generally accepted; but why would it be less appropriate to consider a closed dividing door as a promising sign of general quiet?

Also the conscious way of perceiving, noticed in both the stories and actions of people with autism, incites us to think. Different theories confirm that people with autism are characterized by a particular view on the environment, be it restricted to what is directly perceptible (Lawson, 2003) or just fragmentary (Happé, 1999). Due to a fundamentally different way of information processing, adequate sense-making needs to be consciously constructed step by step (Noens & van Berckelaer-Onnes, 2004). The conscious experiences of people with autism show that bringing a space into use can signify much more than only performing a certain action on a given place. Even the smallest details of the built environment can attract the attention, and in this way, using space includes seeing, hearing, feeling, smelling, ... and thoroughly experiencing different dimensions of that space.

The particular way of experiencing, consistent with the cognitive style of the autism spectrum, makes us aware of the fact that this world of experience may exceed our own experiences; it raises questions about our own view on the world. Considering these fragments of an autistic world of experience in the context of designing space may also inspire designers to burst the banks of their own world of experience. The complexity of the design challenges designers to question the way they think about (designing) the built environment.

First, the awareness of the sense of grip exuded by the physical environment can be put in the light of the design of space. Each designed artefact acquires a meaning in interaction with people, but are we—as designers—also aware of the meaning a 'beneath-the-bed' can imply? Moreover, a lot of extra layers of meaning are provided to a design. A design is loaded up with inherent meanings, which can afford certain behaviours—conscious or not. But do we—as designers—still question how a door can be designed so as to look inviting to enter? And third, the design of space can be influenced by many aspects, connected with the experience of the built environment. Different senses, but also those various layers of meaning, play a role in the experience of space, and this diversity of perception and sense-making could challenge—perhaps inspire—designers. Which aspects of a cupola are important in the design, if besides the incidence of light and the sound of rain, it is also possible to carry the blissful idea of cooling? The complexity of space, couched in the diverse perceptions and meanings, can invite designers to take up the challenge of questioning their own way of thinking, in order to be aware of the relativity of the designers' view.

However, it needs to be mentioned that the view of this research is relative too, simply because of taking a particular perspective on the built environment as a starting point. Furthermore, the analyses rely on a first exploration of the possibilities of this research. Both concerning the auti-biographies and the moments of interaction, we do not pretend to give a complete image of a general perspective on the built environment according to *the* cognitive style of people with autism, if only it should exist. The interpretation of a selection of autobiographies happened from our own limited perspective. And it is not improbable that the image, shown during the interactions, is to a certain extent a disruption of the habitual rhythm, among other things because of the researcher's presence in the different settings. In a next stage of this research, the insights gained through this first analyses are used to refine the method, to consequentially look for more depth in exploring the perspective of people with autism concerning the built environment. Finally, although the discussion of the fragments in the light of architectural design raises more questions than offering answers, it also keeps open a lot of lines of thinking. To get a hold of the implications of these insights for architects, the frame of this research seeks to investigate design cases. The study of realized design projects intends to get a variegated idea of what designers can take in from insights from an 'other' perspective on the built environment.

Despite the mentioned limitations, this study tried to take on an autistic perspective to exceed the designers' view on the built environment. By elaborating fragmentary aspects of an 'other' way of thinking about space, which we do not always give a moment's thought, this paper raised a corner of the veil of the enormous diversity of possible interpretations of the built environment. In this way, the study offers a challenge to designers, a challenge that can be inspiring in dealing with the profound complexity that the design process implies.

Acknowledgements

Author Biography

Stijn Baumers

Stijn Baumers is a Ph.D. fellow at the Department of Architecture, Urbanism & Planning (ASRO) at the K.U.Leuven. Graduated as Master in Engineering: Architecture at the K.U.Leuven, he received a Ph.D. Fellowship of the Research Foundation – Flanders (FWO) to investigate the possible implications on designing architecture, out of another way of interpreting the built environment.

Ann Heylighen

Ann Heylighen is a research professor at the Department of Architecture, Urbanism and Planning at the K.U.Leuven. Her Ph.D. and post-doctoral research in architecture included studies of design knowledge embedded in design projects & processes. Recently the European Research Council awarded Ann a Starting Grant for the project 'Architectural design In Dialogue with dis-Ability' (AIDA), to establish an interdisciplinary research team to explore the spatial experience of people with various capacities as source of design knowledge.

Modélisation sémiotique et systémique de l'objet design comme signe-action complexe

Sarah Belkhamsa, Université Paris 1 Panthéon-Sorbonne, Paris et Université de la Manouba, Tunis

Bernard Darras, Université Paris 1 Panthéon-Sorbonne, Paris

Résumé

Les approches sémiotiques et systémiques du design produit sont à la fois peu nombreuses et peu coordonnées. C'est ce que fait apparaitre l'état de la recherche en ce domaine. Les quelques études sémiotiques disponibles ont par ailleurs tendance à isoler l'objet de ses usages, de ses utilisateurs et de la complexité du système d'objets qui constitue son environnement proche ou des modes et styles de vie qui constituent ses univers. En conséquence, l'objet analysé est le plus souvent réduit à une image figée de lui-même. Seules les études qui relèvent de la sémiotique pragmatique veillent à inscrire l'objet dans l'action, les interactions et différents contextes.

C'est dans cette lignée que la recherche ici présentée propose une modélisation sémiotique et systémique de l'objet. Celui-ci est considéré comme un signe-action complexe inscrit dans le temps, dans l'expérience d'interaction et de relation, dans les habitudes et les changements d'habitudes résultant des tensions adaptatives engendrées par les changements technologiques, culturels et socio économiques.

Une telle approche à la fois sémiotique et systémique impose de reformuler les questions de recherche. Les objets communiquent-t-ils dans l'action et comment ? Comment les traiter comme des signes complexes sans les séparer de leurs environnements de conception et d'usage et sans réduire la dynamique des usages aux seuls «bons usages» décrétés par l'analyste ? Comment penser la relation avec l'objet en action (l'expérience) à la fois de l'intérieur (approches internalistes) et de l'extérieur (approches externalistes) ? Comment penser l'objet complexe comme un système de relations et d'intelligences distribuées dans des représentations individuelles et collectives, mais aussi intégré dans des mémoires externes ? Comment distinguer les différentes phases de découverte, d'apprentissage, d'automatisation des usages et de leurs changements qui constituent la vie des humains avec les objets ? Enfin, comment modéliser cette complexité et tester les hypothèses interprétatives produites par la recherche ?

Mots-clefs

Codétermination ; communication ; design ; modélisation ; objet ; sémiotique ; systémique.

Abstract

Semiotic and systemic approaches to product design are both scarce and uncoordinated, as shown by the current state of research in this area. The few semiotic studies available also tend to isolate the object from its uses, its users and the complexity of the system of objects that constitutes its immediate environment or of the patterns and lifestyles that make up its universes. As a result, the analyzed object is often reduced to a frozen image of itself. Only the studies that fall within pragmatic semiotics analyze the object within the action, interaction and the different contexts.

In line with this approach, the research presented here proposes a semiotic and systemic modelization of the object, which is considered as a complex sign-action recorded in time, in the experience of interaction and relationships, in the habits and lifestyle changes resulting from adaptive pressures generated by technological, cultural and socioeconomic change.

Such a semiotic and systemic approach requires reformulating research questions. Do objects communicate within action and how? How to address them as complex signs without separating them from their design and use environments and without only reducing the dynamics of uses to the 'right uses' decreed by the analyst? How to think the relationship with the object in action (the experience) both inside (internalist approaches) and outside (externalist approaches)? How to think the complex object as a system of relationships and intelligences distributed in individual and collective representations but also built on external memories? How to distinguish the different phases of discovery, learning and automation of the uses and their changes that constitute the life of humans with objects? Finally, how to modelize this complexity and test the interpretative hypotheses generated by research?

Keywords
Co-determination ; communication ; design ; modelization ; object ; semiotic ; systemic.

La modélisation dynamique que nous présentons ici concerne les flux de communication générés par et pour l'objet matériel dans le cadre d'une expérience vécue avec et par lui. Ce modèle s'inscrit dans la tradition des modélisations de la communication élaborées jusqu'alors, mais il tente de les dépasser en intégrant les approches dynamiques, constructivistes, situées et, interactionnistes prenant en considération les contextes culturels des protagonistes.

La première interrogation qui a initié cette recherche est théorique : les objets communiquent-ils, et si c'est le cas, comment les choses se passent-elles et comment peut-on les expliquer ? La seconde question a une origine plus méthodologique, après avoir étudié les différentes modélisations de la communication qui ont cours dans les *design studies*, nous avons constaté qu'elles ne permettaient pas de traiter l'objet comme une partie du système complexe et dynamique que nous avions observé lors de nos enquêtes et études de terrain.

La destination de cette modélisation est à la fois théorique car elle tente d'articuler les diverses connaissances produites jusqu'alors au sujet de l'objet, mais aussi pratique car nous souhaitons que ce modèle devienne un outil d'aide à la création, à l'audit et à l'analyse. À ce titre, nous avons veillé à l'inscrire dans le contexte économique hétérogène qui gouverne la conception, la production et la consommation des produits. C'est d'ailleurs par cette mise en perspective générale que nous débuterons cette présentation.

Pour construire ce modèle, nous avons systématiquement combiné des approches inductives, fondées sur des observations de terrain et des enquêtes, à des approches déductives, générales et théoriques. Cette modélisation a été conçue et perfectionnée dans le cadre de recherches empiriques, appliquées et concrètes consacrée à l'étude de bouteilles d'eau, de cendriers, de clef USB, de portes lunettes et de téléphones portables, et même d'interfaces web, etc. Nous ne présenterons pas ici ces études, mais nous développerons la modélisation qui en résulte en la décrivant et en présentant ses arrières plans théoriques.

Cet article plus descriptif que prescriptif explore une à une les grandes composantes de la modélisation que nous avons élaborée. Il débute par une présentation des niveaux sémiotiques de la modélisation, puis il explore les trois pôles du circuit de la communication avant de présenter les cycles d'habitude et de changement d'habitude qui déterminent la nature des relations entre les trois pôles. Il se termine par une présentation des flux qui les relient.

Contexte général de la production du modèle

Modèles économiques et sémioses des objets

Economie des objets biens : Economie linaire

Dans le cadre de l'économie des biens, la communauté des concepteurs et producteurs réalise des produits qui sont des biens de consommation pour des usagers qui en sont souvent les propriétaires uniques. Une fois que les fonctions de ces biens sont épuisées, ils sont massivement jetés. C'est la métaphore du « berceau à la tombe » proposée par Michael Braungart et William MacDonough (2002) qui convient le mieux pour imager cette économie irresponsable. Les produits-biens sont gérés comme toutes les propriétés personnelles et privées, ils sont résolument conçus pour être appropriés individuellement et servir aux fonctions sociales de projection et d'ostentation identitaire. En conséquence, ce sont les sémioses de propriété privée, de cumul des biens, de capitalisation, de distinction, mais aussi de gestion non écologique qui dominent l'utilisation de ces objets-biens.

Economie des objets recyclables : économie circulaire

Dans le cadre de l'économie bouclée, les produits sont conçus par la communauté des concepteurs et producteurs pour être démontables, réutilisables et recyclables. La philosophie « *cradle to cradle* » et sa certification C2C en sont la manifestation. Cette approche réclame un décentrement de la logique de produit « fini » pour tendre vers une logique de seconde vie des composants. Les produits recyclables sont encore des propriétés privées qui peuvent bénéficier des même sémioses que les biens, mais dès la conception et la diffusion le recyclage de fin de vie est programmé. Ils réclament donc des sémioses écologiques et « responsables » adaptées.

Economie des objets et produits de service : économie circulaire

Dans l'économie d'usage et de service, les produits sont avant tout conçus et produits pour être des relais d'usage et de service et c'est ainsi qu'ils sont consommés. Ceux que l'on appelle les *smart products,* des trois classes du *Product Services System* (PSS) (Brissaud, 2009) mais aussi les *Sustainable Service Systems* (3S) ou les produits non matérialisés (PNM) font désormais partie des stratégies de réduction de l'empreinte planétaire des entreprises et des politiques de développement.

Cette troisième forme d'économie éco-durable veille à ce que ses produits relais puissent être régulièrement mis à jour, compatibles avec des utilisateurs divers, multiples, simultanés et/ou successifs et qu'une fois épuisés par ce service commun, ils soient recyclés. Ils entrent le plus souvent dans une économie de « biens » publics ou collectifs en libre-service. Ces produits relais sont encore très souvent traités avec des sémioses issues de la logique de propriété des biens, ce qui provoque divers problèmes tels que les dégradations et les vols.

En ce début du XXIe siècle, l'économie, l'industrie, le design, les sémioses et les croyances dominantes sont encore réductionnistes mais la prise de conscience des bouleversements écologiques en cours tend vers un design de service systémiquement auto éco organisé. Nous sommes progressivement passés d'un design centré sur l'objet à un design centré sur la fonction, puis sur l'usager, à un design systémique centré sur le système intégral.

La culture matérielle, les flux de signification et les niveaux sémiotiques

L'une des thèses centrales de nos recherches (Darras & Belkhamsa 2009a) repose sur l'affirmation que les produits de la culture matérielle ne sont pas des objets passifs mais des relais d'expérience et des médiateurs de croyances, de représentations, d'habitudes et d'agences. Ils sont articulés en vastes systèmes de signes et de fonctions qui contribuent à l'organisation des rapports entre les humains. Dans ce cadre, ces signes deviennent les lieux d'action, de signification et de rapports de pouvoir, ce sont des agences intégrées et matérialisées capables d'être activées et d'activer des humains dont elles modulent les croyances, les habitudes et les identités (Darras, & Belkhamsa, 2009b).

Le design comme processus de conception de produits et de services constitue donc un ensemble de puissants outils d'adaptation et de transformation du monde des objets et c'est à ce titre un acteur majeur dans le modelage des relations sociales et culturelles (Belkhamsa & Darras, 2007). À ce titre, le design, les usages et la culture matérielle sont mutuellement engagés dans des boucles de co-détermination.

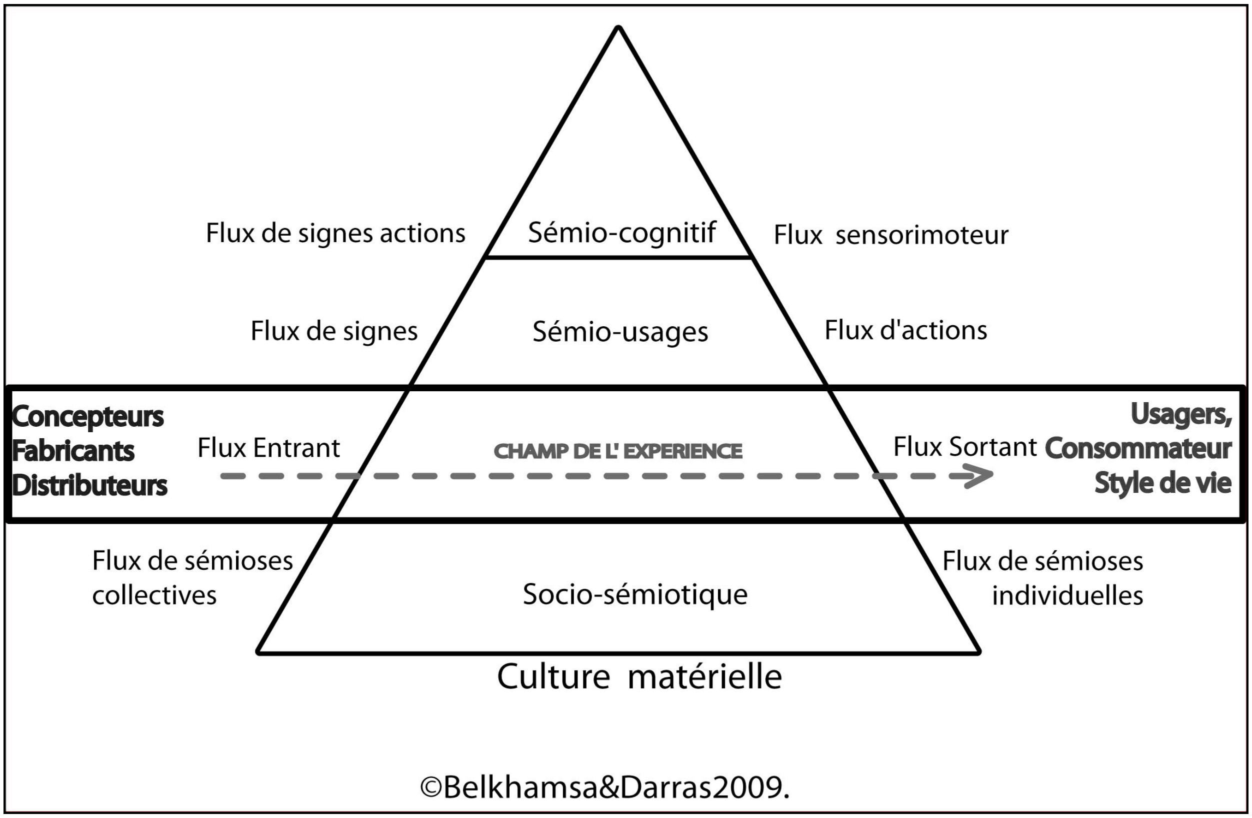

Figure 1 Les niveaux sémiotiques.

Ce diagramme représente les trois niveaux de profondeur auxquels notre modélisation donne accès.

L'expérience est le moment où s'actualisent tous les flux directs, concrets et situés de la relation à l'objet comme représentant d'une culture matérielle. Cette expérience actualise les flux de sémioses individuelles et collectives qui constituent la matière première de l'étude socio-sémiotique. Tel que nous le concevons ce niveau concerne les enjeux identitaires, de classe sociale, de genre et tous les rapports de pouvoir.

Le niveau des *sémio-usages* articule les signes à l'action et aux usages. Il interroge la façon dont un signe produit de l'action et la façon dont un usage produit un signe (Belkhamsa, sous presse).

Le troisième niveau traite du fonctionnement cognitif des processus d'interprétation et d'action et il interroge les processus de fixation et de changement des habitudes.

Ces différents niveaux sollicités par l'expérience avec l'objet en font un artefact chargé de culture réifiée et un signe action très complexe.

Approche en réseau du système de production et de réception des objets et anatomie d'un modèle

Nous avons la conviction qu'une sémiose construite à l'occasion d'une expérience avec l'objet n'est pas seulement le produit d'une personne mais le résultat d'un enchevêtrement de semioses co-construites et co-déterminé par l'individu et sa communauté. Aussi focaliser l'attention sur un seul concepteur ou un seul usager nous semble réducteur de la complexité des instances mobilisées lors de l'expérience avec l'objet.

Le modèle dynamique que nous présentons se compose de trois grands pôles en interrelations qui traitent de l'expérience de la culture matérielle. Afin de représenter les différentes interactions entre l'expérience individuelle contextualisée, située et motivée par un projet et les enjeux individuels et supra-individuels qui sont activés dans le cadre de cette expérience, nous avons choisi d'emboîter deux cercles concentriques, le premier désignant l'individu et le second la communauté dans laquelle il opère.

Les deux pôles des concepteurs-producteurs et de la communauté des usagers sont chacun constitués de deux « horloges » encastrées. Leur rotation permet de situer et de contextualiser les états de sémiose des agents qui sont eux-mêmes en relation avec le système objet. Les « horloges centrales » concernent l'état de ces agents, alors que les « horloges » périphériques permettent de situer tel ou tel état de la communauté interprétative et de la culture matérielle. En conséquence, tout agent[1] est à la fois indépendant et dépendant. Ce sont les interactions et articulations permanentes entre ces niveaux qui constituent selon nous une des originalités de ce modèle. Ce dispositif en horloges encastrées, permet de caractériser soixante-quatre combinaisons représentant les états d'un individu par rapport aux états de sa communauté interprétatives.

Au centre et au sommet du modèle, l'objet possède deux « faces » principales, un côté intègre et matérialise les composantes sélectionnées par le pôle de conception-production : le produit ou le service, l'autre côté est traitée par l'utilisateur comme un bien, une interface d'usage ou un relai de service. En conséquence, à la différence des schémas de communication classiques, qui ont tendance à individualiser ses pôles nous considérons qu'à tous les niveaux de notre modélisation, ce sont des ensembles d'acteurs et d'agents qui sont en interaction avec le monde et ceci vaut autant pour la communauté des concepteurs-producteurs, que pour les communautés d'usager et les communautés interprétatives diverses, mais aussi pour ce que l'on appelle les systèmes d'objets[2]. C'est ce que nous allons étudier plus en détail.

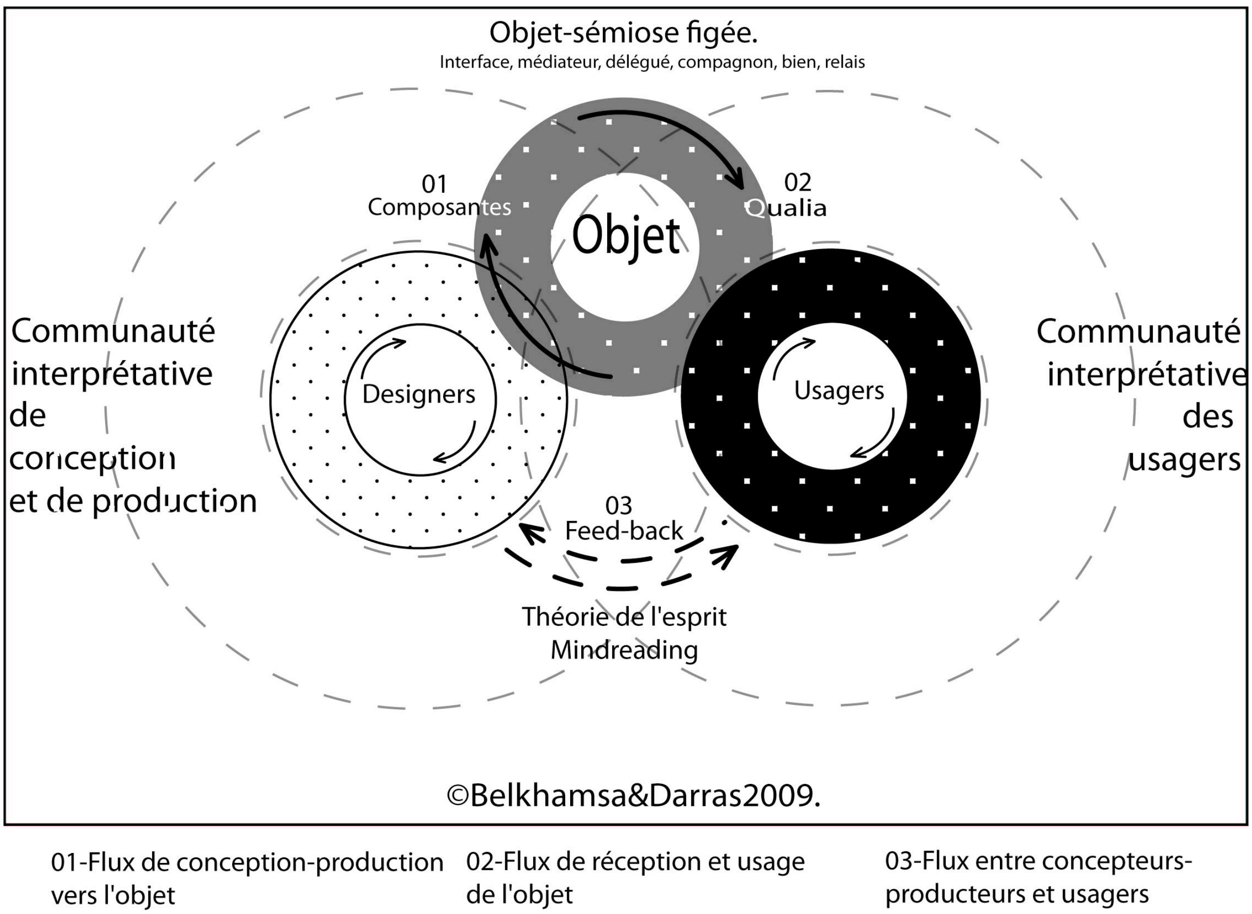

Figure 2 Modélisation simplifiée des flux de sémioses activées par l'objet.

---

[1] A l'exception des sujets très autistes.

[2] Conformément à la définition systémique, ce qui fait un système, c'est le réseau plus ou moins dense des interactions, agences et interdépendances que les composantes du système entretiennent entre elles dans l'action.

- La communauté de conception et de production des biens, des produits et des relais de service comprend le commanditaire, les ingénieurs des différents bureaux d'étude, les responsables du marketing, de la direction artistique, du service financier et bien évidemment les designers dont la position et le rôle varient selon l'organisation de l'entreprise, les productions et les produits. Plus ou moins directement et explicitement, tout ce monde contribue à la définition du cahier des charges ainsi qu'aux différentes opérations de conseils, de sélections, de tests, de validation, de fabrication, qu'organise le projet. Finalement, que ce soit revendiqué ou non, toute conception et production est toujours le résultat d'un co-design et d'une co-production.

- De son côté, le concept de communauté des usagers ne renvoie pas qu'aux seules pratiques de groupe. Il concerne aussi tous les usages singuliers et situés qui sont des occurrences d'actions apprises et maîtrisées lors d'échanges directs (imitation ou instruction) ou indirects (médiatisés par un mode d'emploi, etc.) avec d'autres membres d'une communauté. Cette communauté produit et gère des règles et des normes d'usage et d'expérience plus ou moins incorporées par les individus, mais aussi toutes les interactions improvisées plus ou moins déterminées par une cause et tendant vers un but. Les enquêtes sur les conduites individuelles, montrent qu'elles sont bien des occurrences de pratiques partagées notamment sous la forme des croyances et des habitudes qui constituent une partie des représentations communes.

- Le concept de système des objets ne se limite pas aux familles d'objets (Baudrillard, 1968). Il est enrichi par la conception de l'objet comme un dispositif d'intelligences distribuées plus ou moins figées entretenant des relations objet-sujet et objet-objet (Zinna, 2005). Sur ce point, notre modélisation découle de la conception sémiotique relationnelle de C. S. Peirce (1931-1935) et elle adopte le concept de réseau hétérogène ou les agents humains et non-humains sont considérés comme étant des réseaux en interrelations. Elle a aussi de nombreux points communs avec la théorie de l'acteur réseau (*Action-Network Theory*, ANT).

Selon cette perspective les relations entre objets et objets constituent l'écologie des objets. Ces relations peuvent être de dépendance directe (ensemble d'objets fonctionnant en co présence : un service de table, une table et ses chaises, etc.) ou indirecte (ensemble d'objets fonctionnant entre eux à distance : un téléviseur et sa télécommande, etc.) Ces objets peuvent être reliés entre eux à plus ou moins grande distance par divers opérateurs parallèles de point/contre-point mécaniques (la clef et la serrure) ou chimique (un détecteur de fumée et une chaudière) ou thermique (un thermostat et un radiateur) ou par ondes (deux téléphones cellulaires via un réseau), (Uexküll,1956-1965).

Selon le type d'expérience engagée, l'opérateur sélectionne et active certaines relations entre un objet et son environnement et constitue ainsi un système des objets répondant à ses intentions et finalité d'action. En conséquence, chaque expérience définit un système des objets unique et spécifique à chaque opérateur.

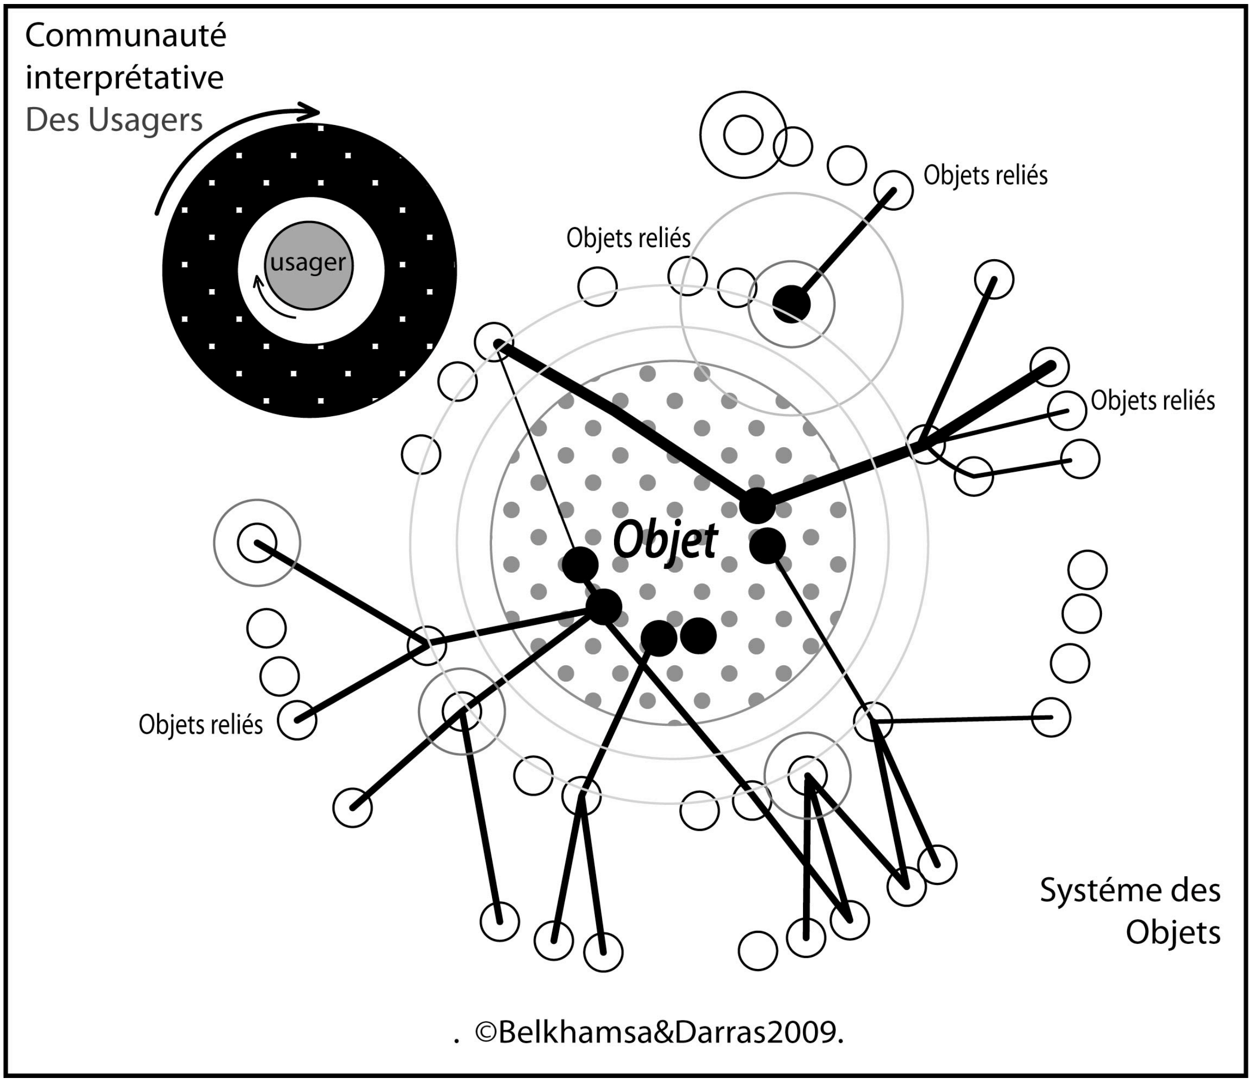

Figure 3 Modélisation simplifiée des systèmes des objets.

Description du modèle

Présentation du cycle des habitudes et changements d'habitude

Cette modélisation dynamique résulte de nos difficultés initiales à modéliser la diversité des actions et expériences avec un objet. Qu'elle soit arbitraire, typique, relative au bon usage ou statistiquement moyenne, aucune des solutions ne nous semblait épistémologiquement acceptable.

Lors de nos différentes observations et enquêtes en réception sur les usages des objets, une évidence s'est imposée, les agents n'avaient pas du tout les mêmes relations aux objets quand ils les découvraient, quand ils apprenaient à s'en servir ou quand ils en usaient régulièrement. Dans les deux premiers cas, ils étaient attentifs à leurs actions et ils pouvaient les décrire, en revanche, ils étaient en difficulté pour en parler dès que leurs relations à l'objet étaient gérées par des automatismes.

Une autre distinction est apparue très tôt, elle concernait toutes les relations avec les objets en crise. La crise apparait notamment quand l'usage d'un objet n'est plus adapté aux besoins. Travaillant à partir de deux territoires et de deux ambiances culturelles sensiblement différentes : la France et la Tunisie, nous rencontrions des objets importés et exportés dont l'identité posait des problèmes, (voir, Belkhamsa et Darras, 2007).

Pour résoudre tous ces problèmes et modéliser la relation systémique, contextualisée et située de la communauté des agents, du système des objets et de l'environnement, nous avons eu recours aux concepts d'habitude et de changement d'habitude développés par C. S. Peirce. Nous les avons ensuite affinés et organisés en un cycle du changement. Ce cycle et ses différentes phases sont représentés dans le diagramme suivant :

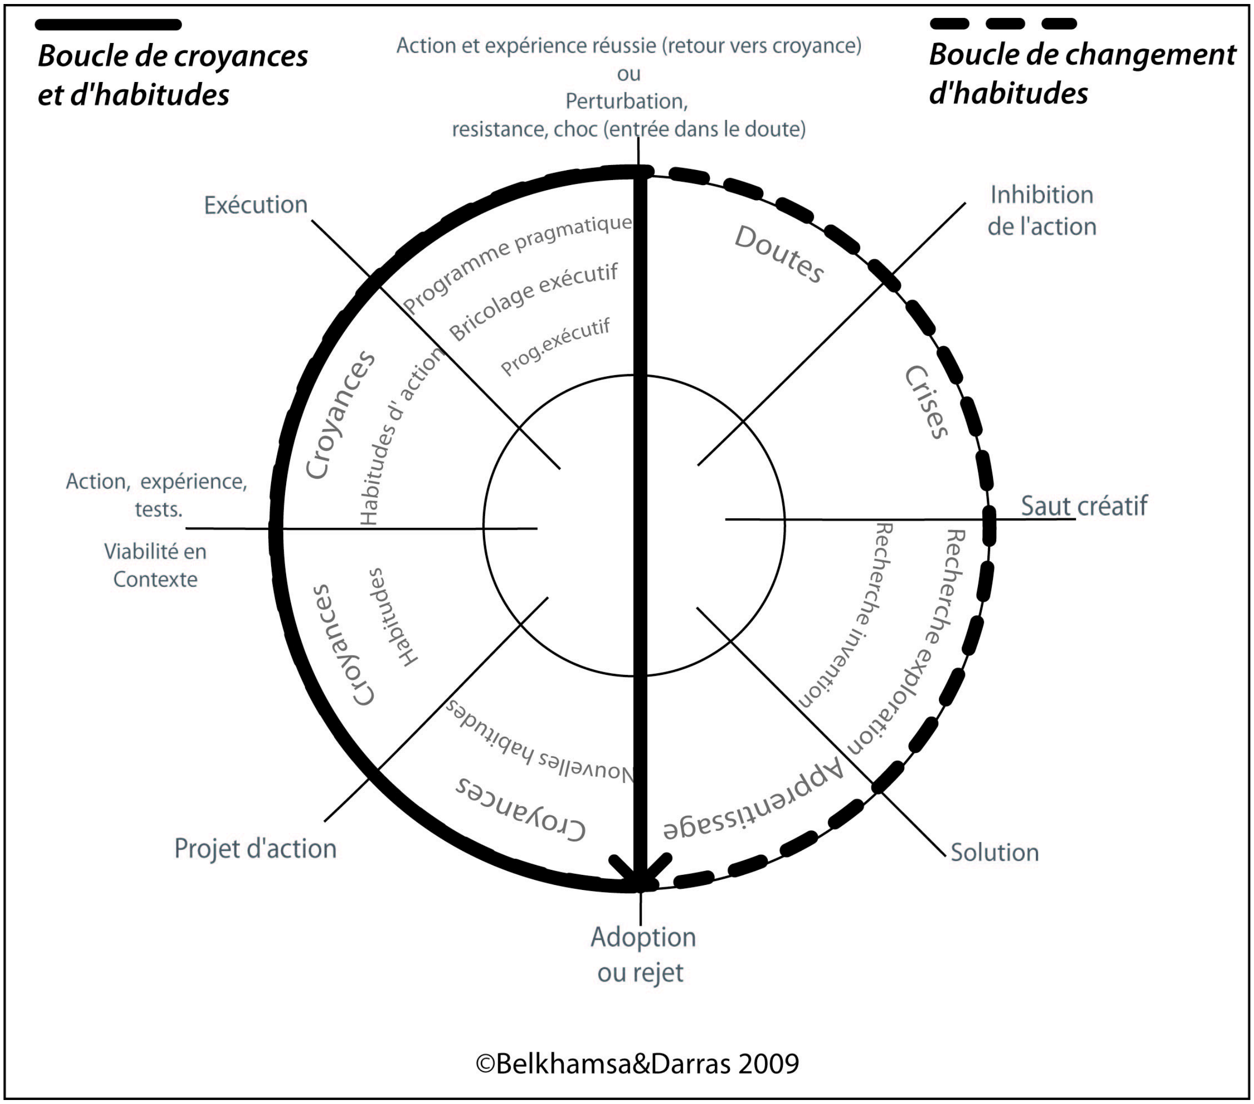

Figure 4 Cycle du Signe-Action dérivé de la théorie de C.S.Peirce.(Auto-eco-organisé)

Tel que nous le présentons ici, la gauche de ce cercle est occupée par les phases en équilibre, c'est le domaine des croyances en phase de stabilité, des habitudes et des habitudes d'action qui en découlent et qui se renforcent et renforcent les croyances quand l'action est concluante (flèche descendante). Cet équilibre est l'état dans lequel se trouve la pensée qui fonctionne dans un environnement prévisible. Nous avons distingué les phases délibératives des phases exécutives. Dans les premiers cas les habitudes sont des prédispositions à agir, dans le second cas les habitudes s'actualisent dans l'action où elles se confrontent aux facilitations et résistances concrètes de l'environnement.

L'hémicercle de droite débute avec le doute qui résulte d'une perturbation de l'habitude d'action, il est généralement suivi d'une crise qui peut se résorber lors d'une phase de recherche de solution. Celle-ci étant trouvée, éprouvée et apprise, une nouvelle habitude est constituée et le cycle adaptatif des habitudes et changement d'habitude peut continuer. Nous allons brièvement présenter chacune de ses phases en notant que le passage de phase en phase est provoqué par des tensions.

Dans la modélisation complète présentée en fin d'article, ces cycles ou « horloges » de base seront, à la fois emboîtés afin de représenter la relation de phase d'un individu avec sa communauté culturelle, et répliqués car ce sont les mêmes phases et tensions qui se produisent en conception-production ou en réception consommation.

Croyances, habitudes, action et signification

Croyances et habitudes

Selon Charles, S. Peirce, a « belief consists mainly in being deliberately prepared to adopt the formula believed in as the guide to action." (Peirce : CP 5.480). La croyance n'est donc qu'une règle d'action et une prédisposition à agir, une formule destinée à servir de guide à l'action. En conséquence, les habitudes qui en découlent sont tendues vers l'action mais elles ne se concrétisent que dans les habitudes d'action. C'est pour Peirce le rôle même de la pensée : « The whole function of thought is to produce habits of action » (CP 5.400, V.13). L'habitude d'action préside à l'accomplissement de la signification qu'est l'action elle-même (CP 5.400). Lors de nos observations, nous avons constaté que les habitudes d'action s'actualisent selon trois process distincts qui peuvent être successifs.

- Les programmes pragmatiques sont des représentations internes ou externes de plan d'action. Une table de multiplication mémorisée ou un système mnémotechnique sont des programmes pragmatiques internes, le mode d'emploi, la recette, une carte routière, un plan de montage, etc. sont des programmes pragmatiques externes.

- Les « bricolages exécutifs », sont activés lors du passage à l'action directe et concrète. Ce sont des actions partiellement « improvisées » lors de l'expérience directe et située. Les agents « bricolent » avec les informations et connaissances distribuées dans leur environnement sous forme de mémoires externes ou excorporées et des habitudes matérialisées et réifiées que sont les artefacts[3]. « Le chemin se construit en marchant » disait A. Machado.

Le programme pragmatique constitue une sorte d'élan initial, d'intention, alors que le « bricolage » exécutif est opportuniste, inventif et adaptatif.

- Les programmes exécutifs sont des bricolages exécutifs optimisés et répétés un grand nombre de fois avant d'être enregistrés dans la mémoire procédurale. Ils deviennent alors à la fois automatiques et cognitivement inconscients. La conduite automobile, ou l'utilisation experte d'un clavier sont des combinaisons d'automatismes et de bricolages exécutifs. Le fait de connaître une action « par corps », dispense de la médiation d'une représentation. Celle-ci devient même gênante quand elle resurgit au milieu d'une action automatisée. Il faut en quelque sorte apprendre à agir sans y penser. Ce qui ne veut pas dire que l'agent ne pense plus, sa pensée n'est plus représentationnelle mais psychomotrice.

Dans tous les cas, passer à l'action c'est savoir fonctionner selon l'un de ces trois modes.

Le doute

L'entrée dans le doute est une situation normale du cycle de la pensée qui tend à la fois vers l'habitude et le confort de la croyance, mais aussi vers l'action qui peut conduire à l'échec et à l'invalidation de l'habitude et de la croyance « Since belief is a rule for action, the application of which involves further doubt and further thought, at the same time that it is a stopping-place, it is also a new starting-place for thought. ». Le plus souvent, le doute n'est pas une phase satisfaisante « Doubt […] is not a habit, but the privation of a habit." Sa résorption inaugure une phase de recherche qui peut s'enliser dans la crise ou se libérer dans un saut créatif. Dans les cas graves la tension se transforme en état de choc qui bloque le processus de la pensée.

---

[3]Tels que nous les définissons, ces programmes pragmatique et exécutif sont conformes aux avancées des théories de l'action et de la cognition située (*Situated cognition*), de la connaissance distribuée et des recherches en HMI (*Human Machine Interaction*) telles quelles ont été développées à partir des travaux de Lucy Suchman (1987 et 2007).

La crise

En l'absence de solution viable le sujet et sa communauté entrent dans une phase de crise dominée par le trouble, l'hésitation, l'échec, la souffrance, l'inhibition de l'action, les cercles vicieux et toutes les formes du blocage. En attendant qu'un saut créatif et adaptatif ne survienne et ne soit adopté, on tente souvent de faire du neuf avec du vieux.

La recherche

La recherche de solution peut emprunter différentes voies qui vont de l'imitation, (emprunt ou copie de solutions existantes) à la recherche méthodique et scientifique de solutions inédites fondées sur différentes procédures logiques dont l'abduction, l'induction et la déduction. Entre ces deux extrêmes, l'imagination et la créativité offrent une grande variété de dispositifs de résolution de problèmes qui vont du surgissement intuitif de solutions aux différents recyclages de blocs de pensées. Comme le disait Albert Einstein : « Les problèmes auxquels nous sommes confrontés ne peuvent être résolus au niveau et avec la façon de penser qui les a engendrés »[4]. L'émergence d'une solution peut se faire dans un temps très court ou très long et cette solution peut être plus ou moins viable.

L'apprentissage de nouvelles habitudes

Beaunieux montre que « l'apprentissage d'une procédure se déroule en trois étapes distinctes : une étape cognitive, une étape associative et une étape qualifiée d'autonome. Lors de la première étape, le sujet découvre ce qu'il doit apprendre : il tâtonne et commet de nombreuses erreurs. Puis il passe à l'étape associative, phase transitoire au cours de laquelle il commence à contrôler la tâche à effectuer, sans pour autant l'avoir automatisée. Enfin, pendant la troisième étape les gestes sont automatiques et atteignent un niveau d'efficacité maximale. » (Beaunieux, 2009 : 52). Cette dynamique correspond à trois zones cérébrales distinctes (Hubert et al. 2007).

« Ce basculement (vers la mémoire procédurale) expliquerait pourquoi nos automatismes sont si difficiles à verbaliser. » (Beaunieux, 2009 : 53). Cette économie procédurale permet au sujet de dédier une plus grande part de son activité à d'autres choses. Si dans la compétition entre les habitudes disponibles, la nouvelle habitude apprise parvient à s'imposer et à être validée puis à être adoptée par la communauté interprétative du sujet, elle devient une habitude partagée (consensus) et éventuellement un habitus. Elle est alors incorporée individuellement et socialement jusqu'à la prochaine hésitation, indécision et jusqu'au prochain doute qui engagera une nouvelle recherche.

L'articulation entre les croyances et habitudes individuelles et collectives

Cette étude des phases et tensions du cycle des habitudes et changement d'habitude est applicable aussi bien en conception-production qu'en réception, usage et consommation. Elle l'est aussi tant au niveau singulier du designer que de sa communauté de production, elle est aussi applicable du côté de l'expérience individuelle et du contexte culturel des communautés interprétatives et agissantes dans lesquelles l'usage se déroule. Toute étude d'une expérience consiste donc en un réglage de ces cycles emboîtés en fonction des phases activées.

En général, ce sont les habitudes qui dominent la vie quotidienne des humains. Dans les environnements conçus pour être stables et prévisibles, il n'est donc pas difficile de contrôler très vite les micros changements et de chasser le doute pour retrouver les bonnes vieilles habitudes.

Sur ce plan, tous les individus n'ont pas les mêmes comportements, ainsi les individus créatifs sont plus attirés par les tensions provoquées par le doute que par la stabilité. Ils aiment les professions et les activités plus risquées où les habitudes sont souvent déstabilisées. Ils apprécient de voir leurs certitudes mises en doute, ils adorent avoir des problèmes à résoudre et relever des défis qui stimulent leur imagination, leur créativité et leur esprit d'invention. Bref, ils aiment être confrontés aux changements et ils en sont les principaux acteurs, en conséquence, ils adoptent vite les nouvelles solutions et les nouveaux produits et services. Ils ont donc bouleversé le modèle de la pensée stable où dominent les croyances, les habitudes et la tradition, au profit

---

[4] Référence exacte inconnue, ce propos est généralement prêté à Albert Einstein.

d'une valorisation positive du doute et de la recherche de solution. C'est leur façon de gérer le cycle des habitudes et des changements d'habitude, mais surtout c'est leur attitude constructive face à l'incertitude ainsi que leur habileté à transformer positivement les tensions et le doute en recherche et en solution et non pas en crise ou en rigidité qui en font des individus créatifs.

La créativité attirant la créativité et les créatifs attirant les créatifs, une « classe créative » se constitue qui dispose du pouvoir essentiel de définir les styles de vie du présent mais aussi ceux du futur et donc d'orienter en grande partie l'économie et la production de biens et de services (Florida, 2002).

Cycle de vie de l'objet

Les objets eux-mêmes sont soumis a un cycle de vie et de changement régulé par les lois du marché, des marques et des tendances (e.g., Barthes, R., 1967 , Baudrillard, J, 1968, Marty, R. 1994 : Klein, N., 2000). Il est évident que la relation aux objets est différente quand ceux-ci sont des « concepts », des prototypes ou des produits innovants, ou quand ils sont des produits de masse ou génériques usés ou des survivants de la banalisation érigés en sémiophores destinés aux collectionneurs.

C'est parce qu'il est pris dans le réseau de toutes les combinatoires entre : les différents systèmes économiques ; les différents niveaux sémiotiques ; la variabilité des systèmes des objets constitués à l'occasion d'expérience spécifiques : les différentes combinaisons possibles entre les sémioses individuelles et leurs interactions avec l'environnement, etc. que l'objet est un signe complexe difficile à interpréter. Les composantes de cette complexité étant identifiés, il s'agit maintenant de les mettre en relation par une approche systémique des flux qui les relient.

Etude des trois flux de communication entre les pôles

Cette dernière partie est consacrée à l'étude des flux de communication qui circulent entre les pôles dynamiques en constituant le circuit de la communication de l'objet. Pour faciliter la compréhension de cette partie de notre modélisation, nous devons préalablement expliciter certains paradigmes que nous utiliserons régulièrement (Darras, Belkhamsa, 2008).

- Proposées par James Gibson (1950), les affordances sont des propriétés de l'environnement associées par un animal ou un humain à des actions spécifiques dans un système donné. Ces "opportunités écologiques d'interactions" ne sont ni seulement des propriétés de l'environnement ni seulement des dispositions du sujet, ce sont des propriétés systémiques (écologiques) émergentes qui sont à la fois complémentaires et relationnelles

- Le concept d'enaction a été développé par Francisco Varella dans un contexte épistémologique post-darwinien où la relation organisme/environnement se définit par l'évolution de leur co-détermination. La thèse de l'énaction réside dans le concept de couplage structurel. Ainsi que le notent Visetti et Rosenthal (2006), l'approche énactiviste se distingue par sa capacité à considérer que "l'intérieur" et "l'extérieur" se co-constituent à travers l'action et ses médiations.

- Selon Greimas (1983 : 74), la factitivité « est un faire cognitif qui cherche à provoquer le faire somatique. » L'acte factitif qui en résulte a deux modalités contractuelles engageant « deux instances de l'énonciation, dotées d'un faire persuasif et d'un faire interprétatif.» (Greimas, Courtes, 1979 : 144). Michela Deni (2005 : 82) distingue quatre niveaux de la factitivité de l'objet : le niveau où l'objet agit comme un manipulateur sémiotique de l'utilisateur, celui où les objets structurent les processus d'action de l'utilisateur, le niveau où les objets créent le contexte de relation interobjective, finalement le niveau où les objets modifient les relations entre les sujets.

- Réintroduits dans la phénoménologie et la sémiotique pragmatique par Charles S. Peirce pour désigner le sentiment de rougéité d'un rouge, de stridence d'un son, etc., les qualia constituent les toutes premières informations qualitatives de l'expérience consciente d'un objet. Ce sont des blocs de sensation qui ne sont pas réductibles à leurs composantes élémentaires. Ils fonctionnent comme des synthèses et des gestalt de relations. Tout l'art de l'assemblage des formes et des couleurs du designer vise à constituer des *gestalt* capables de s'imposer au destinataire qui les traitera comme des entités globales. Si le contexte, les dispositions et les attentes du destinataire sont compatibles avec les intentions du designer, les assemblages produiront les qualia espérés, mais ce ne sera pas toujours le cas (voir Darras, 2009).

Flux de conception-production vers l'objet

Telle que nous l'avons modélisée, la communauté des concepteurs-producteurs a pour mission d'intégrer de la signification et de la culture dans des matériaux, des formes et des volumes, etc.

En tant qu'intermédiaires culturels, les « Designers have to embody culture in the things they design (...) They play an active role in promoting consumption through attaching to product and services particular meanings and 'lyfestyles' with which consumers will identify. Put simply they can be defined as involved in the provision of *symbolic* goods and services. » (du Gay et al. 1997 : 62).

Toute cette intelligence matérialisée et organisée est destinée à favoriser l'expérience sensible des qualia par le consommateur usager, puis à déclencher la chaîne des affordances, enaction, habitudes d'action, représentations, projections identitaires, etc.

Flux de réception et usage de l'objet

Les recherches sur les relations qui sont activées entre l'utilisateur et l'objet ont produit divers paradigmes concurrents. Selon nous, ils décrivent différents aspects et différents types de relation objets/usagers ainsi que différentes conceptions de la relation aux objets. Mais surtout, ils entrent en action en fonction des phases du cycle de la réception. Les affordances et les enactions sont plutôt du côté des habitudes, alors que les représentations sont plutôt sollicitées dans les phases de changement d'habitude, donc de recherche et d'apprentissage.

Nous avons cherché à décrire systémiquement et sémiotiquement ce double flux d'agence réciproque qui caractérise la relation entre un objet et un utilisateur (qu'il soit en phase d'habitude d'action, de changement d'habitude ou d'apprentissage.) Après avoir exploré différentes propositions, nous avons opté pour le modèle interactionnel et exosémiotique proposé par Jacob von Uexküll (Uexküll, 1940, 1956, 1965).

Ce modèle correspond très bien à notre conception du monde comme système composé d'agents humains et non-humains humanisés. Dans un milieu constitué par la rencontre d'un objet et d'un utilisateur, (*Umwelt*), les composantes de l'objet destinées (designées) à l'usage s'affichent sous la forme de « points » offerts aux « contre-points » de l'agent.

En termes sémiotiques pragmatiques et systémiques, nous dirons que dans un milieu constitué par un agir spécifique (une expérience), l'objet est un « porteur de significations » qui s'actualisent lors d'une interaction avec des compléments incorporés par « l'utilisateur de la signification ». Le plus souvent, porteur de signification et utilisateur de la signification ont une longue histoire de co-détermination et d'énaction.

Selon cette approche couplée, l'objet est composé d'un ensemble d'attracteurs s'offrant aux contre-points complémentaires des agents potentiels et à plus forte raison à l'usage d'utilisateur prédisposés à agir (habitude) et aspirant à le faire. Cette relation est optimale quand le design est particulièrement ergonomique et « interpellant ».

L'un des avantages de cette approche pragmatique de la signification, c'est qu'elle permet de mettre fin à la séparation entretenue en sémiotique entre la fonction et la signification. Selon la perspective que nous adoptons, toute fonction est une activation d'un porteur de signification par un agent qui réalise cette signification dans l'action.

- Quand la perspective est en réception, les objets porteurs de signification sont tout d'abord perçus par leur utilisateur au niveau des qualia, certains de ces qualia sont traités à des niveaux sensori moteurs élémentaires par des relations d'affordance.

D'autres affordances plus affinées par l'expérience et les pratiques de la culture matérielle fonctionnent en boucles d'enactions qui font intervenir des habitudes d'action et des représentations.

- Quand la perspective est du côté des porteurs de significations potentielles que sont les objets, ces significations ont été intégrées par des designers lors d'opérations de matérialisation diverses pour que l'objet soit un acteur « humanisé » et cultivé. Il est alors porteur d'agences performatives, factitives, designées pour interpeler un usager et le faire agir selon le programme d'action qu'il matérialise. Lors de la relation, l'objet sollicite et guide les réponses déjà incorporées par le destinataire qui est en phase d'habitude d'action et il induit des tentatives de réponses lorsque le sujet est en phase de changement d'habitude.

Flux entre concepteurs-producteurs et usagers

Cette partie de la modélisation caractérise les relations qui sont entretenues dans le circuit de la production et de la consommation entre les concepteur-producteurs et les usagers. Nos observations et enquêtes nous ont permis de distinguer les opérations de production de « Théories de l'esprit », de *mindreading* et les opérations de *feed-back*.

- La théorie de l'esprit et le *mindreading* ***:*** Nos nombreuses observations de personnes en train d'utiliser des objets dans des circonstances diverses nous ont convaincus que les usagers prêtent aux concepteurs et producteurs une intention de communication, de signification et d'interpellation au travers des objets et de leurs interfaces. Cette communication indirecte avec le concepteur survient à chaque fois que l'on cherche une logique au fonctionnement ou dysfonctionnement de l'objet. Quelques déclarations relevées lors de nos observations en sont de bons témoignages : « c'est pas mal pensé ! », « ce truc est mal fichu ! », « mais comment ont-ils imaginé ça ? » , etc.

Bien évidemment, de son côté, la communauté des concepteurs-producteurs ne cesse, elle aussi d'imaginer les comportements des futurs usagers. Elle le fait en extrapolant ces comportements à partir de tests divers mais aussi le plus souvent en s'auto projetant dans les usages à venir.

À un titre ou à un autre, en sa présence ou en son absence, nous avons tous été confrontés à ce processus de représentation de la pensée de l'autre. Pour ce faire, nous activons une capacité mentale que l'on appelle la théorie de la « Théorie de l'esprit ». Nous sollicitons une Théorie de l'esprit ou une séquence de *mindreading* à chaque fois que nous attribuons à l'objet lui-même une Théorie de l'esprit. Ce processus de « personnalisation » est en fait une extension de propriétés mentales de l'humain aux artefacts non-humains. L'objet s'y prête d'autant mieux qu'il est effectivement un lieu d'intelligence déléguée, distribuée et matérialisée.

Dans notre modélisation, le flux des « Théories de l'esprit » et les opérations de *mindreading* sont donc à double sens, ils sont imaginés et testés en conception-production et projetés ou activés lors de l'usage ou de l'analyse. Notons à ce sujet que la plupart des analystes se contentent de travailler sur les « théories de l'esprit » qu'ils attribuent aux designers et c'est précisément ce biais que nous tentons d'éviter avec notre modélisation tripolaire.

. Pour nous, ces processus sont un des hauts lieux d'activation des flux de communication entre les humains et le monde non-humain humanisé des objets.

- Feed-back : Autant les projections de « Théorie de l'esprit » se déroulent sans conséquence directe sur la transformation de l'objet, autant les *feed-back* sont destinés à le stabiliser ou à le modifier. Nous considérons donc comme appartenant au feed-back tous les tests d'utilisation et toutes les enquêtes de satisfaction qui sont en général conduits par le service marketing, mais aussi lors de toutes les opérations de co-design qui se réalisent dans le cadre du design participatif.

Conclusion

La conclusion de cette étude est matérialisée dans le schéma global suivant. Il rassemble et articule toutes les composantes décrites et explicitées étape après étape et phase après phase dans cet article.

Pour bien fonctionner, ce diagramme doit être pensé dynamiquement et complété par différents zooms sur les parties complexes de chaque phase et de chaque flux.

Selon nous, toute étude d'une expérience avec un objet doit être conçue comme l'étude d'un signe action complexe. Elle réclame non seulement le réglage des quatre phases engagées dans l'interaction mais aussi l'étude approfondie des différentes interactions qui s'y déroulent, ainsi que l'étude des flux qui relient chaque pôle activé.

Non seulement cette modélisation permet de traiter de la signification d'une expérience lorsqu'elle s'actualise dans une habitude d'action prévisible parce que récurrente, relativement stable et partagée par une communauté, mais elle permet aussi de traiter de la dynamique du changement des sémioses, des crises comme des phases d'apprentissage. Ceci, tant en conception-production qu'en réception-usage, mais aussi lors de leur articulation (Darras & Belkhamsa, 2009c).

Author Biography

Sarah Belkhamsa

Sarah Belkhamsa est chercheuse au Centre de Recherche Images, Cultures et Cognitions (EA LETA/CRICC) de l'Université Paris 1 Panthéon-Sorbonne et professeur assistante de design à l'Ecole Supérieure des Sciences et Techniques du Design à l'université de la Manouba, Tunisie. Ses recherches portent essentiellement sur l'approche sémiotique et systémique du design produit ainsi que sur les design studies et les cultural studies. En 2010, elle soutient son doctorat en Arts et sciences de l'art, spécialité Design à l'université Paris 1. Ses publications portent sur le design et la culture matérielle.

Bernard Darras

Bernard Daras est professeur de sémiotique et de méthodologie de la recherche à l'Université Paris 1 Panthéon-Sorbonne. Il est actuellement directeur du Centre de Recherche Images, Cultures et Cognitions (EA LETA/CRICC), du Master Multimédia Interactif, du Master Etudes Culturelles et des formations professionnelles aux Métiers des Arts et de la Culture à l'Université Paris 1. Ses recherches concernent prioritairement les approches sémiotiques, pragmatiques, constructivistes, systémiques et interactionnistes de la culture visuelle et matérielle. Il a publié et dirigé de nombreux livres et revues et publié de nombreux articles scientifiques.

Dis/Ability teaches Design!

Tom Bieling, Design Research Lab, Deutsche Telekom Laboratories, tom.bieling@telekom.de

Abstract

What can Design learn from bodily Impairment or social Disability?
In our paper, we claim that general human and artificial communication systems might be enriched by acknowledging and adding specifics of different ways of communication, perception and locomotion that refer to bodily impairment (Bieling, 2009).

In this regard, we assume, that disability occurs not least through influence by design and culture (e.g. built environment). As Caspers (2006) believes: disability is the lacking ability to “deal with bad design”. Besides the assumption, that design provokes disability, we will furthermore describe how disability can inspire and alter design.

Schillmeier (2009, 79ff) sees disability less as an effect of bodily impairment, but more as a phenomenon of social construction. Oriented towards John Dewey (1929) and Michel Foucault (1963) as well as to Science, Technology and Society Studies (STS) he conceptualizes disability as an event. In this context he asks, who (when, where and how) becomes disabled or not. Schillmeier states ›dis/ability‹ as a “heterogenic, material event”, which connects “social and non-social relations of human and non-human actors, of things, bodies, technologies, sensorical pratices” and becomes able to be experienced in the sense of disabling as well as enabling (›dis/abling‹) scenarios. (Waldschmidt/Schneider, 2009, 17)

„With the multiple objects of ›Disability‹, the parliament of things becomes obvious*:* the assembly of bodies, technologies, and things, as an articulation of reality of natures and cultures“. (Schillmeier, 2009, 79ff) By exploring disability from an *›out-of-center‹* position, we aim to use it as a “knowledge-constituting moment, for the analysis of the (majority of) society”. (Waldschmidt/Schneider, 2009, 15)

In our investigation we consequently focus on integrative processes: An improvement of social integration, as well as an improvement of communication systems and devices through design (research), inspired by and learning from communication patterns of the bodily (and therefore socially) impaired.

We will discuss results and examples of the design research project *Speechless*, an interdisciplinary project run at the *Design Research Lab* of *Deutsche Telekom Laboratories,* Berlin. One main focus of *Speechless* lies primarily on deaf and blind communication and perception, as well as on the transferability of alternative forms of communication to general human (interpersonal) communication and human-computer-interaction (HCI).

During the first project phase, we have been working together with deaf people (in collaboration with *Sinneswandel,* a Society to support deaf and hard of hearing people, as well as with students of Deaf Studies at *Humboldt University Berlin*). The enhanced visual sense, the three-dimensional communication space, as well as linguistic and psychological particularities (Koller, 2008) constitute the main focus of this project phase.

In addition, we developed workshops with sighted and hearing people. By consciously deactivating certain senses or bodily functions (e.g. blindfolding), we aim to gain knowledge for designing multimodal interfaces. How to navigate without seeing? How to communicate without spoken or written language? Etc…

One or more impaired senses sharpen the remaining senses (Montessori, 1952). This can lead to individual skills that differ from common ones. A deaf person for instance, might not hear the music in a discotheque, but in comparison to the hearing people, he or she can to a certain extent easier communicate during the loud music – even over distance.

If we, as e.g. interface designers, understood more about communicative variations caused by bodily impairment, we might be able to create systems that enrich general human communication, by transferring and combining properties of such different variations.

Thus in our research project, we have so far been developing concepts for service- and product-solutions, that might help to overcome some of the limitations caused by bodily impairment on the one hand, and help to enhance the communication and locomotion of “non-disabled” people on the other hand. We aim to open up new perspectives in HCI and add a completely new aspect to design driven inquiries in two respects:

1) By taking bodily impairment as a source of inspiration for the development of Information-Communication-Technology (ICT) in matters of human communication and perception

2) By investigating augmentative and alternative communication (e.g. sign language) from an interfacial point of view. (Bieling, 2009)

Our research project opens up a wide field of new ideas and problems to solve in the learning field about properties of alternative and augmentative communication. It becomes obvious a high potential of knowledge about and systematic use of such systems of communication (Bieling, 2009a), to open up perspectives for designing human-machine-interfaces in particular, as well as for design research in general.

Disability inspired Design/Research; Disability Studies; Alternative Communication; HCI; Social Innovation; Participatory Design; Cultural Studies.

This paper introduces an approach to implement an integrated model of disability in design research, a model aiming at merging aspects from the medical and social perspectives of disability.

The paper illustrates a framework for the approximation of two disciplines – Design Research and Disability Studies. By presenting examples of different aspects of design in a disability context and disability in a design context, the paper aims at revealing fundamental perspectives for design research.

We claim that general human and artificial communication systems might be enriched by acknowledging and adding specifics of different ways of communication, perception and locomotion that refer to bodily impairment (Bieling, 2009). The framework can be considered as an experimental stage set for design practice and theory, envisaging an inclusive comprehension of (inter- and trans-) disciplinary development.

By challenging general concepts of disability and ability (›dis/ability‹) our approach may be both contributing to the field of Design Research and the field of Disability Studies.

Background

Against the background of the demographic change of growing life expectancy across the world, we are facing an increasing number of individuals becoming disabled or in need of care (Tervooren, 2002, 1). Thus the phenomenon “disability” is going to become a “universal experience of our society” (Hermes, 2007). Questions about and definitions of disability will have to be reformulated, in order to avoid exclusion of growing parts of society. This also means to analyze societal norms, traditions and values leading to certain perspectives on disability.

Major questions in this context are related to the general assumptions about what disability is about, and about who becomes disabled when and by what or whom. The World Health Organization (W.H.O.) recognizes disability as a “complex interaction between features of a person’s body and features of the environment and society in which he or she lives” (W.H.O. 2001). Against this background “disability” is particularly being viewed as social disability, caused by bodily variations. As Pullin (2009, 2) states: “People are […] disabled by the society they live in, not directly by their impairment”.

Traditionally, for a long period disability has been subject of interest to the applied sciences (medicine, therapeutic-, special needs pedagogic etc), basically focusing on the prevention, deletion or relief of bodily “damage”.

The intention may be honourable however it contains at least two problems: First, the “problem-solving” approach can not cover the complexity of disability, since disability is a very common experience in human life and human beings are no machines, but highly vulnerable and breakable (and actually only “temporarily non-disabled”). Secondly, viewed from a historical and cultural anthropology position, it becomes obvious that disability has neither been a universal cultural category, nor a uniform social practice. (Waldschmidt/Schneider, 2009, 10)

To understand and analyse disability and phenomena of embodied difference as a historical, social and cultural construction, has been the starting point for ‘disability studies’ to develop alternative perspectives which correct or widen the medical/pedagogical approximations to disability.

Confronting the *medical model* with the *social model of disability* allows not least a critical reflection on fundamental concepts of order, which become manifested in antipodes like ‘normality and difference’ or ‘health and illness’.

Different Models: The Social, the Medical, the Integrated.

The *medical model* of disability (also known as the *deficit model*), defines disability as a direct consequence of an impairment. The biological-medical point of view declares disability as a medical condition of the body that is medically diagnosable. Disability activist groups view the medicalisation of disabled peoples’ everyday lives as a form of social oppression (Anderberg, 2005, 2; Johnson/Woll, 2003). Batavia (1999) describes how this point of view considers people with disabilities “paternalistically as dependent patients rather than as self-directed individuals fully capable of autonomy”. Turner (2001) misses in this context a focus on the “actual functions desired by the individual” (Anderberg, 2005, 2). A quantification of disability, by clinical measuring and classifying is being criticized by Anderberg (2005, 2), who claims that it is “alienating rather than supportive to the individual to be faced with a clinical analysis, a professional language of description and a lack of considerate interest for the functions most relevant in her/his own context”.

The *social model* of disability (UPIAS 1975) originally refers to a “rather materialistic view auf the causes of disability” (Anderberg, 2005, 2), but can generally be referred to the social construction of disability. Anderberg (2005a, 2) summarizes its key message as follows: “Societal structures should be changed to accommodate people with disabilities, not individuals that should be changed to fit into a rigid environment and society”. Disability is not seen as a “characteristic of the individual but rather the situated response to an inaccessible, inflexible and un-adapted environment and society” (ibid.).

However, neither the medical nor the social model of disability is exclusively satisfactory for design (Anderberg, 2005, 1). The medical model, as a “problem-oriented” approach, oversimplifies disability as an “individual characteristic and directs attention towards individual adjustments and means” (ibid.). The social model, on the other hand, directs attention towards ideological and political analysis, not towards proposals for “practical everyday solutions for experienced functioning” (ibid.), or suggestions to practically change situations into preferred ones.

Seelman (2003) introduces an *integrated model* as an attempt to merge, or bring closer the medical and social perspectives. Others have been contributing to this attempt, some of them linked to the fields of biocultural anthropology.

According to the social and medical models, Schillmeier counterposes an object-centred, experience- and occurance-logical concept of the nature(s)/culture(s) of disability. He states ›dis/ability‹ (Schillmeier, 2009) as a “heterogenic, material event”, which connects “social and non-social relations of human and non-human actors, of things, bodies, technologies, sensory practices” and becomes able to be experienced in the sense of disabling as well as enabling (›dis/abling‹) scenarios. (Waldschmidt/Schneider, 2009, 17)

Schillmeier describes, how empirical research in STS on disability emphasizes the complex event-character of disabling and enabling realities in everyday practice. Disability, understood as “dis/abling practices” underlines the situational links and connections of human and non-human actors, processes and practices (Waldschmidt/Schneider, 2009, 91, according to: Schillmeier 2005; Law/Moser 1999; Struhlkamp 2004).

Furthermore he points out, that it is an empirical open question, how, where and when disability appears. He claims that ›dis/ability‹ refers to a complex interaction between bodies, senses, feelings, symbols, experiences, technologies and technological infrastructures, of situational constructed space-/time-relations etc. that let appear social practices in an enabling or disabling sense. (Waldschmidt/Schneider, 2009, 91)

According to Gilles Deleuze and Felix Guattari, becoming disabled is not to be understood as an “evolution through origin and heritage”, neither in a sense of individual impairment, nor as a result of societal structures. It rather appears through “alliances of human and non-human, social and non-social acteurs, objects and processes” (Schillmeier, 2009, 91; according to Deleuze/Guattari 1992, 325)

„With the multiple objects of ›Disability‹, the parliament of things becomes obvious*:* the assembly of bodies, technologies, and things, as an articulation of reality of natures and cultures“(Schillmeier 2009, 79). Moser and Law (1999) and also Myriam Winance (2006) have in this context used ANT (Actor-Network-Theory) to elaborate on disability and ability. We propose to implement the ANT point of view into our perspective to re-examine the mentioned models.

How do these different models influence an understanding of and active contributions within or amongst the disciplinary fields surrounding design and disability? How is this linked to certain “properties” of these fields?

Situation and Disciplinary Properties

Whenever it comes to combine the two parameters “Design” and “Disability”, discussions immediately turn to focus on what can generally be summarized under terms like “Universal Design” (Erlandson 2008, Herwig 2008, Mace et al. 1991), “Design for all”, “Design for accessibility”, “Barrier-free Design”, “Transgenerational Design” or “Inclusive Design” (Imrie/Hall, 2001). Despite the terminological and sometimes normative differences of these, Mitrasinovic (2008, 419) finds that “the ethical principles are analogous across countries and regions”.

According to our argumentation we consider these in the broader sense again to be summarized as Design *for* Disability (DfD). Meaning, that projects in such fields primarily focus on design development that is intended to protect people with disabilities from being excluded from “using” certain designed objects, processes, services, systems or environments.

Complementary to DfD we propose an approach that could simply be summarized as Design *by* Disability (DbD), meaning, that (not only) Design could be generally and specifically inspired by Disability, or better: by experiences linked to certain disabilities.

However in this regard we also acknowledge the existence of the opposite, which could be called Disability *by* Design. While Caspers (2006) describes how Design can provoke disability, and Anderberg (2005, 4) claims that “technology and design can […] be seen as mediators of disability”, Jöhnsson (2005) sees “artefacts as being imprinted with the goals, visions, and thoughts of their constructors. […] No neutral carriers of information”. Technology and its artefacts thus influence on the individual. They “affect how we relate to things and people […] and how we perceive the world. […] From a socio-cultural perspective, we learn and develop by using cognitive resources that are incorporated in the artefacts as information, procedures and routines. Our way of thinking is guided and coloured by the intellectual and physical tools we use”. (Säljö, 2000; in: Anderberg 2005)

The complex correspondence of the individual and technology within the world of artefacts is described at Goggin and Newell (2003), who explain the example of how the wheelchair can be “theoretically regarded as an aid to mobility”, but as an effective enabler it can only be regarded in a system where the environment is adapted to wheelchair use: “Without the necessary pavement, curbs, ramps, and funding of so-called access, the wheelchair as a system has different meanings and effects” (ibid.).

The correlation of body and space in this context is described by Freund (2001), who claims that spatial organisation constructs bodies and offers bodily possibilities and constraints: “The body is not simply a culturally constructed representation nor is it physically shaped like clay by social force, but it is experienced and 'lived-in' differently in various socio-material environments and material cultures (e.g. technologies)" (Freund, 2001; in Anderberg 2005).

We can therefore assume, that disability occurs not least through influence by design and culture (e.g. built environment). As Anderberg (2005, 5) states: "The body and the various technical artefacts around us make up a system that enables or disables us to perform desired actions".

As a "manifestation of economical, political, social and cultural concepts and individual wishes and ideas" (Anderberg, 2005, 5), technology (and design), its consequences, its use and meanings become important for disability studies. Anderberg (2005, 5) complains that the Disability Studies Community fails to directly acknowledge the importance of technology and design for the field, which (if so true) would be unfortunate, because "technology and design are too important to be left only to the technicians and designers; it cannot be seen as being separate from other instances of the culture we live in. Technology and functional aids belong in the heart of Disability Studies." (ibid.).

As far as to our knowledge, the acknowledgement of technology (and Design) within parts of the Disability Studies Community has been evolving. Nevertheless we still assume Design as to be very important for the inclusion into Disability Studies. We like to mention two reasons for that: First, the consequences and correlation of Design and Disability, as we described, are very complex and not to deny. That means secondly a high potential of societal interventions and active change of situations, not least through the help of design.

In order to be able to analyze the correlation, the impact and the relevance of demographic and socio-cultural categories, especially concerning aspects of disability, on form and practice of design (process), as well as its effects on usage and practical use of design within these categories, it could be helpful to define and understand the relevance of the scientific approach of disability studies to design research (and vice versa), by taking a closer look to disability studies' fields of interest and 'self definition':

Carol Gill (1998), underlining that Disability Studies are based on the social model, points out, that disability in every society is being defined through a complex interplay of political, economical and cultural values. Thus Disability Studies are interdisciplinary, meaning that the construction of disability needs to be examined not only from a medical or pedagogical point of view, but also from the perspectives of e.g. sociology, law, economics, literature and media studies, historical or cultural sciences.

Disability studies therefore focus on the social/political/economical/cultural context of disability. A major goal is not, to avoid, optimize or heal certain individual impairments, but rather to critically analyze the social processes of disability. The analysis shall be less intended to find solutions to 'correct' disabled people, but rather to generally find ways out of excluding social systems and processes (Gill, 1998).

We argue that our approach of combining the two disciplines Design Research and Disability Studies might not least contribute to the latter intention, by additionally substantiating and clarifying an enhanced and reflected understanding of disability.

Design Research is especially destined to be complementarily involved in the Disability (Studies) debate, since it is not only descriptive (like Disability Studies could be occasionally recognized as), but also projective and proactive. Nevertheless this implies certain requirements to the discipline of Design Research, first of all a methodology that allows dealing with uncertainty, ambiguity and complexity in real-life situations.

However helpful for design's involvement in the disability debate, is the awareness of design's general stance and relation to "problems".

Problem Solving and Problem Making

Pullin describes how Disability can provoke problems in people's lives, either directly or indirectly. However such problems are "either viewed as being inherent in an impairment itself or as being created by the designed environment and other people's behaviors". (Pullin, 2009, 41) This point of view stands in close relation to Schillmeier's (Waldschmidt/Schneider, 2009, 17) characterization of dis/ability as an event which connects “social and non-social relations of human and non-human actors”.

In the different disciplines dealing with disability, we recognize different approaches and understandings of disability. These stand in close relation to their respective educational backgrounds. Medical engineers for instance seem to be attuned to problems. After Pullin, a typical engineering methodology might start with “*Step1: problem definition*, followed by *Step 2: solution generation*, and so on”. The discussion, to what extent design is to be defined in its broadest sense as problem solving, has been going on for a long period (Antonelli 2008; Funke 2003; Heufler 2005; Mayer 2004). Diefenthaler (2008, 307) claims that the problem solving process in design is “seldom linear because evaluation techniques are an essential feature. The varieties of possible solutions originate for the most part as short-term proposals ”which she relates to the fact that a design process is not always and “only influenced by a rational, analytical work method, but also by an emotional, intuitive process” (ibid.). While ongoing discussions seem to seek the role of a designer between the two poles of a designer as a “Problemsolver” or “Sensemaker”, Antonelli adds a third role, which is the “Problemmaker”. (Antonelli, 2009). An interesting alternative to the (long ago insufficient) term “Problemsolver” and the (also not really satisfying term) “Sensemaker”: The concept of “problemmaking” becomes especially interesting, since it contains two meanings: First, the acknowledgment of Rittel’s *wicked problems* (Rittel, 1973) and second, the idea to cause problems on purpose for instance by irritating people (respective users). The latter is described by Bredies (2008), who argues that “Innovative artefacts without established cultural conventions will necessarily irritate the user to a certain extend. […] Designing innovative artefacts therefore provides an area where designers can exploit the irritating moment as an opportunity” (in context of Bredies’ Paper: for co-design in use).

We will argue in our paper, that without completely denying the aspect of “problem solving”, the concept of “problem making” is of high potential for approaching disability in context of design, as well as it is for backing up the societal process of modifying general perspectives on disability.

Because of the “nature” of disability and the “culture” of engineering, Pullin (2009, 41) sees design for disability and inclusive design as “usually approached as an exercise in problem solving […] This also has something in common with the clinical tradition of diagnosis and treatment”.

We therefore agree on the point, that some of the challenges facing design for disability might “not best described as *problems* to be *solved”* and that “issues not easily defined as problems are likely to be overlooked” (Pullin, 2009, 41).

However in our general understanding and in the specific understanding that laid the foundations for our project, we do not (only) focus on *design for disability*, but wish to widen the research area in a sense of *disability by design* – *design by disability*. Now, why doe we propose and how are we going to achieve this?

Convergence – Design Knowledge and Disability Knowledge

Not all design, and especially not design research, is about solving problems. According to Fällman (2008) the process of a design research project can be seen as a triangular model defined by the activity areas of “design practice”, “design studies” and “design exploration”. The latter may still require solving problems that arise along the way, but “frequently as a means to an end rather than as an end in itself” (Pullin, 2009, 43). We may localize here a “subtle yet fundamental inversion of engineering methodologies that will usually include a creative exploration of alternatives, though as a means to the end of solving the core problem” (ibid.).

However a Designer may “revisit an object, a material, or a medium that has already been successfully designed, designed with, or designed within […] before, in which case the value does not lie in solving an unsolved problem” (Pullin, 2009, 41). Especially Design Researchers may as well explore completely new fields, whilst potential questions or problems to be solved might appear not until the research process has been going on for a while already.

Many art and design school disciplines, for instance, involve exploration that can appear playful, vague, experimental and open-ended, but its intent may be no less serious for possible results to gain from it.

We believe that such exploration approach, which seems to be characteristic for design research, could be an enriching input for Disability Studies. On the other hand, the design exploration could receive important input from Disability Studies' social or integrated model perspective, for widening the spectre of possibilities by simulating or experiencing different role perspectives.

The Design-Research-from-a-Disability-Studies-perspective or the Disability-Studies-from-a-Design-Research-perspective might even be imaginable in a sense of an *about/for/through*-model (Fig 1): While Research *about* Disability would represent a rather critically analytical view on disability, possibly but not necessarily based on the social (or integrated) model, Research *for* Disability would represent the medical-engineering-, problem-oriented perspective, possibly but not necessarily based on the medical model. This second point of view might occasionally also apply to what we summarized before under DfD, but we admit that this might not generally be the case and maybe still has to be discussed). The third point of view would be Research *through* Disability, basically analogue to what we described before as Design *by* Disability. It would represent the most explorative part, where Design Research could provide a broad spectre of methods (empathic modelling, capability simulation, visualisation, prototyping, etc) to understand disability in a productive sense. It would be the field, where we could learn from Disability (better: from certain disabilities) in order to transfer knowledge into general or specific other fields (e.g. transfer properties from blind navigation into digital navigation systems).

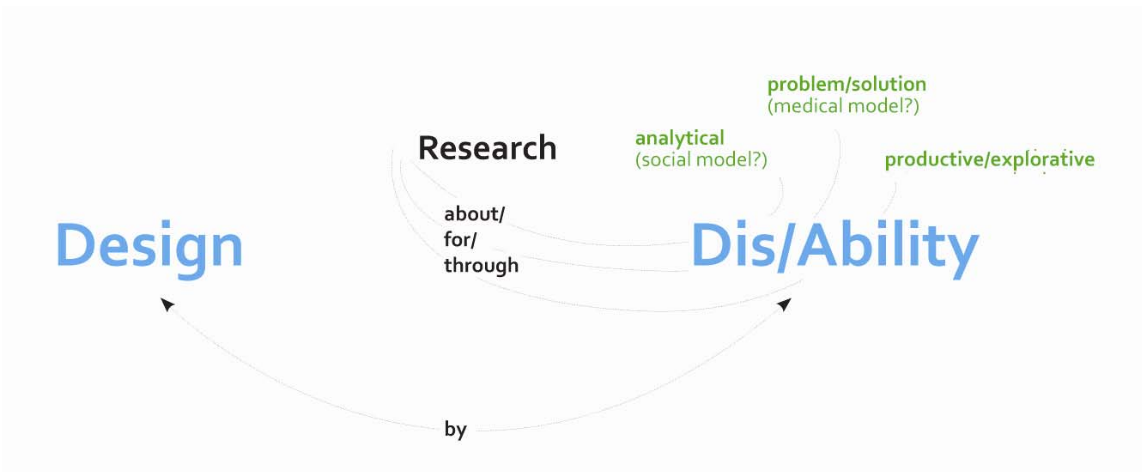

Fig 1 Research about/for/through Design and Dis/Ability

However we must obviously consider disciplinary differences in how we produce knowledge and how we use it.

Thoutenhoofd and Naue (2007) describe how knowledge is socio-culturally and socio-linguistically shared as much as it is empirically demonstrated and peer-validated. They claim that "lived experience is centre-staged as a bottom-up or grass-roots form of knowing that is as often intuitive (or 'native') and phenomenal as it is reflexive and objectified." In their explanation, Thoutenhoofd/Naue (2007) describe deaf and disabled people as subjects of "highly formalised, normative kinds of knowledge practices – in fields as diverse as medicine, economics, biology, education and psychology – which do not speak *with* them, but *about* them (or worse, *for* them). […] Knowledge within these fields is of the body as a site of multiple meanings that fractures any coherent sense of self and identity. In this third scholarly formation knowledge is essentially derivative of professional practice."

Design Research may also offer descriptions and explanations of what naturally or culturally exists, but unlike traditional science, Design aims at producing and conceiving artefacts. As Simon describes it as an "action aimed at changing existing situations into preferred ones".

Design explores different possible solutions for a problematic situation (The definition of "problematic" is certainly a matter of perspective). Unlike traditional social sciences, it is rather about 'what can be' (and how it can be), than about 'what is'. This stance about a future world state does necessarily involve uncertainty. Since knowledge about an existing situation "does not necessarily lead to knowing how to change it, design knowledge […] needs to be useful not only to inform reflection, but also anticipation and projection of those who design (DRLab, 2009).

Thus the knowledge produced in Design Research aims to inform and enable present and future design practice. It is therefore not only descriptive, but also projective. In other words: "it transcends the present to enable projective actions" (ibid.).

Method

In order to disentangle the complex construct of guiding questions within the range of the two parameters "design" and "disability", we fragment it into sub-questions which again shall lead to sub-answers. With this rational method (Descartes), we draw parallels to Choopankareh's (2006) approach: The human subject as part of a society on one hand is being put into relation to the product/artefact as part of the environment on the other hand. In our research project we shall examine disability as a societal phenomenon leading to a complex of problems for (certain) individuals, in order to find out, what role design can play in that context.

In order to face the resulting subdivision into two relations – "Human - Artefact" and "Disability - Design" – we propose to implement these into Findeli's model for design/research questions/answers (Findeli 2008). If we took for example the following as a research question: What can Disability and Design learn from each other? Then, this broad question could be framed into several specific design questions, for example: How can we generally transfer knowledge from Alternative and Augmentative Communication (AAC) into human-computer-interfaces or specifically into ICT-Devices? Or more precisely: What functions (or aesthetics etc.) can an electronic device contain, that is inspired by certain disability related aspects? The possible design answers may here, in turn, be helpful in answering the research question(s).

In our case study, we laid a strong focus on empathic modelling, capability simulation, prototyping, visualisation, interviews or audio- and video-documentaries. In the following we will give an overview about three of our different method approaches (Collaborative workshops with experts and non-experts; Self-Experience; Fictional and non-fictional Input) and describe their application in the respective case. The results show how the methods help designers to structure and organize information about the context and identify productive opportunities of understanding, intervention and transferability for design.

Collaborative Workshops with Experts and Non-Experts

During the first project phase, we have been working together with deaf people (in collaboration with *Sinneswandel* a Society to support deaf and hard of hearing people, as well as with students of Deaf Studies at *Humboldt University* Berlin. The enhanced visual sense, the three-dimensional communication space, as well as linguistic and psychological particularities (Koller, 2009) constitute the main focus of this project phase.

In addition, we developed workshops with sighted and hearing people (Fig 2 + 3). By consciously deactivating certain senses or bodily functions (e.g. blindfolding), our aim was to gain knowledge for designing interactivity. One or more impaired senses sharpen the remaining senses (Montessori, 1952). This can lead to individual skills that differ from common ones. A deaf person for instance, might not hear the music in a discotheque, but in comparison to the hearing people, he or she can to a certain extent easier communicate during the loud music – even over distance.

Some of our guiding questions were: How to navigate without seeing? How to communicate without spoken or written language? These questions were meant to lead us to more general aspects: How can we change or widen the function of an interface? How can we transfer concepts into navigation systems or communication device?

Both types of the workshops were based on a participatory design approach. Whilst the workshops with 'non-disabled' people focused more on explorative aspects, the main focus of the workshops with Deaf people was on actual Co-Creation.

Thus in our workshop approach, we follow a two-poled model of participation, by collaborating with disabled people as experts (e.g. through ethnographic observation), and with non-disabled people as non-experts (e.g. through simulation or empathic modelling).

Figure 2

Figure 3

Fig 2 How to reduce complexity and thereby avoid confusion caused by missing language skills? In this workshop the participants (age: 6-11 yrs) explored the idea of communication without written or spoken language, using visual communication and symbolic language.

Fig 3 In another workshop the participants produced prototypes in context of touchable and sensitive surfaces. How should certain functions or situations become tangible? Therefore they tried out different material and haptics (e.g. hard, soft, cold, rough, clean, even, flat, uneven, flexible etc.).

Self-Experience

In our research project we claim »action« as an important part to actually experience and understand the diverse perspectives that we collect. While we link these to existing knowledge and theory, and then synthesize the assumptions in roughly estimated principles, before we selectively involve external people in collaborative workshops, we try to experience as much on our own as possible. As an example we will present impressions and insights in extracts from our video documentary “One Day blind in Berlin” (Fig 4).

Fig 4 Standing next to a speaker, not being able to see, leads to a different posture of the head

Another example is our experience in Sign Language: One way to deal and to engage with a new communication system is to learn it. Therefore, we have been attending Sign Language classes, which has been a revealing experience physically as well as theoretically. It already gave us the chance to gain insights into the visual and expressive language of deaf communication, the deaf community and culture, as well as, how disability offers new horizons and perspectives to alternative ways of communication.

Fictional and non-fictional Input

As another important tool for our topic exploration, we organize so called *Disability Movie Nights*, where we show and discuss film-related material close to our field of interest. The material we show and watch may range from films, documentaries, short movies, video art to music clips.

We identified these film screenings as a helpful method to dive deeper into a topic and to inspire the design research process, since both the shown material and the involved audience broach the issues of different (external, internal, expert, non-expert, poetic or scientific) positions.

It is generally claimed that movies have an effect on people. Against this background, we see a possibly fruitful connection between science, mainstream and screen fiction. Depending on the platform, it allows different transfers: A documentary e.g. could underline the more analytical part (»What is?«), whilst a fictional movie could represent a rather projective part (»What, if…?«). Thus, we use film screenings for both a deeper understanding and associative thoughts.

Transfer / First Results

The methods we used for exploration and production so far are generally based on a human-centred and participatory design approach perspective, as described in “Collaborative Workshops…”. Nevertheless we maintain a cultural studies perspective in our process, as described in “Fictional and non-fictional Input”.

As Design knowledge has different kinds of representations, the form of our knowledge collection ranges from more theoretical (principles) to more practical parts (specific configurations). Besides our verbal argumentation we therefore argue through visual or multisensual representations, like for example sketches (Fig 5-8), images, videos (Fig 9) or prototypes (Fig 10).

Thus in our research project, we have so far been developing concepts for service- and product-solutions, that might help to overcome some of the limitations caused by bodily impairment on the one hand, and help to enhance the communication and locomotion of “non-disabled” people on the other hand. We aim to open up new perspectives in HCI and add a completely new aspect to design driven inquiries in two respects:

1) By taking bodily impairment as a source of inspiration for the development of Information-Communication-Technology (ICT) in matters of human communication and perception

2) By investigating augmentative and alternative communication (e.g. sign language) from an interfacial point of view. (Bieling, 2009)

After collecting various data, including basic theoretical knowledge, experience based impressions, survey based information and collaborative workshop grounded results, the next step after analysing and interpreting has been to actually find out how to evaluate these data and synthesize them for possible design solutions.

In our investigation for example, we collect different characteristics of deaf communication that seem to be special from a non-deaf perspective. In the following we summarize and classify some of the important characteristics of deaf communication we found (Koller 2008). We claim that it might be interesting, whether these characteristics could be relevant for the communication of hearing people, for the future design of human-machine-interfaces or in design in general.

Relevant for communication of the Hearing:
. Discrete and focused communication, despite variable distance
. Attention control
. No constraints through loudness

Relevant for human-machine-interfaces:
. Referencing objects and persons in signing space
. Definition of pronominal references in signing space
. Concept of time in signing space
. Dividing the signing space into categories of valuation
. Roll change
. Lifting, lowering and projecting the signing space
. Whisper and Scream in Sign Language
. Plural by repetition
. Temporal aspects for the variation of sign language
. Object placeholders (classificators)
. A high amount of the singings can be differentiated by (body) movement
. Non-manual means of expression

Of general interest:
. Advantage in occupational fields with focus on visual work
. High information density through additional visual
support
. Impact on well-being
. Visual Rhythm

After several workshops, the project resulted in various physical, visual and audiovisual prototypes that contributed to visualising the findings and theories explored.

Using the examples mentioned above as a basis for concepts, transfers and solutions, we will present in the following some results from our ideation sessions. An appropriate feasibility check needs to be done as next step. However it is rather important is to imagine concept and solutions, even though some of them might lie ahead. Subsequent, in apparent cases, we will analyse technical methods for solutions.

In the following, we collect some illustrations, resulting from our ideation.

Fig 5: Potential for deaf/non-deaf: high/high

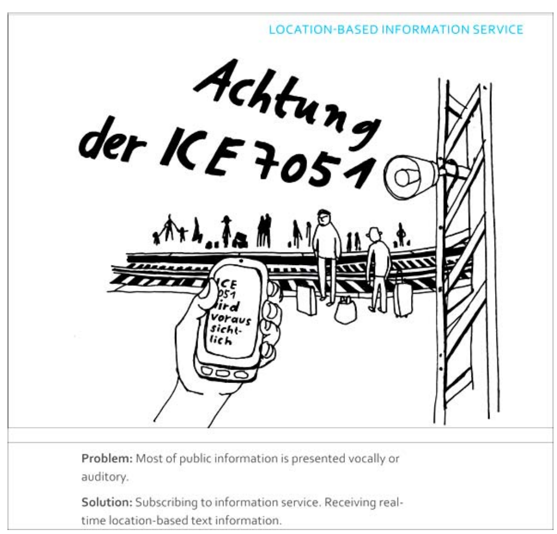

Fig 6: Potential for deaf/non-deaf: very high/very high

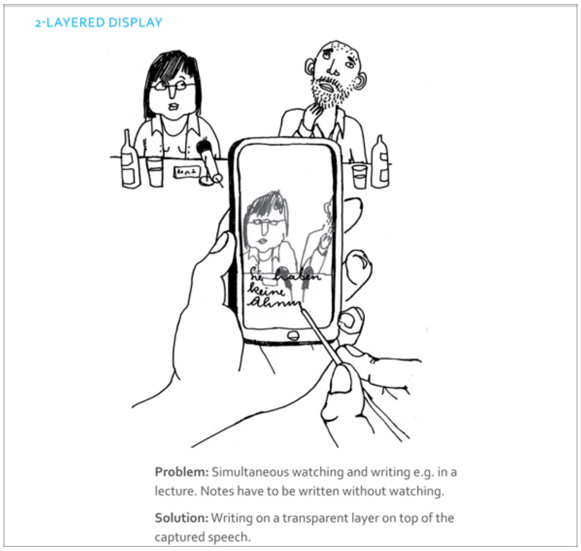

Fig 7: Potential for deaf/non-deaf: med./medium

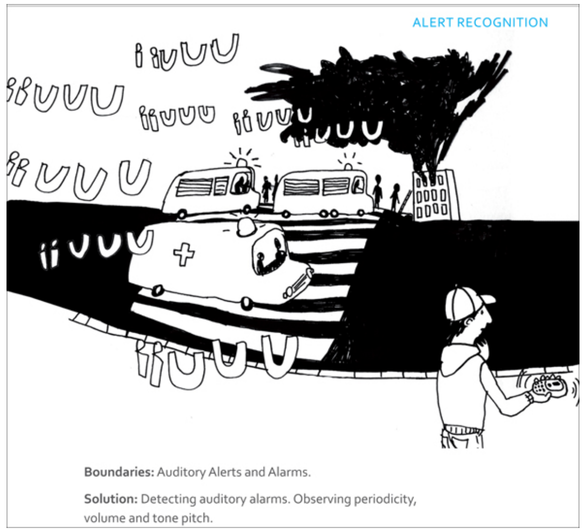

Fig 8: Potential for deaf/non-deaf: very high/medium

Figure 9

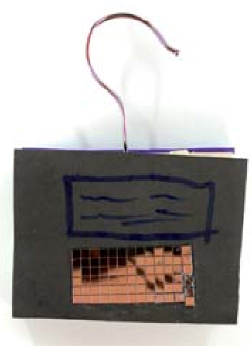

Figure 10

Fig 9 Video Prototype "Virtual Placeholders". The concept of referencing objects in 3D signing space is conceivable for applications in HCI.

Fig 10 Prototype "HangUp" helps to support deaf communication. But also non-deaf people could use such device, for example while cooking driving or working.

Conclusion

Our research project opens up a wide field in the learning field about properties of alternative and augmentative communication. It becomes obvious a high potential of knowledge about and systematic use of such systems of communication (Bieling, 2009a), to open up perspectives for designing human-machine-interfaces in particular, as well as for design research in general.

The transfer of such concepts from augmentative and alternative communication, not least to HCI, can serve designers, engineers, pedagogues in various ways. First of all it can help to overcome communication barriers (by a technique of mediation or translation). Moreover, it opens up new perspectives in learning (language, dialog, cultural/behavioural differences etc.). Furthermore, it widens the spectre of interactivity with the help of human interaction patterns, that are (if not intuitive) at least easy to learn and that have already been proven to function in certain contexts of human (e.g. deaf) communication systems.

For example Sign Language can be an input to human and human-machine-interaction, since it contains transferable rules for syntax and semantics and therefore alternative possibilities to collect, impress and present thoughts. It also enables to use different organs and parts of the body.

Not least in this project, our aim is to find out to what extent we can provide and use a confrontation with and through design within such processes, to evolve innovative methods, products/services and communicative models.

Based on these insights, our research project shall sensitise the design profession as well as related disciplines to realise the various perspectives for HCI, ICT and general human communication as well as for social inclusion through design research, inspired by observations on so called disability.

If we, as e.g. interface designers, understood more about communicative variations caused by bodily impairment, we might be able to create systems that enrich general human communication, by transferring and combining properties of such different variations.

By recognizing disabilities as expertise (e.g. a blind person as an expert in navigation through the dark; a Deaf person as an expert in communication in very loud environments), Design Research in collaboration with Disability Studies might contribute towards an advanced, reflective understanding of disability.

By exploring disability from an ›out-of-center‹ position, we aim to use it as a “knowledge-constituting moment, for the analysis of the (majority of) society”. (Waldschmidt/Schneider, 2009, 15). Siebers (2006, 64) points out the importance to “establish disability as a significant value in itself worthy of future development”. Especially in view of the future challenges of genetic engineering, reproduction and bio-ethics, we might have to reformulate questions concerning disability in modern, medicine-technically dominated societies. What characterizes disability in times of re-inventing the human body? And how do we have to evaluate societal meanings of ›embodied difference‹?

Linking Design Research and Disability Studies to explore ›embodied difference‹ leads towards knowledge, that is relevant not only for the so called ›persons concerned‹, but for the whole society. “Knowledge about disability and the relation between difference and normality […] gives fundamental information about the relation of the individual, society and culture” (Waldschmidt/Schneider, 2009, 13; loosely translated). Thus it leads towards knowledge about im-/possible (use of) things, interactions or configuration of processes and artefacts.

Appendix

As already mentioned above, some of the arguments concerning the fields of design and disability have been discussed in the context of “Universal Design”, “Design for All”, etc. These design approaches shall not be seen as oppositional but rather complementary to what we propose in our paper. However in our research project our aim is to emphasize on certain aspects that are not totally covered by the mentioned approaches. For instance one major focus in our topic is to determine how design can influence (and therefore maybe change) e.g. scientific, political or societal definitions and attitudes. We strongly believe in hybrid research settings and shall furthermore analyze how to use knowledge from other fields such as disability studies in design research. And vice versa: how to transfer design knowledge into other fields.

Dynamique forme-lumière:

Un processus de création et d'analyse de l'espace architectural par modèles maquettes/images

Biron Karole, Université Laval, Canada

Demers, Claude M.H., Université Laval, Canada

Résumé

La recherche propose un regard sur l'objet et la lumière à travers l'élaboration d'une méthode de design et d'analyse spatiale aidant architectes, designers et artistes dans leur exploration créative. Elle tente de réinitialiser le processus de création par des manipulations simples et directes avec la matière, et une expérimentation en maquettes et en images photographiques, deux médiums familiers des architectes et designers. Ces interventions minimales recèlent à la fois une grande richesse de relations spatiales et de nombreuses informations sur le phénomène lumière. Une collecte de plus de 200 compositions spatiales est soumise à l'analyse. Un lexique de paramètres est formulé à partir de notions théoriques relatives à l'espace, l'objet, la lumière et la perception, sous forme de grilles d'interprétation. Celles-ci servent de cadre d'analyse permettant d'identifier les éléments les plus actifs en interaction dans l'espace visuel. Elles orientent la lecture de la complexité spatiale et agissent comme balises dans le processus de décision/création. Le vocabulaire élaboré aide à préciser la nature des interventions et sert de plate-forme d'échange entre les collaborateurs. Ce processus vise également à stimuler l'imagination et la créativité en architecture et en design.

Mots clés

Espace architectural; Méthode de design; Créativité, Perception visuelle; Analyse spatiale; Ambiance lumineuse; Forme; Analyse d'images; Photographie digitale

Dynamic between objects and light

A process of creation and analysis of the architectural space by models and photographs

Summary

The research proposes a look at the object and the light through the elaboration of a design method and spatial analysis helping architects, designers and artists in their creative exploration. It tries to re-initialized the creative process by simple and direct manipulations with matter, and an experimentation with models and photographic images, two familiar mediums of architects and designers. These minimal interventions simultaneously present richness in spatial relations as well as information on luminous patterns. A collection over 200 spatial compositions are submitted to analyses. A lexicon of parameters is formulated from theoretical notions related to space, objets, light and perception, in grids of interpretation. These serve as frame of analysis allowing to identify the most active elements in interaction the visual field. They direct the reading of the spatial complexity and act as beacons in the process of decision / creation. The elaborated vocabulary helps to specify the nature of the interventions and serves as a platform of exchange between the collaborators. This process also aims at stimulating the imagination and the creativity in architecture and in design.

En tant qu'initiateurs d'espaces, les architectes et designers sont confrontés à une multitude de facteurs qui doivent être pris en considération lors de l'élaboration des projets. La recherche s'intéresse particulièrement à la partie créative, en tant qu'exploration, invention et requalification dans le processus de design. Cette étape importante dans la formulation d'une œuvre entière permet d'élaborer des solutions esthétiques aux besoins des usagers.

Les balises et outils d'analyses d'aspects qualitatifs liés à l'approche créative étant peu développés, la recherche vise à offrir de tels outils comme support au processus de création, à travers un cadre structuré organisant la lecture de l'espace visuel par étapes. Face à la complexité liée aux nombreux paramètres de spatialité et de perception visuelle en interaction, cette recherche propose de circonscrire plusieurs d'entre eux pour en définir les actions (tableau 1). Peut-on isoler certains paramètres plus significatifs pour qualifier l'espace? Il est reconnu que la vue constitue actuellement le sens dominant notre perception du monde (Pallasmaa, 2005). Architectes, designers et artistes sont particulièrement sensibles à la relation spatiale et perceptuelle entre la lumière et l'objet. Ces deux éléments se complètent et se modifient de multiples façons, et leur potentiel esthétique est reconnu. Comment lumière et objets sont-ils en interaction et se révèlent-ils l'un l'autre? Quels caractères apportent-ils à l'espace? Comment est-il possible d'analyser ces interactions? La recherche propose deux moyens d'approfondir cet univers. Une expérimentation en maquette avec images photographiques numériques sert de matériel d'analyse. Des grilles d'évaluation et des traitements d'images servent de guides à l'interprétation visuelle et spatiale. La méthode permet de caractériser les ambiances lumineuses, de mieux les cibler et d'élaborer des solutions esthétiques pour mieux les articuler. Elle permet également d'appréhender la relation objets/lumière comme un moyen de créer des espaces plus stimulants.

Contexte de recherche

La séquence temporelle et spatiale sert entre autres à construire des images mentales pour comprendre et définir le monde physique qui nous entoure. Lors de la perception de l'espace architectural, la formation d'une image globale dérive de l'intégration d'une multitude d'images fixes (Arnheim, 1986; Bell, 2001; Gibson, 1950). Pendant le parcours ou la séquence spatiale, certains espaces manifestent cependant une plus grande intensité émotionnelle que d'autres. Par leur géométrie, leur lumière, leurs formes et leurs matériaux particuliers, ces espaces deviennent « primaires », tandis que d'autres sont « secondaires », créant une certaine hiérarchie. Dans ces espaces dominants, le champ de vision d'un occupant est stimulé par des configurations spatiales attractives et uniques. Un design bien conçu de ces points de vue « stratégiques », comme point de repère, a donc une portée très significative sur l'impression d'ensemble du bâtiment et sur le comportement de l'occupant. Le travail de la création de points de vue architecturaux particuliers oblige à s'intéresser à ce qui, dans l'espace, représente le plus d'intérêt visuel. Pour ce faire, l'utilisation de maquettes permet de concevoir certaines configurations spatiales et l'emploi d'images photographiques devient une sélection de points de vue fixes représentant l'espace architectural.

Lors de la conception, bien que la modélisation informatique a l'avantage de réduire le nombre de manipulations matérielles et d'être précise, le temps de modélisation est parfois long en situation complexe. Le résultat donne un aperçu général de la réalité, mais n'introduit pas tout le côté sensible et tactile de la matière. La subtilité des phénomènes et leurs interactions ne peuvent être intégrées, puisqu'ils ne peuvent être programmés, étant trop complexes (Demers, 1997). Parallèlement au monde virtuel, la manipulation par maquettes demande moins d'expertise et de précision et condense en un seul temps, une large part de la complexité de l'interaction matière/phénomènes physiques (Zevi, 1959; Holl, 2000). Le phénomène lumineux n’étant pas physiquement influencé par la différence d’échelle, les maquettes sont d’autant plus pertinentes à ce niveau. Le point de vue unique de la photographie permet, quant à lui, de porter une attention particulière à certains détails et d’évaluer l’assemblage de la composition de l’espace architectural (Michel, 1996). La photographie comme mécanisme, se rapproche en partie du fonctionnement de l’œil humain, entre autres par une sensibilité à la lumière, un système de diaphragme, de lentilles, une zone de précision centrale, une vision de la profondeur (Michel, 1996; Frisby, 1981). Par contre, la sensibilité à certaines longueurs d’ondes, aux couleurs, au seuil de faible intensité lumineuse et la capacité d’adaptation, sont des mécanismes qui peuvent différer (Michel, 1996). Malgré cela, la photographie demeure tout de même un excellent moyen de traduire la vision humaine (Demers, 1997). La version numérique de la photographie, quant à elle, offre la possibilité d’ajout de traitements numériques pour mettre en valeur ou révéler certaines structures de composition en action dans l’image. L’acte photographique peut donc constituer à la fois une prise de données et un premier filtre du regard.

La méthode partiellement informatisée avec maquette et images numériques est donc simple et accessible. Elle se rapproche à plusieurs niveaux de l’expérience spatiale et visuelle réelle et rassemble plusieurs phénomènes complexes.

Théorie-Méthodologie

Thèmes de création

La recherche propose une schématisation d'acquis théoriques et de qualificatifs liés à la perception visuelle, l'espace, l'objet et la lumière. Cette schématisation condense et structure une complexité d'informations. Ainsi, quatre thèmes de création interdépendants émergent : les éléments spatiaux, d'attention visuelle, de composition et d'ambiance. Sans être réducteurs, ils peuvent guider la construction, la description ou l'analyse d'un espace ou d'une image.

Éléments spatiaux :
Le concept d'espace est à l'opposé du vide. Au cœur de l'idée d'interrelation entre les éléments physiques en architecture, il est un lieu de relations entre objets perceptibles se définissant par leur référence les uns avec les autres. Selon Arnheim (1986), une partie de ces interactions est créée par un rayonnement spatial des objets, selon leurs formes, leurs dimensions et leurs distances. Ce concept de champs de forces, bien que peu exploité dans les analyses spatiales, influence pourtant la perception (Arnheim, 1986; Meiss, 1993; Cousin, 1980). Arnheim donne en exemple : un objet courbe peut avoir une extension spatiale interne centripète et une extension spatiale externe centrifuge, chaque rayonnement influençant les objets environnants. Une rencontre de plusieurs rayonnements crée une certaine densité spatiale. Les actions des objets représentées généralement par des extensions linéaires dans la typologie d'Arnheim, sont transposées graphiquement dans cette recherche (Biron, 2009).

Éléments d'attention visuelle:
Le concept d'attention visuelle est fondamental. Plusieurs études démontrent que le processus de compréhension de l'espace est influencé par la sélection d'éléments dans le champ visuel (Lam, 1992; Weber 2002; Livingstone 2002; Michel 1996). Ces centres visuels ou éléments d'attention nous permettent de faire rapidement le tour d'un environnement en le décomposant en points de repère pour amorcer la compréhension, le classement et la catégorisation. Ce sont entre autres, les contrastes et luminosités élevés, les masses proéminentes, les objets tridimensionnels, les formes simples, isolées, les couleurs vives. Le concept d'attention visuelle est au cœur de la recherche et de l'analyse des éléments dominants et structurants l'espace physique et visuel.

Éléments de composition:
Les éléments de composition, sous les dénominateurs communs tels la verticalité, l'horizontalité, la symétrie, la forme concentrique ou excentrique, par exemple (tableau 1), sont reliés à différents états physiques de notre corps (gravité, axes corporels, état passif horizontal, état actif vertical) qui en est la référence. Ils structurent et orientent notre compréhension et notre perception de l'environnement, par la gradation des hauteurs, du poids et des déplacements. Ainsi, les éléments de composition visuelle expriment soit un mouvement, une direction, un axe, une orientation, soit un arrêt, une zone, une surface, un point fixe (Arnheim, 1986; Cousin, 1980; Meiss, 1993). Ces deux états opposés accompagnent continuellement la perception de l'espace architectural. Dans cette recherche, directions et zones sont aussi appliquées à l'analyse qualitative du comportement de la lumière, afin d'estimer son action dynamique.

Éléments d'ambiance :
Les éléments d'ambiance visuelle concernent différents états et qualité de la lumière en rapport à l'espace qui la délimite. Ainsi, les facteurs d'intensité, de contraste, de distribution ou de qualité par exemple ont une grande influence sur la sensation globale de l'espace et sur la perception des objets présents. Ces états de la lumière sont intimement liés aux ombres qui sont en soi visuellement inséparables.

Le dynamisme spatial concerne donc plusieurs facteurs: l'extension spatiale des objets s'influençant mutuellement, le mouvement de l'œil dans la recherche d'informations entre les points de repère importants, la direction et la position des formes objets et lumière, structurant l'espace et le champ visuel par rapport à nos axes corporels et la qualité des stimuli dans l'environnement observé.

Grilles d'interprétation

Ces grands thèmes de création découlent de concepts théoriques identifiés selon une revue littérature et une analyse théorique de Biron (2008). À ces thèmes correspondent des paramètres spécifiques élaborés entre autres par des auteurs tels que Arnheim, 1986 (champs d'influence et rapports de force entre les objets), Lassance, 1998 (familles lumino-spatiales), Louis, 2003 (natures dynamiques des formes architecturales), Lecas, 1992 (modes de perception et d'attention visuelle), Michel, 1996 (design des espaces par la lumière) et Demers, 1997 (méthodes d'analyses digitales). Leur énumération favorise l'analyse en détail et constitue la première grille d'interprétation qualitative de cette recherche. Ainsi, **la grille des paramètres** rassemble une majorité de paramètres regroupés en cinq sections ou cinq dénominateurs communs à la fois à l'objet, la lumière et l'espace. Ce sont : le type de forme, l'orientation, la localisation, l'étalement et la qualité (tableau 1). Certains de ces concepts ont été sélectionnés dans la présente recherche pour leur potentiel d'analyse digitale à procurer une interprétation visuelle préliminaire à un concept de relation espace-lumière-objet (Biron, 2009).

Dans le tableau, l'objet se distingue comme objet libre (indépendant des parois), contenant (limite matérielle et spatiale) ou ouverture (découpe dans une paroi). La forme géométrique, organique, articulée ou unique, l'orientation principale, le nombre et la position des objets dans l'espace, sont des exemples de paramètres, utiles pour caractériser l'action perceptuelle et spatiale des objets (tableau 1).

La lumière et l'ombre sont étudiées simultanément, puisqu'ils se tissent l'un l'autre. La lumière se distingue en lumière-ouverture (forme lumineuse produite par la forme de l'ouverture) et lumière-projetée (*pattern* obtenu par la réflexion de la lumière sur une surface, créant quelques fois des motifs ou dessins (figue 2). L'ombre peut être attachée (à la surface d'un objet ou corps), projetée (portée sur une surface ou un plan) ou fausse (absence de lumière) (Cassati dans Binet, 2002; Demers, 1997). Lumière et ombre acquièrent ces qualificatifs lorsque leur forme est bien définie et visuellement incontournable dans le champ visuel. On distingue aussi l'orientation linéaire, verticale, oblique, la position et le nombre d'éléments dans le champ visuel, la délimitation, la distribution ou la qualité directe, diffuse, naturelle, artificielle, comme exemples de paramètres actifs visuellement et spatialement.

La grille comporte également plusieurs paramètres relatifs à l'espace global. Retracés dans la littérature ou résultants d'effets de la lumière ou des objets, ils sont parfois abstraits et plus difficiles à évaluer, mais demeurent des indicateurs du caractère potentiel de l'espace.

Tableau 1 : Grille de paramètres et qualificatifs relatifs à l'objet, la lumière et l'espace.

	Type de forme	Orientation	Localisation	Étalement	Qualité
Objets	• objets libre objet contenant objet ouverture • géométrique/ organique • forme ou volume articulé/unique	• orientation(s) principale(s): horizontale/verticale/ diagonale linéaire/courbe/circulaire concave/convexe régulière/irrégulière symétrique/asymétrique sans orientation	• position(s): centrale/périphérique gauche/droite avant/arrière haut/ bas zénithale/latérale • gravité visuelle: forte/faible (haute/basse) • nombre d'objets: unique/multiple	• dimension grande/moyenne/ petite • proportion objet/contenant/ ouverture	• texture • matériaux • couleur • réflectance/ spécularité surfaces
	Type de forme	**Orientation**	**Localisation**	**Étalement**	**Qualité**
Lumières/ombres	• lumière ouverture/ lumière projetée/ • ombre attachée/ ombre projetée/ fausse ombre	• orientation(s) principale(s): horizontale/verticale/ oblique linéaire/circulaire rasante sans orientation	• position(s): latérale/zénithale centrale/périphérique gauche/droite avant/arrière haut/ bas • nombre d'éléments lumière et ombre: unique/multiple	• proportion lumière/ombre • motif: simple/complexe • dominance du pattern: dispersion/ concentration • délimitation: bien délimitée/ mal délimitée • distribution: uniforme/ non uniforme	• naturelle/ artificielle • directe/ diffuse • intensité lumineuse • couleur
	Type de forme	**Orientation**	**Localisation**	**Étalement**	**Qualité**

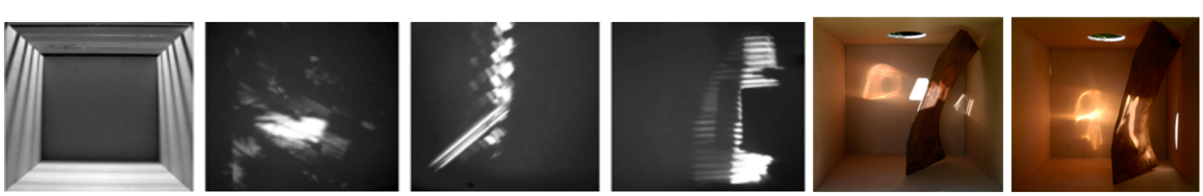

Figure 2 La production des motifs est attribuable la projection de la lumière, la forme de l'ouverture, l'intensité lumineuse et la réflectance des matériaux.

La seconde grille distribue les paramètres du tableau 1 qui peuvent être classés, en **deux types d'interprétations : les directions et les zones** (tableau 2). La recherche démontre que les éléments constituant une image peuvent être analysés sous forme de lignes (directions) et de surfaces (zones), jouant un rôle majeur dans la perception visuelle et indiquant des actions intrinsèques des formes. La direction est le sens d'action ou axe des objets et de la lumière. Elle est traduite par des flèches. La zone implique l'idée d'une région d'occupation dans l'image et l'espace. Elle est identifiée par une surface uniforme et bien délimitée.

Tableau 2 Types d'interprétation des paramètres : par direction et par zones, indiqués respectivement par des flèches et des surfaces lors de l'interprétation des espaces-maquettes.

	A- Directions	B- Zones
Objet libre/contenant/ ouverture	1 • orientation: *horizontale* *verticale* *diagonale* *concave/convexe* *linéaire/courbe/circulaire* *régulière/irrégulière* *symétrique/asymétrique* *sans orientation* 2 • gravité visuelle: *hauteur/poids*	1 • type de forme: *géométrique/organique* *à volume ou forme articulé/unique* 2 • position: *centrale/ périphérique* *gauche/droite* *avant/arrière* *haut/ bas* zénithale/latérale 3 • nombre d'objets: *unique/multiple* 4 • dimension *petite /moyenne/ grande* 5 • proportion objet/contenant/ouverture 6 • qualité de réflexions de surface: *importantes/moyennes/petites/absence*
Lumière/ombre	3 • orientation: *horizontale* *verticale* *oblique* *linéaire/circulaire* *rasante* *sans orientation*	7 • type de forme: *lumière ouverture/ projetée* *ombre attachée/projetée/fausse* 8 • position: *latérale/zénithale,* *centrale/périphérique* *gauche/droite* *avant/ arrière* *haut/ bas* 9 • nombre d'éléments: *unique/ multiple* 10 • proportion lumière/ombre: *petite/grande* 11 • motif: *simple/complexe* 12 • dominance du pattern: *dispersion/concentration* 13 • délimitation : *bien délimitée/mal délimitée* 14 • distribution: *uniforme/non uniforme* 15 • qualité d'intensité lumineuse : forte/faible

Ces directions (axes principaux) et zones (surfaces) acquièrent plus particulièrement la qualité d'être dynamique ou statique, si on les observe à travers la troisième grille d'interprétation : le **tableau des catégories dynamiques et statiques**. Les éléments statiques favorisent l'arrêt physique et perceptuel et les éléments dynamiques favorisent le mouvement. Les directions et les zones se trouvent alors investies de couleurs (rouge et bleue), les rendant facilement interprétables dans l'analyse. Ensemble, ces trois grilles sont des guides qui permettent de décortiquer les éléments les plus actifs d'un espace ou d'une image.

Tableau 3 : Classement de plusieurs paramètres en catégories dynamique et statique

Type d'interprétation		Paramètres	Catégories	
			Dynamique	**Statique**
Directions	**Objets**	1 • orientation objet	verticale, diagonale linéaire selon orientation convexe irrégulière asymétrique	horizontale courbe ouverte, circulaire concave régulière symétrique sans orientation
		2 • gravité visuelle	forte (haute)	faible (basse)
	Lumière/ ombre	3 • orientation lumière/ombre	verticale, oblique linéaire rasante	horizontale circulaire sans orientation
Zones	Objets	1 • type de forme objet	articulée	unique
		2 • position objet	périphérique haut zénithale	centrale bas latérale
		3 • nombre d'éléments:	multiple	unique
		4 • dimension objet	grande	moyenne/petite
	Lumière/ombre	6 • réflexions de surface	importantes	moyennes/petites
		7 • type de forme lumière/ombre	lumière projetée ombre projetée bien délimitée	lumière ouverture ombre attachée mal délimitée
		8 • position lumière et ombre	périphérique zénithale haute	centrale latérale basse
		9 • nombre d'éléments lumière et ombre	multiple	unique
		10 • proportion lumière/ombre	petite proportion ex. : 1/5 contraste élevé	grande proportion ex. : 1/2 contraste faible
		11 • motif	complexe	simple
		12 • dominance du pattern	concentration: contraste élevé	dispersion : contraste faible
		13 • délimitation	bien délimitée	mal délimitée
		14 • distribution	non uniforme	uniforme
		15 • intensité lumineuse	forte: contraste élevé	faible : contraste faible

Expérimentation-Analyse

La partie appliquée de la recherche, sous forme d'expérimentation en maquettes, met en relation des objets (matériaux d'ateliers), des ouvertures et des qualités de lumière. Les angles d'éclairement, c'est-à-dire l'angle de projection de la lumière source à travers l'ouverture, varient également, afin d'éclairer différentes régions de l'espace. La forme et le matériau du contenant demeurent fixes. Leur couleur se traduit par un gris moyen sur les images noir & blanc. Chaque maquette est photographiée de face, à une distance fixe, uniformisant l'échantillonnage. Elles sont traduites en images numériques, traitées par divers filtres et modes afin d'en extraire des informations (Biron, 2008). La figue 3 montre certains espaces maquettes dont les éléments varient selon deux types d'objets de forme géométrique et organique, deux formes d'ouvertures (linéaire et circulaire), quatre qualités de lumière (naturelle, artificielle, diffuse, directe) et trois angles d'éclairement. Elles sont accompagnées d'images traitées numériquement. Le mode *isohélie* décompose l'image en cinq tonalités de luminosité, aidant à mieux visualiser la répartition de la lumière et des ombres importantes. Le filtre *courbes de niveaux* cible des niveaux de luminosité relative (figure 3c,g,k,o), dessinant le contour de zones d'intensités lumineuses. Il est utile pour dégager une orientation et une organisation épurée des formes dans l'espace. Le filtre *tracé des contours* trace la frontière entre les écarts de luminosité, c'est-à-dire les contrastes d'intensité. Les traits obtenus ont une intensité plus ou moins prononcée, selon le contraste qu'ils délimitent (figure 3d,h,l,p). Ces filtres diminuent les détails moins importants de l'espace visuel. Ainsi, certaines régions disparaissent, par insuffisance de détails et de lumière. C'est le cas de l'objet des figures 3f, g et h.

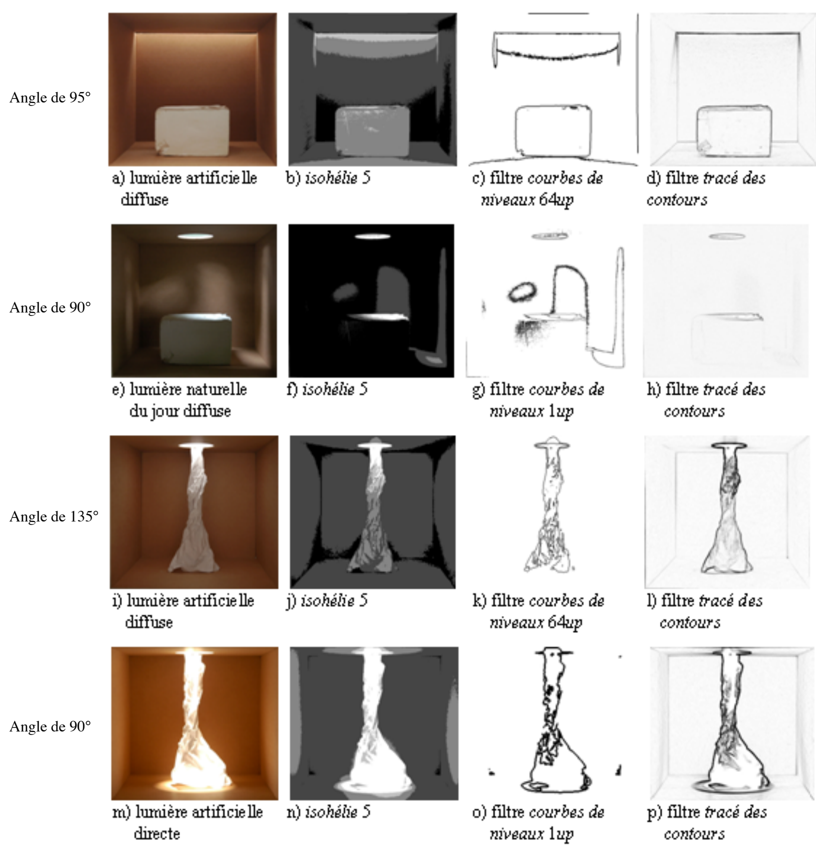

Figure 3 Images digitales avec ouvertures linéaires ou circulaires, différents angles et qualités de lumière naturelle ou artificielle, directe ou diffuse. Les images sont traitées par mode *isohélie*, mode noir&blanc et filtres de courbes.

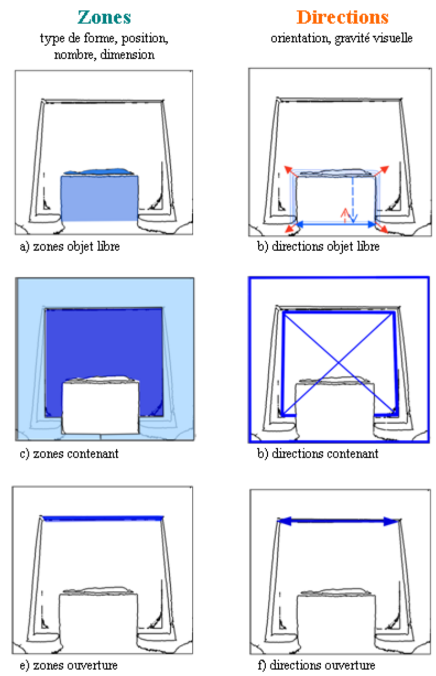
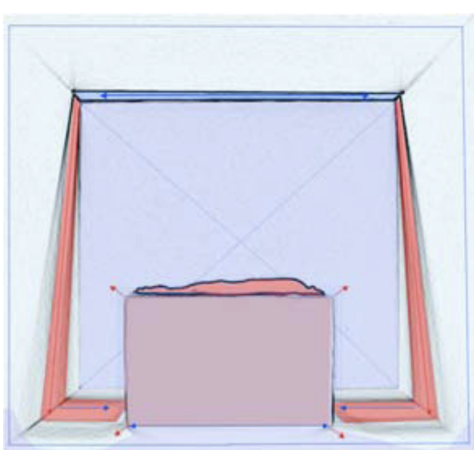
La figure 4a est un exemple d'image de maquette soumise aux interprétations des grilles. Les paramètres de la grille #1 (tableau 1) sont d'abord énumérés et évalués. La grille demeure une référence tout au long du processus. À l'aide des filtres, objets, lumière et ombre sont ensuite examinés de façon distincte, en interprétation par directions et par zones, grille #2 (tableau 2). Les éléments considérés comme statiques (bleu) et les éléments dynamiques (rouge) sont alors clairement identifiés, selon la grille #3 (tableau 3). Une mise en commun est reproduite à la figure 4d.

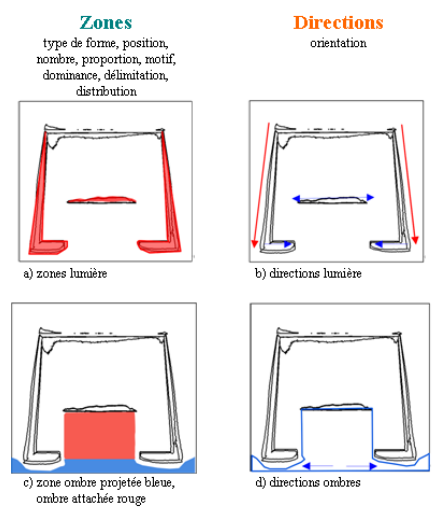
a) image maquette



b) Objets



d) Mise en commun



c) Lumière/Ombre

Figure 4 Représentation graphique d'une analyse des directions et zones d'un espace maquette. a) image originale (bloc de plâtre, ouverture linéaire zénithale, lumière artificielle directe, b) interprétation des objets, c) interprétation de la lumière et des ombres, d) mise en commun des interprétations des objets et de la lumière/ombre.

Dans cet espace, l'objet libre est plutôt statique. Bien ancré au sol, sa gravité visuelle est presque nulle (Arnheim, 1986, 1988). Il présente une légère direction horizontale, sans grande expansion, ce qui lui donne une impression de stabilité. Bien que sa dimension soit assez importante, il perd une grande partie de sa tridimensionnalité due à l'effet dissociateur de l'ombre attachée (avant du bloc) et du dessus fortement illuminé. Ainsi, en accentuant ou diminuant les détails et les contours des objets, l'intensité de la lumière peut produire une impression de matérialisation ou de dématérialisation des surfaces (Demers, 1997; Lecas, 1992; Weber, 2002). Ceci agit sur l'attention visuelle et la définition des objets environnants. L'ouverture linéaire, horizontale et zénithale occupe peu d'espace dans le champ visuel. Elle est donc peu active. Dû à l'angle d'éclairement et de prise de vue, il n'y a pas de lumière-ouverture. Par contre, la lumière directe produit une *lumière-projetée* très bien définie qui encadre l'objet par sa forme presque carrée, prenant expansion au sol. L'ombre attachée au bloc s'attribue une forme géométrique remarquée, dont la visibilité est accentuée par le contraste avec l'arrière-plan. L'évaluation de la couleur n'est pas abordée puisqu'elle demande une considération psychologique approfondie.

Une des forces de cette configuration est sa simplicité. Le peu d'éléments présents et leur forme captent l'attention. Les principales directions et zones y sont bien distinctes. L'analyse des objets démontre des directions et des zones principalement statiques. La lumière a cependant une double action. Elle encadre le bloc et le contenant, renforçant la symétrie et la stabilité de leurs formes ainsi que la centralité de l'ensemble. En contrepartie, sa nette délimitation, son *pattern* lumineux concentré en deux formes géométriques triangulaires définies, sa verticalité et son intensité lumineuse élevée, deviennent des éléments dynamiques importants. L'analyse permet d'affirmer que c'est la forme et l'intensité de la lumière qui donnent la plus grande force à cet espace, surpassant en importance les éléments statiques, malgré leur nombre. La figure 5 montre comment le caractère de l'espace diffère par la modification de la relation objet-lumière, simplement en changeant l'angle d'éclairement de la lumière.

Figure 5 Modifications de l'effet d'encadrement lumineux des objets, par modification de l'angle d'éclairement.

Plusieurs centres d'attention (plan d'ombre, forme géométrique de la lumière, intensité élevée, etc.) sont présents dans la figure 5a et effacés dans la figure 5c. Il faut cependant faire une distinction entre centres d'attention et niveaux d'attention. En effet, nos yeux sont attirés vers les zones rapidement identifiables comme les objets simples, proéminents, les contrastes, les luminosités élevées qui sont des centres d'attention. Nos yeux devront s'attarder plus longtemps pour comprendre les formes complexes, les zones floues, avec peu ou trop de détails ou sans grande direction de lecture, comme parfois en lumière tamisée et diffuse, demandant un niveau d'attention élevé. Les centres d'attention nous intéressent particulièrement, étant des repères dans la lecture et le design de l'espace lors de la création. Ces zones d'intérêt ou d'attention agissent en grande partie comme déterminant du caractère de l'espace et sont intégrées (perçus) rapidement.

La mise en commun de quelques analyses spatiales souligne les principaux éléments révélés par la méthode (figure 6a-e). Les flèches dessinées (figure 6f-j) représentent graphiquement le sens de lecture potentiel ou estimé entre les éléments visuels dominants. Le mouvement ou le sens de lecture est certes minimal et limité, mais il résume simplement les actions concertées ou non des éléments présents. Le parcours du regard est représenté par un va-et-vient (flèches) entre les formes. Bien que subjectifs, ils se basent tout de même sur les éléments visuellement et formellement actifs révélés dans les analyses. Dans la figure 6C, l'œil cible les deux zones de forte luminosité et l'orientation verticale de la forme centrale. Lumière et objet sont reliés ensemble par une symétrie et une forte présence commune des certains de leurs paramètres telles la position, l'orientation, l'intensité et la dominance du *pattern* (tableau 1), orientant le regard en un va-et-vient le long du cône de lumière et de la forme de papier. Dans la figure 6E, plusieurs éléments se partage l'attention. L'ouverture et les deux zones de lumière projetées possèdent une intensité assez élevée pour attirer l'œil, tandis que les tiges de bois, bien qu'occupant un faible pourcentage de l'espace visuel, ont une orientation verticale et diagonale marquée. Les masses du coin droit de l'image, bien qu'assez proéminentes, sont fixées au sol. Elles s'effacent dans l'ombre qui n'est pas assez intense pour en faire ressortir la présence par contraste. Les nombreux éléments ne s'appuient pas les uns les autres, orientant le regard dans plusieurs directions différentes.

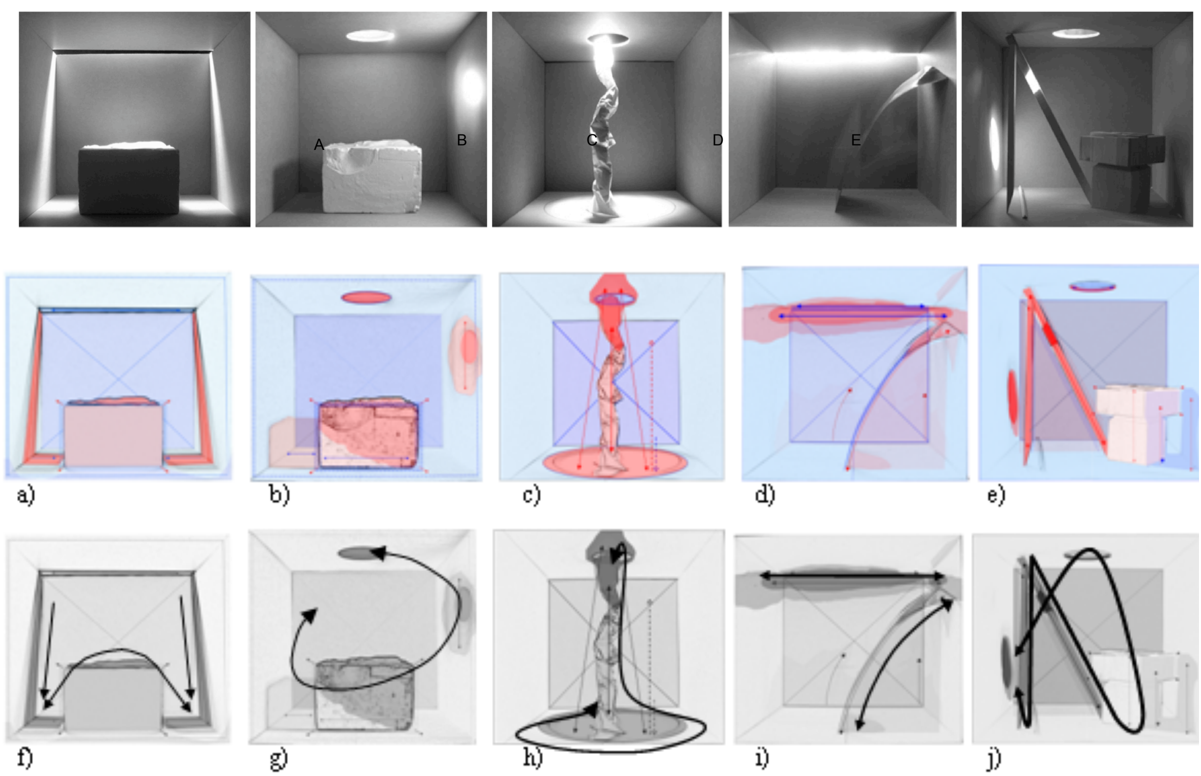


Figure 6 Interprétation de cinq espaces-maquettes, par directions et zones a-e), ainsi qu'une évaluation du sens de lecture potentiel entre éléments visuellement dominants f-j).

Conclusion

En design architectural, l'analyse et le regard esthétique font tous deux parties de l'élaboration de l'œuvre. La recherche tente de tisser ces deux approches parallèles. Elle s'intéresse à l'espace en tant que lieu de relation où objets et lumière dialoguent et se transforment mutuellement. Elle propose un éventail de qualificatifs et de notions théoriques concernant objets et lumière. Ceux-ci sont répertoriés sous forme de grilles d'interprétation. Le vocabulaire développé se compose de paramètres fournissant une compréhension claire et détaillée et une vision globale de l'environnement visuel. Il faut cependant se rappeler que bien que nous compartimentons les phénomènes pour mieux les comprendre, la perception globale de l'espace est complexe et les phénomènes sont inter reliés. Le travail propose également une expérimentation par des manipulations d'objets et de matière, sous forme de maquettes et d'images photographiques. Par la grande accessibilité et la visualisation rapide des interventions, ces deux médiums permettent d'observer plusieurs phénomènes simultanément et révèlent une multitude d'informations. Cette démarche réitère la richesse de ces manipulations comme source d'imagination, plutôt que simple représentation. Cette méthode favorise l'analyse et le design de points de vue « stratégiques ». Ceux-ci ont une portée significative sur la première impression d'un bâtiment. Lors de l'analyse, les grilles d'interprétation et les traitements numériques appliqués aux photographies génèrent des représentations graphiques, devenant des outils pour le design. La recherche présente certaines limites inhérentes à la représentation en maquette, mais situe tout de même un discours permettant de qualifier une relation spatiale intégrant la lumière et l'objet, qu'il serait intéressant de valider en milieu réel. Cette méthode, bien que conçue pour stimuler l'étape de la création, pourrait être confrontée avec l'analyse d'espaces réels, pour en étendre la portée.

La recherche révèle la nécessité de considérer à la fois les **directions** et les **zones** d'une image et d'un espace. Ces deux éléments de composition et d'attention influencent grandement la perception spatiale et visuelle. Elle témoigne aussi de l'importance d'attribuer les catégories **dynamiques et statiques** aux éléments, car ils agissent également sur notre perception et sur le caractère de l'espace. Deux concepts émergent de la discussion : la **compétition** et le **renforcement**. La compétition est définie comme une division de l'attention visuelle entre plusieurs éléments dominants, dont leurs actions perceptuelles ne sont pas spatialement ou formellement liées. Cela crée un effet de **dispersion** et une lecture multiple de l'espace. Elle demande un niveau d'attention plus élevé, car les éléments rivalisent entre eux pour le partage de l'attention. Le renforcement est une **concentration** de l'attention visuelle due à la complicité spatiale et formelle existant entre les éléments ou les centres d'attention. Les éléments travaillent en complicité. Leur position, leurs formes, leurs directions et leurs zones se renforcent les unes et les autres. Lors de la conception, l'espace souhaité (particulièrement les points de vue stratégiques) peut donc comporter un partage de l'attention entre plusieurs points différents ou la lumière et les objets peuvent travailler conjointement dans un but d'unité.

En somme, cette approche détaillée jette les bases d'un travail de création, dont la méthode offre beaucoup de souplesse. Elle élabore une vision globale de l'espace où les éléments visuellement importants sont identifiés et qualifiés. Cette démarche fait de l'interprétation de la relation objets/lumière, un moment privilégié permettant de comprendre leur dynamisme et d'anticiper leurs effets dans la production d'oeuvres artistiques et architecturales. Elle peut également guider les créateurs dans l'univers de l'interaction objets-lumière et donner des balises lors de l'enseignement. Cette évaluation en détail à l'aide de grilles d'interprétation de l'espace physique et visuel est une approche qualitative servant d'outils de réflexion et de schématisation, face au phénomène de complexité lors de la création. Elle doit être considérée comme l'apport d'un vocabulaire servant à développer parallèlement la rigueur de l'analyse, l'imagination et « l'acuité créative », enrichissant les interventions.

Biographie des auteurs

Karole Biron

Détentrice d'un Baccalauréat en Arts Visuels et d'une maîtrise en Science de l'Architecture de l'Université Laval, elle participe à de nombreux jury et critiques d'ateliers. Elle conçoit et réalise des œuvres de grande dimension intégrées à l'architecture et à l'environnement et expose ses productions au Québec et à l'étranger. Membre fondatrice des Éditions J'ai VU, elle a dirigé la publication *Segments et spécimens*. Elle poursuit sa recherche sur l'espace et la lumière par le biais de la photographie, la sculpture et l'écriture.

Claude M.H. Demers

Professeure titulaire à l'école d'architecture de l'Université Laval, elle détient un doctorat de l'Université de Cambridge. Elle est activement impliquée dans la recherche-création fondamentale et appliquée au domaine de l'éclairage naturel et artificiel. Elle est membre et co-fondatrice du Groupe de recherche en ambiances physiques, spécialisé dans l'intégration des systèmes passifs de contrôle de l'environnement à l'échelle architecturale et urbaine.

Complexity in Home Medical Equipment Design

Noemi Bitterman, Industrial Design, Faculty of Architecture and Town Planning, Technion, noemib@tx.technion.ac.il

Abstract

Home medical devices are developing into a major industry worldwide that covers monitoring, diagnostic, disease prevention, treatment, alleviation of disease and rehabilitation equipment. Services are being moved out to the community and into the home; self management is replacing hospitalization and visits to the doctor's clinic; and custom-tailored medicine is making inroads into normative treatment. These developments have great implications for the scope and design of home medical equipment.

The paper will discuss the unique and complex nature of home medical devices, from a human–environment–machine perspective focusing on the changeable unpredictable nature of users, the unknown, amorphous home environment and the level of intricacy of tasks performed by patients having various diseases and disabilities.

The design of home/personal medical equipment should be guided by the need to make it compatible with the needs of different users and diverse residences. The selection of medical equipment should not be determined by passing trends, technological fashions, or search for innovative and hi-tech applications and gadgets.

We call for increased awareness and active, ongoing research by multidisciplinary teams of healthcare personnel, end user patients, caregivers, psychologists, social workers, and especially, the architects and designers who will be involved from the first stages of concept development through to the final stages of medical device marketing. Design of home/personal medical equipment should follow principles of inclusive design (design for all, universal design) criteria, following user-centered design methodologies. It should accommodate the dynamic, uncertain and complex profile of the widest range of users and environments.

Keywords

home care; medical devices; healthcare design; medical equipment; inclusive design; design for all; user-centered design

Medical device design, manufacture and use constitute a growing industry worldwide, having great economic impact and spilling over into various fields, and serving as a driving force for innovation (Klatzky, Kober & Mavor, 1996; The World Health Report 2008). The traditional way medicine as a whole is packaged and delivered is changing enormously. Services are being moved out to the community and into the home; E-health services, remote monitoring technology and self management are replacing hospitalization and visits to the doctors' clinics; custom-tailored medicine is making inroads into normative treatment (Bogner, 1999; Grundersen, 1999). These developments have great implications for the scope and design of home medical equipment.

In parallel, our society is graying as a result of increased life expectancy and a decrease in birth rates. Aging is being accompanied by a rise in chronic diseases such as diabetes, heart diseases, hypertension, COPD (Chronic Obstructive Pulmonary Disease), arthritis, osteoporosis, etc. (Lathan et al., 1999; The World Health Report, 2008). Chronic diseases can be controlled and prevented by patients who care for themselves via self care and monitoring, thus making the care process a more continuous collaborative relationship between patients and doctors. The assertion that "Health is a state of complete physical, psychological and social well being; not only the absence of illness" (WHO), combined with improved technology, primarily in the field of Information Communication Technology (ICT), is further spurring the expansion of the medical device market. This phenomenon is in line with the concept of "Social Design ", proclaimed by Papanek in "Design for the Real World" (1984). It is not surprising, therefore, that the investments made in the hi-tech medical device industry have been among the most successful commercial ventures, even during these dark days of today's global economic crisis.

Nevertheless, design of medical equipment is a unique field, with its own specific design demands. The design of for-home-use devices is an even more complicated issue for planners and designers.

This paper will discuss the unique nature of for-home-use medical devices, and focuses on evaluating the issues of their complexity that are related to the nature of users, the environment and the task performed.

Home Medical Equipment

Medical devices are "any instrument, apparatus, appliance, material or other article, whether used alone or in combination, including the software necessary for its proper application intended by the manufacture to be used for human beings for the purposes of diagnosis, prevention, monitoring, treatment or alleviation of disease" (European Medical Device Directive (93/42/EEC) (Martin et al., 2008). While hospital equipment is becoming more sophisticated and specific, significant numbers of medical devices are moving out of hospitals into community and residential settings for use by the public. This new situation raises problems and dilemmas not faced in the hospital setting.

Monitoring and diagnostic devices are present in every home, from simple universal devices such as thermometers and weight scales (e.g., routine weight watching, pregnancy follow-up) to specific devices such as blood pressure meters, glucometers, "Holter" type devices, INR meters (for patients under anticoagulant therapy), pulse oximeters, peak flow meters (e.g., asthma), macular degeneration detection systems and portable EKG/pulse meters. These devices enable remote and frequent monitoring of patients' clinical status and help in maintaining peoples' well being. Diagnostic self-test kits such as pregnancy tests or urinary tract inflammation tests are a fast developing sector of homecare products, thanks to innovative technologies.

Documentation of clinical and personal data (e.g., personal electronic medical records), linkage to information sources, on-line connection and consultation with physicians and medical/social staff, together with the use of ICT, empower patients and help close the loop among patients, devices, laboratories, data bases and physicians (Rollins &Rayburn, 2003). Taken altogether, these form a "disease management team".

Disease prevention, treatment and disease alleviation devices extend the responsibility for preventing illness, impeding further deterioration and hospitalization from hospitals and clinics to the home and work place. This category includes a range of devices, from simple machines such as inhalators and wound healing equipment to advanced equipment such as CPAP masks (e.g., for sleep apnea), liquid oxygen tanks, oxygen generators, catheters, infusion pumps, pain relief and analgesia devices, and even home dialysis machines.

Rehabilitation home equipment may enable frequent, around the clock treatment in a private and comfortable environment, but requires redesigning of rehabilitation gear. Rehabilitation home devices are in line with the concept of 'well being' and part of the trend of gym and fitness equipment that has also moved to the house setting.

Medical device are subject to complex regulations that vary considerably across the world, making compliance a complex and difficult process (Martin et al., 2008).

The use of home medical equipment and services empower patients, shifting them from passive recipients of care services to active participants. Several studies have suggested that interactive health services in which patients continuously take care of their own clinical data will improve management and control of chronic diseases, promote earlier discharge from acute care settings (replaced with continuous home services), improve clinical outcome, reduce the number of clinic visits, increase patient satisfaction, and shift care process towards more continuous collaborative relationships between patients and providers (Barlow et al., 2007; Garcia-Lizana & Sarria-Santamera, 2007; Rollins, & Rayburn (2003). Nonetheless, a new approach to the equipment is needed, given that most medical devices for at-home use are miniaturized, simplified, portable and some times colourful versions of the original professional hospital apparatus (Bogner, 1999; Wilcox 2005).

Users of Home Medical Equipment

Patients are not the users of medical equipment in hospitals and clinics (they are forbidden to operate the equipment by themselves). Professional staff—the nurse, technician or physician—operate the equipment. They are all experienced, dedicated, and trained users who are physically fit and healthy. They receive guidance and technical assistance during equipment operation (or have professionals on standby to call upon). Those who benefit from the use of healthcare devices neither order nor purchase the devices. Healthcare administrations, insurance companies and regulatory bodies such as the FDA decide what medical devices and technology will be accepted and purchased for the healthcare facility, based on economic, social and institutional factors (Wilcox, 2003).

On, the other hands, the users of home medical devices are heterogeneous groups of the patients themselves (self-care) or family members and care givers supporting the patient. The diverse profile of users includes experienced and untrained/occasional patients, family members ranging from spouses to grandchildren and caregivers of different levels of professionalism who may have conflicting interests and needs (Klatzky, Kober & Mavor, 1996; Lathanet al., 1999).

Common diseases and disabilities such as motor dysfunction (e.g., Parkinson disease, essential tremor, arthritis), visual impairment (e.g., diabetes retinopathy, cataract), loss of tactile sensation (e.g., diabetes neuropathy), cognitive impairment (e.g., dementia), auditory decay (phonal trauma, Presbycusis, deafness), speech disabilities (e.g. stroke) and equilibrium and balance disorders may impair a person's ability to operate the equipment. Motor restriction may disrupt the ability to perform simple functions on the device interface such as turning a knob, moving a slider, or pushing a bottom, or to complete procedures such as puncturing the finger for blood sample and wearing the blood pressure cuff. Visual decline will prevent reading the check-up results or following the color indicator and auditory dysfunction will prevent following the sound indicator (e.g., signaling the start and end of measurement). Cognitive deterioration will disturb various stages from the initial steps of the decision whether to perform the procedure or remembering how to perform it, to final steps of remembering the results of the checkup and reporting them correctly (Bogner, 1999; Wilcox, 2005).

Side effects of medications may further impair the user's ability to operate the equipment. This includes changes in visual sensation (e.g., anti-cholinergic drugs), auditory abilities (streptomycin), alertness (anti-allergic drugs), tactile sensation (chemotherapy), perception, cognition and information processing abilities (psychiatric drugs) and more. Anxiety, fatigue, loss of sleep and depression contribute to decreased attention and performance on the part of both the patients and family members (Klatzky, Kober & Mavor, 1996).

In contrast to the professional personnel at hospitals or clinics, patients may be by and large 'unstable'—going through unpredictable and/or frequent changes in clinical status and performance during the period they use the equipment (Bogner, 1999). Chronic patients and elderly people may have multiple disabilities and disorders that complicate the situation, mandating a tradeoff between modes of actions and display configurations of the medical equipment (Mclaughlin, Rogers & Fisk, 2004).

This diversity, unpredictability and fluctuation in users' profiles and abilities further complicates the design of domestic medical devices, their modes of operation and display options in comparison to the stable, known professional profile of hospital equipment operators (Bogner, 1999; Klatzky, Kober & Mavor, 1996; Lathan et al., 1999; Mykityshyn, Fisk & Rogers , 2002; Wilcox, 2005).

The Home Environment

The hospital environment is a constantly regulated setting, under supervision, with strict regulations and inspection protocols. Environmental variables that are controlled in healthcare facilities include sterility (with separation between isolated sterile and non-sterile zones), illumination levels and glare, electromagnetic disturbances, temperature regulation, moisture and vapor control, background noise (alarms, equipment operation, paging), furniture congestion and more.

As opposed to the controlled healthcare facility milieu, household and community settings are heterogeneous, unpredictable and uncontrolled environments, which introduce elements of complexity and uncertainty into the equation of location, performance and design of medical devices. Each user's home is unique, as opposed to the controlled and standard environment of hospitals. The positioning of medical devices at home, the possibility of electrical disturbances, interaction with other home devices, a non-sterile environment, unpredictable levels of illumination and glare, background noise, crowding of family members, specific maintenance constraints related to varied temperature, moisture, vapors and sunlight, and the need for transportation are some of the factors complicating the design of medical home devices. These factors are less relevant for the design of hospital medical equipment.

In addition to technological and ergonomic issues (Klatzky, Kober & Mavor, 1999), healthcare equipment used at home is also charged with issues of esthetics, design trends, styles and fashion, to the same degree that any consumer product is. For-home-use equipment design considerations are also compounded by the need to avoid images of sickness or disability (Wilcox, 2005).

Conclusion:

This paper presented some of the complex issues involved in designing home healthcare equipment resulting from by the special nature of users and their diverse and dynamic abilities (and especially disabilities) and the mismatch between the atmosphere and design of the house and the image and outlook of the medical equipment. In order to cope with the complexity, and overcome some of the dilemmas in the field of home medical devices, we need the active and continuous involvement of multidisciplinary teams of healthcare personnel, end user patients and caregivers, psychologists, social workers, and primarily architects and designers. The latter group especially will be most involved with concept development through to marketing the medical device(s) as life style articles.

It is necessary to define the objectives of healthcare devices and services at home in terms of life style and “all family" use. Design of home/personal medical equipment should follow principles of inclusive design (design for all, universal design) criteria, so that devices will be usable by the widest possible array of users operating in the widest range of conditions, following user-centered design methodologies (Arsand & Demiris, 2008; Klatzky, Kober, Mavor, 1996; Lathan et al., 1999; Wilcox, 2005).

The selection of medical equipment *should not* be determined by passing trends and technological fashions, or by a search for innovative and hi-tech appliances merely for their own sake. Moreover, design should not be transferred from the medical milieu to the homecare setting (with slight changes) or directly moved from one medical domain to another without first testing the compatibility with the heterogeneous profile of users and the residential environment.

It is expected that in the near future innovative technologies, computing, ICT and virtual reality will enable a holistic approach to medical equipment as an integrated part of the overall surrounding (Lathan et al., 1999). Aware houses (smart homes) and wearable computers will enable optimal personalized performance for each user and improved compliance with maximal integration with the environment whether this is the home, office or a mobile environment (Chan, Estève, Escriba & Campo, 2008).

Noemi Bitterman

Head of the postgraduate program of Industrial Design (M.Sc) in the Faculty of Architecture & Town Planning at the Technion, Haifa, Israel. Holding D.Sc. in Medical Sciences (Physiology) and M.Sc. in Industrial Design.

Research areas include design aspects of medical technology and innovation, the operating room of the future, E- health (Electronic Medical Record and interactive healthcare services) and smart home for the elderly and disabled.

Barrier analysis as a design tool in complex safety critical systems

Amy Rankin, University of Linköping

Daniel Anundi, Swedish Meteorological and Hydrological Institute

Stefan Holmlid, University of Linköping

Abstract

When constructing or improving large complex systems, design activities help establish the needs and goals of users, deepen the understanding of the system and facilitate ideation of new solutions. When service systems are large, dynamic and complex, the need for thorough design work is especially evident. However, design methods usually strive to describe and design best case scenarios and we argue they lack the perspective of safety needed when working in safety critical systems. In order to gain knowledge on how a perspective of risk and safety can benefit design in a safety critical domain, two different perspectives were adopted through the use of two different methods. The methods were service blueprinting and barrier analysis, adopted from service design and cognitive systems engineering respectively. The methods were implemented during the research phase of a service design project in a home healthcare system in Sweden. Service blueprinting is a method used by service designers to visualise services. Barrier analysis is aimed at identifying and categorizing artefacts and functions that prevent unwanted events from taking place, or that lessen the impact of their consequences. A comparative analysis of the two methods was performed, concluding that barrier analysis has the potential to benefit design work performed in complex and safety critical systems. The potential for barrier analysis to be more tightly integrated into current service design methods is discussed, but more research is needed in order to clarify this matter.

Keywords

Service blueprint; barrier analysis; Cognitive systems engineering; healthcare; design perspectives; service design

Large and complex human-machine systems (e.g. process industry, power stations, transport systems, healthcare institutions, etc) present great challenges in organizing, developing and maintaining the successful operation of whatever activity is being performed. In developing these kinds of complex systems we think that adopting a design approach and using design thinking is valuable. It helps establish the needs and goals of users, deepen the understanding of the system and facilitate ideation of good solutions. A design approach helps to put people in focus instead of technology or system architecture (Cooper, 1999).

However, when working with complex human-machine systems the aspect of safety often comes into play. Many of these systems are not only complex but also safety critical, i.e. the risk of serious accidents, injury or death is present. While designers generally have a well equipped toolbox of methods and techniques for user research, ideation and valuation we argue that most designers lack tools to help them consider safety aspects of their design suggestions. Safety consideration is something not generally addressed in the standard set of design tools. We suggest that designers need to turn to other disciplines for methods that can add the perspective of safety and risk when working in safety critical environments. In this paper we will present a case study where such an approach was adopted.

The different perspectives of design and CSE

Formalized methods and techniques used in design work help designers structure their approach to a design case and provide guidelines and step-by-step formulas to best practice work. However, by directing the designer's attention and actions to certain aspects of the design problem a method can also be said to reinforce a perspective or a focus in the design process. Different methods bring different aspects of the situation to the designer's attention, thus making them prioritized in the design work. It has been shown that actively adopting different perspectives in design processes affects the outcome of design work (Hult, Irestig, & Lundberg, 2006). The use of formalized methods can be a way of directing the focus of design work and can add perspectives not otherwise considered by the designer, thus affecting the outcome of his or her work.

The design disciplines, we argue, carry with them a certain kind of perspective that is reflected in the methods and techniques used in design work. Design is about exploring and unfolding a design space, thus finding the best possible solution to a specific situation. The focus in design work is naturally turned to the positive aspects of potential design solutions. It is often about creating beautiful, functional and pleasant objects and experiences. Methods for visualizing and communicating design solutions therefore focus on best case scenarios, which turns the design focus to the aspects that create these best cases. Design methods may address failure and safety, but few have an explicit focus on worst cases. The traditional design communication techniques such as storyboards and scenarios also focus on specific events, putting focus on a small number of all the possible interactions, activities, and events within a system.

Another discipline concerned with complex human-machine systems is Cognitive Systems Engineering (CSE). CSE has its roots in cognitive science and is devoted to studying phenomena that emerge when people use technological artefacts in their work (Hollnagel & Woods, 2005). CSE is a systemic approach used for analyzing, evaluating and designing complex systems, much like systems design, but with a separate set of methods and assumptions. The CSE approach can be broken down into three main concerns (ibid.); (1) how cognitive systems cope with complexity, (2) how to engineer joint cognitive (human and machine) systems and, (3) how the use of artefacts can affect specific work functions. Within CSE a systems approach is adopted. The basic premise of a systems approach is that humans are fallible and errors are to be expected and caused by an "upstream" of systemic factor, a view initially proposed in Perrow's *Normal accident theory* (Perrow, 1984; Reason, 1990). The main assumption is that it is not possible to change human conditions, but it is possible to change the conditions under which humans work (Reason, 2000). Since CSE is devoted to the understanding of how to maintain control in complex environments, the focus of interest is on the prevention of accidents rather than on finding the best solution for situations when everything is working as it should.

There is a significant difference in perspectives between design disciplines and CSE. While design focuses on best-case scenarios, CSE looks at worst-case scenarios and how to prevent them from occurring. We argue that when designers work in complex and safety critical environments, there is a need for a perspective of safety not normally adopted by designers. We also argue that this perspective could be added to design work by the use of methods from CSE. In order to explore this idea further a research project applying methods from both service design and CSE was carried out in a home healthcare setting.

Methods

In this section we will begin by describing the methods used to model the home healthcare system. Two methods were used, a *service blueprint*, representing the service design perspective, and *barrier analysis*, commonly used within the CSE domain. The case is described in the following section which leads to a review of the results produced by the two methods. This is followed by a discussion of each individual analysis and concluding remarks concerning benefits and limitations of merging the two methods.

Service blueprint

Service blueprinting is an approach for service innovation and improvement (for a detailed description see Bitner, Ostrom, & Morgan (2008)). Together with customer journeys, it is commonly used by service designers as a way to visualize services, in order to make them more tangible and susceptible to design activities (Segelström, 2009). A service blueprint provides a description of the service process, customer points of contact and physical evidence as well as the underlying support processes that support and drive the service. Bitner et al. (2008) has described services as “co-created with customers” with examples like; professional services, retail, financial, telecommunication, healthcare, and many others. The original blueprint method was developed in a service management context, and has been adjusted by the service design research community to better fit design activities and goals (Polaine, 2009; Wreiner et al., 2009; Sparagen & Chan, 2008). In this study, the method described by Bitner et al. (2008), has primarily been used, but some changes had to be made to fit the context.

The first step in service blueprinting is to identify and map the process (Bitner et al., 2008; Shostack, 1984). Viewing a service as a process allows the unfolding events to be visualized over time, connected by a number of touchpoints where customers interact with the service. Each touchpoint is subsequently described using five layers; (1) customer actions, (2) onstage, (3) backstage, (4) support processes and (5) physical evidence. When visualizing the blueprint these layers are separated by lines, which allow an illustration of the different interactions over time (see Figure 1). Vertical lines between the components show inter-functional connections between components.

Customer actions include all steps taken by a customer throughout the service delivery process, and are depicted chronologically. Onstage refers to the visible contact made between a customer and an employee, this point is also commonly referred to as a moment of truth. Backstage refers to actions performed by the employee not visible to the customer, for example a telephone call or some other preparation. The fourth layer in the service blueprint is the support processes, which includes all activities executed by individuals who do not have direct contact with the customer but that need to occur in order for the service to be delivered. The last layer, physical evidence, is described at the top of the blueprint and represents all the tangibles that customers come in contact with. The physical evidences are identified for each customer action and every moment of truth. (Bitner et al., 2008)

Barrier analysis

The second method applied to the collected data was a barrier analysis. Identifying barriers is common within risk and safety assessments in CSE. A barrier is an obstruction or hindrance (or defence) that may prevent or lessen the impact of an unwanted consequence (Hollnagel, 1999). This may include stopping, slowing down, restricting, limiting or in some other way weakening an uncontrollable process. The concept of barriers is used to understand and prevent accidents. If an accident has taken place this means that one or several barriers have failed, i.e. did not serve their purpose or were missing (Hollnagel, 1999). Barrier analysis is frequently used to describe accidents in terms of conditions that lead to failed barriers (Hollnagel, 2004).

Often barriers are identified together with other risk analysis methods in order to provide a context to better understand the barriers’ function and how they are related to each other (e.g. Guldenmund et al., 2005; Harms-Ringdahl, 2003; Svenson, 1991). However, in this analysis, barriers were identified directly after the participatory observations and later in the light of the blueprint. To verify that the barriers usage had been correctly interpreted and that no major barriers had been unidentified, several workgroup representatives within the home care service systems participated in a workshop where these barriers were discussed.

Barrier systems and barrier functions

The barrier identification performed on the data collected from observations at healthcare centers included four different types of barrier systems described by Hollnagel (1999, 2004): material, functional, symbolic and incorporeal (immaterial).

- *Material barriers* are physical hindrances, for example buildings, walls, fences, railings, cages or gates. A material barrier does not need to be perceived or interpreted to serve its purpose.
- *Functional barriers* prevent or hinder actions by setting up a number of pre-conditions that need to be met in order for an action to be carried out. This may for example be locks, passwords, distances or delays. The pre-conditions do not necessarily need to be seen or interpreted by a human; they can also be sensed by the system itself.
- *Symbolic barriers* require an act of interpretation by an intelligent agent that responds or reacts to it. Examples are for instance coding (color, shape, spatial layout), instructions, procedures, signs or an approval of some sort. A symbolic barrier indicates a certain limitation but does not in itself hinder an event from taking place, if it is neglected or ignored by the user.
- *Incorporeal barriers* are not physically present in the current situation; they depend on the knowledge of the user. Common incorporeal barriers are rules, guidelines, restrictions and laws.

Barriers can also be categorized according to their function within the system, defined as a specific manner by which the barrier achieves its purpose, the most basic distinction being preventative or protective (see Table 1). As the name implies the function of a preventative barrier is to prevent an unwanted event from taking place. The role of the protective barrier is to lessen the impact of an unwanted effect or action when it has taken place (Hollnagel, 2004).

Case study

We applied the two methods on a case which covered the early research phase of a design process, and the goal was to use the findings from this research phase to create a model of the complex service system of home healthcare. This model, or description, is the foundation for further design work to find new solutions and improvements. The research group consisted persons with experience in design research, as well as persons with experience of adopting a CSE-perspective in safety critical environments.

Data collection

Initially a literature study of the home healthcare domain was performed (Hägglund & Lind, 2006; Orre, 2009; Wallqvist, 2003; Winge, 2007). Then a total of 25 hours of participatory observations with different care giving organizations was performed by the four researchers. Observations were not only performed in the patient’s homes but also at district care centers and at the main hospital in order to gain insight into the workflow of the major organizations participating in the home healthcare system. During the observations, special attention was given to the handling and distribution of medication.

Personnel working within the healthcare system in Sweden are required to report incidents deviating from normal procedure or events that have led to or could lead to injury for the patient. In order to gain insight into issues regarding patient safety within the home healthcare system an initial study of reported adverse events from 2003 to 2009 from several care giving organizations was performed. One of the most common occurrences reported was incorrect handling of medication. This included patients receiving the wrong type of medication, patients receiving medication at the wrong time or medication not given at all.

Within the home healthcare system individual accommodation is necessary in order to meet the patients’ varying needs. To preserve our impressions from the observations and to turn our data into a more living individual, we created a persona (Pruitt & Adlin, 2006).

Persona

Anja, 85 years of age, has lived alone in her apartment since her husband passed away a few years earlier. Anja is treated for age related diabetes, pain in her hip and occasional depression. She has previously had thrombosis and heart related problems which she takes medication for. Her condition requires the involvement and coordination of a number of care givers, including relatives, home care service, food delivery service, the district care center and the hospital. This means that she gets home visits at least twice a day but often more. Anja was used as a representative of our main user group in the subsequent analysis.

Results

The results are presented individually for the two methods. A suggestion for how to combine the results is provided in the discussion, followed by the conclusions of this work.

Blueprint result

The service process described in the blueprint analysis was "a typical day in the life of Anja" and included a 24 hour time period. During this day Anja got five visits; three from the home healthcare service, one food delivery and a visit from the hospital. Anja also has an alarm if she needs any help during the evening or night. Figure 1 presents an excerpt from the blueprint. The excerpt shows a period in the middle of Anja's day when a person from the home healthcare service visits to administer medication. The excerpt ends before the caregiver leaves.

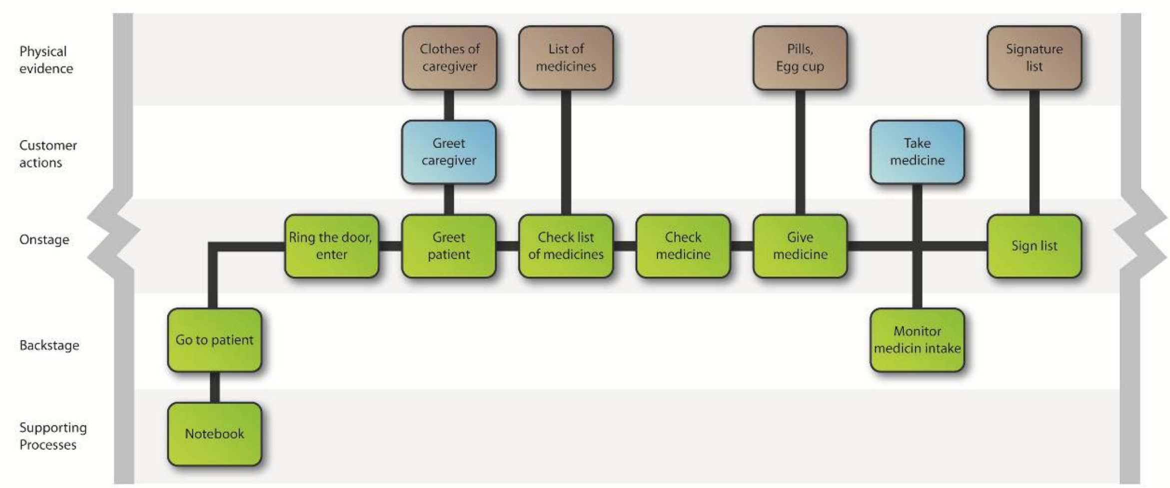

Fig 1. Excerpt from blueprint for home healthcare visit with Anja

Barrier analysis result

Table 1 and Table 2 show the results of the barrier analysis, note that only barriers relating to medication have been identified in the system. In Figure 1 the barriers are identified as well as the barrier system they belong to and if their function is preventative (Pre) or protective (Pro). Table 2 presents a more detailed description of the barrier functions and their distribution; the numbers in Table 1 correspond to the functions in Table 2. For example "egg-cup" and "medicine cabinet" are physical barrier systems, classified as category 1 in Table 1. This corresponds to "Containing or protecting, prevent transporting something from the present location or into the present location" in Table 2.

Table 1. Barrier systems and barrier functions in a home healthcare system in Linköping, Sweden.

Barriers / Functions	Physical 1	Physical 2	Physical 3	Physical 4	Functional 1	Functional 2	Functional 3	Functional 4	Functional 5	Symbolic 1	Symbolic 2	Symbolic 3	Symbolic 4	Symbolic 5	Incorporeal 1	Incorporeal 2

Discussion

The aim of this research is to identify what kind of information, and what image the two different methods convey of a service system. We are interested in clarifying whether or not they can complement each other and whether barrier analysis can be used as a design tool that emphasizes safety issues. The two methods described in this paper are very different and we do not attempt to directly compare them or recommend one over the other.

Blueprint

The blueprint, as expected from a service design tool, was more effective in increasing the understanding of the patient's point of view and the understanding of processes in the home healthcare domain. It also served to visualize the service encounters and thus made them available for design valuations and suggestions of redesign.

Each service encounter is mediated, either by situated instruments (service evidence) or socially (people, rules, and roles) (Sangiorgi, 2009). The blueprint primarily shows the socially mediated actions, and the instruments chosen as part of the blueprint scenario. The instruments and interactions included are the ones most commonly used, or considered to be of greater importance. Since only one of many possible scenarios is considered, a lot of possible outcomes and incidents are not covered. When designers create a blueprint, a choice is made on what to include, which normally leads to a representation of the most common activities.

Barrier analysis

Identifying all the barriers (in the care takers home environment) involved in the medication process was done fairly quickly since we had observations and documentation to rely on. The subsequent workshop verified that the relevant barriers had been included. The most challenging part was to categorize the identified barriers into the predefined classes. The ambiguous nature of many barriers, and overlapping barrier categories, sometimes made them hard to classify.

Many interactions within a system as complex and people-intensive as home healthcare depend largely on the social interactions (e.g. conversations) between individuals. Such interactions are informal and proved hard to categorize in the barrier framework, as well as in the blueprint. Also as a consequence of the social nature of the healthcare system, our analysis showed that most barriers are either symbolic or incorporeal. This is probably the case with most similar systems where service providers' actions are controlled by laws, authority, permissions, and so on. We could also see a large majority of the barriers dedicated to preventing accidents from happening, as opposed to very few that actually protected the system by dampening the effects of incidents. This was also an interesting finding from the barrier analysis that would otherwise have been hard to identify with the standard design tools.

Worth noting is that the barrier analysis identified mechanisms and artifacts that were not mentioned in the blueprint. Some mechanisms and artifacts were simply not used in the blueprint scenario and some were not covered by the levels of the blueprint. For instance, delegation of medicine, laws, supervision, incident reports and routines, are not exposed by the blueprint. These barriers can be seen as somewhat "hidden" in the system and therefore not visualized by the snapshot picture of the system the blueprint provides. However, these mechanisms are important for the system to function and critical for patient safety and would therefore be necessary to consider when creating service design in such an environment.

Combining the results

Currently, barriers exist as context free entities in the barrier analysis. As a way of extending the analysis, the identified barriers was mapped onto the existing levels in the blueprint format, see Figure 2. When the list of barriers was placed into the layers of the blueprint, some interesting things happened. For instance, it was obvious that the barriers could be placed on different levels depending on who were using the barrier at the moment, who could perceive it, where it was currently placed, and so on.

Placing the barriers in the blueprint format provided a context for the barriers, by adding information about interdependencies and relations. Most barriers pertaining to physical evidence in the blueprint framework also have associated available actions. Besides being a physical evidence, an alarm can potentially be used both by the patient (customer action), onstage, or by the visiting care provider, either onstage or backstage (i.e. without the patient noticing). Some barriers also have different manifestations, for instance a manifestation in the real, physical world and a copy in the digital world. Many lists and notes for instance, are kept both in the binder at the patients home and in the medical health records. In Figure 2, the barriers were included on the blueprint layers, with some appearing at multiple layers. This is partly because the function of the barrier depends on where the barrier is, and what action is being performed, and partly because the same barrier can have an artifact, a process, or event associated, thus appearing at multiple layers in the blueprint. This makes the placement of the barriers on the blueprint somewhat difficult. It might have been possible to place the barriers in a slightly different way than in Figure 2.

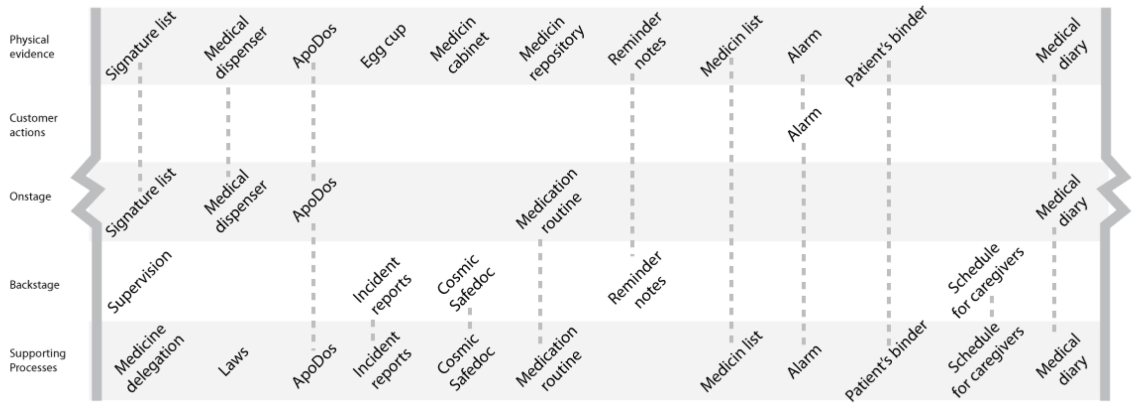

Fig 2. The list of identified barriers translated into blueprint objects.

Conclusion

One goal of the research was to evaluate the potential of barrier analysis as a complementary design tool. The barrier analysis provided a more complete view of the objects and possible events in the system and was not dependent on a specific scenario that arbitrarily included events. The blueprint did mention most of the identified physical and functional barriers, whereas only a few of the symbolic and incorporeal barriers were included. The complete list of barriers offers ways to think about 1) where new barriers could fit in 2) what types of barriers could fit in and 3) implications of taking away existing barriers. The barriers themselves also serve as opportunities for redesign and triggers creativeness.

To be an effective design tool though, barrier analysis needs to be better described (i.e. defined) and customized to meet the requirements of design – quick, easy, and practical. The current form does however create a good floor for reflection and discussions, and the process of categorizing barriers provided insights about the domain. We have seen that actively adopting a safety perspective is important for the design of safety critical systems. The barrier analysis used in conjunction with a more traditional design method provided a richer picture that pointed out safety issues. The safety perspective also underscored that the nature of humans in such systems must be understood and that incidents should be seen as natural occurrences in any safety critical system.

It is also important to note that the barrier analysis per se does not insure that safety issues are regarded. Equally as important was the perspective itself, and using approaches and knowledge from CSE greatly affected the study. For instance, an activity associated with the CSE approach is looking at available documentation from accidents and incidents. The choice to look at the reported adverse events was a direct consequence of adopting this perspective, and lead to our focus on medication. This focus later prompted a more thorough description of our persona's medical condition, which in turn had implications for what was included in the blueprint.

Future research

In an attempt to see how the two methods might work together, a simple mapping of the barriers onto the blueprint framework provided added contextual information, but to make sure that barriers are considered in design for complex systems, a complete merge of the methods could prove fruitful. Any such approach must however consider the different manifestations, uses and temporal aspects of barriers that must somehow be accounted for by the merging method. The blueprint could also be adjusted to account for episodes in the system where barriers are in effect, thus eliminating some of the problems with temporal scope that was encountered.

Furthermore we believe that service blueprinting would be useful as a complement to existing CSE methods. Service blueprinting provides a basis for better understanding complex systems from a user perspective and facilitate the process of finding better design solutions. The merits of such an approach need to be further explored.

Acknowledgements

We would primarily like to thank Fabian Segelström for much support and input. Sture Hägglund, Leili Lind and Pontus Johnsson also contributed greatly. The research was made possible by grants from VINNOVA, the projects SERV (2007-03444) and ICE (2007-02892). We would also like to thank the healthcare organizations of Linköping and the great people within them – we admire your work!

Author Biography

Johan Blomkvist

After about ten years working with care for the elderly and people with dementia, Johan got interested in human behaviour and took a bachelor in cognitive science. From there he went on to a master in design, eager to apply his newly acquired knowledge about humans as social, communicative, and embodied beings situated in cultural and evolutionary contexts. During this time, Johan also started working with user innovation and managing projects where design students collaborated with organisations and companies. His current research, as a PhD student at Linköping University, aims to expand our knowledge about prototyping services.

Amy Rankin

After completing a Bachelors degree of Cognitive Science she spent two years in graduate school studying human behaviour in complex environments. She participated in several research projects where systemic approaches to complex systems were used, for instance accident investigation methods at a nuclear power plant, train evacuations in Sweden and flexibility in crises management organisations. Today he is a PhD candidate at Linköping University. Her research areas are safety culture in complex social-technical systems, resilience engineering and crises management.

Daniel Anundi

As a graduate student in design at Linköping University with a background in cognitive science his studies have focused on interaction design and service design. His research interests includes among other things interaction aesthetics, health care and service innovation. Currently he is employed by the Swedish Meteorological and Hydrological Institute as an interaction designer and writing his master's thesis on the subject of service recovery.

Stefan Holmlid

Stefan Holmlid is assistant professor in interaction and service design at Linköping University, with 15 years of experience of design research in academic as well as industrial settings. He pioneered studio teaching of interaction design and service design in Sweden, and continues to teach user-driven innovation, interaction design and service design.

Currently his research interests are the expressive powers of and the involvement of stakeholders through design methods and techniques in service development and service innovation. The idea that design objects and design materials can be both dynamic, active and that the design is co-created "in use", drive his research of relevant theoretical grounding for design. His research is founded on a critical stance towards institutionalization of user-centered design.

Complexities of teaching and learning collaborations with international partners: the Global Studio

Erik Bohemia, Northumbria University, UK, erik.bohemia@northumbria.ac.uk

Abstract

During the past four years, academics from the School of Design at Northumbria University have developed and implemented an innovative international collaborative teaching and research model named 'the Global Studio'. The Global Studio provides a response within Higher Education to shifting trends taking place in manufacturing and the related emergence of globally networked organisations. This paper examines the challenges of establishing and maintaining teaching and learning relationships with international partners.

During the past four years seven international collaborative research projects involving high profile overseas universities and multinational industry partners have been undertaken within the Global Studio. A focus of the Global Studio is developing a better understanding of product development processes that are conducted by globally distributed and cross-cultural design teams. The Global Studio is enabling staff and students at a university located in the UK to work in a cross-disciplinary and cross-institutional context with staff and students from the participating partners based in countries such as Australia, the USA, the Netherlands and Korea. The cross-institutional collaboration is enabling the intersection of various disciplinary approaches which are facilitating the development of innovative practices.

In this paper we explore some of the complexities associated with conducting the Global Studio. We also provide an example of one of the projects undertaken in 2008. This particular Global Studio was conducted in collaboration with a multinational mobile products manufacturer and two universities based in Korea and the UK. The paper draws attention to complexities of teaching and learning collaborations with international partners.

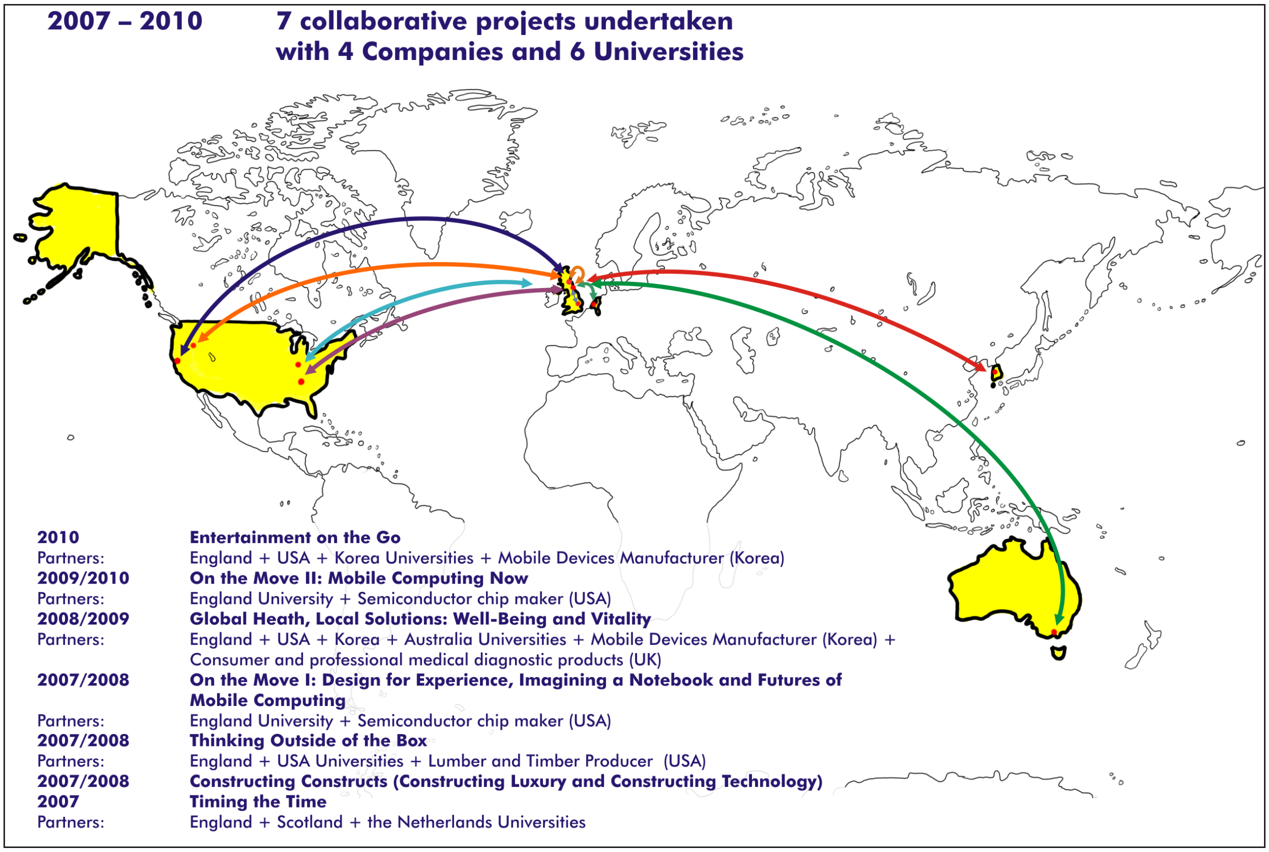
Keywords

distributed design teams; e-learning; design studio; industry based projects; international learning collaboration

Over the past four years the School of Design at Northumbria University has been experimenting with an innovative curriculum design and delivery model named 'the Global Studio'. The Global Studio is a cross-institutional research informed teaching and learning collaboration conducted between Northumbria University and international universities and industry partners. Participating institutions based in the UK, USA, Netherlands, Australia and Korea.

The aims of the Global Studio are linked with current and future industry needs associated with contemporary changes in the organisation of products and services development (e.g. Bohemia & Harman, 2008; Clough, 2002; Cox, 2005; Engardio & Einhorn, 2005; The Design Skills Advisory Panel, 2006) including the shift to the use of distributed terms in the product development process. These changes highlight the importance of equipping design students with skills for working in globally networked organisations particularly the development of skills in intercultural communication and collaboration (Bohemia & Harman, 2008).

Following in the tradition of the design studio, with its emphasis on project-based learning and learning in and through 'doing' (Schön, 1985), students in the Global Studio design a product and/or service using a design process methodology (Cooper, 2001; Pahl & Beitz, 1996; Roozenburg & Eekels, 1995). The emphasis on project-based learning in the Global Studio is underpinned by the assumption that this pedagogical technique contributes to embedding established design practices into the student's own repertoire. However, additional layers have been woven into the course to facilitate the development of skills in cross-organisational and cross-cultural communication and collaboration. Thus, the Global Studio integrates elements from a design studio model of education with elements that equip students with specific knowledge and skills required to work in globally networked organisations and in distributed design teams.



The design of the 'Global Studio(s)'

The initial Global Studio was conceived as a course conducted annually between participating universities located in different countries. There have been a number of initiatives aimed at fostering cross-institutional international collaboration (e.g. Adams, 2002; Akar, Öztürk, and, & Wiethoff, 2004; Coxon, Allen, & de Bono, 2007; Elspass & Hollinger, 2004; Grierson, Ion, & Juster, 2006; Hildre & Fyhn, 2002; Horváth, Duhovnik, & Xirouchakis, 2003; Karjalainen & Repokari, 2007; Novoa, 2007; van Boejen & Babke-Schaub, 2007). However, global projects are often very expensive. For example, a recent collaboration between a European university and an American university cost approximately US$200,000.[1] Another collaboration between a group of European universities cost approximately €50,000.

Thus, one of the major aims of the Global Studio was to provide a learning environment where students could develop skills in intercultural communication and collaboration but in a way that was economically sustainable and that would enable an entire cohort of students to participate.

Another aim was to develop a structure that would enable teaching and assessment to be organised independently at each of the partner universities, thereby overcoming some of the difficulties associated with cross-institutional collaborations (Bohemia, 2004).

In the initial course, student roles and associated activities were structured throughout the project to encourage students to engage in cross-institutional communication and interaction. This was predominantly achieved through having students act in the dual roles of 'client' and 'designer' (see Figure 1). A detailed description of the organisation of the client and designer roles has been reported elsewhere (Bohemia, Harman, & Lauche, 2009).

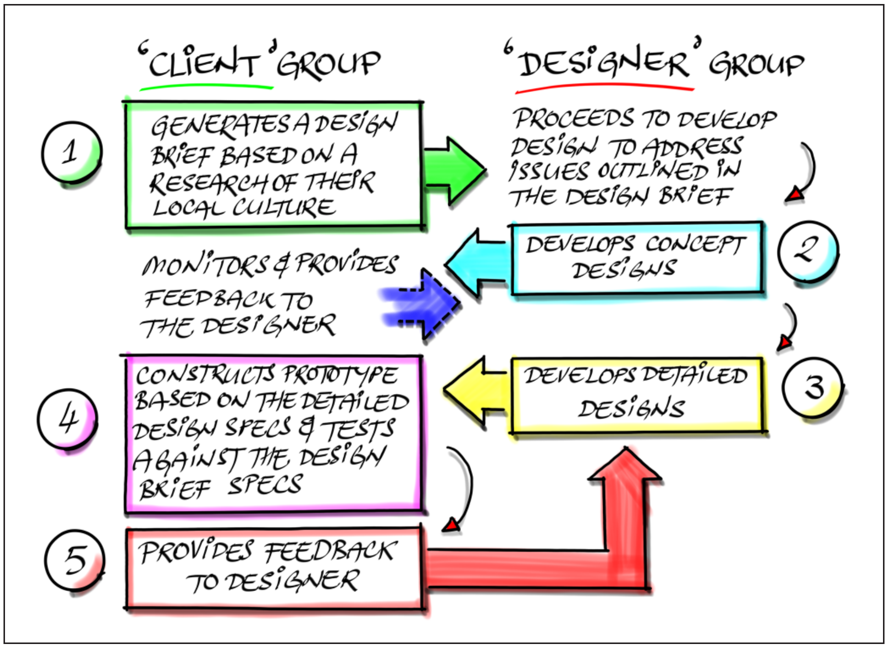

Figure 1 Key stages in the Global Studio

Note: Each group takes up both the designer and client roles

A year later the Global Studio was incorporated into a different programme in the School of Design. This resulted in changes to the design of the Global Studio as the capacity to collaborate with industry partners based in different geographic locations needed to be incorporated into the Global Studio design delivery. This provided additional challenges to those experienced in the previous Global Studio. For example, the inclusion of industry partners increased the complexity of interaction and communication amongst the students, lecturers and industry partners, see Figure 2 and Figure 3 (Bohemia et al., 2009).

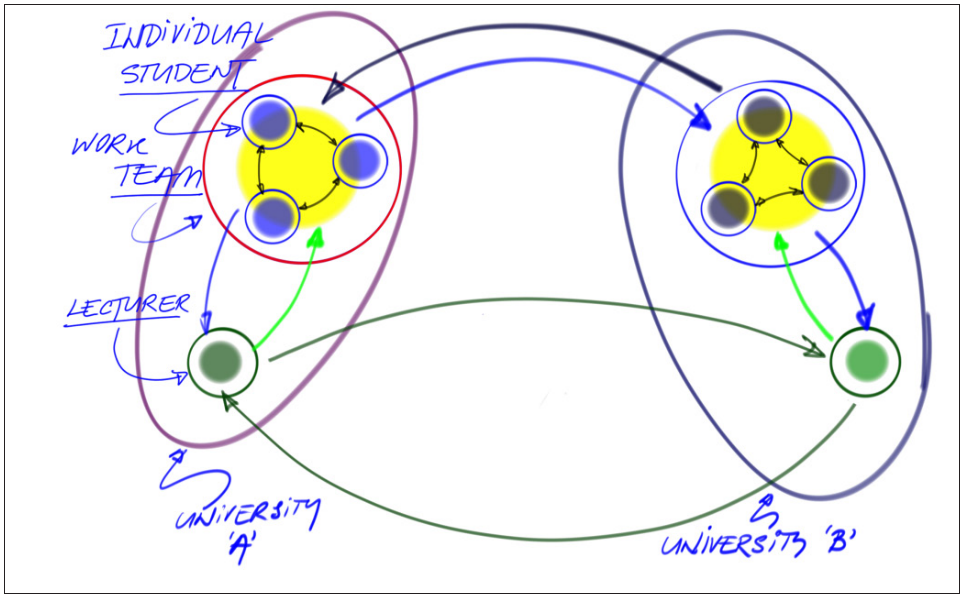

Figure 2 Interactions between student teams and lecturers in the Global Studio conducted in 2007

Note: there were multiple work teams located at each of the partner universities

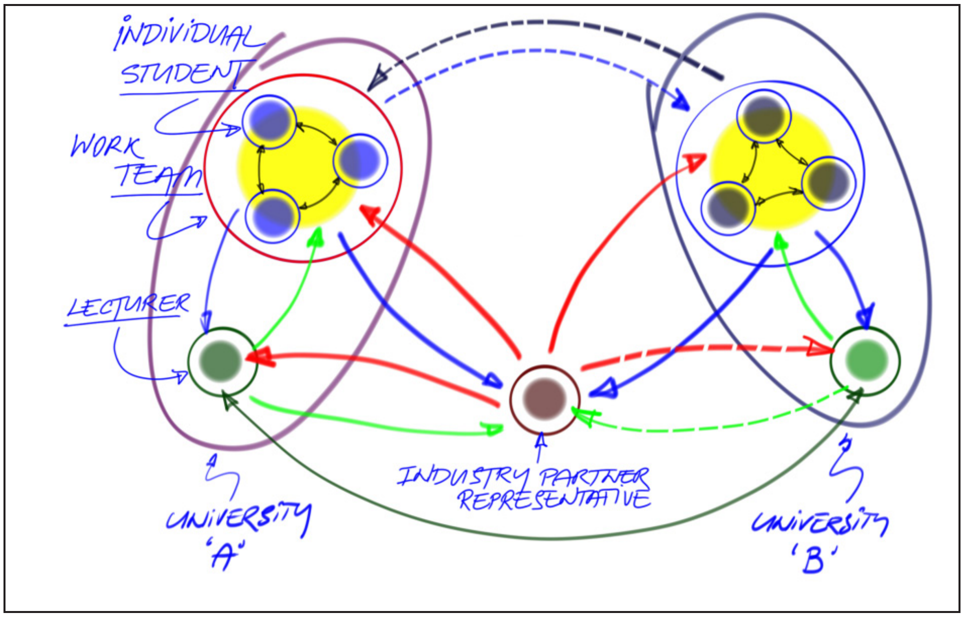

Figure 3 Increased complexity of interactions between student teams, industry partners and lecturers in the Global Studio conducted since 2008

Note: there were multiple work teams located at each of the partner universities

The inclusion of the industry partners also impacted on how projects were structured as well as student roles and interactions. For example, since 2007/2008 it was the industry partners who took-up the role of clients within the Global Studio (see Table 1). This meant that students from the participating universities no longer acted for each other as 'clients' and 'designers' as they had done in the initial Global Studio. This significantly changed the way students from the different participating universities interacted and communicated with each other. For example, having the industry partners acting as the clients shifted the focus of interactions between students from different universities as illustrated in Figure 1 to interaction between students and the industry partner as illustrated in Figure 4.

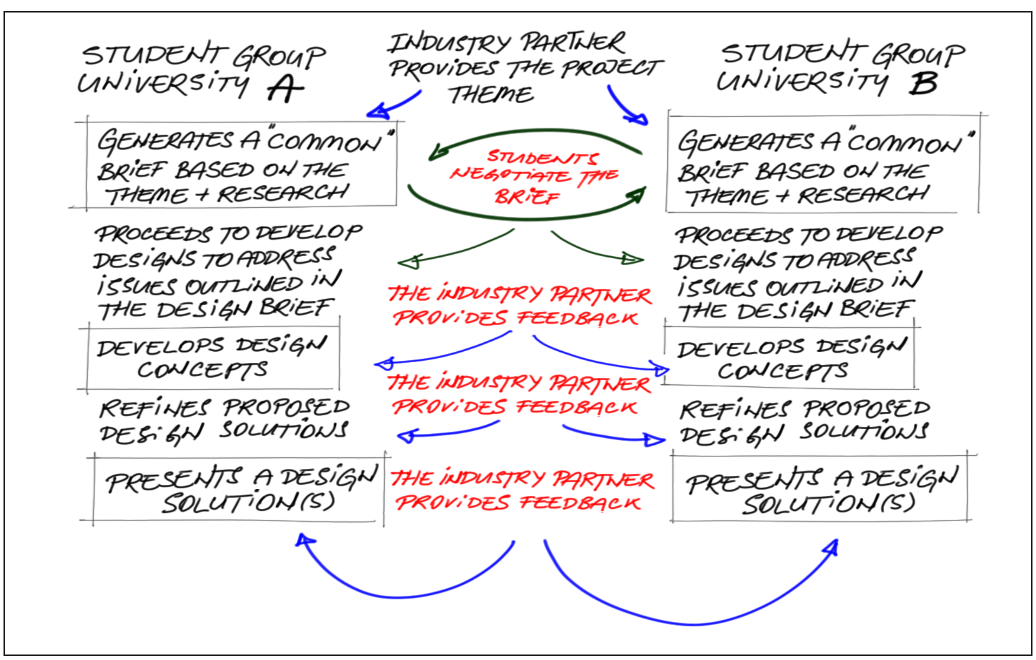

Figure 4 Key stages in the Global Studio incorporating an industry partner's input

This has reduced the reliance of students based at one university from having input from students based at another university. A subsequent outcome was a significant reduction of interaction and need to communicate between students based at the different participating universities. For example, there was less content uploaded on each of the individual group project web pages compared to the previous Global Studio. In addition, data from the student surveys indicated that a lower percentage of students in the 2007/2008 cohort felt that the Global Studio had provided them with the opportunity to explore cultural (53% 2006/06, 40% 2007/08).

Over the four years nearly 450 students have participated on the Global Studio, thus demonstrating that this mode of international studio delivery is possible to be undertaken on a large scale (see Table 1).

Collaborative Partners	**Academic Year**			
	2006/2007	2007/2008	2008/2009	2009/2010
Higher Education Partners based in	• The Netherlands • Scotland • England	• Korea • England • USA (partner A)	• Korea • England • Australia • USA (partner B)	• England • USA (partner B) • Korea
Number of participating individual students	63	60	147	179
Industry Partners		• Semiconductor chip maker (USA) • Mobile Devices Manufacturer (UK + Korea) • Lumber and Timber Producer (USA)	• Consumer and professional medical diagnostic products (UK) • Mobile Devices Manufacturer (Korea)	• Semiconductor chip maker (USA) • Mobile Devices Manufacturer (Korea)

Table 1 University and Industry partners participating within the Global Studio

Key organisational issues

An important question that needs to be asked by prospective partners before proceeding with the design of a Global Studio is: *'Is a cross-institutional collaboration actually feasible?'* Issues that need to be considered include (Bohemia, Harman, & Lauche, 2009, p. 28):

- Timing: Start of academic year, semester length and public holidays differ from country to country. In addition, suitable days and times for synchronous interactions need to be established.
- Level: At what level should the programme be introduced? What prior skills are necessary in order for students to participate in the Global Studio? Do students at different participating institutions all need to be at the same level of study?
- Co-ordination and project leadership: Who is responsible for overall co-ordination of the Global Studio? Is a co-ordinator or project leader required?
- Assessment: What type of assessment would enhance learning in this course? For example, what proportion should be team-based? Should each project milestone be assessed? Can assessment be organised to take into account institutional differences? In addition, a question needs to be asked what should be assessed and who should be assessing?
- Resources: What resources would be needed to run this programme? In particular, are technological resources compatible? Would a potential difference in the level of available resources at one institution disadvantage its students?
- Language: What will be the lingua franca? Do staff and students have adequate skills in the lingua franca? Is this necessary?

- Academic staff skills: What skills should academics have to participate in and manage this type of programme?

In addition to the above issue the following points should be also considered:

- Length of the project: What should be length of the overall project? How much time should be allocated to each of project stages? How might students be provided with low stakes confidence building opportunities to practice various stages of the design process and embed these practices into their repertoire?
- Level of the industry partner support: What level of involvement should the industry partner provide? How do you ensure that students from each participating universities have appropriate access to the industry partner?
- Level of interaction between students: What level of interaction is expected to take between the students from different universities? How should this interaction be encouraged?
- Supporting students: What support should academics provide to students? Should they provide any support/feedback to students based at other universities?
- Research issues: What data should be collected? How should this data be collected? Who has access to the data? University specific ethical procedures/policy.

The above issues and associated questions foreground the complex negotiations required with internal and external stakeholders in order to establish successful cross-institutional teaching and learning collaborations (see Figure 5).

The complex negotiations required to organise the Global Studio, both internally and externally lead us to recommend that the Global Studio be embedded in a core Design Studio module in the programme. This would contribute to making this innovative model of curriculum delivery more sustainable as once the critical negotiations have been worked through they are in place for ongoing delivery.

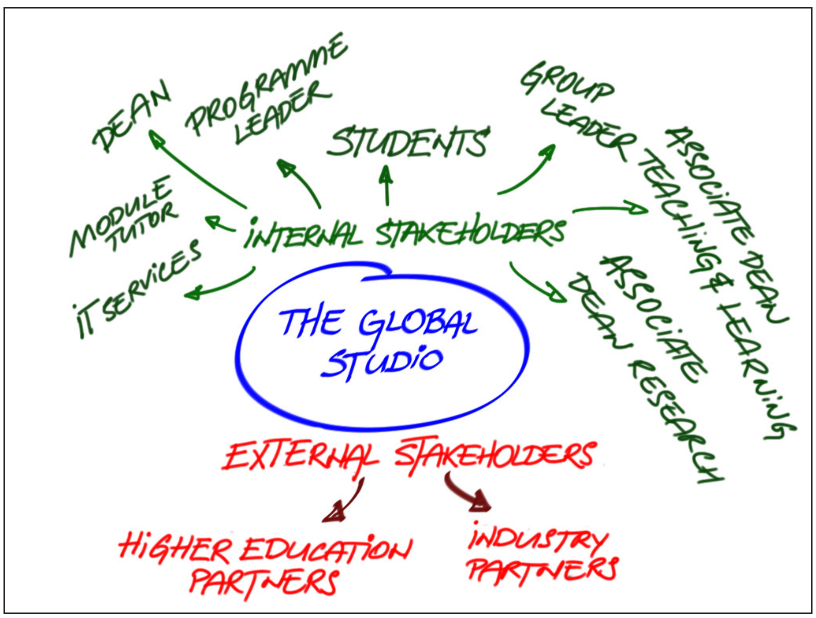

Figure 5 Internal and external stakeholders

Furthermore, generally project-based learning undertaken in collaboration with industry partners requires specific disciplinary skills in order to tackle given project themes. Therefore, these industry based design projects are ‘tied’ to specific disciplinary programmes such as industrial design or fashion design.

Delivering the Global Studio

The Global Studio is delivered using a blended learning approach with a combination of online learning and face-to-face teaching. An important aspect of the Global Studio is the incorporation of Web 2.0 technologies. The focus is on developing skills in distance communication and collaboration by means of these technologies.

There are various models for delivering the Global Studio. For example, the Global Studio can be conducted with other universities, as was the Global Studio in 2006/2007 or with industry partners, as is in the current Global Studio (see Table 1), or with both.

	University	University
University	University + University	University + Industry Partner + University
Industry Partner	Industry Partner + University	

Figure 6 Possible collaborative intersections for delivering the Global Studio

A case study

The 2007/2008 project titled *Constructing Constructs* was conducted between Northumbria University and Korean university in collaboration with a Mobile Devices Manufacturer (UK and Korea design studios). This project explored themes of *Constructing Luxury* and *Constructing Technology*. The contact between the Northumbria University and design studio manager was established at an international conference. This was then followed up by further discussions to establish the project scope, timing and how the project teams were organised.

At the commencement of the *Constructing Constructs* project, students were organised into 3 work teams at each of the universities. Then, the project teams were asked to complete a short design task with the aim of creating a team 'identity'. At the end of this team building exercise each group had agreed on their team name and produced their team logo. The following project teams were briefed by the industry partner via teleconference on the two broad project themes which were New Luxury: *Constructing Luxury* and *New Digital Lifestyle: Constructing Technology*. The next task was for the work teams to develop a design brief addressing one of the two themes. These design briefs were then discussed and fine-tuned with the industry partner. After the design briefs were agreed on the work teams undertook tasks such as brainstorming, mind mapping, market research and user research. At each of the key stages of the project students uploaded their work onto a shared secured space for review by their industry partners. All students, industry partners and academic staff had access to this space. Based on these exercises they then started to develop initial concepts which were presented to the industry partner for evaluation. Based on this feedback they further developed a specific concept to illustrate their design solutions. Again these were reviewed by the industry partner. Final presentations of design proposals were communicated to the industry partner via posters, a movie and design process diaries (see Figure 7).

Figure 7   Constructing Constructs project design process (2008)

Encouraging collaboration

One of the strategies used in the Global Studio to encourage online collaboration is to schedule regular project progress reviews with the industry partners. As industry partners are physically located at another city/country these reviews needed to be conducted at a distance. Therefore, online technologies such as Wiki pages and tele/videoconferencing were used to facilitate distributed communication between the university and industry partners. For example, the *Constructing the Construct* work teams from the Korean and Northumbria universities conducted seven virtual meetings with the industry partner during 10 weeks while the project was running using both Wiki pages and teleconferences (Bohemia, Smith, et al., 2009).

Involving international partners

Regular contacts with representatives from the other universities and industry partners help to sustain these relationships. These contacts can be used to evaluate projects, writing collaborative papers and funding applications and planning for future collaborative projects. In addition, industry partners' ongoing feedback provided to students also facilitates regular contacts.

Attracting funding also helps with sustaining these relationships. For example, funding enables academics to visit their industry and/or university partners as well as disseminating research outcomes at international conferences. It also provides resources to facilitate the development of research networks, support staff sabbatical exchange visits and provide the means for student exchanges.

Managing multiple relationships

There are at least four types of collaborative partnerships that need to be developed. The first is the development of partnerships with other universities. The second are partnerships with external industry partners. The third partnership is with university service support sections such as IT and eLearning and the fourth is with internal and external funding bodies.

Managing and sustaining the above relationships requires the allocation of resources such as time. Therefore, those involved in conducting programmes such as Global Studio need to be supported by their institutions to allow them to engage in cross-institutional collaboration activities.

A model for forging and sustaining successful cross-institutional collaborations

An initial conceptualisation of the Global Studio was that it would enable a research network to be established among the participating institutions in order to gain a better understanding of the ways cross-disciplinary, cross-institutional and cross-cultural design projects are undertaken. This links with an ongoing aim of the Global Studio for the development of collaborative partnerships with industry and the exploration of practice led research on distributed design, see Figure 8. In better understanding how design work is undertaken in distributed work settings, for example the ways particular technologies enable and constrain the design process, innovative solutions might be developed for organising distributed design teams and collaboration across distance. In addition to providing a site for examining product development in geographically distributed work groups, the Global Studio also provides a site for undertaking research with a focus on teaching and learning.

Figure 8 Linking Research, Education and Practice

Contribution of Global Studio

The Global Studio has contributed to a number of key strategic university goals at Northumbria University such as delivering an outstanding student experience; developing excellence in research informed teaching; generating high quality research outputs; increasing research income by engaging with business and funding bodies; and creating a collaborative culture (internally and externally) which actively encourages teamwork, development of staff expertise, and interaction with strategic partners regionally, nationally and internationally. In addition, the Global Studio has enabled participating academic staff to develop research and scholarly activities and it facilitated the development and implementation of research informed curriculum and innovative pedagogic practices. For example, the Global Studio generated close to £100,000 of research income, it enabled the production of more than 20 research outputs including a book (Bohemia, Harman, & Lauche, 2009), journal articles (Bohemia & Harman, 2008; Bohemia, Harman, & McDowell, 2009; Lauche, Bohemia, Connor, & Badke-Schaub, 2008), international conference papers (e.g. Bohemia & Harman, 2009; Bohemia et al., 2007; Bohemia, Lauche, & Harman, 2008; Bohemia, Lauche, Langeveld, & Badke-Schaub, 2006; Bohemia, Smith, & Harman, 2008; Lauche et al., 2007) and it led to numerous invited workshops and guest lectures at leading international universities. During the past four years, seven international collaborative research projects involving high profile overseas universities and multinational industry partners in collaborative research activities have been undertaken within the Global Studio.

Conclusion

Issues associated with initiating and running the Global Studio in some respects are similar to those associated with initiating and running other project-based courses. However, within the Global Studio these issues are amplified as additional factors, such as external stake holders' needs and wishes, need to be taken into consideration. This means that setting-up and conducting the Global Studio is beyond just one person. From our experience, we propose that setting-up and conducting the Global Studio requires substantial backing and support from senior managers within the Schools/Faculties as well as institutional IT support. This is in addition to the commitment that is needed from those who are and/or will be directly involved in conducting it.

However, as outlined above, the Global Studio could provide benefits which potentially address a number issues Higher Education is currently facing. For example, the Global Studio provides an opportunity for internationalising the design curriculum where students are able to practice intercultural communication in collaboration with their international peers. It could also provide students with a novel way to engage with international industry mentors. In addition it has the potential for academics to forge strong international relationships with their academic peers and industry partners thus potentially providing a fruitful ground for developing research projects involving industry and universities.

In addition, the Global Studio provides a platform for teaching staff to continue their professional development in areas such as e-Learning and practice-based Teaching and Learning. The Global Studio could also be used to promote the sharing of resources such as teaching strategies and techniques and collaboration in relation to curriculum development across participating Higher Education institutions.

Acknowledgement

I would like to thank to our industry partners for their generous support and participating academics and students. I would also like to acknowledge the ongoing support provided by staff from IT services. Lastly, I would like to acknowledge funding support from CETL: AfL, ADM-HEA the Higher Education Academy Subject Centre for Art, Design and Media and JISC infoNet. This paper is based on a report prepared for ADM-HEA.

Author Biography

Erik Bohemia

Erik is a Reader in Reader in Design Pedagogy at the School of Design, Northumbria University, UK. As a Researcher and an Educator in the field of design, he is interested in the skills and competencies of designers and the match between these and industry requirements. The results from his research in this area have been used to guide the development of curriculum in design so that future graduates may more effectively fulfil industry requirements. Erik's current research focus is on global product design development processes and its impact on the design profession. His research has been published in international journals and conferences.

Intensive studio experience in a non-studio masters program: Student activities and thinking across levels of design

Elizabeth Boling, Indiana University, Bloomington, IN, eboling@indiana.edu

Kennon M. Smith, Indiana University, Bloomington, IN

Abstract

In conjunction with an emerging view of instructional as a design field versus its traditional identification as a science, the authors have designed, established and studied from 2005—2009 a masters level course using studio-based pedagogy. This paper examines the design tensions involved in that effort from the perspective of the designer/instructors and the design activities and thinking of the students in the most recent iteration of the course. The research is based on analysis of field notes, student work, and syllabi across these five years, as well as on reflections of the designer/instructors. Design tensions center on the difficulties of adapting a pervasive pedagogy into an environment not conceived to support it and on the evolution of the course as it became more studio-oriented. Examination of the student's activities and design thinking was made through the lens of Lawson and Dorst's (2009) models of design, and include analysis of design activities as represented in our field notes together with discussion of sample work from students that illustrate their design thinking. The design models offered a useful vocabulary for discussing student's design behaviors, both with respect to their unique approaches to design and to the observations of the instructors regarding the effect of revisions in the course. We also discuss two categories of design activity used as extensions to the model (using external input and using tools) to describe activities in this class.

Keywords

design pedagogy; studio; instructional design; case study

Although instructional design is a field that has viewed itself for decades as a scientific enterprise, and to a large extent still does (Smith, 2008), questions have been raised about our basic "scientific" identity as early as 1981 (Davies). Recently those questions have been given a clarifying context by the broader discussion of design as an intellectual tradition in its own right (Nelson and Stolterman, 2003), and the recognition that instructional design shares broad characteristics with every other design enterprise, as argued persuasively by Geol and Pirolli (1992) and Goel (1995). This has resulted in the emergence of divergent conceptual tools and broad models of designing within the field of educational technology and instructional design (Boling and Smith, in press).

Questions regarding the way we train instructional designers have also been explored for some time (Boling, 2003; Ertmer and Cennamo, 1995; Rieber, 1998; Rowland, 1994; Sugar and Martindale, 2004; Tripp, 1994). Rowland demonstrated in 1992 that expert professional practice of ISD in the field is not as model-centric as our teaching; it is more in line with the "designerly ways of knowing" described by Cross (2006) and of acting

(Schön, 1983). However, if we examine the standards currently gaining support in the field of instructional design as the basis for masters level curriculum (Richey, Fields and Foxon, 2001) we see that the prevailing view of competent performance is still centered on definable and consistent processes for design (Boling & Smith, 2009). Processes, expressed most often as process models, are useful for designers, but as Lawson (1997) points out in his treatise on architectural design process and its short-lived phase in which process models were popular, the broad scope of design knowledge is in no way addressed by design education centered on process models. Recently, Lawson and Dorst (2009) extend the scope of this argument to claim that the development of design expertise is actually prevented by the use of such models.

The Study

Having considered for some time the various ways in which students in the instructional design program were not developing designerly ways of knowing (Cross, 2006) and behaving (Bichelmeyer, Boling & Gibbons, 2006), the authors undertook in 2005 the adaptation of an existing course in general visual skills for instructional designers into a studio-type course in instructional illustration using a studio model, which is the signature pedagogy (Schulman, 1995) for design education in most traditional fields of design.

This course has been taught, and re-revised, five times since that first revision. We first adapted the ways in which we had ourselves been taught during our respective educations in fine arts and architecture (Boling, 2008) and blended them with the lecture-and-project format prevalent in college-level instructional design programs. Our vision was that we would offer our students an immersive studio experience, which we hoped would compliment and amplify the hands-on project-based curriculum our students already go through. We have used a design tensions framework (Tatar, 2007) to explore the issues involved in making this kind of adaptation of pedagogy, and Lawson and Dorst's models of design (2009) to examine the activities and work of students in the fifth summer class.

The design tensions framework

We make the assumption that designing a course is an act of design and is subject to the tensions inherent in that act. We discriminate between design tensions and "trade-offs," as they are commonly discussed in design. Trade-off implies that one dimension or aspect of a design must be sacrificed or compromised for another, whereas the notion of a design tension requires that multiple valid requirements in a design situation must be reconciled without sacrificing one for the other or compromising either unduly (Alexander, 1979). These tensions have been classified by Tatar (2007) into four types: vision (goals); approach; project tensions; and "as created" situations. During the process of designing and offering a course, particularly when the course is redesigned and implemented multiple times, these tensions tend to arise in a disorderly fashion rather than in neat categories.

Vision

Tatar discusses the tension related to vision for a project as "a tension between what is and what ought to be ... the project vision or potential" (p. 417). While this sounds much like the result of a traditional needs analysis in instructional design, and might very well be, it does not describe the desired outcome so much as the open-ended “problem of active choice” and “interrelationship between the sociological and technological” in design (p. 417). That is, the designers do not attempt to identify a gap between what is known (someone’s knowledge or performance) and what can be quantified as an outcome, so much as to work with the tensions set up by envisioning change.

Approach

Design tensions at the level of approach arise when designers consciously select methods of reconciling what ought to be with pre-existing reality (Tatar, 2007; p. 418). These realities may be anything from limited resources to conflicts in values, and the approach taken toward action by designers is flexible in light of the realities. In other words, there is no single, approach determined by pre-existing realities. Using existing terms from instructional design, this would mean that context, content and audience analyses only tell the designers what the tensions are likely to be for a given approach; they do not bound the choice for an approach absolutely. Designers must choose, or create, that approach in light of the foreseeable tensions present. This is not to say that designers always make up an approach from whole cloth; they may reach for known patterns or “standard configurations” (Vincenti, 1993) with which to reconcile vision with reality. However, this choice will both “narrow the focus,” an outcome well recognized in traditional ISD, and “introduce complex systems” (Tatar, 2007, p. 418), an outcome less often addressed in the basic process models.

Project tensions

The next level in the framework, these are “places in the project that (a) directly or indirectly fall within the designers’ scope of influence but (b) where means, ways, and values come into conflict” (Tatar, 2007; p. 418). Here the designers are moving from a general approach to the specifics of how that approach is supposed to play out in the enacted design. Tensions arising here require designers to attend to specific and concrete realities, versus broader or more conceptual ones.

“ ‘As created’ ” situations” (Tatar, 2007; p. 418).

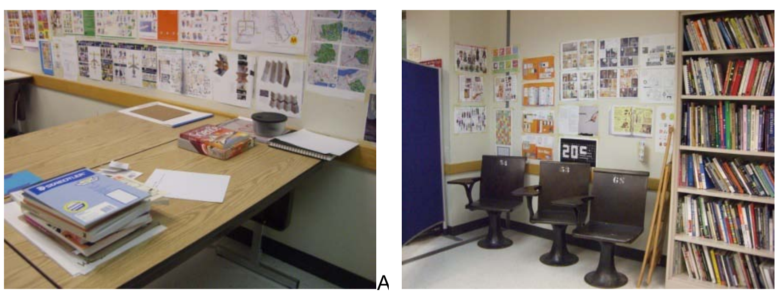
These tensions arise during the implementation of a design as a result of the design having changed the situation into which it is introduced, or of the design having been changed by that situation. “As created” situations give rise to the last level of design tensions in the framework because some of the resulting outcomes of the design as enacted may be in conflict with the original vision. Resolving these tensions may involve reconsideration of the moves that were made to resolve tensions throughout the framework.

The Design Expertise Framework

In their recent extensive exploration of design expertise, Lawson and Dorst (2009) identify three inter-related descriptive models that describe designing; one model covers the nature of design activities, one the levels at which those activities occur, and one the types of thinking in play during design. Design activities are envisioned as affecting one another constantly and in every relationship. The primary activities are: formulate, move, represent, evaluate and manage (p. 51). The levels at which these activities occur begin at the bottom of a pyramid and comprise project, process, practice and profession (p. 61). The third model addresses the types of thinking that may be employed while designing. These are shown as circles within circles, the innermost being convention-based thinking, then situation-based thinking and then the outermost being strategy-based thinking (p.69).

Methods

This repeated single case study extended over five iterations, with revisions, of a course in instructional graphics design in a masters level instructional design program. The authors designed the course collaboratively; it has been taught both cooperatively by both authors and individually by one author. The course is eight weeks long, held in a dedicated studio space with a flat table workspace assigned to each student. Six hours a week are designated as class meeting time; the studio is available to students 24 hours all week. Assignments have varied but always include the conception and production of visuals for specific instructional situations (conceptual or procedural learning, job aids, informational resources, and so on) together with collecting some kind of visual samples from lived experience and completing “Draw 100 Things,” for which students may use any production path they can manage to produce an integrated set of 1”x1” depictions of 100 common man-made objects. It may be worth noting that, in all but the second iteration of the course students and except for Draw 100 Things, project briefs are not the same for each student; students choose their context, audience and subject matter. Participants have included 39 students over the five iterations of the course; these students have been drawn primarily from graduate programs in instructional systems technology and human-computer interaction design.



A

Figure 1 Two views of the studio; A) work-space for two students, B) design books and reading area. Both views show precedent images on the classroom walls.

The data sources for the study include student work and course evaluations for four of the five iterations (2005, 2006, 2008 and 2009), and syllabi and handwritten field notes for all iterations (2005 – 2009). The field notes were most detailed for the latest two iteration of the course when one researcher wrote them immediately following each class session and focused specifically on design tensions (2008; 63 pages) and on student design activities and decision-making (2009; 85 pages). These notes were intentionally as comprehensive as possible, subject to the sometimes overwhelming detail involved in classroom interactions. The unit of analysis for these notes was a statement, portion of a statement, or group of statements representing a distinct idea. After the initial coding, both researchers reviewed, discussed and refined the resulting themes. The researchers used both manifest and latent coding (Holsti, 1969); that is, both explicit and implicit meanings were sought.

For the first phase of the study (Boling & Smith, 2009), explicit statements regarding design tensions (e.g., “Going to the lab … is so far positive. At the same time, opportunistic teaching is less available to all …”) were noted. Implicit meanings that pointed to design tensions (e.g., “I replaced the hard pencils people were using with soft ones – immediate new energy in their sketching;” which may imply a tension between offering an open choice of tools and directing tool use for desired experiences) were also considered. All statements were reviewed and re-reviewed for emergent themes, which were then agreed upon between the researchers as expressions of the tensions consciously felt during the experience of design and redesign and, often somewhat less consciously, captured or revealed in the field notes. We also compared the course schedules and assignments from each summer, and discussed all factors that we considered to have been at play in the course.

For the second, and current, phase of the study, analysis of the field notes began with a close re-reading of them. The notes were then color-coded the notes according to Lawson and Dorst’s (2009) model of design activities. Each notation describing a student framing or re-framing a design problem was marked in pink; each description of a student engaging in evaluation was marked in purple; and so on. During this analysis, the authors conferred on notations describing other activities that took place in class which did not seem to be covered by the model being used and chose to mark up two additional categories of design activity; 1) use of tools and 2) external input. We reviewed these again for themes, but also calculated means and standard deviations for the activities captured in the notes by student to build a quantitative picture of those activities. This phase of analysis also included review of students’ sketches, iterative design products and written papers from 2009, all in light of the field notes and our previous analysis of them.

Findings: Design tensions

Our vision for this course contrasted the “what is” of instructional design—students who struggle with development of designerly judgment (Nelson & Stolterman, 2003), studio thinking (Hetland, Winner, Veenema & Sheridan, 2007), and designerly habits of thought (Cross, 2006)—and what ought to be, specifically, students who do develop these ways of thinking and acting. Tensions at this level included the desire across the faculty for productive change versus the anxiety that experiments in pedagogical format might erode what have long been seen as program strengths, which include strong grounding in systematic processes for design and adherence to reductionist instructional theories rather than design judgment as the basis for rigor in design. This anxiety was most evident in colleagues without prior experience of their own in studio settings, but turned out to be more influential on the researchers than we realized as evidenced by the number of iterations we went through before implementing a well-integrated studio design. n additional tension at this level was that between the resources needed for studio pedagogy and the traditional resources available in the organization. One concrete example involves the use of dedicated space across the duration of a course; this is difficult to do in an environment where classes are expected to move in and out of classrooms every 60-90 minutes, bringing what they need and leaving nothing behind them.

Project tensions included the difficulty of addressing the skills and principles students felt a need to have versus the authentic situated project-based work upon which the course was based. This was related to a tension between offering presentation of principles and techniques versus introducing material opportunistically. For both these tensions the course design needed to provide sufficient support that students were confident to act. However, since the best support was only possible during and after action on the part of the students, we learned that the support could not be front-loaded and that managing “anxiety in action” was more important than creating calculated sequences of prepared instruction. Since this course was not embedded in a full studio environment (where the culture promotes “living in the studio”), we also faced a tension in support of the energy and engagement in the studio through lively discussion/critique versus the time and space individuals need to work and rework tangible products.

“As created” situation tensions involved our concerns over the amount of direct guidance being given to individual students versus their control over decisions and process. In an eight week experience some of them floundered too long without direct guidance, but they seemed to relinquish control quickly in the face of that guidance. Iterations of the course were largely driven by efforts to strike a balance in this situation of tension. Studio pedagogy versus established expectations of instruction, for students and instructors both, was also a major tension once the course was underway. For example, the design briefs we offered were experienced almost as evidence of inadequate instruction by students used to traditional classroom assignments with their full explanations of parameters and detailed rubrics for assessment. In turn, we wondered if we dared to mention to colleagues that the fourth iteration of the course incorporated no prepared presentations whatsoever lest we be seen as shirking the expected baseline responsibilities of an instructor.

Our presentation of design tensions in this paper represents, by and large, the fourth iteration of the course. The fifth iteration incorporated some project refinements, but repeated the basic structure of the fourth. Naturally, the tensions have shifted over time and we have presented those that stand out most clearly across the multiple iterations. Across five summers the course syllabi show a clear shift from more closely specified assignments to less, and from less open classroom format to more open—from 66% structured time in 2005 to 0% in 2009. Critique takes on a different character each class period and is therefore classified as unstructured time. This is particularly true since the “every class” critique plan in the fourth year allowed us to engage in critique without having to dictate the actual structure of critique.

summer	#assignments/ #unique types	minutes of structured time out of 180 total: percent
2005	8/8	120: 66%
2006	8/5	90: 50%
2007	6/5	75: 40%
2008	6/3	0: 0%
2009	6/3	0: 0%

Table 1 Assignments by summer with number of unique types and minutes of structured time out of 180 total per session compared to the total by year

In our efforts to resolve tensions iteratively over the four years, we see the class as having shifted progressively toward a design that resembles studio pedagogy more and more, and looks less and less like an adaptation of that pedagogy. Providing a rich environment and conducting critiques of student work were not course features that could stand alone without sustained periods of time in which students are working and instructors are engaging in dialogue with them about that work *in the moment*. Presentations of principles and techniques, while ensuring that certain topics are covered and that all students are introduced to them, lose their force in a situation where the students' immediate design problems are highly contextual and highly absorbing.

In the most recent summer class we observed them several positive outcomes. Students made active and independent use of the precedent materials in the classroom (primarily a library of about 200 design books and another 150 or so samples of illustration covering the walls), something that had not happened previously. They made more frequent and more complete revisions to their projects than had ever happened before. They began to use critique as a sounding board and an opportunity to benefit vicariously from the design moves of others, rather than showing only their refined work and making minimal revisions in response to input. They experimented more freely with materials than previous classes have done, and several of them made extensive use of precedent models to explore approaches used by previous designers and applicable to their own self-defined design goals. On the whole, they made a stronger shift toward expressing themselves in terms of design principles than most members of previous groups. They grew comfortable in the studio space and were purposeful about spending their work time to solve particular technical and design problems rather than fiddling with tools until someone came around to direct their efforts. In the second phase of our study we focused on this aspect of the course in order to make these observations more purposeful and systematic.

Even so, while the current course does create an intensive "studio bubble" experience for students that seems to exert a strong effect on them, that experience does not last nearly long enough to ingrain the long term changes in thinking and character that we desire for these students. The course is sustainable, and in demand, but it does not do more than give students a start, or a recognition that such dimensions exist within design. This leads us back to the top level of the design tensions framework. We never wanted to leave behind the genuine benefits of a systematic orientation to design—only to address dimensions we saw as lacking; specifically, development of design judgment and designerly ways of thinking. Both of these are traditionally developed in a studio-type setting, and it is not clear how well they can be developed outside such a setting or in a setting that includes only some of this signature pedagogy, divorced from other aspects that support the whole and make it work—or in a setting that offers only one or two courses, or semesters, of studio education. We have seen in 2009 that students coming into the course from a full year in the HICD program which does emphasize design thinking (although not in a classic studio format) brought with them a little higher comfort level with some aspects of design thinking. However, we feel the need to return to the vision level of the design tensions framework to address in more detail the difference between what is and what ought to be in instructional design education. In point of fact, we have done so; our department is planning the conversion of our onsite masters program to a one year intensive, full studio experience.

Findings: Design activities and thinking

The most frequently recorded design activity was working with external input (m=14.8), which may not be surprising for a class in which most students were beginners (in illustrations, if not in general design). This activity was an extension of the framework and covered discussion and guidance from the instructor, peer critique suggestions, and use of precedence materials. Of the activities in the original framework, the move was most common (m=12.3). Formulating (m=6.9), using tools (m=6) and evaluating (m=5.8) followed in descending order, with representing (m=4.8) and managing (m=3.5) lagging behind. (See Table 2 for summarized findings.)

	formulate	move	evaluate	represent	manage	external input	using tools
Han	10	11	6	6	3	13	8
Don**	12	14	9	7	2	18	2
Min	7	13	3	5	2	14	9
Van**	5	9	6	2	2	16	3
Nikki**	9	8	5	5	3	11	4

Andy****	3	8	3	4	4	9	7
Ana**	6	12	4	6	1	16	5
Dan*	9	22	7	5	7	26	4
Dana*	3	14	10	4	8	12	12
mean/SD	6.9/2.9	12.3/ 3.9	5.8/2.2	4.8/1.3	3.5/2.2	14.8/4.5	6/2.9

Table 2 Recorded design activities by student (pseudonyms used) with means and SD for each type of activity. NOTE: *absent once **absent twice ****absent 4 times

The high standard deviation for external input activity may have been influenced by the absences of individual students from certain class periods and resulting lack of field notes for them. In addition, two students completed their projects after the class ended, one for health reasons and one due to loss of computer data, which affected both the mean figure (which presumably would have been even higher) and the difference between numbers of moves (which presumably would have been lower) across the class. However, we also mapped the activities of these students over time and then studied the maps. This study showed that each student exhibited an individual profile of activities across the class sessions (some were fascinated with tools and explored them more than others; some formulated and reformulated ideas then moved quickly to finish their work).

We came to see these profiles as representing in action the combination of predilections, experiences and existing skills brought by each of them to the class in interaction with the experiences afforded to them by the class and the guidance offered to them while they worked. They were clearly not an undifferentiated mass of “novices” who could be led via a pre-calculated set of experiences to become a uniformly improved group of graduates, and neither was any one representative of a fixed point on a path toward expertise through which every other one must necessarily pass; each needed to be developed with reference to her unique profile. Returning to our earlier study of design tensions, this finding informs our observation that a less structured course design produced more of the learning and design behaviors that we hoped to see in these students. External course structure (presentations, exercises, planned discussions, reports) was replaced with enough time for the instructor and opportunity for action on the part of each student to allow for responsive interaction within the context of meaningful work—different interactions and different work for each student.

As we noted informally in 2008, students in the 2009 class were documented reformulating their design problems more often, more significantly, and with less concern for the rework it was going to cause them than did students in previous summers. Every student reformulated one or more designs after the eight class period (halfway through the term) with 37 instances recorded and only four of these indicating projects that were simply started very late. In the illustrated case (Figure 2), Dan pushed his initial concept through three reformulations, one of which required total rework of all 100 images. The substantial amount of work time available to them, frequent critique sessions and desk discussion of their work in progress seems to have shifted their focus from reluctant revision of work after formal review by the instructor to self-motivated reformulations of their core ideas.

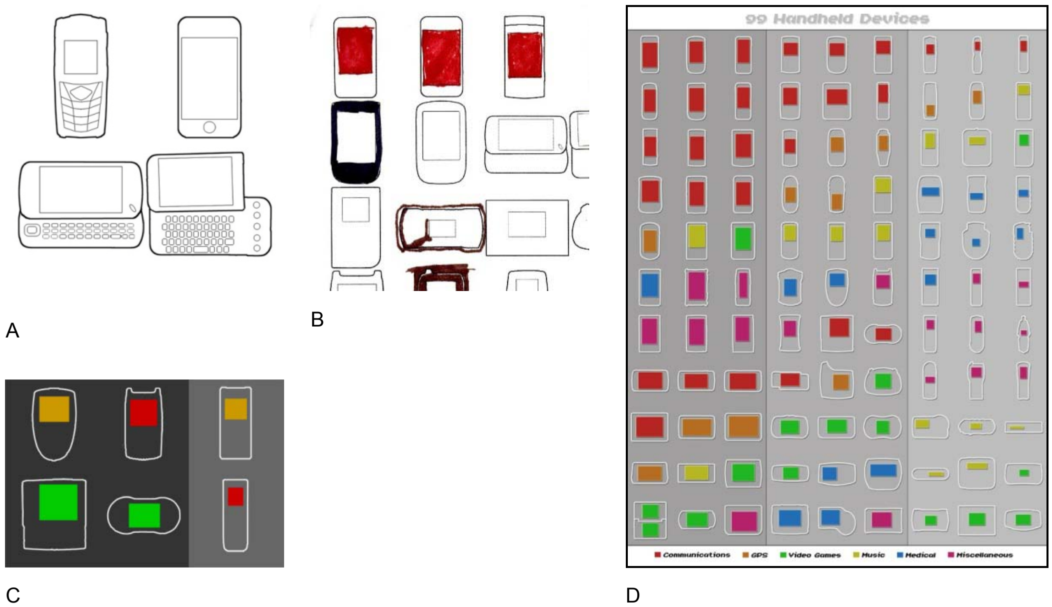

Figure 2. Dan's 100 Things were framed first simply as handheld devices (A), then as types of devices (B), then as demonstrations of different ratios of screen size to device size (C), and then as a more complex diagram showing three classes of screen/device ratio color coded by type of device.

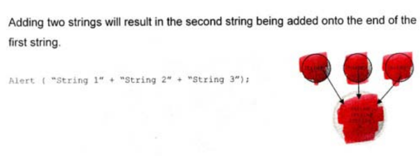
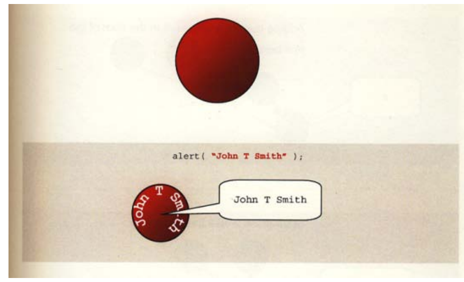
In the first three iterations of the course, we noted that students spent very little time examining the examples of illustration on the walls of the classroom, and no time exploring the books. We logged the books online, assuming that these students might be more comfortable with rapid searching online that with browsing physical shelves and one summer we laid out books each week in the classroom relevant to the presentations for that week. Neither strategy made a difference. In 2008 and 2009, after presentations were discontinued, the instructor had time to pull books off the shelves and point to the walls while talking to students about their work in progress. In the 2009 field notes, of 164 notations coded as external input to design, 18 instances (about 9%) refer to the use of precedent on the walls or in the class library.

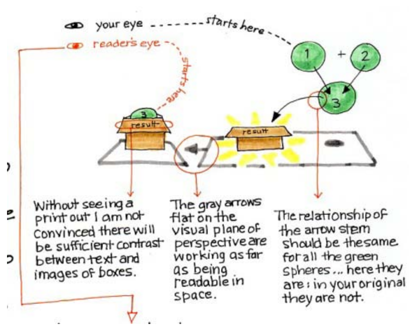
The field notes reveal that students were willing to make decisions about tools based on their goals and the moves they saw as important, rather than restricting design moves to the tools they knew or could manage already. In the two cases illustrated, Dan changed tools (incurring significant extra effort) in order to enable moves he needed to make (Figure 3) and Min chose a tool she had never used before to achieve the look she wanted for one of her graphics (Figure 4).



A



B



C

Figure 3 Dan sketched his vision for a booklet he planned that would teach programming through a combination of text and visuals (A) and he began producing pages in Word, a tool he already knew how to use; in midterm feedback (B), the instructor pointed out several problems with the graphics that Dan could not address with the functions available in Word; he decided on his own to rework the dozens of pages that he had previously considered complete using Publisher—he had never used this or any page layout tool before.

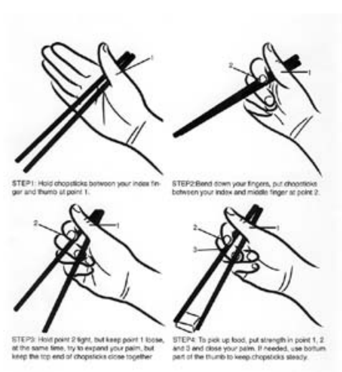


Figure 4 Min used the hand model provided for class to shoot source photos for her procedural illustration on using chopsticks; she reshot the images after realizing that the first set were not taken from the best perspective and was ready to trace these photos by hand to produce the graphic when she saw a classmate using the brush tool in Illustrator; she felt the tool would be appropriate for this graphic—although she had never used Illustrator, she chose this tool to create the final image.

Findings: Types of thinking

Students who situated their projects in contexts well known to them used situational and strategic thinking more often and to better effect than those who chose projects further from their own experience base. Andy and Ana's projects (see Figures 5 and 6) illustrate this connection between choice of project and the type of thinking students employed. While all the students made decisions based on convention, it appeared to us that deep understanding of the context for a design assisted some of the students in recognizing unique factors of a situation that demanded different thinking strategies. In the case of Andy's project, he also employed some strategic thinking, inventing what was for him a new process of design in which he sat with his in-laws and photographed them while they used their TV and CD player.

Paradoxically, strategic thinking did not necessarily produce artifacts that we also judged to have the potential for highest usability or appeal. That is, a student may have been exercising more expertise in one dimension of designing than another student, but have arrived at a result with less overall utility. The difference, at least in this illustrative case, is that the tangible realization of the artifact exerts its influence not just as a failure to realize the concept, but as a confounding factor that interferes with the concept. To make an analogy with writing, fuzzy writing is widely agreed to be a symptom of fuzzy thinking. However, clear thinking does not automatically result in crisp prose unless the writer has a practiced facility in the first place; and lack of such facility can actually infect the thought process. Just as process models are not sufficient to produce a good result (Rowland, 1995), so one or another type of design thinking is not sufficient. Of course this is hardly news, but in the quest to encourage one or another type of thinking in our students, it is worth remembering.

Figure 5 Single page from Andy's instructional booklet created to help his elderly in-laws use their entertainment system; Andy made strategic decisions about where his in-laws would keep the booklet, how easily he might replace it if it were lost (which was very likely); what size the images would need to be for them to be seen easily; and how showing a thumb on the remote would support the viewer—but he also produced an artifact in which it was difficult to follow the sequence of visuals and to interpret the captions.

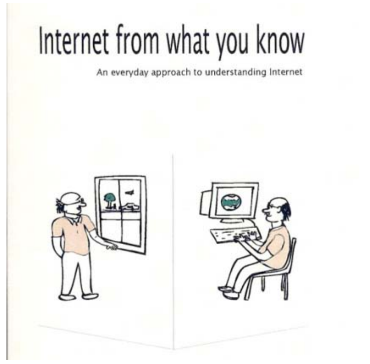

Figure 6 Cover of Ana's booklet explaining internet concepts to elderly people in India; although she was from India, her experience with the elderly ("people over 50") was not immediate or extensive and she struggled with finding appropriate metaphors and the right level of detail for presenting concepts—however, her attention to details in the images and to clear layout resulted in an artifact that we anticipate would reward close study with rich communication.

Findings: Levels of thinking

The students operated primarily at the project and principles levels, as might be expected in a short course focused on one specific aspect of instructional design. A few questions did arise from students, or were introduced by the instructor, regarding practice level issues in design (e.g., the influence of legal departments on what can be shown or not shown in procedural graphics, for example, or the degree to which an individual illustrator is responsible for optimizing a graphic for viewers from different cultures), but this was not the norm.

Summary

As we launched the second phase of this study, we expected to look for evidence that the students were making progress in design thinking during the course as described by the language of the Lawson and Dorst (2009) models of design. In actuality, we used the models not as a way to measure progress directly, but as a valuable lens through which to promote, observe and discuss design thinking and activities in our students, as well as to characterize the unique profile each student brought to the course. We were able to document the guidance given to students during class separately from their design moves and their own evaluations of their work, easing a design tension identified the year before. Some of our findings from these small case studies may not seem very radical to those who teach in studio settings all the time, but they represent important shifts in pedagogy for instructional design. We also found ourselves extending the model of design activities (Lawson & Dorst, 2009) to account for account for the contribution of external input to design and for grappling with the tools involved in designing.

Author Biography

Elizabeth Boling

Boling is an Associate Professor of Instructional Systems Technology in the School of Education at Indiana University. She teaches u design, instructional illustration, media design and production, and writing for instructional media. Her areas of research interest include design pedagogy and the design of visuals to support learning.

Kennon M. Smith, PhD

Smith is an Assistant Professor of Interior Design in the Apparel Merchandising and Interior Design department at Indiana University. She teaches courses related to design fundamentals and theory, as well as design studios for interior design. Her areas of research interest include design pedagogy and the identification of obstacles which tend to impede the teaching and learning of design.

When Will Customers Claim Their Rights as Empowered And Creative Human Beings?

- a rhetorical perspective on co-creation

Kirsten Bonde Sørensen, Kolding School of Design, Denmark, kbs@dskd.dk

Abstract

Designers as well as business leaders are strictly focusing on co-creation and co-creation activities as an effective method to innovation in business and product development. Paradoxically we seem to forget the perspective of the customers.

The intention of this paper is to bring a rhetorical approach to ‘co-creation’. This approach emphasizes co-creation as a specific form of rhetorical design discourse directed at customers who are introduced to new creative ways of expressing themselves. The rhetorical perspective also emphasizes how this discourse is capable of constituting its audience in new roles, here as empowered, active and creative people. This co-creation discourse is considered an art ‘constitutive rhetoric’ (Charland, 1987). The crucial effect of the constitutive rhetoric is the audience claiming its right on behalf of this constitution. This raises the question: when will customers claim their rights on behalf of these new roles - as creative human beings - and how can we possibly develop co-creation and reply to this possible demand?

In co-creation sessions designers are appealing to the customers´s creativity by presenting generative tools in order to make the customers express their creativity, their tacit knowledge, their dreams and needs. The paper agrees with Sanders that these generative tools entail the possibility of growing into a new language not restricted to co-creation sessions and organizational development (Sanders, 2002). Using the generative tools is a way of inviting design thinking and creativity into everyday peoples lives, offering them a way of reflecting and responding as creative human beings. Rhetorically this means offering the capacity to act also called ‘rhetorical agency’ (Hoff-Clausen et all., 2005) and as such a possible solution to customers claiming their rights as creative human beings.

The paper will outline different understandings of co-creation as well as bring experiences from co-creation activities conducted in a present research in a Danish bank. The paper will also bring an example of customers claiming their rights.

Keywords

co-creation; constitutive rhetoric; agency; generative tools; creativity.

Different perspectives on co-creation

The popular business researcher Richard Normann claims we are moving towards a veritable revolution where value creation will be the core activity of the organisation and customers will act as co-producers, co-creating values. Normann claims organisations to be value creating systems and co-creation to be a practical tool for involving the customers both in the value chain as a whole and in the business system of the company (Normann, 2001). According to Normann we are leaving an industrial strategic paradigm and moving into this new paradigm with focus on value creation. The industrial paradigm was about producing goods and services to be ‘pushed’ into a marked, where consumers were acting as passive receivers of the goods. In recent years companies have moved into a kind of in between state where the central concern is about 'relations' as seen in service and service management. Central here is customer relation management as customers are regarded as a source for information, ideas, needs etc. According to Norman we are now facing what he calls 'the real revolution' – the absolute opposite to the industrial paradigm – where the customer is regarded as co-producer involved in the creation of value.

In this move user centred innovation has been the dominant paradigm of the past decade and 'users' and 'co-creators' have been popular terms both in the field of design and the field of business. Unfortunately different and confusing understandings of co-creation are ruling. Here a crucial difference is whether you regard the user as 'a subject' or as 'a partner'. In von Hippel´s notion about 'the lead user' and in Prahalad & Ramaswarmy´s idea about co-creation the user as 'a subject'-perspective is present (Prahalad & Ramaswarmy, 2004). The fact that designers regard 'customers' or even human beings as 'partners' is a crucial matter and a very important reason why designers are having their heydays in relation to user studies. As Verganti claims designers are having an amazing capacity to get close to users and understand their needs (Verganti, 2009). An essential reason for this is that designers do not 'fixate' human beings into specific roles as 'customers', but consider human beings as co-creating partners. In that sense designers are releasing themselves from a very limiting organisational perspective and presenting a more holistic view on organisations and human beings – in fact the picture of organisations that Norman is sketching. Unfortunately designers are often employed by business leaders and as the business leaders tend to have the 'user as a subject'-perspective, this is the dominant perspective in business and the reason why co-creation activities often are limited into 'user inputs' rather than real co-creation activities in organisations. In this way designers seem to hold the key to real co-creation activities and to the reframing of organisations (Normannn, 2001).

Locked in an organizational perspective

The tendency that business leaders seem to overlook the fact that 'co-creation' means 'creating together' rather than getting inspired and getting ideas from users leaves both designers as well as customers in a locked position. Sanders who have developed 'Make Tools' as a new type of language already claims: *"Design is serving markets, not people. Design is serving the needs of companies, not people"* (Sanders, 2006, p.28). This article goes beyond Sander´s view in offering a rhetorical perspective that brings new insight to co-creation. The article focuses on how co-creation activities constitute customers as 'experts', 'creative human beings' or 'co-creators' and how these 'new' experts and co-creators often end up in the business organisation reduced to 'user inputs'. This raises the question: what effect does such a discourse have on the audience? Applying a rhetorical perspective on co-creation brings useful insights for designers when understanding and developing co-creation. First of all I will outline the nature of co-creation activities and techniques, among these also the activities used in a current research in the Danish bank, Middelfart Sparekasse.

Co-creation activities and techniques

In the field of co-creation designers and design researchers are developing an increasing amount of tools and methods for co-creating activities. (Gaver, Dunne, Pacenti, Mättelmaki, Sanders, Stappers, Visser et all). Some serve as cognitive tools that 'leave room' for the participants to express their creativity, their dreams, needs and tacit knowledge. Due to completed experiments in my current research in the bank, Middelfart Sparekasse I consider these methods powerful as the participants explain they achieve higher awareness about emotions and relation to certain issues.

When designing material for creative sessions Sanders suggests a converging perspectives approach that combines different methods, tools and artifacts that furthermore combine what people 'say', 'do' and 'make' (Sanders, 2001). A combination of approaches from marketing research *('what people say'),* anthropology *('what people do')* and participatory design *('what* *people make')* is applied. Following the converging perspective, the participants were interviewed, asked to do things and asked to make their own expressions. Central to this way of 'asking' is the idea that the designer leads the participants through a 'guided discovery' appealing to their creativity and inner feelings and hereby sets a stage for them to express their thoughts and ideas.

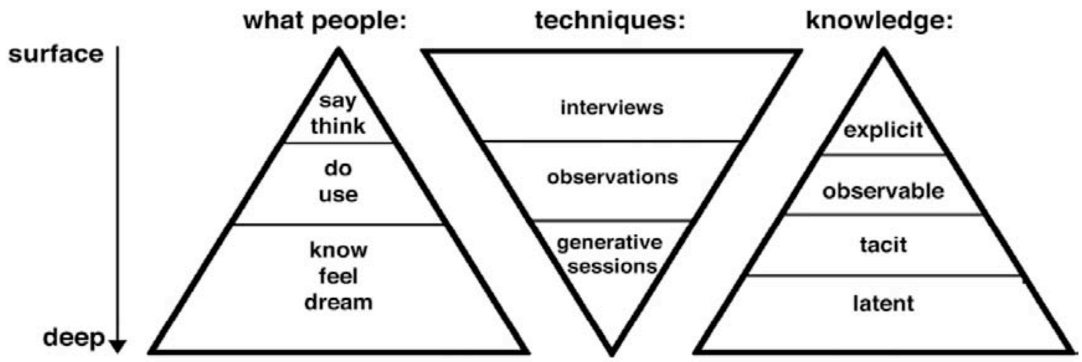

Fig. 1. Different levels of knowledge are accessed by different methods. (Sleeswijk Visser et al., 2005)

Talking with people by, e.g. interviewing them, provides information about what people can say, which is mainly explicit knowledge. Observation studies give insight into the physical context of people and how people do things. Generative techniques use the creativity of people to become aware and express their own experiences. Creative tools or self documentation techniques (Gaver et al., 1999; Mattelmäki, 2006) help people reflect on their memories, feelings, motivations, create awareness about their experiences, help them express themselves in a visual form, and help them use these representations as a basis for talking about the experiences (Stappers and Sanders, 2003).

Central in the field of generative design research are the 'generative tools', the thinking tools non-designers can use to express their inner dreams (or fears) for the future. Generative design makes us see how things *could be* and empowers everyday people to generate and promote alternatives to the current situation. In this field you find researchers such as Sanders, Stappers, Visser et all. A central concept in the field of critical design is 'probes'. Cultural Probes originate from Gaver et all. (1999), who designed them to provoke inspirational responses from elderly people in diverse communities. Originally probes are packages containing maps, postcards, a camera and a diary. These packages are sent to the private homes of the participants, who respond to them and return them to the designer. Probes are primarily used in places or circumstances too private for researchers to show up in person. Their aim is to "*make the participants think*", to "*provoke existing values"* and aim at "*generating and promoting alternatives to the current situation"* (Sanders, 2006, p.1).

In the present research project approximately 4 different types of creative sessions have been conducted with all in all 21 participants. The intention of the creative sessions was to meet human beings and to let them reflect and express their relation to money, private economy, banks, financial advisors etc.

Experiences from the creative sessions

When designing artifacts for the different co-creation session at the bank, I designed a box (Fig. 2). The intention was to make a private 'room' for the individual to respond in, but still having the possibility to observe and start plenary discussions. I have completed different co-creation sessions (a total of 22 persons). I one of the experiments, the participants were invited into the same room, and each received a box filled with material and tasks. I designed the box as a private 'room', leaving space for reflection, memories and ideas when responding to the questions, the provocative statements and the creative tasks. This 'reflective room' was designed with a happy artificial long green grass carpet in the bottom, topped by the material: pictures, pieces of paper, scissor, glue, coloured pencils. The box had an appealing and accommodating look, almost like a gift with long green ribbons attached to small notes, telling people what to do.

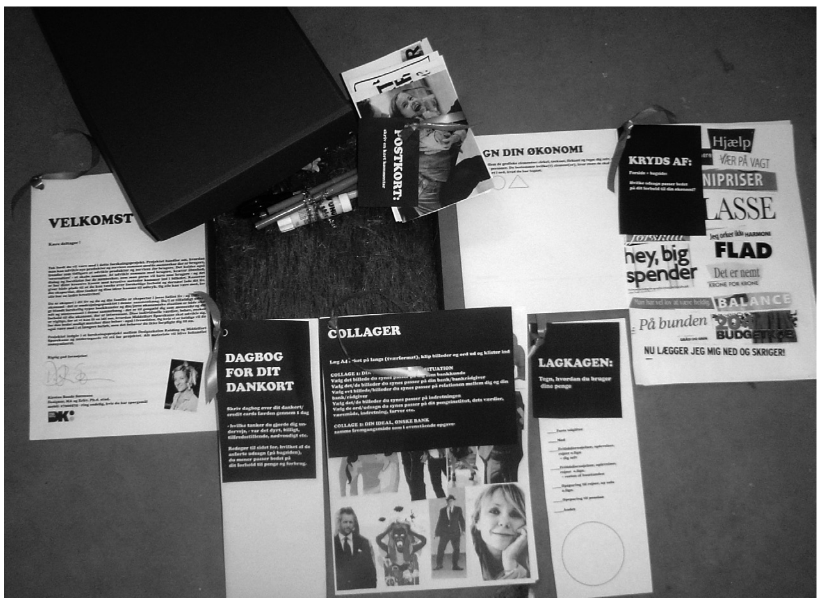

Fig.2: Illustrating the box containing different creative tasks, pictures, pencils etc.

The workshop started out the in the easy 'making' level of the creative tasks and ended up in the 'creating' level. As per Sanders (2008) there are four levels of everyday creativity, ranging from 'doing' to 'adapting', to 'making' to 'creating'. Where 'doing' represents an ordinary productive activity, 'adapting' means to make something one's own by changing it in some way. The motivation behind the third level of creativity, 'making', is to use one's hands and mind to make or build something that did not exist before. And finally the most advanced level of creativity is the fourth level, 'creating'. The motivation for 'creating' is to express oneself or to innovate and these types of real creative efforts are both guide by a high level of experience and executed with passion, Sanders claims.

At the 'making' level, the participants were asked to make comments to statements printed on postcards, asked to underline the preferred sentences, for example describing their relationship to their private economy. At the end, at the 'creating' level they were asked to make a collage (Fig. 3A) illustrating their current relationship to their economy by adding: 1) a picture illustrating themselves as customers, 2) a picture illustrating their bank/financial advisor, 3) a picture depicting the relationship between the two, 4) a picture illustrating the surroundings and 5) words underscoring the chosen pictures, all in their own words. Afterwards they were asked to make a new collage, (Fig.3B) in a similar way, but illustrating an ideal future situation. Finally they were asked how to get from Collage A to Collage B. These collages and answers were primarily used as material for analysis, as they were 'the final creations' presumably incorporating all the reflections. An important point is that the participants were asked to present their collages in front of a camera and these verbal presentations formed the primary material for analysis supported by the visual expressions.

Co-creation as constitutive rhetoric

From a rhetorical perspective co-creation can be considered an art 'constitutive rhetoric'. In the field of co-design researchers have introduced the importance of seeing and regarding the customer as 'empowered', 'creative', 'co-creators' and 'human beings'. Approaching the customer, it is crucial the participants (customers) feel 'empowered' and as 'experts'. Researchers from the field of co-creation are underlining this by purposing to give badges to the customer saying: "*I am an expert in my life".* Having completed several co-creation sessions in a bank (with approximately 20 participants), this manoeuvre is quite powerful and the participants actually do feel empowered and experts.

Charland´s notion about constitutive rhetoric (Charland, 1987) implies the idea of rhetoric that 'constitutes' the audience in a double way: It constitutes the audience in a specific subject position (here customers being creative and experts in their lives) but in the same time, Charland claims, this audience will claim its rights on behalf of this constitution, this 'new' subject position. Charland´s notion about 'constitutive rhetoric' is presented in his article: "The Case of the Peuple Québécois" (Charland, 1987). In Charlands study of the "Peuple Québécois" he shows how advocates for Quebec's political sovereignty *''addressed and so attempted to call into being a people quebecois that would legitimate the constitution of a sovereign Quebec state''* (Charland, 1987, p. 134). A key term in rhetoric is 'persuasion' which implies the existence of an audience free to be persuaded.

In Charland´s study of the nationalistic movement in Quebec he argued that certain forms of discursive practice function as constitutive rhetoric. Charland claims constitutive rhetoric does more than create an image of its audience, it generates the conditions of possibility that can structure the identity of those to whom it is addressed - analogues to Althusser´s notion 'interpellation', Charland claims. Interpellation occurs at the very moment one enters into a rhetorical situation, that is, as soon as an individual recognizes and acknowledge being addressed. Althusser uses the example about an individual walking down the street. He is challenged by a policeman calling: "Hey you!" and the individual reacts by turning around. By turning around he acknowledges the call was pointed exactly at him. In this simple bodily movement, by turning around, he gets transformed into a subject.

In Charlands study he concluded that *"it is up to the Québécois of 1980 to conclude the story to which they are identified"* and into which they have been interpellated. In Charland´s study he emphasizes the way narratives function: *"In other words while classical narratives have an ending, constitutive rhetorics leave the task of narrative closure to their constituted subjects. It is up to the Québécois of 1980 to conclude the story to which they are identified"* (Charland, 1987, p.143). Charland claims constitutive rhetoric to be an ubiquitous force that shapes the identity of its addresses. In the 'act of addressing' auditors, an advocate´s message awakens or energizes certain possibilities or a specific identity or subject position for that audience. In certain cases, Charland noted, this process is akin more to one of conversation as audiences come to inhabit a *"reconfigured subject position"* (Charland, 1987, p.142). An example to illustrate this is: *"In a television commercial for toothpaste, managers not only to sell its product but also to energize certain identity possibilities as it positions its audience in the role of 'consumers'. We become consumers or we are (re)positioned in the role as consumers, as we are addressed by the commercial",* Jasinski claims (Jasinski, 2001, p.107).

Charland´s conception of constitutive rhetoric was developed to illuminate the workings of political discourse, yet it provides a framework to understand how audiences are rhetorically constructed by advertising texts. Charland builds on Kenneth Burke´s proposal in "A rhetoric of motives" (1969) to use 'identification' rather than 'persuasion' as the key term of the rhetorical processes.

Nike – a case

Maybe we have already seen the first examples of interpellated and empowered customers claiming their rights in the following NIKE co-design case: On the internet, at NIKEiD it was possible to design your own shoes. Although customers are not explicitly constituted in new subject positions, NIKE implicitly addresses the audience as creative human beings with *"the freedom to choose and freedom to express who you are".* (http://shey.net/niked.html). A customer, Jonah Peretti ordered a pair of shoes with his personal ID: "sweatshop". NIKE rejected his order claiming "sweatshop" to be "inappropriate slang". Peretti referred to Websters dictionary saying "sweatshop" is standard English with the meaning: *"a shop or factory in which workers are employed for long hours at low wages and under unhealthy conditions".* Peretti continues in his mail to NIKE: *"I was thrilled to be able to build my own shoes and my personal ID was offered as a small token of appreciation for the sweatshop workers poised to help me realize my vision. I hope that you will value my freedom of expression and reconsider your decision to reject my order."* Peretti never had his shoes, but had to change his ID. The mail thread was sent to some friends, now it is available to everybody on the Internet, a menace to the brand and especially to their image as they were not capable of delivering what they promised.

This is an example of implicitly constituting customers with 'the freedom to choose and the freedom to express who you are' and customers claiming their right on behalf of this constitution. This also is an example on how companies are using the right words in order to appeal to the new customer, but unfortunately they have not realized the effect of the discourse.

In a broader perspective the NIKE example is only a small part of a present and immense promotional discourse including co-creation- and user-driven discourses. The case also illustrates how NIKE *apparently* offers huge 'freedom to express yourself '.

Co-creation - with or without rhetorical agency

In co-creation and co-design (a subnotion of co-creation) the very notion includes the idea about equality and freedom to create, design and act. In rhetoric the notion, rhetorical 'agency' stands for the capacity to act rhetorically. On one hand the notion refers to the instrumental aspects of rhetoric like rhetor´s use of resources in order to reach a goal. As such agency can be translated into rhetor´s capacity to act in relation to his talents and strategies. On the other hand the notion refers to both the circumstances in which rhetor constitutes him self and the circumstances rhetor is constituted by. Generally agency is focusing on the constellation of individual and structural elements and how the interaction between the speaker and the situation is of relevance to the rhetorical construction of meaning and influence. In a rhetorical analysis or discussion the chosen focus on aspects in a specific constellation will reveal the use and understanding of 'agency'. (Hoff-Clausen, Isager & Villadsen, 2005).

To elaborate on the notion 'agency', Hoff-Clausen et all. give an very illustrative example of a human being with an ethos based on the idea about rhetorical agency: Günther Wallraff, a German author and critic was hired as a reporter on the tabloid magazine 'Bild Zeitung' under false name. During 3 months he worked under the editorial principles he intended to bring into light and his following accounts of misrepresentations and fabrications, extortions, tappings and housebreakings caused a sensation all over the world. Hoff-Clausen et all. claim this to be an example of a citizen who responds intentionally to a discrepancy in the public space, as he uses his rhetorical competences in order to accomplish a rhetorical strategy that establish his personal drive and striking power and moreover gets an effect on the discrepancy in question. In the example 'agency' is illustrated in Walraff´s use of his capacity to act - his talents and strategies, but Hoff-Clausen et all. also claim that in this rhetorical scenario the persons who are 'borrowing

Wallraff´s voice', the persons who are being giving rhetorical agency, are the victims of the journalism and colleagues at Bild Zeitung.

Going back to the Nike case, the company actually acts and communicates as if they were offering rhetorical agency for the customers by offering them *"the freedom to choose and freedom to express who you are*". Peretti acts on behalf of this rhetorical constitution and agency and illustrates thereby that there actually is only very little and very limited agency.

This raises the questions in relation to co-creation activities: what kind of agency are these companies offering? Through co-creation activities customers and users as constituted as 'co'creators', 'creative human beings' etc. but what kind of reactions do they actually tolerate?

According to Buchanan´s mapping of design and designers, the Nike example also illustrates both the development but also the power within design. In Buchanan´s mapping (2001) design and designers are mapped within four orders: In the first and second order focus on 'symbols and images' and later on 'things' and gave rise to graphic design and industrial design. In the third order changed its focus to 'action' and gave rise to interaction design. The fourth order is related to action, but focuses on the 'environment and systems' within which action takes place. This is the area of 'thought', since it is fundamentally concerned with the organising idea of principles that operate behind environment and systems, i.e. human systems. Designers in this order can be seen as facilitators of organizational processes. *"They organise conversations and debates about the values of a community and how those values may be implemented with productive results"* (Buchanan, 2001). In this Nike example it gets very clear how the NIKE company considers the 'ID-shop' as a matter within the first order of design, but the design discourse, the very co-design discourse affects the customers, so Peretti 'answers' from the fourth order of design, this co-design thing is not only a matter of designing your own cute logo, it is also about 'the freedom to express who you are'. Rhetorically Peretti answers from the 'offfered' rhetorical agency. This leads to the question**:** *If rhetorical agency is the act of effecting change through discourse, how can we develop co-creation activities to include rhetorical agency?*

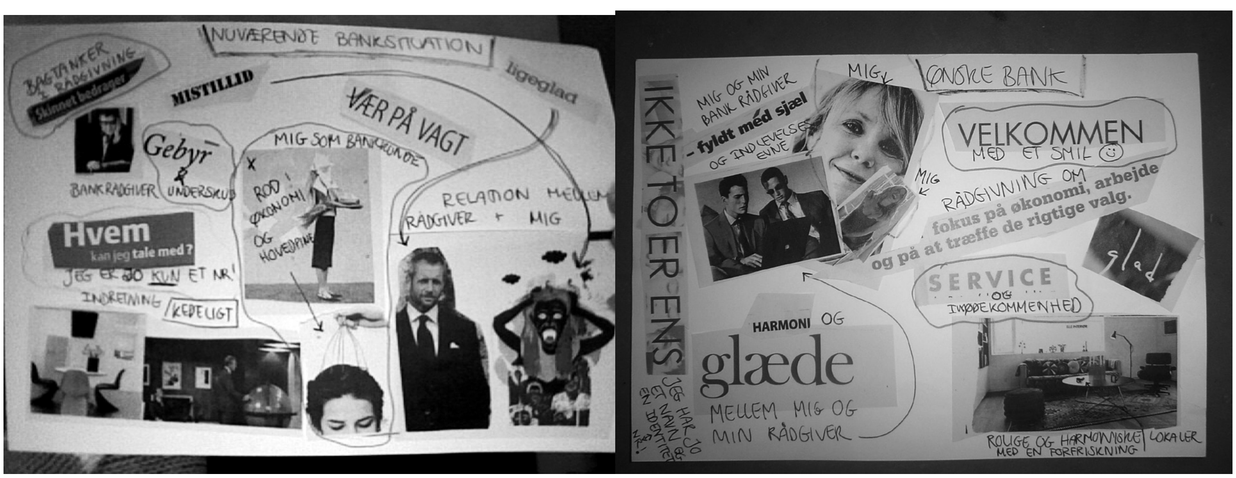

Fig. 3 A+B: Collage A illustrating the present situation, and collage B illustrating the future situation.

Changing the focus in the co-creation sessions

A look back to the completed creative sessions and the reflections of the participants, they rather precisely outline the nature of the generative tools and equal to Sanders description. The different levels of creativity, the guided discovery that appealed to the participants inner feelings and tacit knowledge is for example described by one of the participant, Anne Marie: *"…performing the tasks in the box was one long process, where I got deeper and deeper into the concept of 'economy': first filling out the postcards, choosing statements and so on. I think these tasks were necessary in order to make the final collages. In these collages I felt I was able to express my reflections and final statement; my frustration about my personal finances got released. Actually I was surprised I got so emotional upset, now I am more aware that I must do something about my economy."*

The process performing the creative tasks made her reflect, and finally she claims she ends up being more aware of her specific needs and wishes. When she explains her wishes for the future bank she expresses that she wants to get in control of her economy and how this is supposed to be done.

Another participant claims in the interview before doing the creative session that she is quite satisfied with her bank and her financial advisor, but having done the creative session she tells she actually is quite irritated on her financial advisor as he has a certain way of talking to her and accusing her for having only 'a small arrangement' in the bank. This example illustrates that also smaller issues can be revealed during the creative sessions using the generative tools.

This creative session resulted in a lot of information about financial customers in general (here 21 persons) and their thoughts about the bank – and *this* is the focus of the traditional co-creation sessions and research. To me there are plenty of new and much more interesting perspectives: the fact that this guided discovery is having a personal effect on several of the participants like Anne Marie is triggering my creativity and interest in developing these tools. The facts that the use of generative tools actually is letting people get more aware of their financial situation and sometimes make them want to act and change their situation, is triggering my creativity and interest in developing these tools into a new type of banking service.

Future perspectives

Business leaders still consider co-creation a new and interesting way of getting information and ideas from the customers. Designers are having their heydays as they are very good at getting close to users, understand their needs and generate ideas (Verganti, 2009). This leads to new challenges, because executives now think about design and designers in two perspectives: the first – and the very traditional one – is styling. Designers are asked to make products look nice and beautiful (Buchanans 1.order of design, 2001). The second – and more recent perspective – is user-centred design. And as Verganti stresses, first the styling and then the user-centred design have been portrayed as vehicles by which companies differentiate themselves from the competition. Many analysts claim design in these ways make the difference (Verganti, 2009) and no company would dare release a product without caring about style and analyzing user needs and as such design is in its heyday. But what are the visions in the field of design?

Looking deeper into the co-creation activities and especially the generative tools, there seems to be plenty of possibilities if these are developed and not only limited to 'user studies'. Using the generative tools in co-creation sessions is also a way of introducing creativity and creative thinking to non-designers.

In the current research these generative tools are being developed into a new type of service offered for people in order to become more aware about personal values, needs and dreams. The service presumably will be offered for customers in the bank but there will be no expectations except for the customers to become more aware of their values in life, including their economy. As such customers are treated as creative human beings and offered the agency to act - to feel free to go to another bank or stay in Middelfart Sparekasse. As such the service will become a radical new way of doing consumer communication, based on customer awareness rather that persuasion.

Conclusion

Normann (2001) claims we are moving towards a veritable revolution with organisations as value creating systems. Maybe we *are* moving towards a veritable revolution, but until now co-creation mainly is conducted within the dominant organisational perspective and that is the reason why co-creation has primarily been operating on the outer edges of companies´s value chains. As a result of this the paper claims customers are being left in a gap. The claim is underpinned by applying a rhetorical perspective that sheds new light on the communicative consequences, how these co-creation and co-design discourses affect the audience. The notions, 'constitutive rhetoric' (Charland, 1987) and 'rhetorical agency' (Hoff-Clausen et all. 2005) illustrates how the popular user-participation and co-creation discourses actually constitute customers in new subject positions, as 'creative human beings', 'co-creators' and 'co-designers' 'with the freedom to act' and 'to express who you are' ect. The example from NIKE precisely illustrates how customers are constituted as creative human beings and with the capacity to act, but here the customer, Peretti makes visible how this rhetorical agency is only an illusion – in reality the case showed is only offering very limited agency. Unfortunately companies have not understood the effect of these discourses and here the Nike example also proofs customers have already started 'claiming their rights' on behalf of this constitution (Charland,1987) here as empowered co-creators and creative human beings.

Considering co-creation an art design discourse is a way of regarding design and creativity as a 'new language'. The paper brings examples from a current research in a Danish bank, Middelfart Sparekasse. Here co-creation sessions resulted in different, but no radical information or ideas from the users, whereas the very meeting with the generative tools gave inspiration to the designer and researcher to develop a new and total different type of service. The idea is to transform the generative tools in a new service as they work as tools for reflection and can create more awareness about values in life, dreams and needs – a rather central issue in private economy. The service will presumably be offered in the bank in the future and without any expectations. On the contrary, the bank will let the customers feel free to change bank or stay. As such banking service is changing its meaning (Verganti, 2009) from an issue about money and economy to include a service that offers reflection and greater awareness about underlying and sometimes unconscious presumptions and essential values in life. As such the new service also will become a total new way of doing customer and company communication based on increased awareness instead of persuasion.

Transforming the generative tools into a new service is only one way of inviting design thinking and creativity into everyday peoples lives, offering them a way of reflecting and responding as creative human beings. Rhetorically this means both constituting people as creative human beings and in the same time offering them the capacity to act also called 'rhetorical agency' (Hoff-Clausen et all., 2005). The example is just one of presumable many solutions to customers claiming their rights as creative human beings.

Author Biography

Kirsten Bonde Sørensen

A graphic designer from the Kolding School of Design, Denmark and Utrecht School of the Arts, Holland she also holds a MA in rhetoric (MARC) from Aarhus University, Denmark. She is currently working on an Industrial PhD project funded by the Danish savings bank Middelfart Sparekasse and attached to Kolding School of Design. Her research is within the field of strategic design and investigates how design and design thinking can contribute to business development and innovation.

Reframing Business – and Design?

– A critical look at co-creation

Kirsten Bonde Sørensen, Kolding School of Design, Denmark, kbs@dskd.dk

Malene Leerberg, Kolding School of Design, Denmark, ml@dskd.dk

Abstract

The collaborative aspect has become a prominent focus in design discourse and words like *user-driven innovation*, *user studies*, *participatory design* and *co-creation* are frequently used in the design terminology of researchers, practitioners, not to mention business organizations. This reflects a shift in attention from product and manufacturing to users and experience.

Normann (2001) speaks of reframing business and arguably the changing landscape of design as described by Sanders and Stappers (2008) is making designers reframe their practice. (cf. Schön, 1991). Employing user studies, participatory design and co-creation looks like an easy and accessible way towards innovation, unlocking the creativity of the customers to develop future business. To no surprise these words are buzzing around the business and design offices.

However it seems, the buzz is failing to deliver, and it is important to question why. Using *co-creation* as an example, we claim that businesses and designers are stuck on the buzz. Borrowing a term from cognitive psychology, we argue that co-creation has created a *fixation* among businesses and designers, where the strong focus on the innovative potential of users as co-creators paradoxically has become an obstacle for both radical innovation and *real* co-creation.

The paper brings an overview of different and conflicting perspectives on co-creation, and explains how these perspectives stem from different paradigms. Furthermore, the paper suggests designers to consciously reflect upon the image of design and designers.

We want to highlight researchers from both design and business who claim design and design thinking to be a new way of bringing both insight and innovation, a new way of working with thought, human systems and *design-driven innovation* (Buchanan 2001; Verganti 2009). We think it is time to encourage designers to expand their current vision from user-driven innovation to design-driven innovation. It is time to reframe design from a designer's perspective – and why should designers not have the capabilities to reframe business as well?

Keywords

Co-creation; fixation; design practice; business perspective; design perspective; paradigms; innovation.

The origins and original meaning of co-creation

Co-creation can be defined as any act of collective creativity, i.e., creativity that is shared by two or more people (Sanders & Stappers, 2008). Opinions vary widely on who should be involved in these collective acts of creativity, when and in what role, but basically co-creation, as the abbreviated prefix indicates, implies some sort of equality between the co-creators, whether we are speaking of designers and users or companies and customers. However, this essential and seemingly obvious definition does not appear to be equally obvious and easy to act in accordance with.

Co-creation is not a brand-new phenomenon; nevertheless, it represents a radically new definition of what constitutes value to consumers. From a business and innovation angle, co-creation is interesting not because everything has to be or will be co-created in the future, but because co-creation is tapping into the collective experiences, skills and ingenuity of consumers around the world, and thus provides companies with valuable information. As such co-creation *could* look like a complete departure from the inward looking, company-versus-consumer innovation model that still is common in companies all over the world.

In the literature, co-creation is described as a phenomenon, which started out several years ago with enthusiastic amateurs, who for example wanted a bike that could be ridden off-road. The amateurs created the mountain bike themselves, and later on it was put into production (von Hippel, 2005). Enthusiastic users also developed equipment for kite surfing. As the existing kites did not meet the needs of the super users, they themselves developed new and better kites. On the Internet these super qualified users exchanged drawings and models and software for rapid prototyping and developed new super kites (von Hippel). Eric von Hippel's point in his notion about *the lead-user* is that kite manufacturers should ask these super users to help innovate their products, and the result would be better kites for the company, the super users as well as other users.

The above-mentioned examples illustrate, how co-creation started from real life needs and wants, furthermore, von Hippel notes that the Internet had an enormous influence. The Internet enables knowledge sharing and provides access to sophisticated computer programs, which is pushing forward democratisation of innovation, co-creation activities, and open source innovation; an obvious example is Wikipedia (www.wikipedia.com). In that sense, the Internet as a medium gives people a voice and calls upon open source and democratic innovation. Additionally, the Internet gives people agency, a capacity to act rhetorically as co-creators as they have a genuine interest in developing a specific item or feature. The problem seems to arise when researchers, designers and especially business leaders seek to develop this autonomous and self-directed group activity into a new way of *running* innovation. It is essential to acknowledge the difference between co-creation evolved from a self-directed group activity and co-creation evolved from an organisation.

According to Richard Normann co-creation will be an essential part of the future for organisations. Normann claims that we are moving towards what he calls *the real revolution* (Normann, 2001). The influential business researcher accounts for his radical view in his book *Reframing Business*. He argues that we are moving beyond the industrial paradigm with a focus on the production of goods and services being *pushed* into a marked with consumers acting as passive receivers of the goods. In recent years, companies have moved into a kind of in-between position where the central concern is about *relations* as seen in service and service management (according to the service-dominant-logic by Stephen L. Vargo and Robert F. Lusch (2004)). Customer relation management has become a central issue as customers are regarded as a source for information, ideas, needs, etc. In turn, we are now, according to Normann, facing the real revolution – the absolute opposite to the industrial paradigm – where the customer is regarded as co-producer involved in the creation of value.

The conflicting perspectives on co-creation

In the move from the industrial paradigm into this new paradigm with customers involved in value creation, *users* have been brought into focus. Likewise, *user centred innovation* has become the dominant paradigm of the past decade and *users as co-creators* has become a popular term both in the field of design and the field of business. Unfortunately, different and confusing understandings of co-creation are ruling. A crucial point of difference is, whether you regard the user as *a subject* or as *a partner*. In the business field there is a tendency to regard the user as a subject – C. K. Prahalad and Venkat Ramaswarmy, (2004) represent this approach and so does von Hippel's notion about *the lead user*. In contrast, research in the field of participatory design often represents the user as a partner. These two and different approaches stem from the different paradigms. Co-creation originally evolved as a self-directed autonomous group activity where users were creating values together, like the above-mentioned kite surfers. Business leaders saw this activity as a new and interesting way to innovation. Business researchers predict co-creation to be the future and some bring special details like Prahalad and Ramaswamy declaring *empathic dialogue* to be one of the building blocks of co-creation (Prahalad & Ramaswarmy). However, these authors do not leave any explanation on *how* to obtain co-creation or indeed empathic dialogue. This results in a huge demand for tools, methods and instruments for facilitating these user-involving processes.

Roberto Verganti claims design is in its heyday. As opposed to organizations, designers are users themselves, thus, they are empathic to user needs and wishes and seem to possess the capacity to provide insight knowledge about co-creation and its use. In the field of participatory design and co-creation, an increasing amount of different tools, methods and projects testify not only the designers´ interest in co-creation, but also their ability to get close to users (Verganti, 2009). Figure 1 gives an overview of the different approaches and related tools and methods in the fields *led by research* and *led by design*, respectively.

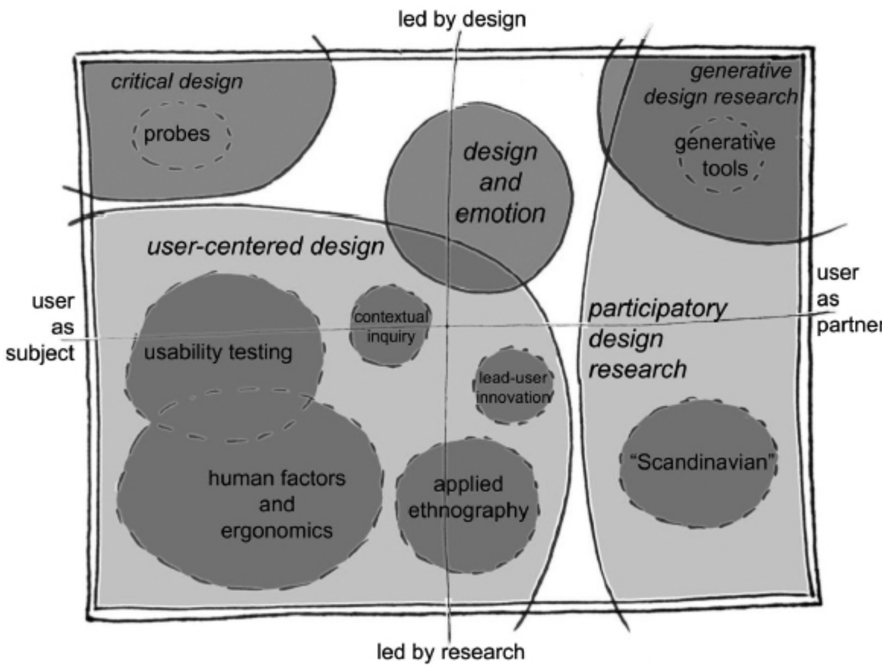

Figure 1: Current landscape of human-centred design research as practiced in design and development of products and services (from Sanders & Stappers, 2008, 2).

The rapidly growing research in the led by design field indicates a huge interest in co-creation and an eagerness to meet the demands from the business field in terms of providing tools and methods to unlock the creativity of costumers and pave the way for innovation and future business.

We are aware, researchers and practitioners will claim they have conducted plenty of successful co-creation projects – even when these projects have been conducted only at the outer edges of the companies´s value chains, and also when they have only resulted in refinements of existing products or services. We consider this type of co-creation to generate user insights and not to be *real* co-creation with users as partners. The high expectations for the innovation potential of co-creation in business as well as design have yet to be met. Whereas the user insights may contribute to incremental innovation, we have failed to find evidence of radical innovation based on user-driven-innovation or co-creation sessions. A subtle reason for this could be rooted in the human psychology and the notion of *fixation*.

The notion of fixation

One of the obstacles to come up with new and innovative ideas is that human beings are creatures of habit. Speaking of innovation and design, we often refer to the notion of *thinking out of the box*, which is in fact much more difficult than it sounds. Thinking out of the box means mentally divert from familiar paths or patterns, often however, our way of thinking remains fixated inside the already known framework the proverbial box.

Originating in gestalt psychology, the notion of fixation has become a subject of special interest in experimental cognitive psychology to understand innovation and creative problem solving (cf. Purcell & Gero, 1996). Fixation or fixedness is a general psychological phenomenon that in simple terms stems from the nature of human information processing, which is inherently selective and thus connected to our decision-making abilities. This is of great value to our everyday life as the cognitive system prevents information overload, however, this selective aptitude can be a hindrance to creative problem solving. Fixation is a familiar occurrence in design process and is to designers often "experienced as a premature commitment to a particular problem solution" (Purcell & Gero, 364). In a seminal paper from 1991 entitled *Design fixation*, David G. Jansson and Steven M. Smith introduce a possible definition of design fixation as: *"*A blind adherence to a set of ideas or concepts limiting the output of conceptual design, [that] is a measurable barrier in the conceptual design process*"* (Jansson & Smith, 1991, 3). This is a simple and comprehensible description of a complex and difficult to explain cognitive function. Within the context of this paper, the full complexity of fixation and related cognitive workings cannot be addressed, for an in depth discussion, we refer to two recent papers by Edward Chronicle, James MacGregor and Thomas Ormerod (2002; 2004). For our purpose, we find it useful to present three cases of fixation; two from the experimental psychology literature, and one from our own design research.

Case 1: The two-string problem

Experimental psychologists have studied fixation in problem solving processes since the 1930s. A classic study from this period is Norman R. F. Maier's *two-string problem*. In the study, volunteer subjects were placed individually in a large room with two long cords hanging from the ceiling, and each subject was presented with the problem of tying together the ends of the two strings (cf. Maier, 1931). However, the cords hung so far apart, that it was impossible to hold onto one string and reach the other. In addition to the cords, the room was furnished with a number of objects, among them were poles, a pair of pliers, clamps, tables and chairs, and the subjects were told they were free to do or use whatever needed to solve the problem.

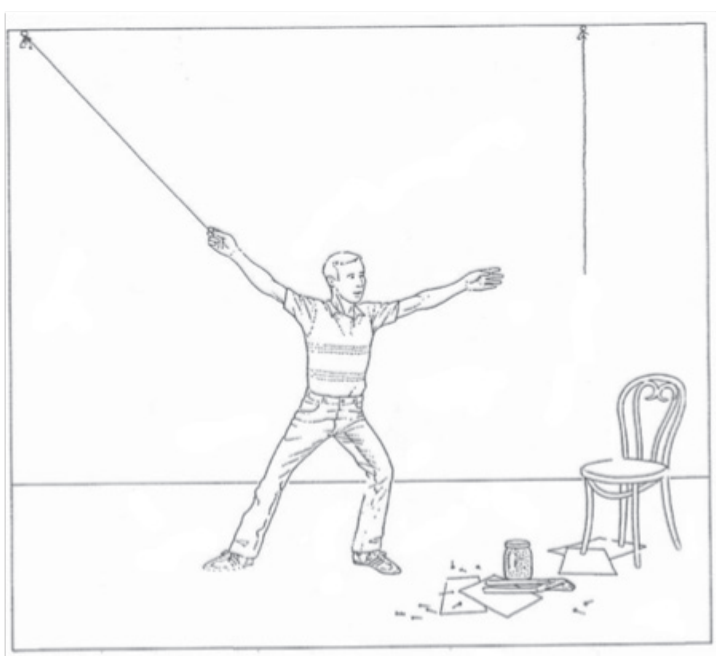

Figure 2: The two-string problem, illustrating the impossibility to hold onto one string and reach for the other (after Maier, 1931, 181-194).

The two-string problem experiment had several possible solutions, one of which was using the pliers to grab onto one of the strings and make it work as a pendulum weight, thus making it possible to hold onto one string and capturing the other as it swung by. However, such a use of pliers is unusual, and what Maier observed was that many subjects found it difficult to see beyond the usual function of the pliers and employ them in a new way to solve the problem at hand. The subjects experienced a type of fixation in problem solving termed *functional fixedness*, which characterizes a restriction in one's handling of an object to previous encountered functions of similar objects (Jansson & Smith; Purcell & Gero).

Case 2:The eight-coin problem

A recurrent topic of interest in the experimental psychological literature is the question of insight in problem solving. The insight process is somewhat a mystery and it has proven difficult to determine what exactly constitutes an insight problem (Chronicle et al., 2004). However, recent literature argues that for insight to occur in problem solving activity, it requires "removal of one or more unnecessary constraints imposed upon the problem solver upon the actions that they take in attempting to solve the problem" (Ormerod et a., 2002, 791). In the experimental psychology literature there are many variants of insight problems, a novel example of an insight problem is the *eight-coin problem*, designed by Chronicle, MacGregor and Ormerod (Ormered et al.). Basically, the eight-coin problem presents a subject with a configuration of eight coins, which through a number of specified moves must be transformed into a new configuration, where each coin touches exactly three other coins.

The constraints of the problem are embedded in the initial configuration, which is presented as two-dimensional. This restriction creates a fixation. The primary insight needed to solve the problem is to perceive the configuration as three-dimensional, which allows the subject as well to move the coins in three dimensions (cf. Ormerod et al.).

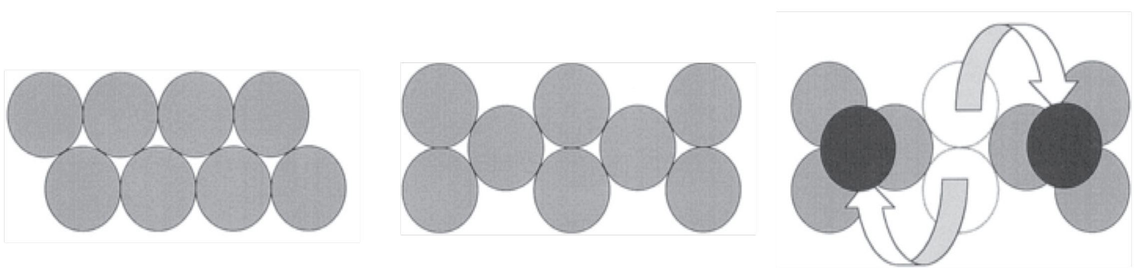

Figure 3: A configuration of the eight-coin problem and the two moves to create the new configuration, where each coin touches exactly three others (after Ormerod et al., 2002, 793).

Fixation can be associated with a wide range of information processing biases that lead to selective attention to a problem. Whereas Maier's two-string problem revealed a bias related to our perception and use of objects, the eight-coin problem illustrates a bias, related to a the perception of the constraints in a given context – if perceived as two-dimensional, movement in the context is perceived to be restricted to two dimensions. For most subjects, the selected strategy for solving the problem adheres to the initial representation of the problem; however, to actually resolve the problem, a restructuring or re-encoding of the representation must occur.

Case 3: Experiences from co-creation sessions in a bank

In her research conducted at a small savings bank headquartered in the Danish town of Middelfart, Kirsten Bonde Sørensen included experiments that mixed probes from the critical design approach with generative tools from the generative design research (cf. Gaver, Dunne & Pacenti, 1999; Sanders, 2008).

People's private economy is often considered a personal and somewhat intimidating issue, which Sørensen experienced in her first creative sessions. This led her to experiment with a mixture of probes and generative tools. She ended up making a box filled with different creative tasks just like the probe, but instead of sending it to the participants, she experimented with inviting people in groups to a *neutral* room or conducting the creative session with the participants in their private homes. In her approach, she considers the tools to be generative and the user to be a dialogue partner.

In the creative experiments, different themes were used in order to ask people about their needs and wishes for a future bank. The answers were dominated with suggestions and ideas in the category *more of what we already have*. People responded with statements like "closer contact to my financial advisor", "extended openings hours", "better rates", etc. When suggesting the bank could offer a new special banking service, a *saving coach* for people with financial problems, most of the participants, who responded positively to the idea, were the ones who had seen the Danish television show: *The luxury trap* (in Danish: "Luksusfælden") – a television show with two professional financial consultants helping out families struggling with their ailing economy.

The creative experiments illustrate an important weakness in user studies: people often are fixated in what they already know. As Alberto Alessi claims: "There is a way of doing design that is giving people what they ask, which is never something innovative", (quoted in Verganti, 2009, 48). Sørensen discovered no radical ideas about a future bank in her experiments. Instead, she got inspired by the way the generative tools were working, as people actually got more aware of their relation to money, their private economy and their bank. As such the creative sessions served as an inspiration for a designer to develop a new type of customer service in a bank.

As part of a design research or design investigation into the bank's services, the creative sessions resulted in the prospect of developing new meaning in banking business with costumers being offered a way to obtain greater awareness about values – and economy – in life. Asking the participants about this, they did not know how to react, saying: *"*But is it possible to do this in a bank?*"* or *"*I cannot imagine doing this in a bank". These expressions underpin Verganti´s claim*: "*If a company tests a breakthrough change in meaning by relying on a typical focus group, people will search for what they already know*"* (Verganti, 2009, 49). Sørensen's creative experiments with bank costumers become a real-life example of how difficult it is to think out the box and how biases can produce fixation. As noted earlier, human beings are creatures of habit. Most of us have a very conventional perception of what bank is, how bank business is conducted and which services a bank provides. The participants in the experiments were restricted by these conventions, they fixated on already known paths or patterns to express their needs and wishes as well as their take on new ideas for a future bank.

Co-creation as fixation

As noted above, the rapidly growing research field of co-creation can be seen as an indication of a huge interest in co-creation and a readiness in designers to respond to the demands from the field of business. But the success in the designers' amazing capacity to get close to users, understand their needs and generate ideas creates new challenges.

Businesses generally think about design and designers from two perspectives: the first, and very traditional one, is styling. Designers are asked to make products look nice (cf. Richard Buchanan's 1rst order of design: *symbols*; Buchanan, 2001). The second, and more recent one, is user-centred design. As Verganti stresses, first styling and then user-centred design are perceived as vehicles, by which companies differentiate themselves from the competition. Analysts claim that design in these ways makes a difference (Verganti). Today, almost no company would dare release a product without caring about style and analyzing user needs. However, there is more to design and innovation, which begs the question: Are user studies and co-creation actually contributing to innovation or has the idea that they do become a fixation for business and design?

If businesses are not aware of how users use their products, co-creation sessions can bring insightful knowledge when developing better products, but as a way of obtaining radical innovation, they seem to be of little value. As the case with co-creation sessions in a bank showed, it was difficult for the participants to let go of the conventional perception of what a bank is and does and imagine new types of bank interactions and services. Verganti claims that user-driven innovation and co-creation can only to bring incremental innovation (Verganti, 2009). To obtain radical innovation, we need to think out of the box and not be fixated into something we already know. In that sense, user-driven innovation and co-creation may actually be putting a brake on radical innovation. Whereas users may have difficulties with thinking out of the box, business leaders have difficulties in changing their perception of users as subjects. Yet, they continue to put their trust in co-creation, user studies and user-driven innovation enabled by designers, developing the requested tools and methods. And in that sense, co-creation, user studies and user-driven-innovation have become a fixation both for business leaders and designers.

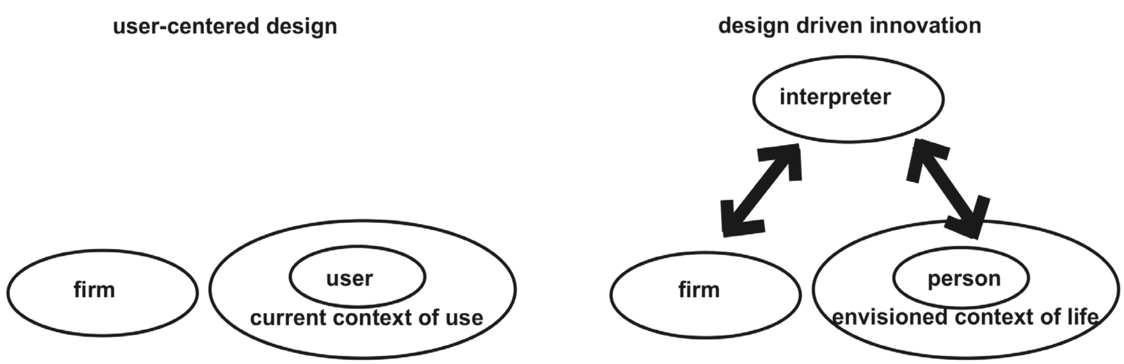

Figure 4: User-centered design versus design-driven innovation (after Verganti, 2009, 118)

Design driven innovation instead of co-creation

For this paper we have been very inspired by the business professor Roberto Verganti. In his recent book *Design Driven Innovation* he gives designers a well-deserved wake up call. He claims that designers at present design in accordance with a “codified, predictable, and mandatory process – making it more digestible for executives educated in traditional management theories” (Verganti, 2009, p.xi) He predicts the consequences of doing so are that designers lose their ability to do forward looking research.

As co-creation brings only incremental innovation, we contend that the *real* success to co-creation lie in the very perspective of the designers, the design thinking, the thinking out of the box, which t is crucial to obtain radical innovation. Verganti claims *design-driven innovation* to be the way to radical innovation. He defines design driven innovation to be about *meaning innovation*, which means understanding, anticipating and influencing the emergence of new product meaning. The way to do this goes through *"*a broader, in-depth exploration of the evolution of society, culture and technology" (Verganti, xi).

The original meaning of design also goes back to the latin "de" plus "signare", which means making something, distinguishing it by a sign, giving it significance and designating its relation to other things, owners, users or gods. Based on this original meaning, one could say: Design is making sense (of things) (cf. Krippendorf, 1989).

The meaning that a user gives to a product depends on her/his cognitive model, which in turn is significantly affected by her/his inner socio-cultural context. Proposing new product meaning therefore implies understanding the inner dynamics of socio-cultural models, beyond what is explicitly visible. The shaping of socio-cultural models and their impact on the interpretation of product languages depends on millions of unpredictable interactions between users, firms, designers, products, communication media, cultural centers, schools (Verganti, 2009).

In his study of some of the successful Italian design companies such as Alessi or Artemide, Verganti found that their innovation process hardly ever starts from close observation of user needs. Instead, they follow a different strategy, which he calls design-driven innovation – a strategy that aims at "radically change the emotional and symbolic content of products (i.e. their meanings and languages), through a deep understanding of broader changes in society, culture and technology. Rather than being pulled by user requirements, design driven innovation is pushed by a firm's vision about possible new product meanings and languages that could diffuse in society" (Verganti, 2008, 436).

Alessi and Artimide can be considered to create radical innovation in their respective markets. It is a common perception, that the world needs radical innovation and subsequently, there is a need for radical designers and radical researchers. These are, according to Verganti, experts who envision and investigate new product meanings through a broader in-depth exploration of the evolution of society, culture and technology. Radical designers and researchers are not asking people about what they want. So Verganti´s point is to make designers stop customizing design and making it digestible for managers educated in traditional management theories.

Looking back at the Sanders and Stapper's mapping of participatory design, we could identify different conflicting perspectives: a business approach considering the user as a subject and a design approach thinking the user as a partner. Thinking *the user as a partner* is crucial and the only way to *real* co-creation, but in the field of business, co-creation is reduced to user inputs and the customers, users, *co-creators* or whatever they are called, will always remain *a customer*, buying products or services. The traditional business perspective is fixated into an image of an organisation, producing something to be sold to customers or users outside the organisation. From this perspective co-creation is a tapping into the brains of the customer in order to get more information about him or her to be transformed into better selling products, but this is not co-creation. Co-creation implies equality; co-creation is the kite surfers doing an autonomous and self-directed group activity. The problems in co-creation arise when business leaders seek to transform this autonomous and self-directed group activity into a new way of *running* business innovation. You cannot run innovation in that way, and you cannot expect users to contribute radical ideas, but you can start regarding users as your partners and appeal to their interest in a certain issue. This is the design approach. In their heart designers know that, but in their eagerness to meet the requests from business leaders, they seek to develop new tools, methods and instruments for co-creation sessions within a fixated business framework. This is what Verganti called the "codified, predictable, and mandatory process" that makes design more palatable to business leaders educated in traditional management theories.

Designers seem to forget that the idea about the practice of collective creativity has been present in the design field for at least 40 years! Yet in business literature, books about co-creation have become bestsellers and are considered to contribute absolute new insights (e.g. Normann, Prahalad & Ramaswamy), but the idea about collective creativity was presented at the very first international conference by the Design Research Society in Manchester in1971and was simply entitled: *Design Participation* (DRS history website; Sanders & Stappers, 2008). *Participatory* *design* was the terminology used until the recent fixation on what is now called co-creation. Before co-creation, participatory design was a common practice in design and design research in Europe, in particular in Scandinavia (cf. Sanders & Stappers, 2008). The designer has never been far removed from the user. Just take a look at a Charles Eames sketch on the design process from the1969 exhibition *What is design?* at Musée des Arts Decoratifs in Paris.

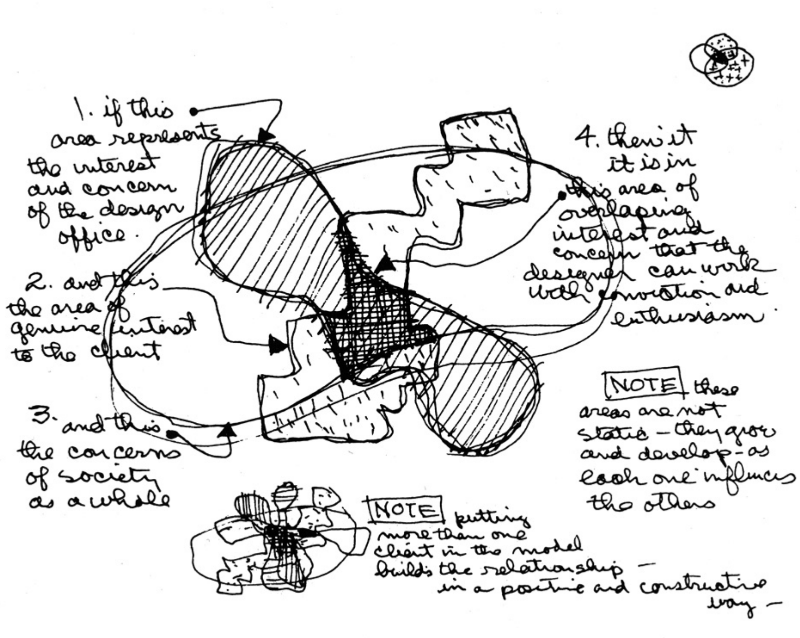

Figure 5: Charles Eames: What is design? (from Eames, 2002, inside front cover).

In his mapping of the design process, Eames considered design to be a dynamic activity consisting of four areas influencing each other noted in the diagram:*The interest and concern of the design office*, *the genuine interest to the client*, *the concerns of society as a whole*, and finally the area of *overlapping interest and concern that the designer can work with conviction and enthusiasm*. In Eames´s notes he underlines that “these areas are not static, but grow and develop as each one influences the others,” and furthermore, he writes next to the thumbnail model: “Putting more than one client in the model builds the relationship in a positive and constructive way” (see fig. 5). Eames saw design not as something removed from the user (the client) or society, but at something created in dynamic relationship with the user and society. The drawing testifies to the fact that Eames was thinking of design process as a process in line with Verganti´s ideas about designing in a socio-cultural context.

According to Richard Buchanan´s mapping of the development of design, designers are moving from a first level focus on *images* or *symbols* onto *things* and later *services* and finally to the fourth level, which related to action, but focused on *the environment and systems within which action takes place* (cf. Buchanan). This is the level of *thought*, since it is fundamentally concerned with the organising idea of principles that operate behind environment and systems, i.e. human systems, Buchanan explains. Designers in this field can be seen as facilitators of organizational processes. They are capable of organising “conversations and debates about the values of a community and how those values may be implemented with productive results” (Buchanan, 2001, 202).

The different examples of Verganti, Eames and Buchanan should remind designers not to leave their own perspective behind in their keenness of meeting the demands of business. The design perspective is a precious asset and includes the ability of bringing new and useful insights to create new meaning.

A meeting between two opposite paradigms

What happens when design thinking meets management thinking? The field of *design management* is about the integration of design into management and vice versa. Talking about co-creation from a design perspective versus a business perspective, it seems relevant to look into the field of design management. The design management field is only a few decades old, whereas the management discourse is about hundred years old and the design discourse about half of that. In their paper 2008 *Towards a better paradigmatic partnership*, Ulla Johansson and Jill Woodilla uses the well known framework on sociological paradigms by Gibson Burell and Gareth Morgan (1979) to illustrate the paradigmatic differences between management discourse and design discourse. The authors problematize the way knowledge from design merges with knowledge from management – a kind of rigid partnership between design and main-stream management research (Johansson & Woodilla, 2008).

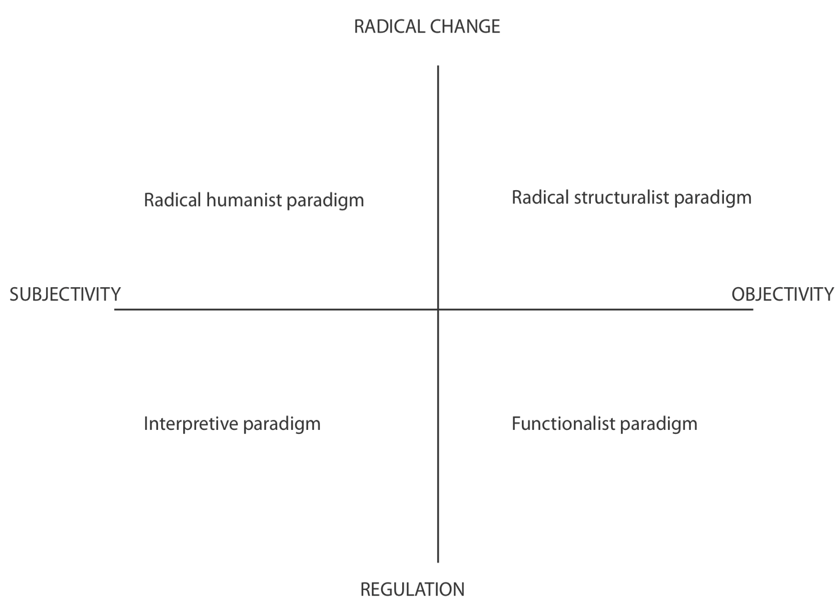

Figure 6: Burell and Morgan divides management history into four social paradigms (after Johansson & Woodilla, 2008, 7).

The field design management was expected to bridge design and management and consequently be represented in all areas; however, this has not been not the case. In fact, the field of design management is only represented in the functionalist paradigm, relying on objectivity and regulation as foundational assumptions. From a design perspective this is somewhat problematic, claim Johnsson and Woodilla, because design thinking is being differentiated from rational, analytical processes, rather than being defined as a holistic way of creating something new and unanticipated: “Management most often lacks sufficient knowledge about design to take advantage of the strategic potential that design promises. As a consequence, research is most often of a normative and prescriptive character” (Johansson & Woodilla, 2008, 16).

Conclusion: Designers need to take the lead

From a business perspective co-creation may look like an easy and accessible way towards innovation, unlocking the creativity of the customers and letting their creativity be part of the development of the future business. Different understandings of co-creation result in co-creation often being reduced to user inputs used for improvements or incremental innovations. In fact, co-creation brings enormous challenges.

Borrowing a term from cognitive psychology, we argued that co-creation has created a *fixation* among businesses and designers, where the strong focus on the innovative potential of users as co-creators paradoxically has become an obstacle for both radical innovation and co-creation.

We think it is about time to *reframe design* (and business), to think about the future role of the designers, to think out of the box and not fixate on user studies, as they may already be the paradigm of yesterday. When business researchers as Normann speak about *reframing business* and turning business organisations into value creating systems the job requires a total different look at business organisations, which is not limited to – and fixated in – a traditional organisational perspective. But as long as business leaders are the ones to decide, co-creation activities will mainly result in user inputs or value creation at the outer edges of the value chain.

Verganti brings a refreshing and to some maybe also a provocative point of view into the field of design. We are inspired by both Verganti and Buchanan, but also the designers and design researcher who developed the idea of participatory design (now called co-creation) back in the early 1970, including Eames, who back in 1969 sketched a design process in line with Vergati´s contemporary idea of designing in a socio-cultural context.

Design history shows designers have the holistic perspective and the possibilities of bringing useful insight. Design thinking both stems from a humanist paradigm and represent an abductive way of reasoning that makes designers think in a radically different way and far removed from traditional causal reasoning in business.

The intention of this paper is not to belittle business leaders and managers, but to remind designers and business leaders that we need to prepare the ground for meetings and exchanges of meaning and ideas *between* the two different paradigms, both the business oriented functionalistic paradigm and the designers humanist oriented paradigm. Right now the functionalistic paradigm is dominating the discourse and unfortunately there is a tendency for designers to seek only to meet the demands from business leaders in terms of providing tools and methods.

We hope to stimulate the discussions and to encourage a reframing of design and the designers´ image as practioners who do more than user studies or beautiful styling of products. Radical designers and researcher do not give the business leaders what they want – radical designers and researchers offers a totally different perspective and a fundamentally different way of reasoning and that is why they truly have the capabilities to reframe business.

Author Biography

Kirsten Bonde Sørensen

A graphic designer from the Kolding School of Design in Danmark and Utrecht School of the Arts in the Netherlands, she also holds a MA in rhetoric (MARC) from Aarhus University in Denmark. She is currently working on an Industrial PhD project funded by the Danish savings bank Middelfart Sparekasse and attached to Kolding School of Design. Her research is within the field of strategic design and investigates how design and design thinking can contribute to business development and innovation.

Malene Leerberg

An art historian, she holds a MA research degree from Aarhus University in Denmark and California State University, Northridge in the USA. She is currently working on a PhD project funded by the Kolding School of Design in Denmark. Her research is within the field of design process and methodology and investigates the interactional role of sketches in individual as well as collaborative design processes.

Expanding Design Space: Design-In-Use Activities and Strategies

Abstract

This paper introduces an analytical framework for understanding the collaborative nature and distributed structure of what is often referred to as *design space*. We propose that the design space should be conceptualized as the space of possibilities for realizing a design, which extends beyond the concept design stage into the design-in-use activities of people. By locating different activities and mapping participants' possibilities in a continuum from consumption to active creation, we develop a framework for understanding and locating design research interventions and a tool for mapping design activities. We argue that: 1) a design space is always actively co-constructed and explored by multiple actors through their social interactions with and through technologies and 2) the participating actors, resources, conditions and supporting strategies frame the design space available. In doing this, we bring forth relationships between an expanded view of the design space, contemporary discussions on the nature of innovation and the imperative to support explicit collaborative and participatory design activities.

Keywords

Design-in-use, design space, collaborative design, participatory design, practices, social practices, use, user innovation

The term design space seems to be fairly common concept in design research literature (see e.g. Westerlund 2009). While many make use of the evocative dimensions of the word-pair to convey a place that can be explored, few define it explicitly. In general terms we can say that the concept of design space is used to highlight the freedom to choose from many options and to explore alternatives (e.g: Fischer & Giaccardi 2004, McKerlie & MacLean 1994, Sanders 2001, Westerlund 2005). Sometimes it also seems to refer to all design relevant information that is available in a design process (e.g: Hassenzahl & Wessler 2000). Another common use is to describe it as a territory that expands and contracts as the brief or challenge for the project changes during the process (e.g: Gero & Kumal 1993). However, two common threads emerge from the literature. First, the fact that the discussion of the idea of a "design space" is taken up from the point of view of a typical ”design actor” – a designer or an organization involved in the creation of a product. It is usually the professional who defines and explores the design space, or if it is done in collaboration, he or she will be the one typically initiating the explorations. Second, the design space seems to be considered as a space that is mostly present at the concept design stage or rather a feature of it.

This is in contrast to other strands of research located in-between innovation and science and technology studies, which could contribute to the design field new dimensions for understanding the nature of a design space. For instance, the capacity of so-called lead users (von Hippel 2005) to actually envision and construct the design space themselves leads them to create new product genres, as e.g. described by Baldwin et al. (2006). Building on those insights, distributed accounts of innovation that focus on the role of users suggest how a design space could be effectively and collectively explored and constructed by a network of users alone (von Hippel 2007). Furthermore there is a range of research contributions that argument for expanding the scope of what counts as innovation, suggesting a richer and varied view of what counts as the design space that is been explored when innovations emerge (Tuomi 2002, Shove & Pantzar 2005, Hyysalo 2007). These accounts, for example, point out how individual user customizations and more importantly, the social practices of users, form a part of the design space that is being collectively charted and created.

There are two important and most immediate implications of this view: firstly, more people are exploring the design space (not only producers or designers, or designers inviting users into some user centred process) and secondly, what counts as design space should also be expanded to include other things like social practices and agreements and not only physical artefacts. In so far as the design space available to stakeholders frames largely the evolution of the artefacts involved and the practices that carry them (e.g Hyysalo 2007, Shove & Pantzar 2004), a clearer account of what could be considered as design space and what are its components is needed.

In the rest of the paper we will follow Redström's invitation to develop accounts that explore "*what it is that we do rather than who we are*" (2008:410p) with respect to a design process in order to avoid unproductive user-designer dichotomies. The paper is structured as follows: first we will introduce our definition of the concept and its relationship to design-in-use discussions. The next section concentrates in locating different activities in a continuum from consumption to creation in order to develop a framework for understanding and locating design research interventions and a tool for mapping design activities that make those design spaces explicitly visible. In addition we introduce some design research cases and related support strategies for designers that we have experimented with. The paper closes with some remarks and directions for future research.

Expanding design space

Westerlund´s elaboration of the concept of design space, in terms of a conceptual tool to design and understand design processes (2009), is a good starting point to elaborate more on the potential of this concept. In his work Westerlund describes how workshops are ideal locations to explore jointly the design space of future product functionality with a variety of actors in a user centred design processes (UCD). He found out that the exploration of the design space is not only done from the point of view of problems, but rather from the vantage point of view of possible solutions. Those solutions, he claims, are what actually constitute the design space. From this perspective, the design space is turned into a useful concept to reframe and develop more up-to-date design process by focusing in "possibilities" rather than dwelling in the problems alone. While his conceptualization identifies the co-operative nature of this exploration and moves the focus from problems to possibilities, it leaves a lot of explanatory weight on the shoulders of complete "solutions" or at least ideas that are considered as meaningful solutions. In this conceptualization other surrounding factors, like for example the resources available to participants to actually imagine those solutions are not thoroughly explored.

In this paper we will refer to the design space as the space of potentials that the available circumstances afford for the emergence of new designs. This space though, is not constituted in a vacuum or somehow "pre-existent". It is rather made possible through the presence of different stakeholders, tools, technologies, materials as well as social processes and agreements. Within that space all of those who are designing make choices and eventually a design comes to being in an ongoing process that extends beyond the concept design. The design space in this case is actively co-constructed and co-designed by multiple actors in their social interactions with and through technologies and processes, which are brought to the design space and mobilized by the participating actors.

Building on this expanded view of the design space, we believe that it is increasingly important to recognize the role of the former "users" as designers, more so because of changes in our technology landscape and new opportunities for collaboration. In an earlier era, where the capability to manufacture products was tied to an industrial mass production process, considering the idea that so-called end-users have always been designers in their everyday life, at home as well as at work, was philosophically interesting but had very little significance for design practice. However, in the digital, globally networked circumstances, a dramatically wider diversity of roles and potentials beyond consumption and production become relevant.

Design-in-use

From an earlier exclusive focus on the role of the "object" and "the design brief" as the focal points of the design process, we have seen a gradual opening up towards more situated perspectives on design activity. It is more common today that designers and researchers situate design activities in a wider complex socio-technological context, where it also matters how a project is approached, and not only its results (Findeli & Bobaci 2005, Krippendorff 2006). As asserted by several commentators, the relationship between "design" and "use" has become central concern in developing design approaches and theory (Jones 1984, Redström 2006, Ehn 2008). The opening up of new concerns is perhaps more evident today in the growing popularity of techniques for user orientation and user experience and a general embracing of so called user-centred design approaches. As a matter of fact, studying people and use situations to inform design process has become a recommended design practice in many areas, especially in relation to computer artefacts and digital systems and services (see Bekker & Long 2000 and Iivari & Iivari 2006 for reviews). These approaches, especially the pragmatic orientations, are today no longer an obscure research endeavour of a few, they are rather relatively well recognized lines of practice, or at least featuring high in the list of differentiation factors of design “expertise”.

There is no doubt that concerns regarding user orientation and involvement have brought a wave of fresh air and new insights for professional design practice. However it has been questioned whether these stances truly recognize the complexities of what it is at stake (Iivari & Iivari 2006, Stewart & Williams 2005); or whether they are able to recognize that so called “user needs” and “experiences” are not phenomena that exist a priori or in isolation (Shove and Pantzar, Shove, Watson, Hand & Ingram, 2007). In line with insights made through decades of research in areas like Science and Technology Studies, there is a need to recognize that a variety of people, through their everyday activities, are already engaged in a continuous and dynamic process of learning, creative appropriation, domestication and shaping of technology (Shove et al. 2007, Haddon et.al. 2006), and furthermore, that these appropriations take place even under adverse circumstance (see e.g Eglash et.al. 2004). Some commentators even remind us that people are not necessarily waiting to be taken into consideration by a user centred process (Spinuzza 2003), and that there is an unproductive stance that needs to be challenged, specifically when some of the user oriented perspectives in design tend to portray designers as the “heroes” that fix the situations while users are considered sort of “victims” in need of salvation (Spinuzza 2003, Stewart & Williams 2005).

In contrast, the idea that indeed a variety of use situations can display design-like characteristics invites us to consider that it is in supporting those instances (of design-in-use) that more work needs to be carried out from professional designers’ side. Already in the early 60’s design theorist and architect Christopher Alexander described processes of “unselfconscious design”, in an attempt to account partly for the pervasive enactment of design activities over time well beyond the professionals’ intervention. These activities, he claimed, were usually taken for granted but nonetheless exercised by all kinds of people; in order to maintain the equilibrium of designed systems (Alexander 1964). More recently Brandes (2008) and Wakkary & Maestri (2008) have provided concrete illustrations of some of the resourceful, adaptable and emergent qualities of everyday designs in contemporary mundane and domestic contexts. To support these types of pervasive design-like activities, several propositions have been made. An important earlier conceptualization made by Henderson and Kyng (1991) identified continuing design-in-use and tailorability as key things to consider for truly collaborative design. Extending these arguments, Fischer & Scharf (2000) and Fischer and Giaccardi (2004) amongst others have advocated for strategies to support meta-design. Despite these advances on our understanding of design-in-use activities, the fundamental ways in which these activities are articulated in our everyday life practices and vice-versa have not been fully understood and analysed (Shove et. al. 2007).

When new practices and contemporary forms of innovation have flourished in parallel to the growing access to network technology, collective endeavours and sometimes bottom up creation projects have been made visible. There is no doubt that computer users and developers are probably one of the most recognized and discussed user-designers and innovators in the literature (see e.g. Tuomi 2003, Floyd et. al. 2007). The case for blurring up the division between design and use (production and consumption) has been made several times using examples from Free and Open Source projects. These communities have a long history where software developers and advanced users engage in a collaborative design and development process with established tools, methods and work practices.

Unfortunately, everyday people without particular technological expertise (i.e. knowledge of specific programming languages) have had very limited possibilities to explore some areas of the design space of these technologies. However, recent emergence of collaborative digital tools, technologies and their associated practices (e.g. linked to blogs, wikis and RSS-feeds) have also made other types of active and concerted participation more visible. It has also opened the possibility for more diverse contributions that are not limited to programming. This effectively expands the design space that is visible and available for the people. These developments locate current discussions of design-in-use in a very different setting than the one that existed when user centred design approaches emerged.

These issues outlined above effectively invite us to reconsider: What does design-in-use mean for professional designers interested in creating partnerships and collaborative alliances, and what should we do about it? In doing this we propose that a better understanding of the scope and structure of the design space is needed. We proceed now to introduce the main components of the framework and its relationship.

Structure and components of the design space

In this section we present an analytical framework that aims to understand the structure of the design space we see emerging and to locate and identify different strategies. The following key questions are discussed in particular: What kinds of activities are people engaged in? What kinds of possibilities for appropriation are available? To construct the framework we have made use of several strands of research that have discussed similar issues in the past, and complemented it with empirical observations of current digital practices, when deemed necessary.

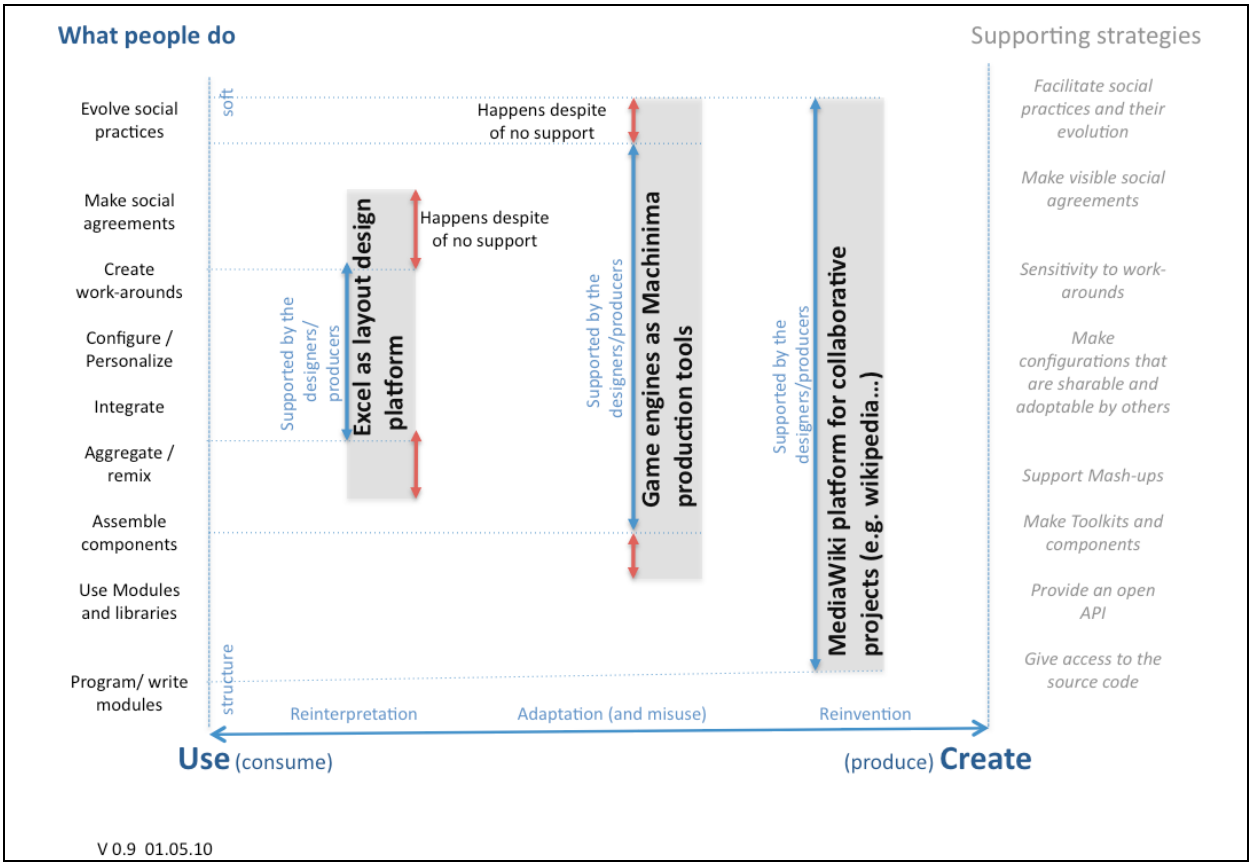

Figure 1 Framework for a structure of the design space

Figure 1 presents the basic dimensions of the framework. The vertical dimension presents an account of "**What people do**" as a *layered view* on different design activities in the digital realm. The activities are located in a continuum from “structural” to “soft” types as a way to convey the different points of view that need to be reconciled and that effectively complement each other. The horizontal dimension is meant to qualify those previous activities, by proposing that they might relate differently to the continuum between “**Use and Creation”**. Some of these activities might be more linked to basic aspects of consumption (understood in its more passive side), and others are aspects more linked to engagement and creation. To elaborate the discussion further, we illustrate the framework by positioning three contemporary examples along the continuum. In this case, their particular position depends on the conditions and possibilities that surround the activity carried out, which, effectively makes “slices” of the design space more explicitly available for people. We will now elaborate further on the components and meaning of each element.

What people do:

The bottom part of these design activities deal with issues of composition, material selection and definitions of structures. These are easy to recognize as activities pertaining to design or development professionals. In identifying them we draw on contemporary practices around human computer interaction, interaction design and software programming, all which deal with the design of digital media and technology. Every time a layer is added, the upper element represents more of an organizational or social type of activities. Some of these top layer activities would not necessarily be considered as design activities from a pure product design point of view. However, these activities increasingly account for what can be considered as design (Shove et al. 2007, Hyysalo 2007). To define and synthesize these "soft" design activities, we used concepts and ideas from literature in Science and Technology studies (STS) and issues explored in e.g., Participatory Design (PD).

- *Program / write modules:* On the basic level, digital system design operates with compiled software programming languages, such as C, C++, Java, and on a slightly higher level with interpreted languages such as JavaScript and Python. These activities require understanding of algorithms, data and information management, and include design decisions and exploration that affect the technology choices and production tools. Moreover it deals with the actual writing of code and the abstraction process required. The resulting designs are usually organized into modular reusable components that provide streamlined services for other designs through an Application Programming Interface (API).

- *Use modules and libraries*: On the next level of software design, software is composed into applications that perform some functions relevant to users. These integrated software packages take advantage of underlying modular software libraries. This usually takes place within one computer.

- *Assemble components*: Some software design can take place without extensive software experience, and many toolkits have been designed with the intention that non-experts could design their own systems or at least customize ready-made systems for some more specific purpose. Usually some, but most often quite a lot of programming expertise is still required. (MacLean et. al. 1990, Henderson & Kyng 1991). These types of design activities customize and expand a system by attaching new components, such as plugins, that bring new capabilities to the system and create localized manifestations of it.

- *Aggregate / remix*: A complex ecosystem of loosely connected services is evolving (Hartmann et al 2008, Nestler 2008), where mash-ups (a recent evolution of Internet applications and representative feature of the Web 2.0 phenomenon) can be considered as new service designs created by aggregating selected information from other web services, to some extent relying on services that offer an open web API.. A lot of contemporary design activity is concentrated in developing skills to aggregate and remix in inspiring ways. (Several web services, such as Google Maps, YouTube and Flickr, have quickly embraced the opportunity to become the platform of choice to be a standard component in mash-ups by offering e.g. map, video or image related services).

- *Integrate*: Most of the software that we use daily in our personal devices is in some ways connected to other software, those particular configurations are only known in use. Since the diversity of circumstances of use calls for a diversity of tools this represents a formidable and growing system integration and design-in-use challenge that faces us in our everyday lives.

- *Configure / personalize*: This is a typical area where more and more end-users need to engage in design activities when it comes to digital products. Software based systems usually include many kinds of settings, and as they often also mediate communications and interactions, they often contain also a lot of various types of information that is very much context dependent and often quite personal.

- *Create workarounds*: Workaround is a type of activity used to describe the ways in which users of some product or system develop creative ways to overcome a shortcoming of the product or service they have encountered. Creating workarounds is not only creative but also dynamic way of weaving artefacts to own working and ways of doing thins. It is an especially familiar term for software developers, but has also been used widely within the sociology of technology community, to highlight the ways in which users can act when facing an inflexible technology (Pollock 2005).

- *Make social agreements*: A social agreement is a shared understanding or consensus around a particular task or objective within a certain group or community. The nature of the agreement is usually a small group initiative that later evolves into a commonly implemented convention. One example of a social agreement with growing creative and practical consequences is *hashtagging*, the use of the hash symbol (#) to precede a term when microblogging in services like Twitter. The hashtag (e.g. "#opendata") adds additional context and metadata to the posts/tweets that makes it also easier to follow, organize and disseminate later.

- *Evolve social practices*: Social practices are embodied and materially mediated arrangements of human activities; they describe a particular way of going about an activity with its associated resources (Reckwitz 2002). Social practices, as an analytical unit, are shared and persist, because a group of people continuously reproduces them (De Certeau 1984). Eventually a set of social agreements (like the ones described above) or patterns of behaviours can evolve into a social practice that makes use of specific artefacts and conventions. For example, in video sharing sites like YouTube there are very advanced community initiated social practices for inviting and sustaining audiovisual conversations, via specific uses of visual genres, annotation workarounds, making visible of time-coded information and so forth.

Use-Create:

The Use - Creation continuum is structured around three intermediate positions: reinterpretation, adaptation and reinvention. These analytical categories are borrowed and further adapted from the ones introduced by Eglash when referring to technology appropriation (2004:xi), which we found insightful and relevant to this endeavour.

- *Reinterpretation*: This stage refers mostly to possibilities that exist for surpassing the semantical associations that are proposed to people in relationship to a given structure. An example provided by Eglash was that of the graffiti artists' interventions into the urban space, which provide a reinterpretation of the function of that space as a place for self-expression or political commentary without changing the structural conditions of the space itself. In digital environments, reinterpretation is obviously a possibility that is always available and relays strongly in the activities occurring at the soft layers of our "what people" do categories. An interesting case of reinterpretation can be found in the unintended uses of spreadsheet programs designed to calculate and manipulate numbers, as graphical layout design programs to create interiors and user interfaces (Berger 2006). This is done by reinterpretations of certain features of the software and basic shared agreements between a group of users. As seen in Figure 1, from a design process point of view the explicitly available design space is made visible mainly through the possibilities for basic configuration of the product, but there is little support to share and or extend user practices as this are mostly developed informally or in closed circles. In this case the possibilities of changing or adapting the lower layers are also more restricted; although there is always hacking strategies, this is not something that is encouraged.

- *Adaptation*: this second stage according to Eglash, implies a certain degree of flexibility in the underlying technology coupled with a sense of violation of intended purpose. These means not only of the designers' intentions, but also equally of the marketing strategies and / or gender assumptions embedded in a product. An adaptation involves creativity to look beyond assumed functions and recognize new possibilities, while the underlying structures are not necessarily changed. Eglash's classical example includes the "misuses" of early cassette players by Beduine tribes that saw beyond the playback machines (as they where marketed and sold to them) and used them as recording equipment for their own cultural productions. An example from digital realm can be found in the use of real-time three-dimensional game engines to produce computer animations. These animations where originally made to record playing episodes and performances, and they soon evolved to include the creation of new story lines and different creative appropriations for game-based movie making (Lowood 2008). This practice generated a new genre termed "Machinima". In Figure 1 we illustrate the layers that are covered by this example. Besides of being a very clever reinterpretation of what computer game software is meant to be for, the further development of the practice includes activities such as custom made adaptations and hacks of the software engines, in some cases supported directly by the game engine producers. Machinima practitioners gather in online forums to develop and discuss the genre as well as present their work in festivals, which effectively support the consolidation of a community with a shared practice.

- *Reinvention*: In the category of reinvention, a manipulation of semantics, use and structure is usually achieved and new functions are created. A true reinvention usually involves being able to produce changes and alterations to the original structures, like the case reported by Eglash in which Latino mechanics appropriate automobile shock absorbers to create shock producers for their low-rider cars. The multiple adaptations and recreations of the MediaWiki engine that runs Wikipedia to endeavours different than and encyclopaedia writing can be considered as an example of reinvention on the digital realm (see an overview in: MediaWiki 2010). As Figure 1 shows the platform is offered with open access to the code, so it includes explicitly the possibility of altering the lower levels. However reinvention is complemented strongly by the soft layers as well. The Wikipedia project exemplifies how it also involves adapting and evolving the social practices that made these type of collaborative production possible through many sophisticated and well-documented community agreements (Slattery 2009).

Making the design space explicit: some supporting strategies

In previous sections we introduced a layered view on design activities in the digital design domain by giving examples of what people do in the design space; with the focus on revealing design-in-use activities. In the digital realm shifting and moving between stages is –in theory– easy to perform, but in practice it is hampered by such things as the type of programming knowledge required to make the changes, standards conflicts between products and services, providers' and producer's use and licensing policies (open or closed), lack of support and shared practices, to mention just a few. For these reasons, the project of making the design space more explicitly available also in design-in-use, requires changes and support in mostly all the layers of the design activities.

In this section we will briefly introduce three design research cases we have conducted that have helped us to reflect on the possibilities of the suggested analytical framework. Based on these cases we have identified resources, conditions and supporting strategies needed; these characteristics will be elaborated and discussed further.

Facilitating practices of creative production and reuse of media: Today more communities are engaged on audiovisual creative activities, while some have not yet been able to take advantage of the many possibilities that audiovisual media could bring to their activities. How to make it easy for anyone to create, reuse and share audio and video productions over the Internet legally, without costly servers and complicated system management? As part of our research strategy we designed and implemented the Fusion platform (http://p2p-fusion.org/). The platform binds together a peer-to-peer network, a distributed metadata layer, social processing and enrichment features, support for embedded licenses and a component-based toolkit called Social Media Application ToolKit (SMAK). A Specific, practical goal for the system was to support social activities that include the creative use and reuse of audiovisual content, and to provide a software toolkit with re-usable components. The aim was to enable people to build their own applications with SMAK to share and distribute videos, edit and socially enrich them collaboratively. The work was carried it in collaboration with different Finnish communities (possible end-users) ranging from a music makers' community, to an extended family as well as enthusiast practitioners of acrobatics and parkour (For a more complete account of the case see: Marttila et. al. Forthcoming).

Facilitating practices for active citizenship: This case deals with the role of digital technologies, specifically location based services, in the emergence of new forms of citizen participation in the urban environment. As a research strategy we initiated the collaborative design of a prototype environment and service called Urban Mediator (UM). UM is a server-based software that provides users with the possibility to create, obtain, and share location-based information (http://um.uiah.fi). The service contains a set of tools for both city administration officers aimed at increasing their capacity to construct more active forms of citizenship and thus initiate innovations in the way digital participation services are being planned and delivered, by offering an in-between-space that is not in control of any actor. Collaborations were initiated with both active citizens and city officials in

Helsinki (For a more complete account of the case see: Botero & Saad-Sulonen 2008, Saad-Sulonen & Botero 2008)

Facilitating the coordinating of everyday life in a project of growing old together: This case intertwines with a collective project to develop and experiment alternative social arrangements for growing old initiated by a seniors association in Helsinki. Together we asked ourselves what kind of applications and digital media would be interesting and meaningful in such a community? Besides of other experiments, the biggest intervention made was centered around the collaborative design and development of what the community called their Everyday Life Management System (DailyWorks) and it's articulates to their project of ongoing design of the communal living arrangements. In concrete terms this is a collection of web-based tools for the seniors, which assists in the coordination and sharing of everyday life activities and information (http://arki.uiah.fi/adik/dailyworks). (For a more complete account of the case see: Botero & Kommonen 2009)

Based on the experiences gained in the cases, we want to discuss how e.g. professional designers or other stakeholders who are in a position of power regarding the design structures in question, could support and facilitate these multiple activities that vary from "soft" creations into "structured" and more rigid designs. In other words: How to expand the design space, in Eglash (2004) terms, to accommodate more explicitly "reinterpretation", "adaptation" and moreover, the "reinvention" activities (the results of design-in-use activities)? We open up the discussion by proposing four key factors we have identified based on our projects:

* *Support open-ended design process and flexible agency:* Design space, as traditionally perceived by designers, has been available for everyday people only by invitation or engagement through a professional designer or a predetermined process with objectives and outcomes that are identified a priori. This setting implies also preset roles and agencies available for people, which might prevent the richness of design-in-use activities that would trigger and uncover the social patterns, agreements and practices that people might possess in the design space. Moreover, these "soft" social designs should be carefully turned into design descriptions, structures and functions without losing the essence of the design knowledge (e.g. practices, agreements and workarounds).

* *Provide meaningful access to the resources available:* In order to facilitate the creative design-in-use activities and expansion of the design space, professional designers should provide access to infrastructures a pool of resources that are reusable. By granting open and meaningful access (e.g. contextualization of data, digital tools and guidance for various levels of engagement) we might enhance the different agencies in the space. Also access to knowledge can be critical when people are experimenting and being creative.

* *Create means for sharing designs:* another key factor is to create means for sharing "designs" that have been created in design-in-use. Individuals, groups and communities share their design knowledge and experiences with peers, social networks and other stakeholders in the design space e.g. in discussion boards, wikis and social media platforms. In these environments for sharing, professional designers should acknowledge existing procedures and collaboratively design and develop mechanisms for giving recognition and attribution to contributors, aim for nurturing trust and building motivation, and when applicable, create means for compensation.

* *Design for openness and designability:* The fourth and final aspect of supporting strategies of design-in-use is the design for openness and further designability of other designs. Fischer (2000, 2003) refers to a similar stance with the concept of Meta-Design. This strategy should acknowledge people as potential designers of future applications and platforms, and should provide an open access to different levels of software from source code to API's and CSS, through appropriate licensing and publishing of the designs – for instance: Free, Libre and Open Source and Creative Commons, and so on.

Formulating insights and sharing these design-in-use strategies are focal to the extended design space and its vitality. The means of exchange of design knowledge, e.g. solutions, workarounds, practices and innovations, varies from diverse things such as ad-hoc crowd-sourcing to the formation of communities (see e.g. Botero et.al. 2009). It is also important to notice that sharing design knowledge and experiences in a design space does not only happen between peers; but also with other stakeholders who have access to the information (e.g. what companies like Google can infer based on their user data).

Conclusion

The emergence of the digital environment and its ecosystems has created a new set of circumstances for design. These new circumstances provide many new opportunities for all types of stakeholders to benefit from new design interventions and engage in design activities. The framework presented here has been of great value for our work, as we have tried to make such new potentials visible and relate them to already familiar design processes and patterns. The framework highlights how the design-in-use activities of a very diverse set of actors can become realistic sources of innovation and material for other designs. By mapping specific activities on the graph, and through considering their potential design interactions with new actors or the adoption of new strategies, new collaborative design spaces can be envisioned and possibly explored. Since, these different activities have not been discussed with in a single framework it is possible that further refinement of the categories would be needed in the future. In any case, we believe that the novel combination and holistic understanding of the activities we are proposing has interesting implications and presents a useful view of the design space. Our future work includes testing the validity of the model with other empirical cases with a view to iterate the concepts and the structure of the framework.

As design is usually a pragmatic activity, the actors engaged are concerned with finding a workable solution, and are likely to draw the boundaries of the design space so that they exclude unrealistic options. This of course also means that things like ideas, ideals, imagination and inspiration belong all to the category of conditions that influence the dynamic composition of the design space. Along the same lines, all design operates with tools and on the basis of earlier designs and design expertise or experience that is available to stakeholders. These aspects can become available through personal experience, knowledge sharing, external services or collaborative team effort. In this sense, the design space of a stakeholder that has the necessary economical means, access to tools, a good design network around and working experience of collaboration within it, has most likely a persistently wider design space for a variety of projects than an actor with few means or bad and un-motivating earlier experiences. Thus for supporting successful design-in-use, it would be important to make available useful and realistic sets of resources and conditions for constructing solid design spaces.

The expansion of the design space has also wider societal significance. If the design capacity of free and collaborative actors that operate in the various levels of design-in-use activities we outline, is grown through open strategies as we propose in this paper, and they are linked together in a well functioning and dynamically self-organizing ecosystem, the collaborative design space is expanded and made more persistent for all – in effect increasing the design capability of all people in society. This is a very powerful strategy to increase the capabilities of more people to influence the transformations that are taking place in society. We hope our work is a contribution in this direction.

Author Biography

Andrea Botero

Andrea is a Doctor of Arts candidate in the Media Lab - School of Art and Design of the Aalto University. Her interest lies in theoretical and practical implications of broad participation in creative design processes and how this relates to "innovation". Her design work explores services, media formats, genres and technologies for communities and their social practices

Kari-Hans Kommonen

Kari-Hans Kommonen is the director of the Arki research group in the Media Lab, part of the Aalto University, Finland. The Arki group studies how everyday life is changing as it becomes more digital, and explores how digital technology and software can be designed to better serve and support people in realizing their own interests.

Sanna Marttila

Sanna is a Doctor of Arts candidate in the Media Lab - School of Art and Design of the Aalto University. She studies participatory culture, especially in the context of audiovisual media. As a designer her interest is to support and facilitate open and collaborative design activities. Currently Sanna works as a researcher and a project lead in Aalto University.

Food Orbits: A novel design tool for complex systems

Stephen Brogan, University of Dundee, Scotland, s.k.brogan@dundee.ac.uk

Seaton Baxter, University of Dundee, Scotland

Abstract

Food and our relationship with it is important to our very survival. To understand the different natures of various food systems it is critical to understand some of their general characteristics. We must know the components of the system and how they work together. Currently, there are several conceptual models of food systems available to facilitate the understanding of such: the linear, radial and loop models, none of which seem suitable for a design application. Natural food systems are complex adaptive systems that operate in a closed loop, with all inputs emanating from and all residuals returning to the source. However, rather than resembling these closed-loop ecosystems, modern food systems have much more in common with 19th century factories designed around a strong input/output efficiency model. Food Orbits is a novel graphical tool for plotting the relative industrial intensity of a food as it moves through the system from soil to dinner plate. This paper will introduce the concept of food orbits through a brief discussion of their context in the modern food system, their composition and construction, and an overview of a brief study done to assess their graphical intuitiveness. The focus of the paper will be the application of food orbits as a design tool and a device for understanding complex adaptive systems.

Keywords

sustainable design, systemic, eco-design, life cycle analysis

In this paper we consider the 'food system' as all those products, processes and activities that become entrained in the passage of a component of human nutrition as it moves and transforms from source to residue, a cradle-to-cradle system (McDonough & Braungart, 2002). There is a long historical association involving design and components of this food system from the design of simple utensils like bowls, pots, knives and forks through complicated scientifically-based appliances like microwave ovens and eventually genetically modified (designed) foods like tomatoes (Martineau, 2001). All of these associations, however, tend to reflect the activities of conventional design practices and operate at the low systems level, i.e.: a product rather than a system of products.

Design practice is now entering a higher systems level, often referred to as strategic design, and whilst this has generally been associated with design's relationship with and in business (Best, 2006) it also gives rise to new kinds of designers (Press & Cooper, 2003; Inns, 2007). In these respects, we believe strategy also applies to food systems and that 'food orbits' is a strategic design tool, which applies to the designer's visual and intuitive skills in this field (food) and at the systems level. Recently, Baxter (2010) has referred to this strategic move as “design thinking entering new domains”. In doing so it widens its perspective and links the systems' scale, from product, to service and ultimately to a “comprehensive anticipatory design science” (Fuller, 1969). This latter perspective is at the worldview level. Baxter also suggests, however, that this is only one dimension (vector) of what will create the new 'field of play' for designers. A second key dimension is the ecological perspective in which “ecological thinking enters design domains”. These dimensions taken together – ecological thinking entering design and design thinking entering new domains, constitutes what Orr (2002) has called “ecological design”, Wann (1990) has called “deep design” and Baxter (2005) refers to as “natural design”. This new combination will, according to Baxter (2010), lead to the *transmutation* of design and give rise to a new breed of designers, who he refers to as the “new alchemists”. Orbiting (Brogan & Baxter, 2010) often applied to the design of food systems (food orbits), is a technique which is located at the interfaces of these two dimensions of thinking (ecological design). It is a contribution to the transmutation of design practice.

Design and complex systems

Understanding the system or the environment in which a design functions is critical to the efficacy of that design. Conventional design methods are, often by necessity, reductive – reducing difficult design problems to systems of smaller solvable problems. Whilst this approach is powerful and effective it means the solution will be optimised, and essentially designed for that simplified context. However, even these designs are always part of larger systems that then operate as part of other truly complex systems such as the greater human society or a natural ecosystem.

Some designs function directly within a complex system, such as a social network. It is within these systems that a reductionist approach often yields unintended results because the design process cannot model the level of complexity needed to explore all consequences. There are numerous examples of large-scale designs, such as hydroelectric schemes or highway networks, having large and unpredictable impact on society and the natural environment. There are also many examples of small designs such as mobile telephones or web-based social networking sites, having similar effects.

The designer, by training and experience, is prone to immediately designing toward an end defined by brief or specification, whether real or implied. If one is employed as an engineer with a large microwave oven manufacturer it is unlikely that any non-microwave oven solution would even be considered when developing a new cooker. Part of this problem exists at the beginning of the process when the design problem is defined. The problem is defined in both context and scope. Often widening the scope of the design is referred to by the cliché of 'Thinking outside the box'. This is often done through a brainstorming exercise in which different possible solutions are explored. In the example of the microwave, “thinking outside the box” might mean investigating microwave-convection ovens, halogen cookers or possibly even a gas cooker, but almost certainly not solar cookers, raw food diets, or communal campfires. Clearly, this level of complexity is too much to handle.

Simply thinking about these systems, possible problems, possible solutions and their consequences is too much for a designer or even a design team – no matter how large. The usual outcome is to simplify and return to the proverbial box. Our ability to effect change has now outstripped our ability to understand the consequences of the change.

The problem with design and complex systems is that the systems cannot be assessed by standard design methods, as the least understood part of these systems tends to be at a higher scale and traditionally conventional design works at a lower scale. Therefore, a new suite of methods are required to better assist designers in their understanding of these systems and to help them design *within* the system whilst leaving space for emergence and growth.

J. Chris Jones explained something of these levels of complexity in his justification of the need for new design methods, breaking the sphere of design influence into four strata – community, systems, products and components. He explains that “Many of the unsolved problems of designing occur at the systems level of the hierarchy.” but that conventional design methods are only effective at the two lowest levels. He goes on to suggest that:

> such an extension of the design process is at least as great as that from craft work to design-by-drawing (a shift from the lowest tier to the two lowest tiers). This change (to what Buckminster Fuller has called 'comprehensive designing') cannot fail to have drastic consequences, implying, as it does, the power to continuously remodel the whole fabric of industrial society from top to bottom. (Jones, 1992)

Jones contends that the tendency to move the designer's role from the products level into the top two tiers results in too much control and he rightly dismisses it as having drastic (likely catastrophic) consequences. However, the notion of 'comprehensive design' may be appropriate when one considers 'comprehension' to mean 'understanding of the whole'. It is this area of design that is lacking in many established methods and practises.

To date there have been some methods, such as systems modelling (Odum, 1983), pulsing, lensing (Baxter & Bruce, 2008) and orbiting (Brogan & Baxter, 2010), developed to help designers navigate this 'systems geography'. Orbiting is an exercise that designers can participate in to understand something further about the interrelationship between a system and a design. This concept is exemplified here in relation to food as it provides an excellent example of complex systems and the implications of design. It also provided the original basis for the concept developed by Brogan and Baxter.

Food orbits

Aside from design issues, there are many reasons why we may want to understand the origin of our food and especially the system, which brings it from the field to the plate. Of most importance to the consumer is probably that of food quality. Issues of food adulteration are as old as food itself - Unscrupulous producers or processors somewhere along the way 'bulking out the loaf' or 'watering down the whisky'. The Food Adulteration Act of 1860 banned these practises and eventually led to a system of inspection and enforcement that guaranteed foods to be safe, sanitary and pure (*The fight against...*, 2005). However, the lack of international standards and the lax definition of what is safe, sanitary and pure can lead many people to look deeper in to a food's origin to assure themselves of its claims.

After food quality, concerns might be expressed about a food's secondary or external qualities. These issues might not be directly linked to the food's internal quality, but often have what are best described as *health* implications. An example is feedlot-fed beef. Two physically near identical steaks purchased at a supermarket may be clean and unadulterated beef that earns the highest grade, but have travelled through very diverse channels. One may originate from a local farm where the animal was raised on pasture grass until it grew to market weight after which it was processed, humanely, in a local abattoir that sold it directly to the supermarket. The second may come from the American mid-west where the animal spent 80% of its life in the cramped and dirty conditions of a feed lot eating low-grade corn, subsequently being slaughtered in a large plant employing unskilled migrant workers, boxed and sent along to a cutting plant where it was cut into a steak, frozen, shipped a few more times until it landed at the supermarket, where it was thawed and repackaged for sale. The second steak represents what many consumers would term 'unethical' food, but in terms of health (of the environment, animal, workers and the local economy) it is also the unhealthy choice, despite the identical nutritional information 'sticker' on either steak.

To add to the ambiguity of the various food choices, the process of tracing the origin and genesis of foodstuffs in a globalised market has become quite difficult. Most processed foods contain a myriad of ingredients from different sources, which then merge to become one product that may then be again combined with other products shipped onwards through a complicated distribution network. Even whole foods, foods that are consumed in the same state in which they were harvested, may have equally complicated origins as evidenced by the aforementioned steak example.

Adding to these problems, there is the general situation of public knowledge. Whilst a certain sector of the population may be well informed about food and its origins, an American study showed that most people think very little about the origin of their food, mostly due to the lack of a mental 'model' of the system, stating: “...the lack of a specific model of food systems means that certain kinds of information has no place to 'stick' in people's minds.” (Aubrun, Brown, & Grady, 2005). Unpacking this mystery inevitably leads to the construction of a model or simplification of some sort.

The first type of model we considered to help us understand such complex systems was a spatial-survey model showing where food had been and perhaps some detail as to what had happened to it at each point in the food system. The result would be either a geographic map with pinpointed locations and descriptive boxes or a more logical box-and-arrow systems diagram. The latter affords the viewer a more generic depiction that can then be easily compared with alternatives by eliminating the spatial confusion of a map and crossing lines. Such box diagrams are commonplace in engineering and science fields and are best suited to analyses that target process efficiencies. The focus of such box diagrams is on the process rather than the product itself.

The process-based model has at its core the weakness/strength problem of most models. In any model, the more that is left out to help focus the user on a solution, the greater the danger in neglecting certain parts of the system. In a complex, non-linear system, leaving out what might appear to be a small or even insignificant component can have large effects. So, whilst a systems-based model is critical to the understanding of systems-aspects such as layout, relationship and flow, it is only a part of a suite of models that could together shed light on the entire system.

One of the main challenges of constructing a systems-model for something as complex as a food system is actually gathering information about the system, especially when so many systems converge and diverge. Often what is most critical about the process (the product and the environment) is lost. In the 1980s, engineers facing just such a problem in one aspect of the food system, potato production, developed a novel solution to view the system from the inside by creating what is now commonly referred to as the 'electronic potato' (Anderson and Parks, 1984). The electronic potato is a potato-shaped data-logger, which monitors various physical parameters that a potato might encounter, such as: physical force, temperature and relative humidity. The 'potato' is then buried in a field and eventually retrieved at the processing facility days (or weeks) later. The data, once downloaded, provides a story of what has happened to the potato. This can illuminate where in the process the potato is exposed to excessive heat, moisture or physical force. It is a 'potato's eye view' of the post production process and often shows a very different story from that told by the systems model.

An alternative method at the early design stage is the use of a model, which exploits tacit knowledge, readily accessible information and intuition.

Understanding macro organic mass flow through the world's modern food system ultimately leads us to the study of naturally occurring food systems, because, despite our best efforts to mechanise, the food system still has living systems at its base. It is comprised of living organisms and systems that have been modified by our efforts to adjust or control the flow of water, nutrients and organic mass, resulting in natural systems with varying degrees of intervention. Whilst systems thinking has been applied to ecology (Odum, 1983) and this has, to a great degree, influenced our understanding of how they function, there are still many unknowns. Nevertheless it is known that natural systems have a variety of common characteristics such as a tendency to be highly stable over the long term, a high degree of complexity, self-sustaining characteristics and usually operating in a closed-loop with a high degree of feedback and redundancies. They are resilient. The entire premise of agriculture is the isolation of small components of natural systems with intensification of certain aspects for the benefit of mankind. By definition it is a disturbed ecosystem. Agriculture, in effect, takes humans, as a species, not just to the top of the predator-prey pyramid, but out of it, free to browse the entire structure. This then gives humans the unique ability to stand back and consider the structure, which compromises every other living organism. In recent history it would appear that we have seen this system as a simple machine that can be optimised and fine-tuned.

The degree to which we intervene in the ecosystem might be referred to as 'intensity', coming from 'intensive agriculture'. The idea of intensity can be applied to most processes such as: intensive training in education or intensive care in health. At its root, 'intensity' simply means the application of stronger or more forceful action and is well appreciated by most people at the intuitive level. Applying the term to systems it can be said that intensive systems are those which are designed to apply strong or forceful action toward the achievement of their purpose. Living systems, by their very nature, are not intense. They may well be complex, detailed and adapted in execution, but usually eschew strong and forceful action, despite often having very significant outputs. Food systems, being comprised of living systems, which cannot be designed themselves, must then undergo intervention. In food system terms, it is not the intensity of the system we refer to but rather the intensity of the intervention.

Quantifying intervention is easiest done in qualitative terms with an arbitrary numerical scale (i.e.: one through five or one through seven). Whilst it would be possible to develop a numerical or statistical method to derive an intensity 'score', this is unnecessary given the simply didactic application of the food orbits tool.

A qualitative numerical scale has been adopted here. Such a scale allows for the scoring of various aspects of the system – a rating for each major part of the system that is encountered. This activity allows the designer to think about each aspect of the system individually in terms of intervention and how they affect the complexity of the overall system.

To further develop this scale into a powerful visual tool, we decided that the best form would be that of a loop or orbit, further emphasising the 'cradle to cradle' concept. The food orbit is then formed between concentric circles denoting the intensity scales. Radial arms show each step of the process from beginning to end. Typically, the following stages are represented – Source, Processing, Marketing, Consumption and Residuals, giving five arms. The arms are scaled as per the intensity scale chosen and points plotted and connected to form an orbit around the centre. An example is shown below in Figure 1:

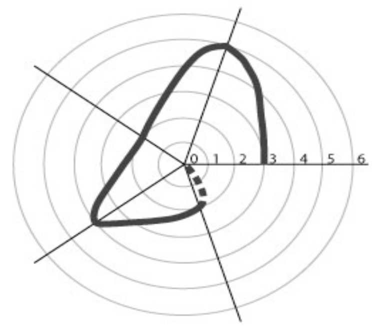

Figure 1: Example food orbit.

The orbit itself was developed as a design tool, but can have application elsewhere. Visually, it offers a very simple way of seeing the intensity of the system. The circular shape adds emphasis to greater intensification. A designer can look at the orbit and quickly see which part of the system is most intense. The orbit and the process of creating it are quite intuitive, simple and holistic, making it a quick exercise for designers to perform to help them balance some of the detail-oriented systems modelling.

We acknowledge that there may be many other applications for this concept – including those which take it down a much more predictive or calculated route – but at this stage it was most critical to evaluate the strongest property of the concept: its basic intuitiveness. What follows is an early exploration of the intuitive nature of the food orbits concept.

Preliminary exploratory experiment

A group of design students from the University's Masters of Design and Masters of Design Ethnography programme were taken as a sample group. The group were not all specialist designers, but most had some traditional design experience, either in the form of a Bachelor's degree or in industry.

The group was given a very brief introduction to the concepts of intensity and orbiting, totalling no more than fifteen minutes and then given the task of drawing four food orbits for selected foods, individually. Each food was described minimally (see Table 1). Two minutes were given to draw each orbit on a blank sheet, showing only the scale via concentric circle. Questions were answered on specifics as asked – although no numerical intensity values were given for the first food. In the three subsequent foods, intensity scores were given for parts of the orbit. The table below summarises the information given. A picture was also shown to the participants.

Local Strawberries	Grown locally under poly-tunnel, some chemicals use, sold at nationally branded supermarket, consumed at home with cream.
Tinned Baked Beans	Beans grown in USA under conventional agriculture, processed with sauce added in the this country, tinned and sold here, bought and eaten on toast, *Source = 5.*

Olive Oil	Cold pressed from organically grown Spanish olives, bottled in Italy, sold locally at a small organic market and eaten on a salad, *Residuals = 3.*
Baguette	Locally baked from conventional Canadian HRS wheat flour, purchased from a small shop near the university, *Source = 4, Residuals = 0.*

Table 1: Information given to students to generate food orbits.

The group consisted of 24 individuals who produced a food orbit for each specified food. The resulting sketches were collected and results compared. It was expected that, should the food orbit concept be basically intuitive, the results would be similar in shape and scale.

As it would be impossible to visually compare the results, each food orbit was converted in to a series of numerical values, representing the five stages of the process. The standard deviation for each sample of intensity values was calculated, shown in Table 2 below.

Table 2: Standard deviations of intensity scores.

	Source	Processing	Marketing	Consumption	Residuals
Strawberries	*1.5*	*1.2*	*1.1*	*1.4*	*1.1*
Beans	*0*	*1.2*	*1.1*	*1.3*	*1.3*
Oil	*1.4*	*1.2*	*1.5*	*1.1*	*0*
Baguette	*0*	*1.4*	*1.3*	*1.7*	*0*

Omitting the standard deviations of zero, where the value was given, the others ranged between 1.1 and 1.7. This indicates that, whilst there were a range of values, the majority sat within one to two units of the mean. We realise this is not an exhaustive analysis, nor was the experiment intended to be conclusive, but simply a first look at the validity of the concept.

As discussed in the main body of the paper, the greatest value of the orbiting concept is as a design tool to work in concert with other systems modelling tools. Further research is planned to both further investigate the intuitive nature of the food orbit as well as its efficacy as a design tool in assisting the designer's awareness of complex systems

Conclusion

Understanding complex systems is critical to the ability able to design in a holistically effective manner. Not simply knowing the environmental impact, which is usually framed in a negative sense, but the place and appropriate function of a design as part of a natural system is necessary. Natural food systems are complex adaptive systems that operate in a closed loop, with all inputs emanating from and all residuals returning to the source. Food Orbits are a novel graphical tool for plotting relative intensity of a food as it moves through the system from soil to dinner plate. This concept has been shown to have some intuitive value and future studies are planned to investigate further application outside the realm of food. It would appear to be well suited to the early design stages of a complex problem.

Author Biographies

Stephen Brogan

Born in Charlottetown, Prince Edward Island in 1978 and raised in Nova Scotia, Canada he trained in Agricultural and Bioresource Engineering at Nova Scotia Agricultural College and the University of Saskatchewan. Steve worked for several years in Western Canada in field crop research and later with an engineering consultancy. His varied design experience includes abattoir layouts, municipal waste treatment and green energy systems. He is currently pursuing a PhD in Natural Design at Duncan of Jordanstone College of Art and Design at the University of Dundee and lecturing in mechanisation topics at the Scottish Agricultural College, Aberdeen. His research interests include design methods, salutogenic design, sustainable food systems and eco-building. He lives in Dundee, Scotland.

Seaton Baxter

Seaton was born in Aberdeen, Scotland in 1939. He has academic qualifications in building technology and philosophy. He worked for 20 years in agricultural research mainly concerned with the design of buildings and equipment for animal welfare, before joining the Robert Gordon University, Aberdeen in 1983 as Head of the School of Construction Management, Property and Surveying. At the Robert Gordon University he acted as Assistant Principal, Dean and Reader where he established the Centre for Environmental Studies (c1994) and the first ever MSc in Ecological Design. He is currently an Honorary Professor at Dundee University where he heads the Centre for the Study of Natural Design. Seaton has worked with several Scottish environmental NGO's - Scottish Environment Link, Association for the Protection of Rural Scotland, Deeside Forest Advisory Group and was formerly a board member of Scottish Natural Heritage.

He was awarded an OBE by the Queen for his services to Scotland's Natural Heritage in 1998. He currently lives in Fife, Scotland.

Poetics as a Strategy of Inquiry:

Productive Science in Design Practice and Research

Kaja Tooming Buchanan, The Cleveland Institute of Art, USA

Abstract

For many years practicing artists and designers, as well as design researchers, have struggled to find useful models for their creative work. To understand this struggle, we will use a model that gives intellectual strength and direction to research and creative projects, offering an alternative to other approaches such as *Design Science, Dialectic* and *Rhetoric*. The strategy is called *Productive Science* or *Poetics*, and it is a way of focusing and understanding the struggle of a practicing artist or designer as he or she seeks to develop creative work. There are three central features of the strategy: the identification of the essential functional elements of design; the exploration of those elements with an appropriate degree of precision; and the *integration of those functional elements* in design and artistic practice. The exploration of the elements is the process of designing: phases of analysis and synthesis in concrete production, with reflection on the implications and principles that emerge in the course of creative work. The goal of this paper is to explore the potential and significance of *Productive Science* as a strategy of inquiry in design practice and design research. I will illustrate the importance of this strategy with a concrete example drawn from my own practice-based design research. The deepest hypothesis of my work was that *perception, meaning, and emotional expression work together in creating a unity or wholeness in the products of design and in the experience of the people supported by such products*. Exploring this hypothesis in the different stages of the analysis and synthesis is what this research was about.

Keywords

Poetics; Productive Science; experience; perception; emotions; unity; design practice; aesthetics/acoustics

The term *practice* resonates well with designers as well as with artists through concepts such as intuitive thought, imagination, emotional expression, and what Richard Sennett calls “the spirit of craftsmanship” (Sennett, 2008, p. 286). However, the name and historical lineage of *Productive Science* or *Poetics* may not be entirely familiar to practicing designers and design researchers. The community of researchers and designers has struggled for many years to find useful models for their work. For example, researchers in the Design Methods Movement found it important to seek a new “scientific” basis for designing that would lead to a methodology of design. Whether this effort was successful is open to debate because of conflicts among the various proposals, leaving the issue open for further exploration. As an alternative to other approaches such as *Design Science, Dialectic* or *Rhetoric,* we will focus on a model that gives intellectual strength and direction to research and creative projects. The strategy is called *Productive Science* or *Poetics*, and it is a way of focusing and understanding the struggle of a practicing artist or designer as he or she seeks to develop creative work.

There are three central features of the strategy: the identification of the essential functional elements of design; the exploration of those elements with an appropriate degree of precision; and the *integration of those functional elements* in design and artistic practice. The functional elements include the materials of embodiment, the manner or technique of execution, form as the unifying structure or idea, and purpose as the ultimate goal of the work. The exploration of the elements is the process of designing, divided into phases or stages such as finding a meaningful problem, doing background research, finding creative ideas, developing those ideas in the process of creation and iteration, and finally synthesizing a work that has impact and emotional integrity. The final integration of the functional elements of design in practice is the creation of a work with compelling correctness of expression, both in achieving a practical purpose and in bringing appropriate emotional force to the solution. This summarizes the creative aspect sought in *productive science*, but there is a further outcome. This is found in reflection on the implications and principles that emerge in the course of creative work. It is *reflection* that transforms practice into a *productive science*, a systematic study of human creation based on principles. The goal of this paper is to explore the potential and significance of *Productive Science* as a strategy of inquiry in design practice and design research.

Four Strategies of Inquiry

As with most of the methods and strategies of intellectual investigation, the strategy of *productive science* may be traced to the ancient Greeks. Aristotle was the first person to employ the method of *productive science* in the investigation of the human-made world. For him, *productive science* or *poetics* covers any kind of making, including both useful products as well as the products of all of the fine arts. His inquiry is recorded in the *Poetics* (Telford, 1961), a treatise on the art of tragedy. By Aristotle's approach a work of art or an artificial "thing" is a unified structure or synthesis of parts. The unifying structure of the work of art is what Aristotle calls its *form*, while "the parts are the *material* which is unified by the form" (Telford, 1961, p. 63.) By this approach, the problems of making are stated and solved in terms of the requirements of the work of art that arise from the process of thinking, doing and making.

The method of *productive science* has been employed by many writers and researchers in the investigation of literature, the visual arts, music, and in the twentieth century, the design arts. For example, a variation of this method was important at the Bauhaus and in the work of the designer Laszlo Moholy-Nagy. As in the case of other writers (Santayana, 1955; Sessions, 1958; Telford, 1961), Moholy-Nagy (1970) also emphasized the role of inspiration that comes from nature and the importance of the unifying structure or *form* as an interconnecting link of parts or essential elements in the creative process. But it has also been an important method for designers and design theorists holding quite different positions on the nature of design. An example is Herbert A. Simon's *The Sciences of the Artificial*. Richard Buchanan argues convincingly that the structure of Simon's book follows key structural features of Aristotle's *Poetics*. He suggests that Simon's book could be regarded as a modern variation of *poetics* and *productive science*, although Simon employed and positioned the approach well within the framework of his positivist philosophy and his vision of a *design science*. In other words, Simon ultimately turns the pattern of productive science into a strategy of *design science*, seeking the basic elements that underlie the complexities of the material world, and to investigate the processes and mechanisms by which those elements are combined to yield to world of experience and the cognitive processes of designing.

John Dewey's (1958) *Art as Experience* employs a variation of *productive science*, positioned within the framework of his philosophy of pragmatism and his theory of *logic* and inquiry. In *Art as Experience*, Dewey focuses on what he calls "*an* experience" rather than discuss experience in general. *An* experience, Dewey argues, has form and structure. It is a coherent interaction with the world, with a beginning, middle and end that embody the activity of a person and the conditions of the environment. It moves from resistance and struggle to a consummation in a completed work, whether the "work" is practical, intellectual, or aesthetic. The work is not an object. Rather, it is an activity. And the activity has a mixture of practical actions, intellectual dimensions, and emotion. Inquiry, as Dewey argues in *Logic*, "is the controlled or directed transformation of an indeterminate situation into one that is so determinate in its constituent distinctions and relations as to convert the elements of the original situation into a unified whole." (Dewey, 1964, p. 104-105). The strategy of inquiry, in this case, is "to seek the resolution of theoretical, practical or productive problems and move toward the advancement of knowledge in the various branches of human learning and activity." (Buchanan, 2009). Productive Science focuses on the discipline and methods of making, the properties of the made-thing, the analysis of the functional elements of products, and the synthesis of all these functional elements.

However, there are two other important strategies of inquiry: *rhetoric* and *dialectic*. Instead of focusing on methods of making and the production of human-made products, *rhetorical* inquiry focuses on the ethical and inventive character of the artist and designer, and his or her ability to effect social change through argument, communication, and action. *Dialectical* inquiry is most difficult to manage, but at the same time adopted and used in many fields, among them design. Donald Schön (1983), in his book *The Reflective Practitioner*, calls for "reflective conversation" in the work of designing. The central feature of *dialectical* inquiry is to overcome oppositions, conflicts and contradictions encountered in everyday life by bringing them within a system or ordered whole.

These four strategies – *productive science, design science, rhetoric* and *dialectic* – have significantly shaped the methods employed by designers. According to Buchanan (2009), they also point toward two of the philosophical problems that are significant issues in design practice, the problem of *parts and wholes*, and the *problem of means and ends*. The interplay of these four strategies, Buchanan (2009) summarizes, helps to explain the otherwise bewildering diversity of design practice and design research in the 20th Century.

However, the potential of productive science as a strategy of inquiry is still not fully understood, and the significance may remain unclear for many researchers. For this reason, I will illustrate the importance of this strategy with a concrete example drawn from my own practice-based design research (Tooming, 2007).

A Concrete Example of Productive Science

An idea expressed by John Dewey speaks well to the complex mixture of art and philosophy that a reader will find in my work: "Philosophy is said to begin in wonder and end in understanding. Art departs from what has been understood and ends in wonder" (Dewey, 1958). It is not for me to say whether the ensemble of works produced as the centerpiece of this inquiry are wonderful, but I can say that the philosophical foundations of *productive science* and the philosophical problems of the unity of art and design and emotional expression are a central expression of what I have come to understand about fiber art and design through the inquiry.

The inquiry is an example of what I consider "practice-based research" in art and design. What the term means to me is that the inquiry began in the practical experience of my work as an artist and designer. It continued through practical experimentation with a technique of production, and it has yielded results that have practical as well as theoretical value. It does not matter whether we call the research practice based or something else. It is a design inquiry and an example of design research.

The *central question* of the inquiry was whether fiber art and design could serve a practical purpose in enhancing the quality of sound in interior spaces as well as an aesthetic purpose in adding beauty to an environment. The problem of sound absorption has been addressed in a variety of ways by different professions. They have tended to use unappealing materials in the form of panels attached to walls or suspended from the ceiling. Solutions are typically hidden from view, or when visible they are not aesthetically pleasing. And if solutions are aesthetically pleasing and are not hidden from view, they do not have a high quality of sound absorption. The selection of materials is more often random rather than based on any systematic analysis of acoustic properties. In short, there is limited understanding of the acoustic properties of materials, and the research in this area is often inadequate. Where there is testing of acoustic properties, most of the materials are simply not adequate to solving the problem effectively. The answer to the question “could fiber art serve purposes that are practical as well as aesthetic?” is that it can, under certain qualified conditions. Finding the nature of those qualifications is more than a matter of artistic intuition and sensibility. The artist’s intuition and the engineer’s common sense tell us that the fiber art work must have some proportionality to the total surface area of the environmental space. Beyond this, we know little more, unless we have specific knowledge. Gaining this knowledge, and understanding how it bears on the practical and artistic matter of creation, is one of the problems of inquiry, calling for what I earlier referred to as the exploration of functional elements with an appropriate degree of precision – in this case the exploration of material properties and a manner or technique of execution.

The inquiry pursued two closely related lines of investigation. The first issue was the nature of materials and the manner or technique of production. It was necessary to investigate the acoustic and aesthetic properties of a variety of fiber materials. In all cases, the materials were subjected to careful acoustic testing based on recognized methods of measurement of sound absorption and speech transmission. However, it was not enough simply to test the fiber materials. The materials had to be formed in such a way that they could be tested – and, hence the testing was a study of the technique of handling the materials as well as the materials themselves. The technique employed in this research is called *hand tufting*. Hand tuft technique designates the modern weaving technique by which thread is shot into a vertically suspended backing by means of a hand-steered machine that is driven by compressed air (Figure 1). This is an emerging technique whose history and characteristics are not well addressed in the literature. Hand tufting is a powerful technique of modern weaving, when it is used appropriately and with imagination (Figure 1-4).

Figure 1. Hand tuft technique

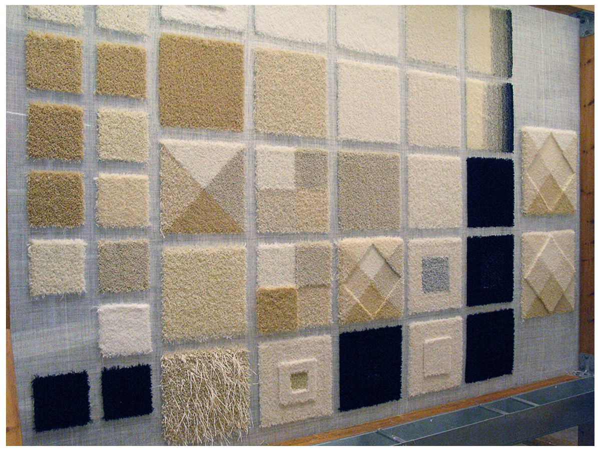

Figure 2. Hand tuft samples on frame.

Figure 3. Kaja Tooming, *Celebration*, 1999. 61x61cm

Figure 4. *Celebration*, 1999. Reverse view.

The second issue, already foreshadowed in the technique of hand tufting, was the artistic and design use of the technique in creating forms that possess some measure of beauty and charm (Figure 3-4). In formal theory and design methodology this is called "synthesis," but this is a dry, academic term for the struggle of the artist and designer who seeks to bring together all of the functional elements of his or her craft, art, or discipline. How do we study the *informed intuition* and *inventiveness* of the artist and designer? This is a critical question because it is not enough to understand the acoustic and aesthetic properties of materials. The materials must be formed, and formed by an idea that is progressively realized in the work of art and design.

To pursue these issues, one must settle on a specific strategy of inquiry, and this is when my work turned toward productive science. This involved a deliberate decision to turn away from what is sometimes called design science. Design science, as understood by some investigators, seeks an explanation of issues of design practice by a reduction to the underlying materials of the world and the mechanisms of the mind by which decisions are made in art and design. Instead of a study of the physics of the materials or a psychological study of the fiber artist or a consumer study of the fiber art and its reception by an audience, I turned to the functional elements of art and design – the elements that are necessary for the existence of a work. In the traditional and contemporary use of this strategy, I explored:

- *manner of production*,
- *materials employed by the artist and designer*,
- *qualities of form in the created work*, and
- *purpose or function to be fulfilled by the work*.

I assumed, in accordance with the assumptions of this strategy, that artistic and design creation is the *integration of these functional elements* by whatever means or methods are suitable to the individual artist or designer.

The inquiry began with an analysis of the manner of production (hand tufting) and the fiber materials (various kinds of fibers and threads). It continued with an exploration of form and function, testing through artistic creation the combinations of manner and material that may be suited to the final product. In the course of the work, small samples were developed and then tested in a solo exhibition *Backside* at the *Town Hall Gallery* (see Tooming, 2007, p. 77-83). The *Backside* exhibition was the first step toward formal synthesis of the elements of fiber art in expressive forms (Figure 5-10).

Figure 5. The view of the *Backside* exhibition.

Figure 9. Floor installation *The Japanese Garden* with hand tufted rug elements and sand. Detail.

Figure 10. Installation *The Japanese Garden*.

Based on the results, this preliminary step led to the second phase of the research: the creation of an ensemble of fiber art works for a specific architectural environment, where aesthetic and acoustic problems are the central issue. I was using fiber art as a design element in a complex and culturally important building: the *Jonsered Manor*, known in Sweden as the *Jonsered herrgård* (Figure 11. See Tooming, 2007, p. 85-104).

Figure 11. Jonsered Manor, Sweden.

Figure 12. Dining room.

An elegant dining room presented a difficult problem of poor acoustics (Figure 12). When many people were in the room, echoes created disturbing level of noise. The architects have been cautious in attempting to solve this problem because of preservation ambitions; obvious solutions were ruled out because they conflicted with the historical nature of the room. The design constraints imposed by the historical setting of the room suggested that a subtler approach was needed to deal with the poor acoustics. It is in this context that a fiber art approach began make sense. The goal was to meet two needs simultaneously. The first need was for fiber art work that would add an appropriate aesthetic expression, enhancing rather than detracting from the experience of the room. The second need was to design the fiber art work in such a way that they might help to improve the acoustics of the room. Behind this, there also had to be careful consideration of the larger context of the building, including historical, social and cultural factors.

The first step was to investigate the environment through perception, observation, interpretation, and reflection on what factors should influence the final creation of forms suited to the history and traditions of the building and its contemporary use. It was important to experience the dining room in its entirety, as a place of social interaction and communication. This is the “experienced whole”, which brings together the perceptual elements and the meaningful relationships of the space and adds to these the expressive qualities of human interaction. A key point here is that fiber art becomes an art of design when the purpose of creation is more than pure aesthetic expression. In this case, the work of fiber art no longer exists as an isolated object but becomes part of an environment, supporting and sustaining practical experience in the lives of human beings.

My work took John Dewey’s idea of *an* experience as a beginning point. However, I have found it important to develop Dewey’s idea in a somewhat different direction than he did. I found it important to focus on three considerations or three aspects of experience: *perception, meaning,* and *emotional expression*. Of course, Dewey discusses issues related to these three themes, but for the practicing artist and designer the role of perception is very significant and deserves careful attention as the first step in one’s interaction with the environment of daily living. Therefore, a major part of the early research focused on perception: the perception of materials, sound, and other features of the materials with which the designer must work. This is an analytic, scientific task. I have found phenomenology to provide an initial framework for such considerations and to be helpful in the observational method employed as part of the investigation. A theoretical foundation for this work comes from the phenomenologist Edmund Husserl (1969), and the existential philosopher and phenomenologist Maurice Merleau-Ponty (1963; and 1964).

Perception is important, but how we interpret perceptions and make meanings out of them is also important. That is, the role of meaning is also important for the fiber artist who conceives of his or her work as an art of design. In fact, the designer works in an environment that is rich in associated, traditional, historical, and cultural meanings. Any new work of design must engage and interact with such meanings if it is to be successful in supporting the experience of people in their concrete environment. For this reason, I have also found structuralism to be helpful, particularly in the form developed by Roland Barthes (1964). The idea that an environment possesses a deep structure of parts and relationships is very useful to the designer. It enables one to explore the details of placement of objects and artifacts in an interior pace, and it also enables one to better understand how other meanings – social, cultural, and historical – enter into consideration in the activity of making meaningful experiences.

Ideas about perception and meaning come together in John Dewey's concept of experience, but under a third consideration that is also critically important for the designer: *emotion* and *expression*. For Dewey, emotion is what unifies an experience, whether the experience is artistic and aesthetic or intellectual or practical. In short, if the designer is to be successful in supporting the practical experience of people living in interior spaces, he or she must explore the emotional and expressive aspects of the final solution. As Dewey argues, emotion is not something separate from an experience – something added onto everything else. Rather, it is the heart of an experience – the unifying "glue" of daily life. The deepest hypothesis of my work was that *perception, meaning, and emotional expression work together in creating a unity or wholeness in the products of design and in the experience of the people supported by such products*. Exploring this hypothesis in the different stages of the analysis and synthesis is what the research was ultimately about.

Productive science has an affinity with what is sometimes called "practice-based research." It is certainly more precise than the vague descriptive phrase "research through design." Productive science suggests the artistic logic of someone who studies a situation, reflects on all of the factors that bear on creation, carries out the work of realizing an idea in concrete form and materials, and then reflects on the total experience in order to gain deeper understanding of an art. Intuition is informed with the results of analysis, just as this work has been informed with the initial technical studies and then with a careful consideration of the environment of the Jonsered Manor.

Reflections on Principles and Results

What we have learned from this strategy of inquiry and its organization of the methods and techniques of research is at times surprising and at other times a confirmation of initial ideas. For example, we learned that some of the fiber threads that were tested are nearly ideal in sound absorption, as determined by acoustic science (Tooming, 2007). This was a surprise not only for me but also for the acoustic engineer who performed the tests. We also learned the specific absorption properties of all of the materials that were tested. In addition, the weaving technique of hand tufting appeared to contribute to the quality of sound absorption because of the intertwining of fire threads and the use of unglued backing.

The solo exhibition *Backside* demonstrated that audiences found the color and forms of the fiber models to be warm, inviting and intimate, surprising, natural, and almost sacred (Figure 5-10). In fact, many viewers were surprised at the combination of aesthetic and practical purpose. We were encouraged that this is a reasonable direction for further artistic and design exploration. The *Backside* exhibition also generated more knowledge on how to use the technique of hand tufting, and to use it in unusual and innovative ways.

The creation of the ensemble of fiber art works for the Jonsered Manor led to more complex insight. For example, it led to the recognition that fiber art and the hand tuft technique could be used to create sculptural forms. There are other examples of fiber art sculpture, but none that we know about that are formed with the double-weave hand tuft technique (Figure 15-16). This is something new and innovative in the field of fiber art that deserves further exploration. We also learned – and this is a personal learning related to professional development as an artist and designer – that it is possible to create fiber art works deliberately within a specific environment, and that a working method which grows out of analysis and research can achieve a degree of alignment with the traditions and history of that environment (Figure 13-16). No strategy of inquiry or method of research can predict the final quality that an artist or designer can bring to a work. At best, we hope to explain the factors that bear on the problem and gain insights that can better inform creative intuition.

Figure 14. *Flow*. Detail.

Figure 15. Kaja Tooming, Sculptures *Growing I* and *Growing II*.

Figure 16. *Growing I.*

The matter of acoustics is more precise. Acoustic testing at the Jonsered Manor yielded several important findings. The first finding is that the choice of fiber materials and the form of their presentation resulted in an absorption pattern that closely approximated a so-called ideal absorber, as understood within acoustic engineering (Tooming, 2007, p. 59-72). That result was expected, based on earlier testing and analysis. What testing at the Jonsered Manor further revealed was that the total surface area of the works of fiber art was not large enough to considerably reduce reverberation time in a vast, hard-surfaced space like the dining room of the manor. That is, further use of fiber art would be needed to effect a major change in enhancing the quality of sound in the room. This was not unexpected. Indeed, our initial proposal suggested three alternatives, each of which would have increased the surface area of the fiber art works. An appropriate proposal was selected for a variety of reasons. Nonetheless, the test provided a proof-of-concept that is encouraging for further exploration.

Of special interest for further work is the idea of mobile fiber art screens. Properly designed and fabricated, screens of fiber art could easily support the idea of a "reconfigurable" room or even an office space. The dining room of the Jonsered Manor is a grand room, with high ceilings and many hard-surfaced tables. Sound control in this space is certainly a challenge. In other rooms and kinds of work or social areas, fiber art works, for example screens, could function effectively. However, one thing that has been learned is that fiber art and design, used most effectively, should be site specific. It should grow out of the unique features of each situation and environment as much as possible.

Significance

The final step in poetic inquiry or productive science is a reflection on the nature of unity and emotional expression in a work of design. It speaks to the question "what is the significance of this work and how does it advance understanding and practice."

The significance of this work is quite practical. It contributes to the body of knowledge that may be useful for architects, designers, and design researchers as they pursue the practical problem of enhancing the quality of sound in interior spaces. We have discussed the nature and value of the double-weave hand-tuft technique, the specific acoustic properties of a variety of fiber materials, and how the exploration of form and function may contribute to enhancing the experience of interior spaces. These matters are certainly an aspect of the unity that we have sought in understanding how fiber art becomes an art of design. Unity is found in an integrative discipline of thought and action, informed with appropriate and relevant technical knowledge.

However, there is also theoretical significance. This approach contributes to the theoretical foundations of the study of design and the place of fiber art and design within the broader domain of the design arts and sciences. This first form of contribution is the demonstration of the strategy of *productive science* as a strategy of inquiry. As Richard Buchanan (2007) has argued, this strategy has emerged from time to time throughout the twentieth century, and the present work shows its application to a new area of design thinking in exploring the aesthetic and acoustic qualities of fiber art and design. While the strategy of *productive science* is perhaps unfamiliar in its name and its formal rigor, it is a strategy that is quite familiar in the common sense of the practicing designer and artist. And, of course, it is familiar to some design researchers, although not necessarily by the name of *productive science* or *poetics*. As noted earlier, the central feature of the strategy is the identification of the essential functional elements of design, the exploration of those elements, and the integration of those functional elements in design and artistic practice. By elaborating this strategy and developing an inquiry around its concepts and methods, we have contributed to further use of the strategy in other inquiries.

The second theoretical contribution concerns the nature of unity and emotional expression. If the first contribution lies in the area of strategy and method, the second contribution lies in the area of principles. We have sought principles in three unities: the unity of the *perceptual whole*, the unity of the *meaningful whole*, and the unity of the *wholeness of experience* (see Tooming, 2007, p. 109-118). In the course of our search, we have discussed the ideas of Maurice Merleau-Ponty, Roland Barthes, and John Dewey – leading figures of phenomenology, structuralism, and pragmatism. By combining some of these ideas in succession, we have found principles in the progression of unities that lead to emotional expression. This has yielded the paradox of necessity in fiber art and design – the *necessary intelligibility of emotional expression* arising from the intimate connections of form and purpose as they work together to integrate materials and the manner of human action. This is the basis of the compelling correctness of the artist's decisions in creating a work of art and design. It is the criterion that we sought for artists and designers through our reflections on principles and unity.

Author Biography

Kaja Tooming Buchanan

Kaja Tooming Buchanan is Assistant Professor of Design Theory at the Cleveland Institute of Art, USA. She is currently investigating the positive social influence of design through perception, the construction of meaning, and the forms of experience in human interaction and services. She received her Ph.D. in Design in 2007 from the Faculty of Fine, Applied, and Performance Arts at Göteborg University, Sweden in 2007. Her doctoral research is an example of practice-based design research guided by the strategy of Productive Science and Poetics, offering insight into the aesthetic and acoustic qualities of hand-tufted fibre art in the context of interior spatial design. A central feature of her work is a philosophical reflection on the nature of unity and emotional expression in art and design. She received her Fil. Licentiate degree in Design from the same Faculty in 2005. She also has Master of Arts in Art History from Göteborg University and a Diploma (5 years program) in Art and Craft from the Estonian Academy of Art. As a practicing artist, she has had more than ten solo exhibitions, and has participated in a dozen international group exhibitions. She has received more than twenty cultural and research grants and fellowships.

Visual Creativity and the Threshold of Uncertainty in Product and Automotive Design

Karen Bull CEPAD, Coventry University, UK

Michael Tovey CEPAD, Coventry University, UK

Abstract

An investigation into the development of visual and spatial creative capabilities in industrial design students is described. It focuses on establishing whether or not spatial intelligence represents a threshold concept in studying industrial design and evaluating whether or not visuo-spatial intelligence can be a measure of a student's cognitive ability to design. A four year longitudinal study highlighted a number of threshold concepts the most significant of which was the toleration of design uncertainty. A separate range of tests and studies covered spatial comprehension, drawing exercises, and pattern-solutioning capability, and they demonstrated that spatial capability represents a baseline requirement and is not a key threshold concept. Further reflection on the uncertainty threshold located it within the concepts of the designerly way of knowing, as a key ingredient in a 'conversation' between two modes of thought in a dual processing model. This was seen as key to facilitating the development of visual creativity in a holistic approach to Coventry University's design curriculum. A range of teaching interventions can be mapped onto this approach. This has informed the basis for an enhanced industrial design study programme which is being introduced.

Keywords

Creativity, Technology, Education, Industrial Design, Spatial Design Intelligence.

Introduction

The Centre of Excellence for Product and Automotive Design (CEPAD) is one of Coventry University's three HEFCE-funded centres for teaching and learning. It has implemented a five-year plan to reinforce existing teaching excellence within the Industrial Design Department of Coventry School of Art and Design (CSAD) and reflect upon its practices to inform future design education. The project pursued a number of themes such as the exploration of design education in the context of the design community of practice; the internationalisation of design education, threshold concepts in design education and the exploration of visual and spatial creativity through digital technologies.

This paper discusses visuo-spatial design intelligence and its relationship to the industrial design curriculum in CSAD. It focuses upon three questions:

1) Is spatial intelligence, pertaining to industrial design, a threshold concept for students?
2) Can visuo-spatial intelligence actually be a measure of a student's cognitive ability to design?
3) How do we engage with 'design uncertainty' in the industrial design curriculum?

Methodology

The first question was addressed through a four year longitudinal study of student experience involving interviews, observation and focus groups to investigate the identification of threshold concepts within industrial design in CSAD. Staff interviews were also conducted.

Question two included three interrelated activities. The first two involved implementing the The Purdue Visualization of Rotations Test (Bodner and Guay, 1997) in parallel to an internally developed test with a cohort of first level undergraduate transport and product design students (Osmond and Turner, 2008) The aim of these two tests was to identify whether it was possible to measure student conceptions of spatial awareness on entry to the industrial design courses and correlate this with their end of year assessment results. The third activity involved conducting a pattern solutioning exercise to establish whether it is possible to recognise visual solutioning capability that could reliably indicate design capability.

Question three is centred upon the results of the first two and leads to the exploration of curriculum interventions that can promote confidence to engage with solutioning processes at the early stages of industrial design study.

Is spatial intelligence a threshold concept for students?

Staff and student understanding of spatial awareness was addressed through interviews with staff and ten first year transport students in 2007. The question explored whether spatial awareness, considered by staff as being at the heart of the Transport and Product Design course was a Threshold Concept (Osmond, Turner, 2008). Meyer and Land describe threshold concepts as “akin to passing through a portal” or “conceptual gateway” that opens up “previously inaccessible way[s] of thinking about something”. Cousin (2009) also provides a practical description of exploring threshold concepts in education.

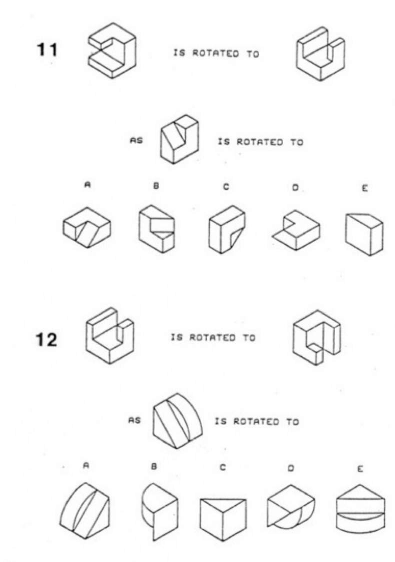
Threshold concepts provide a useful framework for exploring design learning because for the design student, design learning is highly focused on aspiring to become a practitioner and aligning with the design community of practice (Tovey and Owen, 2006, Wenger, 1998). From the beginning of this study design learning was recognised as a transformative process that required a range of cognitive shifts based on engaging with practical design experiences and professional communities along with the acquisition of design knowledge. The research team endeavoured to define the thresholds associated with design learning and findings led to a focus specifically on the toleration of design uncertainty.

A literature search demonstrated that the examination of spatial awareness was well established. Gardner (1983) for example provided useful definitions of spatial intelligence. However sources were more difficult to locate when CEPAD identified that spatial intelligence in the context of industrial design moved beyond the bounds of ‘transformation’ and ‘modification’ to the creative interpretation and progression of form-based ideas. The study became even more challenging when it was identified that even design experts differed in their interpretation of what spatial awareness meant. However interviews led to some themed categories associated with: all-around awareness; co-ordination; design sensitivity; space; intuitive/6th Sense; looking at an object from the outside; mental rotation; positioning system; time; visualisation; and, volume (Osmond, Turner, Land, 2007).

The student interviews, which took place in their first term of study showed a relatively untheorised appreciation of the concept of spatial awareness – some students said that they had not heard of the term, others offered approximate guesses such as ‘Like distance from things and if something will fit into a certain space or if it doesn’t?’. It was evident that spatial awareness is not a threshold concept and that after a few months students developed a more sophisticated spatial understanding. This seemed to indicate that design teaching is effective in the development of spatial ability. While students may arrive with a ‘baseline’ capability in spatial intelligence e.g. show the potential to sketch in three-dimensions, it needs to be nurtured through teaching practice both in terms of skill and articulation.

This phase of the research highlighted that within the field of industrial design education, skills and knowledge practices that staff share with the students in relation to developing visuo-spatial understanding are also relatively untheorised and tacit. However design teaching is recognised by the researchers in CEPAD as being part of a characteristic ‘episteme’ (a system of ideas or way of understanding) of design education practices. The interviews reinforced the perception of spatial intelligence as a fundamental component of the ‘designerly way of knowing’ as defined by Cross (2006). In the context of industrial design this ‘knowing’ is concerned with integrating spatial understanding with solutioning capability along with the application of cultural, technological and empathetic appreciation. The processing involved in this holistic and solution focused approach seems to be centred on matching linear and holistic modes of thinking.

Measuring spatial intelligence



The Purdue Visualization Test

Task	
Draw a simple cube at a size you feel comfortable with (5 minutes)	
Draw the object (boxes or bin) in front of you from the angle you can see (5 minutes)	
Draw this object in 3D from the authographic views. (5 minutes)	Draw the unseen side of the chair in front of you. (5 Minutes)	

The Transport and Product Design Test

Figure 1: Spatial Intelligence Tests

In parallel with the threshold investigation, two spatial intelligence tests were organised to ascertain if there was a correlation between student scores on the measurement tool on entry to the course and in relation to end-of year assessment results. If a significant correlation existed pedagogic interventions could then be targeted at students on entry to the courses. No clear correlation would require further exploration to understand the centrality of spatial awareness to the first year of study.

The first test was The Purdue Visualization of Rotation Test (PVRT) (See fig. 1 - left) which was developed by Bodney and Guay (1997). It was specifically designed to evaluate courses developed to enhance the spatial skills of students. It focuses on Gestalt processing and the transformation of visual images as a whole, rather than breaking down the whole and re-mapping relationships. The time constrained test involved asking students to recognise a rotation pattern and then select from a range of alternatives a form that represented a similar rotation. This test acted as a benchmark for an internally piloted tool that required students to complete a series of drawing tasks within a limited timeframe to demonstrate skills in spatial awareness (Osmond and Turner, 2008a) (See fig. 1 - right).

The testing showed a lack of correlation between the performance in the PVRT and the internal tests. Performance on the course suggested that the elements of spatial intelligence measured through the tests are not explicitly assessed in the first year of the programme. It was recognised that students already possessed baseline level of skills and creativity sufficient to underpin work for their assessments. Those who scored poorly in their PVRT test did not score poorly in the course assessments. It was concluded that spatial awareness was not a threshold concept, but a required capability that may underpin other potential threshold concepts.

Can visuo-spatial intelligence actually be a measure of a student's cognitive ability to design?

The third test designed by CEPAD centred on the measurement of pattern-solutioning capability at the early levels of study. A small exercise was implemented with a sample of students from both visual and non-visual disciplines at Coventry University. It included students from all levels of industrial design study and a group of non-visual students. The exercise required participants to organise shapes into a harmonious and orderly arrangement (See fig. 2).

The results emerging from visual analysis of the arrangements highlighted that in many instances patterns of solutioning correlated with assessment marks where they were available. However it did highlight differences between sample units in terms of constructing narrative, layout, and accuracy of arrangement, as well as having the confidence to challenge the brief. Non-visual students for example paid less attention to narrative and characteristics such as juxtaposition, use of grids and proportion. It was evident that as students progressed through their study they showed a greater ability to challenge the brief and stretch boundaries in solutioning. However, at the early levels of study the results were less distinct. Students with no visual training were generally able to produce results showing similar capabilities to first level designers.

The exercise highlighted that a student's articulation of their solutioning efforts seemed to be only a coarse measure of solutioning capability. Non-visual students were often more experimental than first year industrial design students, who were often more concerned with geometry and layout. There were also cultural differences in the way the results were organised.

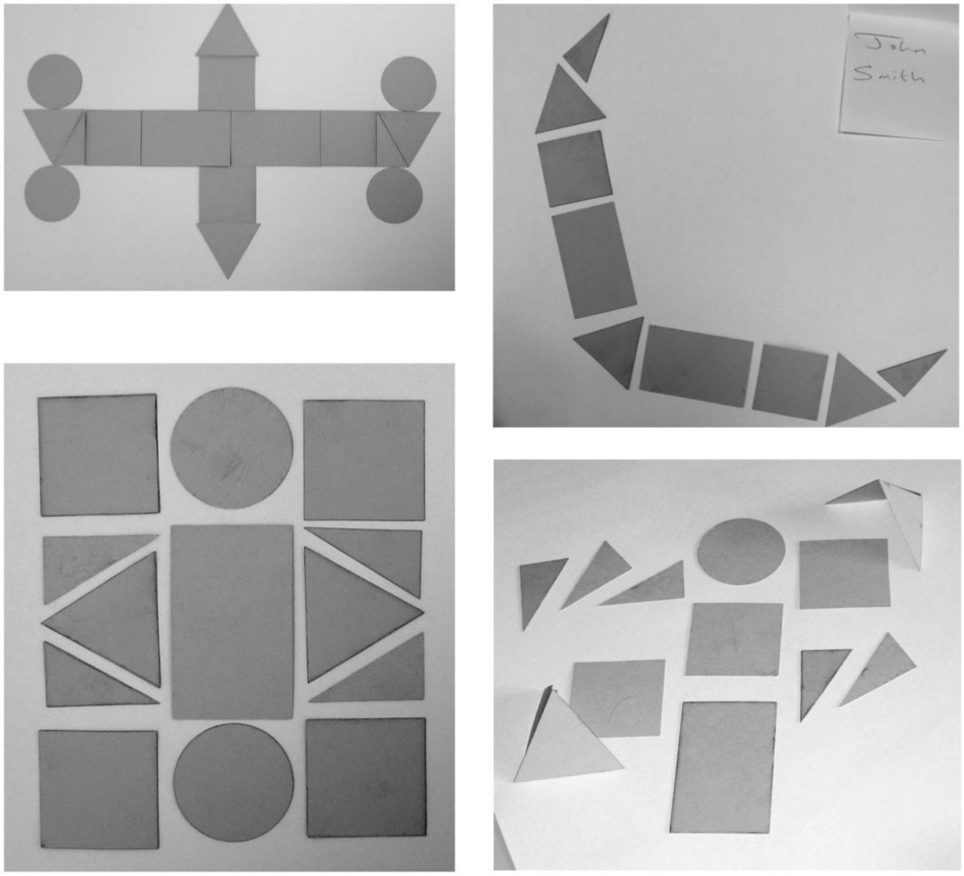

Figure 2: Examples of the visual creativity exercise

Initial Conclusions

From these investigations we came to the slightly unexpected conclusions that we had not demonstrated that spatial intelligence was a threshold concept, and we could not say that visuo-spatial intelligence was a measure of students' cognitive ability to design.

We came to a somewhat more obvious articulation of the importance of spatial ability as a baseline requirement which we perceived as underlying the development of design capability.

'Design uncertainty' in the industrial design curriculum

The results of the evaluation of spatial awareness showed no distinct correlation but did reinforce the view that spatial awareness is a baseline capability that underpins the potential to be a successful industrial design student. What appeared to be more significant was that students needed to gain confidence in design processing activities in order to progress their visuo-spatial capabilities. This 'confidence' relates to the identified threshold concept the 'toleration of design uncertainty'.

CEPAD researchers propose that this threshold manifests itself strongly because it sits between two modes of thinking which range from the analytical (linear and logical) to synthetic (holistic and simultaneous) modes. The ability to integrate these two cognitive modes is core to developing design thinking capability. Experience of new Industrial Design students arriving at Coventry (especially where they have not received a broad, art and design foundation like experience) is that they often have a highly analytical approach to design thinking and have followed a strongly procedural approach to problem solving and project management. The 'free-thinking' engagement with synthetic approaches appears to be predominant to the early years of school education and it could be argued that it is somewhat 'unlearned' during higher levels of study. This means students can often arrive with a lack of confidence to engage with open briefs which require from them the ability to engage with problem and opportunity definition, and a strong solution focus. They are not equipped for 'risk-taking' and conceptual thinking, and often get stuck in the 'conversation' that enables them to engage effectively with the solutioning process.

Designerly thinking

The importance of the design 'conversation' and its relationship to the threshold of design uncertainty became evident in this research. Our investigation into how it might sit within a design process framework suggested two fundamental characteristics of designing that locate the toleration of design uncertainty within the design process as something familiar and routine. They were:

- 'Wicked problems' that commonly present within the 'designerly way of knowing'
- The analysis –synthesis dialogue that sits at the core of the design process

In the 'Designerly Way of Knowing' Cross (2006) characterises design as an activity involving tackling 'ill-defined' problems through a 'solution-led' problem-solving approach. Designers employ constructive thinking by using codes to move from the abstract to the concrete and deploying these codes as an object language. Cross makes a number of useful and relevant observations about the design cognition process, noting that designers are solution-focused not problem focused. The designer's attention oscillates between the problem and its solution, in an appositional search for a matching problem-solution pair, rather than a propositional argument from problem to solution.

Designers are pro-active in problem framing, actively imposing their view of the problem and directing the search for solution conjectures. Problem framing, co-evolution and conceptual bridging between problem and solution seem to characterise design behaviour. Effective design teaching supports and encourages visual creativity within a solutioning framework. However, observations of our curriculum and the longitudinal study have suggested that solutioning needs to be more clearly 'labelled' and consciously supported in the curriculum to reduce apprehension surrounding 'uncertainty' and reinforce familiarity, especially at the early stages of design learning where the threshold issues are most visible.

These factors are relevant to and support CEPAD's view that design education should reinforce activities that strengthen the way students engage with the 'conversation' that is at the heart of design cognition. This conversation begins with a 'concept design' which involves the designer's attempt to provide a sketchy representation of what the finished design might be or look like. If the designer or design manager sees the concept as providing a basis for proceeding then the structure of the rest of the process falls into place. This is the solution-led approach.

At its core is the process of moving from an abstract statement to a visual object. The designer learns to think in a sketch-like form, in which the abstract patterns of user requirements are turned into the concrete patterns of an actual object, using the code to effect this translation from individual, organisational and social needs to physical artefacts. This is the use of the visual language of designing, employing its translation codes. It is the match of the analytical (left hemisphere) statement to the holistic (right hemisphere) solution. The manifestation of this outcome will be as a visual representation, a drawing or a 3D or virtual model.

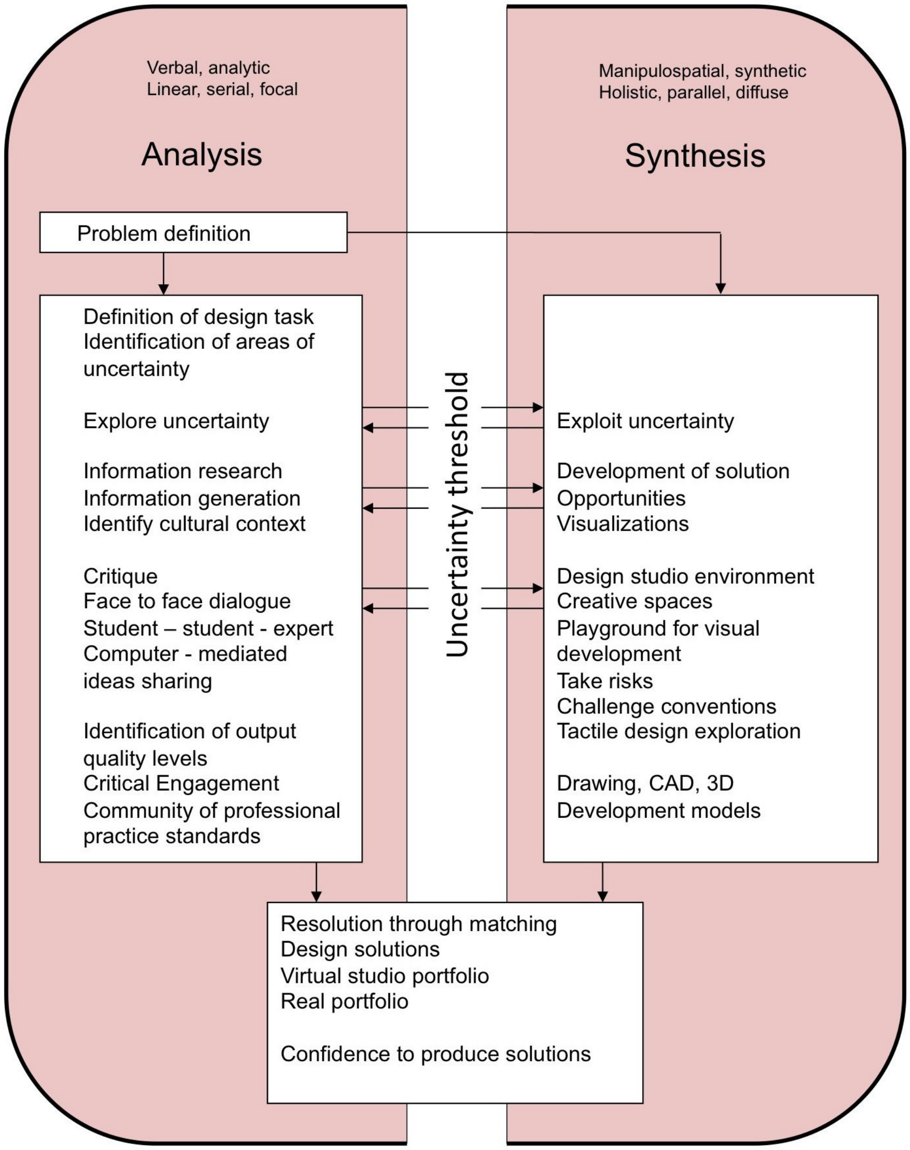

Figure 3: Dual-Processing Model for Industrial Design Education at Coventry

The analysis synthesis dual-processing model

Based on the identification of the preferred processing modes of the two halves of the brain, the essence of the dual processing model (See fig. 3) (Tovey, 1984) is the interaction of the two modes of thought, each stimulating and modifying the other. The evidence for such difference is based on long established research into cerebral laterality. The left hemisphere preference is for local, linear, narrowly focused attention. As figure 3, 4 and 5 demonstrate, the right's preference is for simultaneous, broad, global and flexible attention (McGilchrist 2009). Bruce and Bessant also reinforce this notion, suggesting that creativity is not an entirely rational or conscious activity but rather that "It involves the interplay between conscious and rational thought and unconscious and apparently random or dream-like association and activity".

Serial and simultaneous thinking

Both types of cognition are crucially involved in the evolution and resolution of a fully detailed design proposal. Although the application of such a model to design is of course speculative, it does provide a framework within which different design approaches can be accommodated. The relative emphasis given to serial-analytical and to simultaneous-holistic thinking varies both between designers and between types of design problem. For example engineering designers may give first priority to analysis and the derivation of a specification, whereas product designers may concentrate more on the holistic processes used to derive a design concept presented as a drawing or a 3D model. Nonetheless it is assumed that the design process will always involve both modes of thinking (see fig. 5), in the approach identified as appositional matching (Cross, 2006) and that it is their relative proportions which will vary.

CEPAD and curriculum innovation

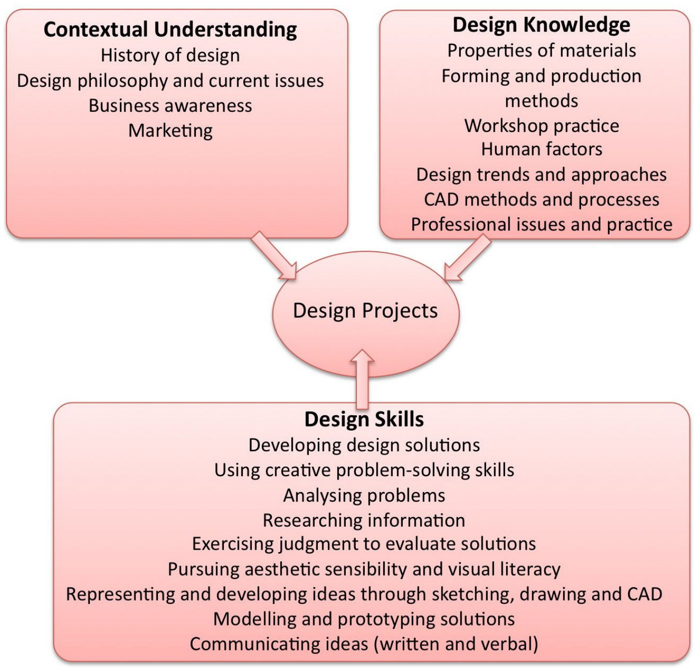

Figure 4: Design education (Adapted from Cooper and Press, 1995)

Cooper and Press (1995) highlight the distinctive nature of design education, explaining that it is based on a 'traditional learning by doing' approach. Design students conduct projects (see fig. 6) that help to integrate knowledge and skill through practice, essentially engaging in a dual-processing approach. They stress that industrial design education encourages students to gain and experienced-based knowledge that involves experimentation and risk of failure. Industrial design education has therefore always supported more novel and participative forms of teaching, however this has often been difficult to embed in a strict modular structure (familiar in the UK HE environment) that works well with linear and highly structured models of teaching. It is more challenging, within a modular structure to incorporate more flexible and holistic practices that are required if both analytical and synthetic modes of design exploration are to be engaged with simultaneously. However in CSAD we have explored a number of activities that have helped us to move from the 'standard' and established practices of teaching that are fairly straightforward to implement within a modular framework, to exploration of a set of activities built around the 'Dual-Processing Model for Industrial Design Education' as defined in this paper (see fig. 7).

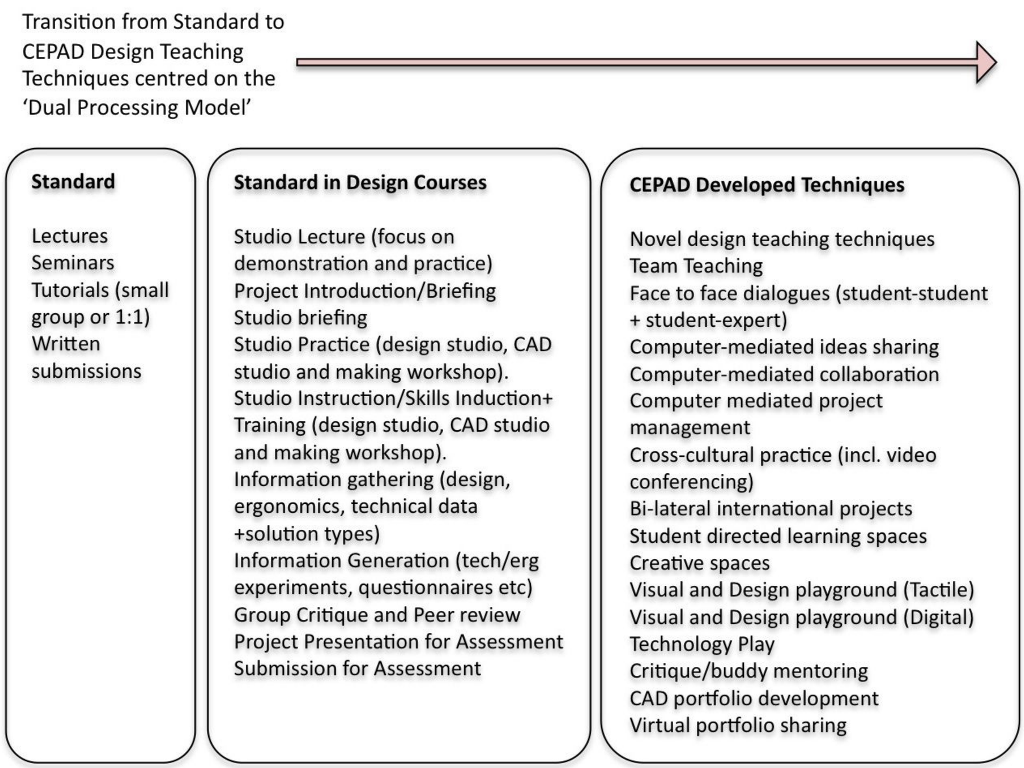

Figure 5: Types of Teaching

Based on this understanding the intention in CEPAD has been to explore teaching interventions that would focus around developing student engagement with the toleration of design uncertainty threshold. This is recognised as sitting at the centre of the two modes of thinking, analytical and synthetic, and across both linear and holistic design approaches. The aim is to encourage a 'conversation' or engagement with design problems and opportunities by drawing a student through a set of activities, modes of thinking and design approaches that support a more exploratory and playful approach without too much systematic constraint (See fig. 3).

As a result the following recommendations were developed:

1) structure course around larger more holistic packages of learning;
2) create a 'playground' for unrestricted, unconstrained design thinking;
3) provide flexible and adaptable environment for organising teaching groups;
4) encourage a personalised and individualised teaching environment;
5) introduce formative 'gateway' reviews rather than formative assessments;

6) provide an explorative environment that integrates both traditional and advanced technologies for designing;
7) provide opportunity for professional and international engagement.

Many of these recommendations have been applied in October 2009 to the first two levels of our four year industrial design courses in CSAD. Early feedback collected via interview and focus group is positive – further data is being collected.

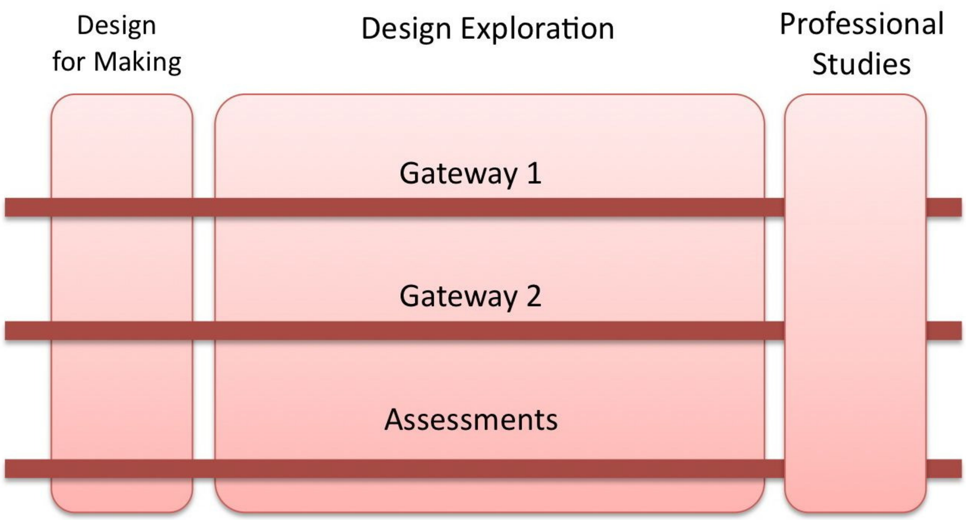

Figure 6: Simplified Curriculum Model (A year of learning)

The above simplified model (See fig. 8) based on a revised model of the industrial design course specification (Owen, 2009) shows design exploration being placed at the centre of the course, rather than being separated out within singular specialist module activities phased during the year. At level one and two multiple modules have been introduced. These enable a much more open learning environment that is not driven by a single brief. The objective is to have a number of smaller assignments with different emphasis and depth, some of which are interrelated. For example, new students were given a five week induction project (rather than the traditional one week) that: provided space to reflect upon personal aspirations, promoted broad design horizons; and, instigated an explorative and experimental approach without an assessment focus. The project required students to explore their own identity, design costumes against a fantasy scenario and present them in a social setting. The teaching environment encouraged a playful approach with little constraint. This appeared to give students confidence and a sense of their emerging identity as a designer. Following projects had more focused learning objectives, introducing ergonomics and other specialist subjects in a highly integrated way so students would engage with design learning as a whole rather than in assessment driven silos of study (See fig. 7).

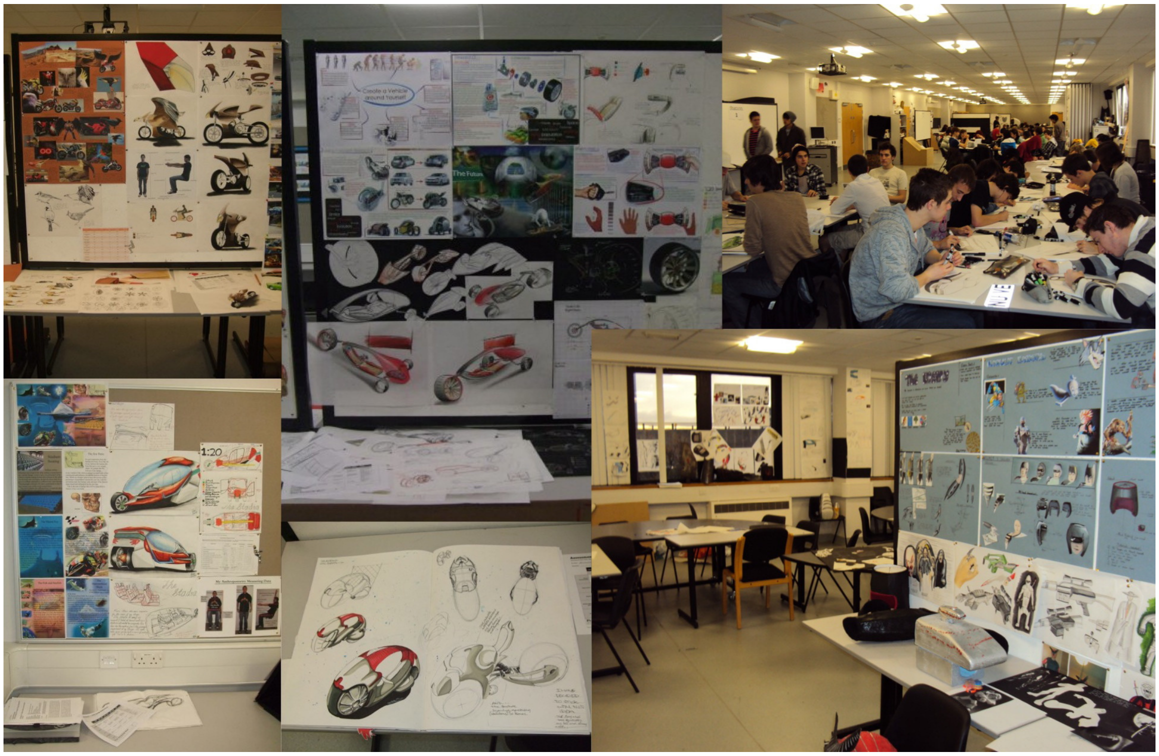

Figure 7: Students in first term of industrial design study

Because large group sizes also proved to be a problem for the encouragement of a personalised and individualised teaching environment, students were divided into smaller sub-groups for teaching at the early stages of their course. This enabled them to get to know a sub-group better rather than being lost in a sea of students. They were encouraged to develop a group identity.

The quadruple modules include small one day/ one week projects in the teaching mix. These have been labelled as 'Wild Card' projects. They enable students to engage with a project of very short or focused duration, such as a rapid concept generation project for car merchandising. Importantly, the choice to submit this work for review is given to the students. This is made possible by the Gateway model that has been adopted. It also allows the tutor some opportunity to provide additional teaching support where necessary, or to allow students the opportunity to relax and enjoy a bit more freedom after an intensive phase of activity.

Gateways (see fig 6) are review events that happen two to four times a year. They enable tutors to 'take stock' of student progress and provide formative feedback to students. The gateways are strongly centred on the student. Whilst they are themed according to level and some learning outcome requirements, the student is in most cases given a large amount of freedom to select and choose what they want to submit at the relevant Gateway. This requires the student to be more reflective and questioning about their skills and capabilities development and also allows them the opportunity to select the best of their work for presentation.

Portfolio surgeries
Client led/informed projects (Group projects with finalists)
Leonardo module development. Module set up to both be a tool for independent learning and directed and mentored with expert knowledge base.
Students come in to talk about their experiences.

Computer-mediated ideas sharing
Skype (Student projects – placement students)
Google Groups
Tanberg (Group conferencing – international staff collaboration
Facebook (Boat design students
Qube (Chinese students)
PebblePad (group work)

Synthesis

Design Studio Environment
Ownership of spaces – challenging in a mass-education culture – getting students to propose how to organise spaces for learning through client projects such as IKEA and in relation to finalists.
Portable projectors to enable practical demonstrations to be delivered to groups of students.

Creative Spaces
Design of the curriculum (introduction of periods of open play and discovery)
Adaptability of teaching spaces to shift from large group teaching spaces to small group teaching.

Playground for Visual Development
Clay heads to develop spatial understanding through sketching, modelling and freedom to develop form narratives – no prior constraint.
Digital form development projects – intensive 3D and digital animation input.
Workshop activities – making toys using laser cutting
Placement students engaging with learning about Motion capture
Development of new approaches to model making using technology e.g.
Tools provide a playground fro students across disciplines e.g. jewellery design students using rapid prototyping

Taking Risks
Wild Card projects that enable students to conduct a project and have the choice of whether they want to submit it for assessment
Holistic design of course allows more flexibility for 'risk taking' . Larger modules, more selection of activity, assessment focuses upon students selected work.
Gateway designs (each module has a set of Gateways that both allow students to select best work for presentation – enabling choice and focus on 'selection' and awareness of critical abilities.
Flexible course design – choices made in year two about specialist progression.

Challenge Conventions
New induction phase to ID course based on allowing students to take a highly explorative approach – a foundation to testing and trying out ideas
Highly conceptual phase to early learning – based on very individual and unconstrained briefs – unmarked.

Tactile Design Exploration
Clay heads and Trophy designs – students given freedom to engage with tactile form development with emphasis on hand sculpting.
Students are not allowed to progress their digital design exploration until they have engaged with the physical.
New course designed to emphasise the relationship between the tactile and the technological e.g. exploring form languages and methodologies emerging from the technology.
Example rapid prototyping to create new form possibilities and effects for jewellery design or for furniture construction.
Final year students make physical models in clay.

Figure 8: Bridging between the two: Uncertainty Threshold Diagram

CEPAD researchers observe that one of the best ways to increase student confidence is by nurturing them in an environment that is centred on professional engagement and cross-cultural experience. Students usually study with the goal of entering the professional community of practice, which is increasingly global in scope. The course has traditionally maintained good relationships with industry, but with shifts in industrial centres and the international perspective it is necessary to find opportunities beyond the placement as a means by which professional experiences are gained. To this end, school internships, international exchanges, cross-cultural collaborative projects have been reinforced within the curriculum. An ongoing example is a student collaborative project between Coventry industrial design students and students at EAFIT in Colombia (Atkinson, 2009). This enabled students to engage with different cultural approaches to designing, language and time-zone differences, collaborative project management over a distance. The culmination of the second year of this project was an exhibition in the Coventry Transport Museum. This useful exercise has supported our comparison of approaches in different countries and cultures to developing design capability (Osmond, 2010).

The curriculum design embraces a range of digital tools for communication and designing. To enhance and facilitate the analytical part of the design conversation we developed a number of communication techniques. Tools such as VOIP video conferencing, social networking tools such as Skype and Facebook have been adopted to support responsive and flexible communication.

The technology to facilitate the synthesis part of the conversation has been located in studios and creative spaces. To support spatial learning plentiful seats of Alias, Rhino, and Maya are available as well as physical tools such as rapid-prototyping, milling, laser-cutting and large scale printing. These enable students to work with digital visualisation as part of the processes of designing as well as at the representation stages. The integration of technology into the curriculum is organised around the philosophy of exploration and discovery. The aim is that technology can help to represent and review solutions as they develop such as by using the live projection of Alias models in 3D stereo. In addition teaching staff are encouraged to develop and engage with digital tools such as Cintiq to demonstrate sketch techniques to large groups of students.

Conclusion

This review of an analysis of spatial intelligence highlighted that there was a need to give greater attention to the Threshold of Design Uncertainty within the industrial design curriculum. It was observed that spatial design intelligence is a baseline capability that is hard to measure but a required attribute of applicants. Spatial intelligence itself is not specifically a measure of design capability, but a necessary component of it. However, the 'nurturing' of spatial understanding can be accommodated effectively in a dual-processing activity or 'conversation' that brings together analytical and synthetic approaches (See fig. 8). This is the process by which the Threshold of Design Uncertainty can be addressed effectively within the design curriculum. This can be challenging for students but they need to be able to develop confidence to take risks, deal with 'wicked' or 'ill-defined' problems and be solution-focused, even when they do not have all the information necessary to complete a solution. As a result of the findings made by CEPAD researchers a number of curriculum recommendations have been developed which incorporate the techniques which have been found to support effectively both parts of the design conversation. These include evaluative communication techniques and solutioning activities which centre on risk taking, playfulness in personalised, holistic and flexible study environments. Our first feedback from the implementation of these interventions is positive and encouraging.

Author Biographies

Professor Michael Tovey

A graduate of the RCA, Professor Mike Tovey was in industrial design practice prior to entering education. In 1973 he joined the institution which was to become Coventry University, as a lecturer in industrial design. He was appointed to Head of Industrial Design in 1985 and in 1989 was made Dean of the Coventry School of Art and Design. In 2007, he changed position to take on the University-wide post of Director for Design. Professor Tovey is responsible for developing courses and applied research in design across the University and is Director of the Centre of Excellence in Product and Automotive Design (CEPAD).

Dr Karen Bull

Dr Karen Bull is Deputy Director, Centre of Excellence in Product and Automotive Design at Coventry University. This centre focuses on evaluating spatial design understanding and identifying the transformative threshold concepts associated with students entering the Global community of practice for industrial design. Her expertise is in industrial design theory, design analysis and design context. Her background is in product design and her PhD is titled Advanced Personal Telecommunications Products and Industrial Design'. She has continued to research pedagogy in relation Art and Design and is especially interested in the area of critical and reflective learning, e-teaching and learning and e-portfolio.

Joinedupdesign for Academies: Enhancing Design learning through complexity

Dr John Butcher, University of Northampton, United Kingdom
Friedemann Schaber, University of Northampton, United Kingdom

Abstract

This paper reports on research undertaken on the Sorrell Foundation's *Joinedupdesign* for Academies programme, a pilot scheme with four universities in the United Kingdom (UK) aiming to inform the transition of 'failing' secondary (11-18) schools into academies (involving substantial re-designs and re-building). From the authors' university, 12 undergraduate Design students participated in *Joinedupdesign* for Academies, in partnership with two secondary schools in the Midlands region of England. Like other universities in the UK, it has well-established links with local schools and programmes of community engagement, corresponding with reported US experiences (Lerner & Simon, 1998). The Sorrell Foundation model is an example of university design departments working in multiple partnerships in order to align with government initiatives (such as the Labour policy *Building Schools for the Future* to rebuild or renew nearly every secondary school in England over a 20 year period). By embedding the pedagogy of live projects, there is potential to impact significantly on local regeneration.

The aim of the study was to investigate *Joinedupdesign* for Academies as a new model of off-campus learning. In order to do this, we explored: the impact on student learning for employability; the effectiveness of undergraduate learning with pupils as clients, and the challenge of working with multiple partners in a complex environment. In terms of Design education, this provided a rare and timely exposure to the complex demands of the kind of regenerative, publicly-funded work on a large scale which will be providing opportunities for designers in the UK over the next decade.

Keywords

Design pedagogy; Live client collaboration; Multiple partnerships; Community regeneration; Employability Skills

Recent drivers of government policy in the UK following the Education Act of 2002 (Working Together, 2004; Cox, 2005; Leitch, 2006) have prompted a new impetus to Design education and the importance of educational partnerships. This has led to a number of funded initiatives including *Creative Partnerships* and *Building Schools for the Future*. One prominent example emerging from these drivers is the Sorrell Foundation's *Young Design Programme* (YDP), (The Sorrell Foundation, 2005), which aims to enhance the scope of design education at secondary school and university (and in so doing, dovetails with government policy to raise standards in education). Research indicates (Butcher, 2009) that undergraduate Design students on the YDP benefitted significantly from enhanced employability skills, and in return make an impact on the community (Rudd, Marshall and Marson-Smith, 2008). In this study, the authors will relate enhancement in student learning to the complexity inherent in the sister programme *Joinedupdesign* for Academies.

Contextual factors

Design pedagogy

In university Design studies, live client projects are enhancing the curriculum and challenging undergraduate students with outside constraints and deliverables, furthering their knowledge. In return, the community benefits from university links on various levels. 'Service Learning', which involves matching a community need with academic goals, is becoming increasingly important in Higher Education (HE). Student assignments are developed in consultation with academics and external partners requesting input from students to solve a particular problem. These live client collaborations are run as problem-based equivalents to traditional theoretical studio based design assignments. As such they deviate from the more common models of work placements and learning through work programmes, in which the learning is supposed to be integrated into the work experience. This definition of a live client project is described by Viljoen and Hoskyns (2007), who further review current practice in UK HE and relate these to research in Learning and Teaching. We argue in this paper that involving design students in regeneration projects has the potential to impact on the communities in a real way. In focusing on design pedagogy, we explore the impact on undergraduate learning, in particular the enhancement of skills through live client engagement.

Widening Participation/Outreach

From our UK university perspective, engagement with the *Joinedupdesign* for Academies programme offered a new form of community outreach work, in a collaborative partnership which was different to the prevailing agenda of *Widening Participation* (WP) which has driven UK HE policy for over 15 years. WP (HEFCE, 2001) can be represented as a range of policies and funding streams designed to: target groups disengaged from HE; remove barriers to HE; and increase the proportion of citizens with university level qualifications. For Design education in HE, WP has often been 'one-way', through portfolio advice/enhanced curriculum projects in schools or external pre-16 and post-16 aspiration-raising summer schools, (at its worst, 'selling HE to kids'). In contrast, *Joinedupdesign* for Academies has offered a very different conceptualisation of a community partnership, with schools and particularly their pupils serving as clients for the Design students, and industry mentors advising in the context of authentic live briefs. This has been a much more dynamic, two-way learning process, although the Sorrell Foundation's original impetus, to empower the pupil voice in the design of schools, has ensured the WP mission to raise pupil aspirations as part of a social justice agenda, has not been lost.

The Young Design Programme as a national initiative

The YDP is externally coordinated as part of a national initiative, with ten universities and thirty-five schools involved in 2009. It is managed systematically as a regular and continuous part of the curriculum at the participating universities. YDP aims to promote collaboration between design students and secondary school pupils, by asking the latter: "what they want to improve in their schools?" (The Sorrell Foundation, 2008) This programme informs the process of regeneration of school campuses and surrounding community. The approach, established in 2000, follows UK policy initiatives (see above) and *Creative Partnerships*, a creative learning initiative fostering long-term partnerships between schools and creative professionals, including architects, scientists, multimedia developers and artists.

Crucial to the conceptualization of YDP is that, with the support of Head teachers and staff, pupils should take ownership of their brief and present it to as many audiences as possible.

Joinedupdesign for Academies

This approach is refined still further in the *Joinedupdesign* for Academies development, a pilot project undertaken by the Sorrell Foundation with design students at four UK universities. Undergraduate design students from the authors' university worked with school pupils whilst being supported by the *Joinedupdesign* for Academies team and industry-based mentors. These, a practicing designer and a chartered architect had a significant effect on the students' work, concerned with visualisation and building technicalities.

The pupil client team was a group of children from five schools (the two 11-18 secondaries and three 'feeder' 7-11 middle schools), representing the views of the existing school community in formulating a pupil brief informing the master plan for their new academy to engage architects, sponsors and local authorities in what pupils want their academies to be like. This involvement was represented in the subsequent rebuild of the school campuses. Pupils attended a number of sessions throughout the spring term 2009, with the undergraduate designers facilitating (The Sorrell Foundation, 2009).

The university's Design staff, having attended an explanatory talk at a launch event at the London headquarters of the organization, developed a student assignment and mapped this onto the curriculum. Twelve students (four male, eight female) worked with two Academies (with representatives from their feeder schools) in three teams of four students grouped to share skill sets, deliberately cross-disciplinary in order to provide them with the experience of working with people from different subject specialisms: Product and Interior Design. At the university's 'Challenge Day' the pupil client teams met the student design teams for the first time and were tasked to work out what design problem they would like solved. For many, this would have been the first time they had ever entered a higher education environment (Smith, 2008). During this meeting, design teams showed their clients around the college and the client teams presented their design problems; these included school communal and reception areas, outdoor spaces, toilets and specialist classrooms.

Following these initial meetings and throughout the project lifespan, the student design teams attended meetings at the schools to gather background information, develop ideas, show progress and get feedback from their clients. This whole process is described as "the conversation" and included meetings organised by the University Design tutors at creative destinations in London. These visits were arranged to help the pupils reflect on their school environment in comparison to contemporary "designed" spaces. Sponsors met the student designers to discuss their vision for the Academy. They explained to the students why the Academy's specialisms had been chosen, and analysed its proposed relationship with the local community, before addressing issues of design and sustainability. The stakeholders discussed the local issues and the students described early discussions relating to the pupils' priorities.

The pupil clients presented the information they had collected to their local authority representatives, project managers, sponsors, teachers and Design students. They showed them the brief boards they had created for the top three common issues, and explained why they thought it was crucial to resolve these issues. The brief for the student design team was to prepare concepts for a dinner hall and social space. In three subsequent meetings at the school, the students presented design ideas through sketchbooks, colour drawings, material samples and 3D models, and the pupils offered feedback and further suggestions. The student designers developed and refined their ideas with the support of other students and their tutors. Upon completion of this project the finished design concept was presented to the client team for feedback and was separately assessed by course tutors at the university.

At the beginning of June, the teams gathered for a local celebration of their work on the *Joinedupdesign* for Academies project at the university, where they received certificates for their contribution to the project. They travelled to London the following week to join pupils from the other academy projects. Here, the pupil and design teams discussed their work with stakeholders and sponsors in a special marketplace. Their work was exhibited in the Sorrell Foundation's exhibition *What's Next for Schools?* and the event culminated in the presentation of the finished Pupils' Brief for each academy (See below Fig. 1).

Figure 1 The Pupils' Brief, documenting young peoples' participation in school redevelopment programmes

Methods

In order to gain evidence to address our research question, data was collected in a series of exploratory stages. The researchers monitored each interaction between undergraduate designers and school pupils through field notes. Multiple evaluations were conducted via a range of structured questionnaire and a reflective student group report. Triangulation came from industry mentors, school pupil and teacher feedback. At the end of the project, two focus groups were conducted with the undergraduates to elicit their perception of learning from the project. Findings were compared with a national evaluation (Rudd et al, 2008) and with previous 'live client' engagements conducted within the university sector as mapped in the literature (Viljoen and Hoskyns, 2007).

Analysis was undertaken drawing on an inductive framework informed by educational case study research (Bassey, 1995). In this, indexicality, in which meaning is elicited by coding and categorising from statements shared by participants through grounded theory approaches, allowed themes to emerge.This was iteratively informed by the authors' ongoing review of the programme structure and design in terms of pedagogical principles; the effectiveness was assessed through (a) student oral and written feedback, (b) client engagement and oral feedback, and (c) summative student assessment through presentations and multi-angled feedback by staff and peers, recorded through a scribe and documented with audio visual footage for inclusion in the students' Personal Development Portfolio. The captured participants' perceptions align with the Pilot Evaluation of the Young Design Programme 2005-2008 concludes that the "*the client-centred model encouraging 'real life' experience of the cycle of a design project, has been extremely effective in bringing institutions and individuals together*". (Rudd et al, 2008)

Student learning

In this *Joinedupdesign* for Academies case study, students were extensively briefed by the client team and group work and plenary sessions identified problems leading up to the design brief being finalised. The *YDP* structure enabled students from differing design subject backgrounds to work together and share a range of learning outcomes such as:

- developing support structures within and between teams
- university design student teams engaging with clients
- developing clear mechanisms to communicate one's message and ideas to others

Throughout the term-long project, work was monitored by means of individual and group tutorials and practical demonstrations. The student design teams presented the newly designed environments back to the school children giving them the opportunity to gain an insight into the design industry and university design study process. Just as with previous presentations to professional clients, the undergraduate students took this seriously, preparing elaborate physical and computer generated models, supporting their proposals with well-prepared powerpoint presentations. The researchers noted a high level of nervousness prior to the final presentations, suggesting an authentic engagement with pupils as clients. The school children themselves gained much from the experience and regarded the students as professionals, which bolstered their confidence and helped them to adjust to working with different client groups. This was captured in pupil comments:

It was fun working with real architects; they could transfer our visions for the new Academy into proper designs that looked amazing, we can't wait to see the final designs. (quoted in Schaber, 2009)

The students' feedback, sampled through questionnaires, suggests that this project has been useful to all members of the student design teams involved. A student reported that it *"had allowed all of us to gain valuable experience, and develop skills, which we would have been unable to do through a typical university lead design project. In particular I have been able to develop better time management, which will be of great value in the future. This project also allowed me to improve my communication skills, and has enabled me to work younger aged group of clients than a typical design project, which further helped to develop communication and presentation skills."* Students addressed the problems concerning the organizer's communication and programme management: *"Overall this has been a useful and enjoyable project, however at times it could have been better organised, and … more advanced notice of the event would have allowed us to better prepare for the boardroom meeting with the sponsors, which would have made to event more useful in terms of the information extracted from the meeting."*

As reported in previous research on its sister programme, the Sorrell *Young Design Programme* (Butcher, 2009), undergraduate student learning from *Joinedupdesign* for Academies was both wide and deep, although less about developing specific Design skills (as perceived by the students) than broader interpersonal skills (which of course are integral to Design planning). Some self-reported evidence did include the acquisition of design skills in: *using a laser cutter… in model-making… in photographing work for presentations, improving my computer skills in Photoshop… I am more confident knowing I've got that skill… designing for different types of clients and thinking about the needs of disabled pupils… working with other design disciplines… learning how Product Designers draw products… sketching in CAD.*

However, this acquisition of new design skills was viewed by undergraduates as a by-product of their involvement in the programme, rather than a core learning experience. The greatest evidence of perceived enhancement of their learning came in the ‘softer’, interdisciplinary skills related to employability. In this, the bulk of feedback was around: team work; problem-solving; time management; working with clients, and in relation to future employment.

Learning in teams

For example, when asked in the focus groups about working in a mixed team, a number of students commented on the enhancement gained from sharing strengths across different design disciplines and collaborating on a shared problem:

You’ve got to be able to see the difference between our skills and their skills… we had a product designer in our team, she was more knowledgeable in material areas whereas I’m not, but there were also some areas where I could help her… I remembered she had better knowledge in materials than me so I went back to her and asked for help.

Working in a team makes you understand more about your strengths and weaknesses as a designer… so you can work on your weaknesses… Learned to appreciate one another’s skills, and compromising, as you can’t have it all your own way.

So students recognised this innovative learning experience had ‘forced them’ to reflect on their own skills, to learn experientially how to compromise and negotiate, and to gain insights into the different design skills of others in a project team. This high level of reflection resulted from being put in a situation in which peer communication (especially between students who had not previously worked together) became a vital component of success:

Communication with different disciplines in our team, with any discipline, is what I’ve learned… being able to explain what you’re doing, being able to listen to what they’re doing too, and collaborating with each other… keeping in touch with each other, meeting regularly to exchange ideas.

While this was not an easy experience for most students (as evidenced by the body language during the focus groups), the authentic live brief, though complex in its demands, pushed students to see themselves as operating in a more ‘professional’ environment when they had to deal with real clients:

You just get things done, it’s professionalism… you just don’t want to let the rest of the team down.

When you work with a team that you’re not normally used to working with, you find different ways of doing things rather than the way you’ve been taught to do things… sometimes they’re better, as working with other people helps you discover better things when designing from your point of view… even if there is a ‘collision’ with others!

This element of working in a mixed team was reported as a critical learning enhancement, especially considering students perceived themselves not really used to working in a team.

Learning through problem-solving

The focus of the team's work together was also an important aspect of the learning, exemplifying problems to solve. One problem in particular was accommodating different design ideas from the team members (and the clients) into a final 'pitch'.

It made me realise how important it is to learn how to take the views of others into consideration and be able to put them together to find a solution rather than just taking one person's… it's quite a learning curve to know how to put them all together… everybody has really different opinions… it's difficult to mesh them all into one design.

Individual students were able to develop a strategy to address that problem, which they represented as taking a professional approach to others' ideas – something they had not had to do on their degree course previously. This problem-solving was an important aspect of personal learning as perceived by individual students:

Learning your own strengths and weaknesses through the timescale, and trying to get things done in a group… you can recognise what you're not so good at.

The 'problem' of over-enthusiastic pupils as clients also had to be sensitively dealt with:

Our client team wanted a juice bar but it had to be a reception so we had to dissuade them by encouraging their other ideas.

Students were thus in a position to utilise their novice designer personas to find a creative way to shift a preoccupation with a single (in this example, inappropriate) design idea. Our commitment to the importance of teaching visual communication is confirmed, as oral presentation skills have to be refined when presenting to live clients, often at community and board level, with direct implication on employability.

Learning time management

Interestingly, the opportunity to learn time management skills was linked to the challenge of operating as an effective team in a way which could enhance problem-solving. This became a particular feature of the way this project was structured, in that students operated semi-autonomously, and recognised:

We had to ensure we kept the lines of communication open… if you were with a 'difficult' group it made it harder, some members were willing to come in earlier… communication had to be strong between members of the group to ensure we got that extra time.

This resulted in further personal learning:

I prioritised this work over other projects… worked a lot of hours outside college time.

It also enabled key roles to emerge in relation to the challenges faced:

At the beginning everyone was on an equal footing, but towards the end there were two of us that had to become leaders, to take a leadership role to ensure the group even stayed together.

Learning from pupil clients

However, the most strikingly innovative aspect of the *joinedupesign* for Academies programme was the crucial involvement of pupils (aged between 10 and 14) as clients, in the context of planning the rebuild of their own schools. For them, this was not an abstract exercise, and they brought a lot of passion to discussions of what they wanted their new school to look like. In working with clients, our design students learned a great deal, much of it unanticipated:

You need to think what you are going to say a bit more… we were describing a particular part of our model, we had to explain to them that you can physically build glass walls… they thought it was easily smashed, they thought vandalism would be a problem and it would break… technically we understood that, but we had to find a different way to explain it.

We had a double skin on ours (a roof, then another roof). Trying to explain that without a model was quite difficult – until we managed to sort out a computer-generated image… it was the visual aid that helped rather than relying on explaining it through words.

Figure 2 Client conversation aided by physical and digital models

These 'language clashes' were evidence of communicative dissonance which prompted our undergraduate design students to find creative solutions to overcome their initial reliance on 'taken-for-granted' technical language. This learning experience was reflected on as a positive one, in forcing recognition of client needs:

From the first visit we learnt that just describing something was not enough… the best way to communicate was to show, because they had showed us around the school… the enthusiasm came from them saying 'look at this', running ahead to point something out… images were the way forward.

It also opened up an important insight into the needs of different partners:

I really enjoyed working with children, communicating with different age ranges… I was excited working with them rather than school governors, who were only interested in money, not in our designs.

Students were also able to articulate the benefits from working with this unusual client group:

It helps you to adapt… they can want something that will never work, but as a designer you can take it and mould it to what will work.

I didn't see it as unusual because you have to adapt to your client… but they're going to have slightly different views, they haven't seen much of the world yet.

So the learning was coming from a sense of empathy and insight with the fact that all clients will be different, and the pupils merely offered one step on the client continuum. This authentic client undoubtedly added to the students' learning experiences:

Working with an external client outside the university was quite exciting.

It gave me a sense of professionalism…we knew we had to present properly to proper clients, rather than imagining a client.

Learning for employability

The complexity of the project (involving our design students working with pupils, teachers and governors, academy sponsors, Sorrell Foundation staff and industry mentors) led to a number of important personal insights into individuals' intended career paths. For some, the innovative link with pupils and schools was timely:

It made me think more about teaching design… I really wanted to work with children – their imaginations are incredible and limitless… adults have the realities of practicalities - like costings.

I thought it was cool working with the kids because you might not work with them otherwise as a designer… you wouldn't normally go back to work in a school… and they were so enthusiastic.

For others, it confirmed different paths:

Working with a school was useful, I wanted to work in a commercial environment rather than domestic…and it was great to have more scope for a wider range of design ideas.

Even though I enjoyed working with my group, when it comes to employment I will consider working for myself now rather than for a company… as such it was a (negative) learning experience.

Discussion

Complexity of multiple partnerships

Complexity in Design has been outlined by Alexiou, Johnson and Zamenopoulos (2005). They conceptualise Design as an interactive process taking place in a social environment requiring cooperation and the exploration and construction of common knowledge. In this study, complexity was apparent in the multiplicity of partnerships, and to some extent in the 'measure of ignorance' (Alexiou et al, 2005 p.91) between the partners. Thackara (2006) focuses on the changing role of design in a complex world, and the need to reform learning in design, which is part of that. Correspondingly, for some students, the reflection was deeper, about the nature of complex learning:

It was interesting that so many different groups wanted to get so many different things out of the project…there were competing agendas between the children as clients, the Sorrell Programme idea of what should happen, and what we wanted. It helped me understand you need to know what you want from a project…we had to go at the project from all perspectives.

We suggest the complexity inherent in the *joinedupdesign* for Academies project comes from its origins as a 'social innovation', in which collaboration between individuals (pupils, teachers, Design students), organisations (schools, governors, sponsors, education authorities) and environment ('failing schools' and a well-resourced government school rebuilding programme) is the focus. Complexity is represented as a top-down intervention to engage bottom-up participative aspiration in order to improve pupils' lives, driven by those pupils as 'agents of change'. The premise is that another way (of designing schools) is possible.

As a result of the complexity, there were inevitably advantages and disadvantages. Although student debriefing was facilitated through the feedback and interview sessions, the continuation of the relationship was not built into the programme. Interestingly, some of the students involved exchanged business cards in the hope to gain placement opportunity once the architects are appointed to execute the planned new-builds, but it is uncertain that students identified the various stakeholders' intentions during the session the Sorrell Foundation facilitated at an event in London. There, they had opportunity to query the sponsors, local authority representatives and teachers.

The applied research undertaken by academic staff in the context of the case studies provides up-to-date understanding of multilayered communication and managerial skills and the awareness to planning issues, publicity strategies and manufacturing processes, which can be fed back into teaching. Also, the experience confirmed that *"community organizations, agencies and government bodies each have rules, procedures and practices that either facilitate or inhibit collaborations"*. (Todd, Ebasta and Hughes, 1998)

Benefits for academia and community

The relationship between community, local schools and academic institutions is likely to produce more than short-term gains, and provides insights and networking opportunities to benefit the parties involved.

Through the university's involvement with *the joinedupdesign* for Academies project, the students have worked with what were 'failing schools', known in the communities as 'sink' learning environments. These schools are, by their nature, unlikely to send many pupils to study design at Higher Education level. Whilst engaged in programmes stimulating social regeneration within the community, it has to be asked whether or not it has galvanised the pupils' thinking and challenged them beyond conventional design considerations. In their feedback, our undergraduate students cherished *"the opportunity to work with the school children"* with one of their colleagues stating that "*I am considering working with schools."* A student remarked that the most important point of the brief was *"to create an environment that both pupil and staff can be proud of, and provide all users of the school including visitors with a sense of belonging."* Good design builds reputation and identity in a place and the community at large, and could be "a way of showing they are proud of their school" (Sorrell, 2008).

Most importantly, from the viewpoint of the Sorrell Foundation, *"pupils work in client teams to debate each common issue, noting what it is like in their school now, and proposing how things could be improved in the future. This information produces the Pupils' Brief, a publication informing architects, head teachers and the local authority about the pupils' ideas"* (Sorrell, 2008). Through this, the students, in turn, contribute to the process of urban regeneration. Furthermore, the students impact upon the clients by being positive role models and raised "ambition" in the pupils. One of the children said: *"I liked working with proper architects and as a result of this experience I would like to train to be an architect myself, they made it look really easy".*

Conclusion

This pilot of *joinedupdesign* for Academies ran concurrently to the much larger YDP, but had distinctive characteristics which we were reminded of at the major launch event: a depth of rigour (through keeping closely aligned with the dates set out in the process guidance's and funding (with the Sorrell team double manning all sessions, recording all student-pupil interaction, and providing direction when appropriate). In addition a coordinator was placed at each school overseeing the transformation into an Academy (in one school there was an external consultant and also a member of an educational charity who will be a sponsor, responsible for the new school. The second school had the assistant head teacher facilitating. This differs from the YDP, which has to rely on an enthusiastic teaching staff, or champion of the engagement.

This innovative community partnership has provided an opportunity for powerful situated learning in Design, with the authentic brief offering HE Design students opportunities to: enhance their skills (through creative problem solving); develop their attributes (through preferences for learning through doing); and improve behaviours (by putting things together creatively). This learning was achieved in the context of a creative/social entrepreneurship model which, as collaboration, was more embedded in the Design curriculum than work experience, and more holistic in terms of facilitating employability skills than work-based learning.

Findings suggest the *Joinedupdesign* for Academies partnership is an effective approach to bringing various stakeholders in Design education together. However, compared to commercial live client projects, the complexity of the multiple sites and partners appeared to make this project markedly less efficient. Students highlighted the repetitive nature of some elements of the project and some felt ill-prepared to present at board level, and struggled to identify stakeholder intentions and underlying agendas. Facilitation from members of university staff was found to be highly demanding (a point acknowledged in the national feedback sessions by the project managers). In terms of undergraduate learning, a wide range of employability skills were demonstrated: community consultation; interpreting a master plan or survey; eliciting feedback from planners, pupils and local government; team work; time management; project planning; presentation to a panel; public/media relations. The authentic complexity of the tasks associated with the partnership project challenged the students to cope with co-learning (involving the merger of expertise in communities with expertise in universities), in a context of less-predictability.

Therefore, key outcomes for the Design students included in this *joinedupdesign* for academies project were positive. In relation to employability skills, their learning was enhanced by the experience of working in teams, of working with pupil clients and working to an authentic life brief. However, as a new model of off-campus learning, significant challenges emerged for tutors running the project, with the complex multiple partnerships requiring additional time and resources. The potential outcomes for pupils are less easy to measure, and will require further research of a longitudinal nature to see if impacts are sustained beyond the life of the programme.

Dr John Butcher is Senior Academic Development Advisor at the University of Northampton, UK. He is an experienced leader and manager of funded projects in HE. These include awards from the Teacher Training Agency (TTA), Teacher Development Agency (TDA), National Arts Learning Network (NALN), Art, Design , Media subject centre (ADM) and the Sorrell Foundation. He is currently leading an inclusive Learning and Teaching project through the Higher Education Academy (HEA). He has extensive experience of research supervision and project dissemination, and edits the online journal *Enhancing the Learner Experience in Higher Education*.

Friedemann Schaber has been working with Design students at the University of Northampton since 1997 and was awarded a University Teaching Fellowship in 2008 for championing the live client project approach, challenging undergraduate students with ‘outside’ constraints and deliverables. He is supporting the university’s knowledge transfer and industry through Knowledge Transfer Partnership (KTP) schemes and community outreach, utilising co-learning engagement. Collaborating with the Sorrell Foundation, he has been programme coordinator for two government-funded *Joinedupdesign* for Academies pilot projects.

Design history education and the use of the design brief as an interpretative framework for sustainable practice

John Calvelli, Alberta College of Art and Design, john.calvelli@acad.ca

Abstract

Over the last several years, designers, researchers and educators have been increasingly concerned with what effect design has had, and could have, on the current condition of unsustainability. If design has had a significant part in materializing unsustainability, then we must try to change its disciplinary parameters and relationships. How can we teach design history in order to engage students in this critical work?

This paper will document an ongoing experiment in the teaching of design history to undergraduate students in visual communication in two colleges of art and design. The course asks students to interpret images from the broad history of design through the lens of a common form of a “reverse design brief,” modified to engage the student in the task of pondering designs’ future effects. It is hoped that this pedagogical tool will not only allow the student to internalize this strategic tool of design practice, but as well allow them to understand the present-day consequential effects of designing. I will attempt to judge the success of the modified brief, from the standpoint of the qualitative insights of students into the ongoing designing effects of historical design objects.

This pedagogy raises questions regarding the uses of design history, the relationship between historical study and practice, the understanding of contemporary and historical frameworks and the engagement of an historical and ecological imagination. Can the design history classroom become a locus for a critically engaged, experimentalist pedagogy that can be experienced by the future designer as an essential tool in developing a sustainable practice?

Introduction

This paper will document an ongoing experiment in the teaching of design history to undergraduate students in visual communication in two colleges of art and design, which I began in 2002 and am still teaching today. Based on a common form of a “reverse design brief,” the course asks students to interpret images from the broad history of images, spanning epochs and cultural contexts. This pedagogical technique raises many questions, the most interesting among them for this researcher being the engagement of an historical and ecological imagination.

As Orr (2004) suggests:

> We will need schools, colleges, and universities motivated by the vision of a higher order of beauty than that evident in the industrial world….They must help expand our ecological imagination and forge the practical and intellectual competence in the rising generation that turns merely wishful thinking into hopefulness. (p. 185)

I start from the assumption that teaching is the most effective means of changing practice, at a time when fundamental changes in how design interacts with the world have become necessary (IPCC, 2007). If design has had a significant part in materializing unsustainability – which I define as a condition whereby the material impacts of a species within its ecological framework, when pursued over a finite length of time, result in the species’ extinction or its likelihood – then we must reframe our learning outcomes towards the end of creating future. Can the design history course become an essential tool for the future designer in developing a sustainable practice?

The discipline of graphic design history is rather short: the first North American history of graphic design course in a program of graphic design was begun in 1971 at California Institute of the Arts, and taught by practitioners—Keith Godard for one year, followed for the next 25 years by Louis

Danziger (Heller & Balance, 2001). The first symposium of graphic design history in the U.S. was held in 1983 at Rochester Institute of Technology, organized by Roger Remington (Twemlow, 2006). Until recently, its history was generally written and taught by practitioners or by scholars from other fields. In universities it is still not uncommon for it to be taught by a doctored art historian for reasons of academic accreditation or departmental politics.

I state this simply to call attention to its status as an open area of inquiry, where it is still possible to fiddle with its foundational assumptions. This is important, as design history grew out of the discipline of art history, also a young discipline, and has shared some of its assumptions (Calvelli, 2009). Design history is often taught as a history of artifacts, with an emphasis on authorship and historical movements, often following contemporaneous art movements. When social content is brought into design history, it is often done so in terms of its mirroring of an historical *zeitgeist.*

Thus, in the students' history of design course, the *agency* of design is displaced from the artifact and placed mostly in the hands of the designer. Concomitantly, in studio courses the assumption of agency is placed in the hands of the client. A more adequate understanding of agency would, following Anne-Marie Willis' discussion of ontological design, privilege neither designer, client nor designed artifact (Willis, 2006). Rather, it would open up the possibility of studying the *designing* effects of design in time (Fry, 1999), and allow us to pose the question of how design extends or limits our future.

Background

This first iteration of the course was developed for the Art Institute of Portland as their required history of design course for graphic design majors. The Art Institute is one of 46 colleges owned by the for-profit Educational Management Corporation. It calibrates its program and course outcomes carefully to the market through professional advisory committees of respected professionals in its community. Its defining metric of success is what percentage of its students is able to land jobs in their chosen field within six months after graduation (when I taught there during the recession following September 11, 2001, their metric was about 85%).

I brought some of the elements of this course to an upper-division seminar I developed, *Image and Ecology,* taught at the Pacific Northwest College of Art (also in Portland). PNCA is a private non-profit art college, traditionally based in the fine arts but with a small percentage of its students studying Communication Design. Many of the programs' students are as interested in or influenced by the surrounding educational environment of the fine arts. It views itself as experimental and conceptual and aims to graduate "boutique" designers to fill positions in prestigious studios or agencies. A case study of this course is included in the article cited above (Calvelli, 2009).

The most recent iteration of the course was taught in the fall semester of 2009 at the Alberta College of Art and Design (ACAD), one of the four provincial art colleges of the Canadian system of higher education. Like PNCA, it comes out of a fine art tradition, but their visual communication program has a strongly separate self-identity as a design-focused program. Students follow a highly structured sequence of courses; a particular methodology of solving communication design problems is reinforced throughout. The program views itself as international in their outlook, with a roster of alumni internationally, some of who contribute to current students' education through projects managed virtually over the Internet.

First iteration: Meaning and value in image-making

In 2002, I developed for the Art Institute of Portland the required survey course for majors in graphic design, using as my text the third edition of Philip Meggs' *A History of Graphic Design* (Meggs, 1998). To the traditional learning objectives of a survey course I brought two additional ones: first, to understand the history of graphic design within a broad framework of the history of image-making; and second, to be able to interpret this broad swath of images in terms of their meaning and value. This allowed me to foreground the strategic value of a wide diversity of images—from the Sistine Chapel to a Denny's lunch menu. Images typically associated with art history were examined in ways that brought to the fore parallels with contemporary design practice.

Fig. 1: Braun Citromatic de luxe citrus press, model MPZ22

Traditional and modern design images were analyzed in ways that removed them from the expediency of a commercial context in order to understand them as a cultural artifact.

The clear articulation of meaning and value is a challenge, and especially so in graphic design where the meaning of an image – what it communicates – is so closely correlated with its value – what the image *does*, its purpose for being created. A Braun fruit juicer (fig. 1), for example, might look like it is meant to juice fruit, and thus *communicate* its function; but this is only partly true: it also communicates, for example, modern efficiency and stylish classicism. Its function of squeezing juice out of fruit is more easily ascribed to its *value.* On the other hand, the value of a WPA poster for a dance (*fig. 2*) is intimately correlated with its meaning, the communication of the *what/where/when* of the event as well as its *why*, the joy of dancing.

Fig. 2: Charles Verschuren. *Dept of Parks water carnival: Music, dancing, singing*. 1936.

An image is an extremely efficient means of communicating complex information, which becomes apparent through the challenge of attempting to isolate and separate its meaning and value. We can read images in an instant, even though the effort to manage the communication on the part of the producer can be immense. A designer might achieve this effect not through an immense analytical effort, but rather through an extended synthetic mental process not dissimilar *in kind* to the mental process of a viewer. The ability to synthesize may be dependent – particularly in the case of a young student of design – on a repression of critical awareness of the strategic interests at stake in the image. The exercise of clearly separating the meaning from the value in an image, through the application of a *retrospective* critical analysis develops in the student a strategic understanding of how meanings are constructed for specific social purposes, in a variety of historical and cultural contexts.

Fig. 3: Lester Beall. *Radio*, from the series "Rural Electrification Administration," 1937.

For example, if we were to analyze the meaning and value of the *Radio* poster that Lester Beall designed for the Rural Electrification Administration, we might say its *meaning* is, simply, “Radio is coming to your home, courtesy of the Rural Electrification Administration.” Although it isn’t technically wrong to say the *value* consists at least in part of informing citizens that “Radio is coming to your home, courtesy of the Rural Electrification Administration,” this is both redundant and ignores other values, such as that the poster contributes to a feeling that the government is working to improve your life, or that it increases the chance that you might vote to re-elect FDR for a second term in the 1938 election later that year. Through this type of historical analysis, students begin to understand that the creative activity they engage in not only has the effect of communicating a message in an imaginative or instructive way, but is also implicated in a complex social and political equation of interests and value.

The Beall poster also lends itself to the examination of core meaning, as it is designed with such modern and effective simplicity (especially for America in the 1930s). Encapsulating the meaning of an image into a short statement requires of the student that they unpack both the overt and subtler messages in an image and synthesize them. This process is relatively straightforward in the case of the *Radio* poster: the strong white arrows, with the overprinted “RADIO” text leading to the house, signify “*radio is coming to your home.”* The foreground, in perspective, leads our eye to ”RURAL ELECTRIFICATION ADMINISTRATION,” suggesting “*from* (*or courtesy of*) *the Rural Electrification Administration.”* What’s missing from our analysis is the dominance of red white and blue, the colors of the American flag, and the *modern* design. This latter element might be missed if one didn’t know, through historical study, that it was unusual at the time. What we arrive at through the addition of these elements is the following meaning statement: “*The* modern technology of *radio is coming to your home, courtesy of* your government*.”*

A more complex image, such as the cover from the 1899 Sears catalog, presents a greater challenge. How do we articulate the totality of what is communicated to us here, in a simple statement? We are presented with a “cornucopia” of elements on the page, to wit: the title of the company, a globe, a goddess emerging from a cloud, a rural landscape, a tagline “Cheapest Supply House – Our trade reaches around the world,” a title “Consumers Guide,” and a literal cornucopia of overflowing consumer goods – among other elements. This requires a significant effort of synthesis.

The exercise of producing a meaning statement from a complex image (not only number of elements, but also subtexts, ironies, strategic positioning and the like) develops in the student an imaginative ability to put oneself *in the place of* a material artifact for the purpose on understanding the agency of design. “*If you were this image,* I ask them, how would communicate your meaning to me verbally?” I encourage them to use the first person: “I [Sear’s Roebuck] reach around the

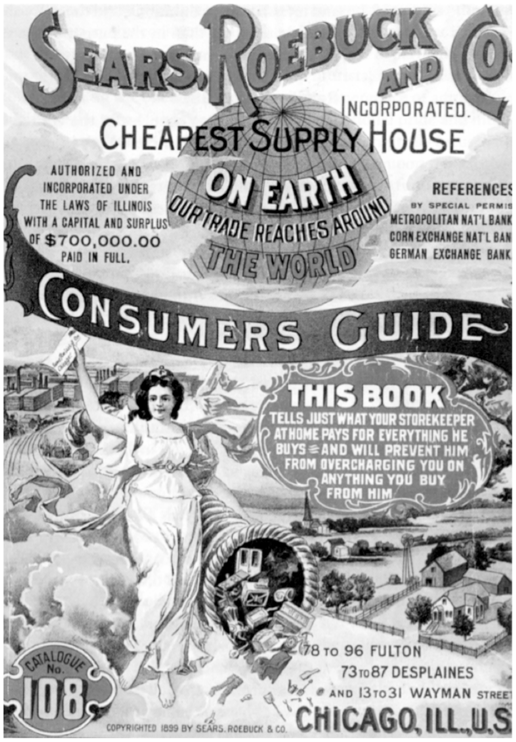

Fig. 4: Unknown. *Sears catalog cover*. 1899

world in order to magically bring to your remote hamlet an abundance of useful things to consume. Here is your guide to our riches."

Second iteration: Introduction to the reverse design brief

I introduced the reverse design brief to the course in 2003 and still use a modified form of it today. There were both pragmatic and pedagogical reasons for its introduction. I wanted to create a more relevant framework for students at the Art Institute of Portland, all of who had solid ambitions to enter industry. I also felt that the core concepts of meaning and value would be better understood within the more context sensitive design brief format.

The design brief I use is oriented towards visual communication practice, and consists of six questions: *What is the project?, Who is the client?, Who is the audience?, What is the core message?, What is the hoped-for outcome?, and What is the graphic strategy?* The core message and hoped-for outcome correlate closely with the meaning and value; the additional elements add the possibility for more analytical rigor as well as strengthen the tie to design practice.

For the purposes of this paper, I ask the reader to keep in mind a few points: first, although the form of the brief is quite simple, the reverse brief technique requires a considerable amount of practice on the part of the design student. Indeed, even after teaching this course over a dozen times, I still find much to discover through the dialogic analysis we engage in. It becomes both an analytical and synthetic exercise; the students' historical imagination is provoked, and the need for historical context is emphasized. More importantly, even though during this pedagogical iteration I wasn't yet emphasizing designs' future effects, the reverse brief technique squarely places the artifact in a conceptual space that foregrounds its *designing agency*, unlike courses based on a more traditional art historical model.

The following is an example I have used to introduce the format to the class, which analyzes a UPS logo from 1961 by Paul Rand, a designer who is often already known and respected by students before they take the history of design class. By citing this example, I intend only to demonstrate its basic organizing structure and use – how it works.

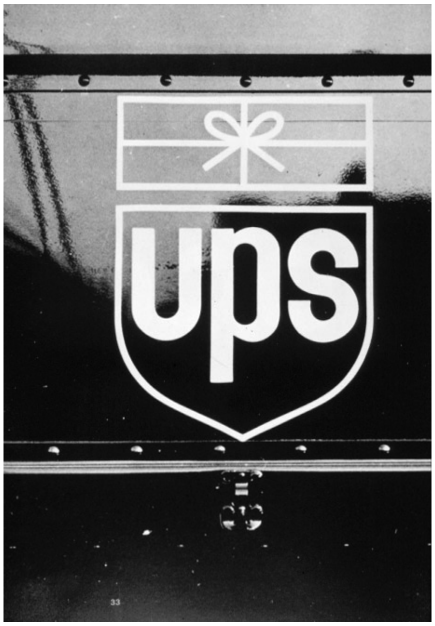

Fig. 5: Paul Rand. *UPS logo on truck*. 1961.

Reverse design brief as applied to the 1961 UPS logo designed by Paul Rand

1. **What is the project?** *Design a logo for UPS.*
   The project is defined as a denotative statement that clarifies the final image artifact. It is also an important entry point for students to imagine themselves as the designer with a project crossing their desk (in whatever historical era is being considered).

2. **Who is the client?** *UPS was the largest parcel delivery service in the United States at the time, competing with the US Postal Service.*
   The client is described in terms that add strategic value both to the brief and the resulting design. This encourages the students to examine their assumptions regarding the client. From an historical perspective, it is also an opportunity to examine the diverse institutional relationships (the "client" writ large) that exist between image producers and those they are answerable to, in whatever manner.

3. **Who is the audience(s)?** *Businesses that regularly ship or receive parcels; Families outside of large metropolitan areas who rely on the mail for deliveries.*
   There are also a wide variety of *types* of audiences, depending on the particular historical and social circumstances. Many students have only a vague sense of audience even in a contemporary context. This part of the brief allows them to see the work they do not in terms of a universal "other," but rather in relation to specific, historically based social bodies.

4. **What's the core message?** *"Your special package is safe with us."*
   "Core message" correlates with the term "meaning" used in the meaning/value analysis. The brief form allows the message to be isolated, disencumbered by extraneous information that fits better in other "buckets" of the brief.

5. **What's the hoped-for outcome?** *Potential customers would trust UPS for all kinds of packages from delicate equipment to Christmas gifts, and come to rely on its service.*
   This question and response correlates with "value" in the meaning/value analysis. In order to articulate the hoped-for outcome, the student needs to have an understanding of the values of the particular historical time and place for which the image was created, which requires not only research but also the beginnings of an historical imagination, an ability "to join the past, the present and the future" (Munslow, 2006).

6. **What's the graphic strategy?** *Paul Rand kept the logo simple so it was easily recognized. The color brown became associated with UPS and differentiated the company from the US flag colors of USPS. He designed it as a shield form in order to convey safety. The ribbon was used to suggest the anticipatory joy that comes from receiving a gift, which would become associated with using UPS.*
   The graphic strategy is an opportunity for the student to put himself or herself into the position of the designer solving the strategic design problem which, in general terms, can be defined as using visual communication to produce social value. They can imagine, each step of the image-makers' moves, and tie it to an existing element of the already-articulated design brief. Otherwise, they can focus on elements of the brief and figure out how the image-maker solved the problems encoded there.

Third iteration: Design history and designing effects

I was hired by the Liberal Studies department at the Alberta College of Art and Design in Calgary to teach their design history and theory courses beginning in the fall semester of 2009. The history course – *Critical Contexts in Modern and Contemporary Visual Communication Design* – is the major survey for Bachelor of Design students in the Visual Communication Design program.

In order to focus attention on the designing effects of design, I added an additional question:

7. **What are the designing effects?** *The brown logo-branded trucks would become ubiquitous on American streets as UPS became the only competitor to USPS. Consumer shopping became much easier and goods could be made farther from the consumer. This increased the use of fossil fuels for transportation.*

Note that the example imagines the designing effects of the simple logo and graphic identity within a reasonably grounded historical framework. A direct correlation between the logo and what is described is not assumed: in a complex relationship involving business, transportation, consumer behaviour and other factors, it would be impossible solely to isolate the role of design. Lorraine Code calls this "ecological thinking," which she observes "may indeed appear to restrict the range of justifiable, definitive knowledge claims, yet it maintains vigilance for irresponsible, careless, too-swift knowings that fail to do justice to their objects of study" (Code, 2006)

Elements of the traditional historical survey course were still present though weekly slide lectures and the use of the updated *Meggs' History of Graphic Design* (Meggs, 2006) as the required text.

It is a complex endeavour simply to adequately represent the history of design in a traditional chronological fashion. In addition to this objective, I also set myself the task of teaching the students to use the design brief to interpret historical images, and to foster an awareness of the "designing effects of design." By midterm, it was evident that I needed to find a way to increase depth of understanding while teaching to all of these objectives. To achieve this, I ceased reviewing students' reverse brief assignments during class, and instead used the time to engage the entire class with a dialogic analysis of a few images chosen for this purpose.

This had the effect of transforming the course into an in-depth, exploratory workshop in image analysis. It became a collaborative dialog of perspectives, relying both on analytical skills and imagination, with historical suppositions validated through on-the-fly online searches conducted by a few laptop-enabled students. Sometimes, the entire second half of the class would be devoted to the analysis of one image; we seldom were able to adequately analyze three images in the time allotted to us. Considered from this standpoint, the class was a success. In terms of an exit competency of being able to apply a course in design history to the task of creating future, we will have to rely on the modest evidence of written excerpts from the final assessment, for the purpose of this paper answering only the question: *what is the designing effect of* [*this*] *design?"*

Examples

For the final, I selected twenty images as a study guide, testing them on five, using the revised reverse design brief format. I emphasized that I would be expecting a thorough knowledge of historical context, and placing particular emphasis on their ability to analyze the images' designing effects. In the responses that follow, it should be kept in mind that the ones included do not represent the level of competence of the students as a whole. In teaching liberal studies courses to studio art and design students at three colleges of art and design, I have come to expect a wide variance of interest and ability in non-studio courses. Although it is important to reach the widest range of students when the purpose of the course is to affect practice, I did not find the responses of those students who have less interest or ability to succeed in the course to illuminate in what manner the pedagogy might have succeeded or failed. I will therefore not be sharing them. I will address some potential future revisions, however, in the findings.

Fig. 6: Wurlitzer Jukebox and Vending, Inc. *Wurlitzer One More Time CD jukebox*. 2006.
Based on the 1946 Model 1015 by Paul Fuller.

The Wurlitzer jukebox

The first image I presented to the students was a Wurlitzer jukebox – actually, a 2006 remake of the original version. As a faithful remake of the 1946 Model 1015, whose image was unavailable, I encouraged them to analyze it as if it were the original. I instructed them to pay close attention to its image design.

One student focused on copyright issues:

Jukeboxes, like every other advance in musical technology, created a stir among music rights owners (corporations, not artists), leading to lawsuits in the 40s and 50s. The recording industry lost, as it was judged that they had already been paid for the royalties of selling the storage media (like phono-records like vinyl and CDs that the jukebox used).

Another was more concerned with its effect on music production and technology:

It probably had a hand in shortening music to the 3- to 4-minute song we are used to today. By allowing the user to dictate the music and order, they jukebox became an early precursor to today's iPods or mp3 players, with their own personal collections and playlists.

This response notes the possible effects upon the musician:

Since live music had always been part of the social scene in all pubs and bars across every continent, a machine that replaced musicians could have been potentially damaging to their income. Freestyling in a small venue would be less common, as managers and owners of said venue would cut back continually.

The jukebox hasn't held such historical significance since Jack Kerouac wrote the introduction to Robert Frank's *The Americans*:

It is only a short step from soda pop culture to the revolution of the hippies: the jukebox opened the door to more cultural freedom.

One can see in these examples sensitivity to legal, technological, aesthetic, labor and cultural issues as an effect of the introduction of a designed artifact into the world.

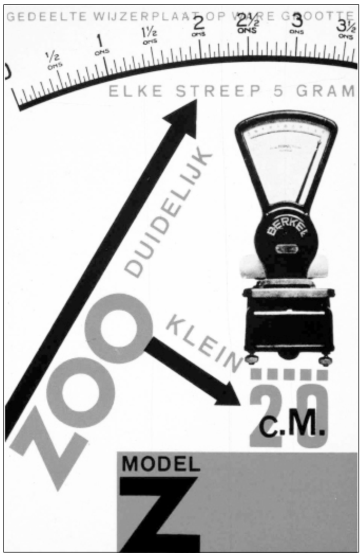

Fig. 7. Paul Schuitema. *Brochure cover for P. van Berkel Ltd.* Rotterdam, circa 1928

Brochure cover by early modern Dutch designer Paul Schuitema

Many students commented on the rise of efficiency and standardization arising from this promotional flyer for P. van Berkel Ltd., Rotterdam:

By the use of these scales, along with other products like automated slicers becoming widespread, a more accurate standardization in food purchases began to develop….This accuracy came to be expected, in the same way that we today expect our Starbucks triple-grande extra-hot caramel macchiato to taste exactly the same every time. Standardization!

It is interesting that the student is able to make a leap from a rather unconventional layout design (even in today's terms) to an effect of standardization. Would this insight have been made in a course that restricted itself to analysing the historical specificity and radical innovation of the phenomenon of Constructivist design, or its influence on future design movements?

Cranbrook Academy of Art recruitment poster by Katherine McCoy

The analysis of a Cranbrook Academy poster became an opportunity to reflect on the influence of the design profession itself, as can be seen in both these examples:

Work like this acts as an early bearer of the responsibility of bringing the digital method into general acceptance and to merge it with real life. If the designers – who are altering the experiential world of everyone else to a huge degree – begin to utilize a technology, it becomes ingrained in culture. The acceptance of computer technology owes as much to projects like these and to schools like [the] *Cranbrook Academy.*

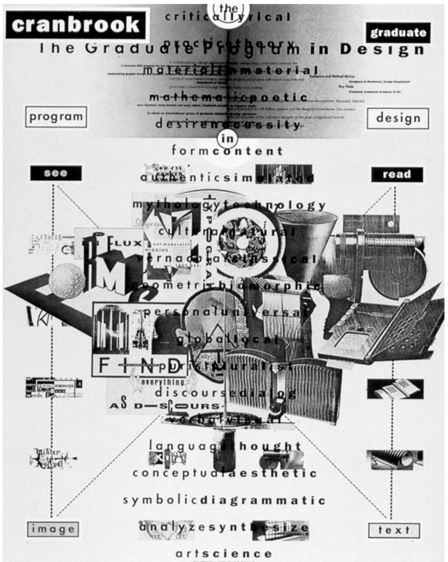

Fig. 8: Kathy McCoy. *Cranbrook recruitment poster.* c. 1988.

Another student commented:

According to New York Times in 1984, "the effect of Cranbrook and its graduates and faculty on the physical environment of this country has been profound."… Perhaps this has created a desensitivity in Americans, and all the developed world; that in being used to seeing innovative design around them all the time, they have stopped appreciating the beauty of images in favor of demanding things also be new?

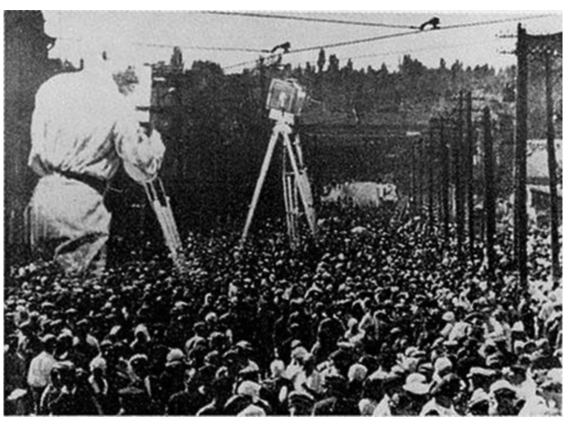

Fig. 9: Dziga Vertov. Still from *Man with a Movie Camera*. 1929

***Still from Dziga Vertov's* Man With a Movie Camera**

A few of these interpretations of this still from his seminal early Soviet film, *Man With a Movie Camera* might have stirred Vertov from his grave. The responses point to the limits of predicting the designing effects of design, as well as to the nature of design as always already co-opted.

(Student 1) Perhaps this did work to create a sense of pride and unity among people. Perhaps they worked a little harder for a while. Could this movie have assisted in lulling them into a sense of complacency, while Stalin's iron fist gripped them tighter and tighter?

(Student 2) He…in a large part foresaw the unobtrusiveness of cameras and the ability of a cameraman to go almost anywhere.

(Student 3) [*His*] *controversial documentary film led to the very beginning of the billion-dollar industry that is reality television. His ideas about not staging [a scene] yet [still staging it] behind-the-scenes are the very basis of most television today.*

Findings

As these last responses attest, a designer cannot fully predict the effect his work will have on the future. There is a good argument to be made that it is better to teach to the possible – how to solve a specific design problem located at a specific point in time and space – than to flirt with the impossible – how to take in account the enormous possibilities of permutation and perversion that comes with the releasing any artifact into the world to begin its work of designing over time.

But if we agree that our global society exists in a state of unsustainability (IPCC, 2007), and that this condition limits the time of human future, then we must develop ways of being in the world that have the capability of creating more future rather than less.

We cannot validate a claim that the knowledge gained from a course in the history of design will contribute to the creation of more future. The selected student responses to the question of the designing effects of design do exhibit sensitivity to the work of design in time, in ways that exhibit both insights and elisions characteristic of undergraduate work. I believe they *were* able to parse existing designed artifacts in ways that exhibit an ability to understand these artifacts in terms of their potential future effects – though more could be accomplished.

Additional class time could be spent in the analysis of images rather than in the presentation of chronological lectures. The recent publication of the *Design History Reader,* by Hazel Clark and David Brody presents, by its very publication, a compelling reason to abandon the survey textbook in favour of an approach that prioritizes a critical framework that has relevance to, but is not overdetermined by a chronological approach to history. Students easily become overwhelmed by the confusion of priorities that is caused when critical concepts, like futuring, conflict with expectations they bring with them from their art history survey course.

The reverse brief technique, adapted to emphasize futuring effects, has provided a context where both past and future have a relevance to present practice. It is not a necessary prop, however. It is useful only insofar as traditional design history pedagogy may be inverted into one that prioritizes future by re-contextualizing historical knowledge. Where once we emphasized the past for students without historical consciousness, now we can emphasize the future in order that our students may respect the past for its power either to limit or extend future.

The deciding questions would remain: does this awareness have the likelihood to be applied to practice and, if so, would it have better potential to create future compared with a practice not so informed? If internalized by practice throughout the course, the inclusion of a question concerning the designing effects of design within the format of a commonly used design brief makes its application to practice more likely. As to it’s potential to create future? *Time will tell.* Compared to a pedagogy that stresses the designed artifact more than the artifacts’ *effects,* it seems it would have a better chance.

Conclusion

At a time when the additive material extraction and cumulative environmental degradation exceeds our ability to sustain human life into the indefinite future, the context of our learning and our designing must change. Historical study then becomes the imaginative, practical and necessary challenge of our time.

Everyday People: Enabling User Expertise in Socially Responsible Design

Christine Caruso, Carleton University, Canada
Lois Frankel, Carleton University, Canada

Abstract

This paper examines the contemporary relevance of interdisciplinary research practice specifically within the field of design for social need. Examining the complexity of current social problems using the concepts of Rittel & Webber's *wicked problems*, this paper looks at the potential for the application of co-design methods within an interdisciplinary framework. By proposing the use of a social model of design, it is argued that it is through co-design methods and the use of generative toolkits such as Liz Sanders' *MakeTools* and *IDEO's Human-Centered Design Toolkit* that the design process can be enhanced in the early stages. This paper argues for interdisciplinary practice by enabling user expertise so that the user can equally contribute to the design process. This paper also explores the changing role of the designer from researcher to facilitator, and how this can benefit communities dealing with complex problems. Finally, this paper looks at the benefits of active user involvement in socially responsible design through discussions on empathy, user empowerment and benefits to communities within design education.

Keywords:

Co-design; Participatory Design; Interdisciplinary; Socially Responsible Design; Design Research; Toolkits; User; Expertise

There has been increasing demand for a change in design thinking with regards to socially responsible design. In recent years a *call to action* has grown increasingly louder. Buzzwords around social action are widespread in contemporary media and political platforms, with issues surrounding environment, poverty, health, and education. The role of design must adapt in response to the effect of economic and social change on a population of nearly seven billion people. While design has been commonly associated with beautiful objects of desire or luxury, the significant change in design thinking lies in the belief that "If designers have begun to figure out how to design 'better experiences' for high-end consumers, what about improving the experiences of those who belong to the population segment that design activists have dubbed 'the other 90 percent?" (Berger, 2009, 185).

The call for socially responsible design is urgent, with leaders in the industry setting the pace. These initiatives have emerged as both a necessary and inevitable next step. The Cooper-Hewitt's touring exhibition *Design for the Other 90%* sparked knowledge about the radical difference in quality of life in which the majority of humankind find themselves. Design associations such as *Design for the Majority*, (a chapter of the *IDSA*) enlist members with a bold mission on this changing social climate stating "we as designers can either lead this shift, or we can follow" (*IDSA* website). In addition, initiatives by Denmark's *INDEX: Design to Improve Life* have also been undertaken to further international education by incorporating their socially conscious process model into national education. Most notably, *INDEX:* implemented the largest international design award, in recognition of designs that substantially improve the lives of people.

At the root of these initiatives lies the central belief that “design is fundamentally grounded in human dignity and human rights” (Buchanan, 2001 36), and that the designers need to respond conscientiously through responsible action. In other words, with human consideration during the design process. On new design thinking, *IDEO’s* Tim Brown jokes, “design is too important to be left to designers” (Brown, 2009). With the increasing recognition of human consequence to any design decision, designers will need to consider both interdisciplinary and participatory methods to further consider humans, or *users* as active participants in their own future.

The complexity of social design problems calls for interdisciplinary practice. By examining the role of the user within a participatory framework, this paper argues that participation in the design process is a critical success factor for increased benefits to the end result. However, it is only through exploring the means of involvement through co-design and the use of generative tools that the user can be viewed as an equal contributor– an “expert”– in the interdisciplinary design process.

1.1 Clarification of Terms

This a theoretical paper based on a literature review. As the field of design practice and research evolves, the terminology continues to evolve and expand as well. Some of the sources are initial publications on the subjects, so it is important to clarify the terms that may have changed. *User* will imply *humans whose lives are directly affected* and “who stand to have their activity and experience transformed” (Carroll & Rosson, 2007, p. 258). *Socially responsible design* refers to design within the realm of social need, and upheld by a definition where it is “grounded in human dignity and human rights” (Buchanan, 2001). This paper will take *Human-Centered Design* to mean a “design process specially focused on socially responsible design, with the end aim of responding to basic human need” (IDEO Toolkit, 2008). *Design Thinking* is inspired by a “process that endeavors to solve problems and create new possibilities, generally relying on empathic research […] combined with creative experimentation and extensive prototyping and refinement” (Berger, 2009, p. 302). The term *design* will be in the scope of socially responsible design.

2. Socially Responsible Design

2.1 New Design Thinking

As social problems of the world change, so does the role of the designer. It can be argued that earlier definitions of design do not effectively cover the wide range of theory, knowledge, and methods used in new design thinking. The role of the designer, once viewed as a profession based on principles of aesthetics, and creation of beautiful artifacts “has expanded into a more thorough and diverse interpretation of the physical, psychological, social, and cultural relationships between products and human beings” (Buchanan, 1992, p. 9). Until recently, it seemed suitable to pigeonhole designers into specific subcategories; graphic, industrial, urban design, with each designer approaching individual problems with their own unique knowledge. However, the increasing complexity of social problems has, as a result, made solving them increasingly difficult. Because of this, “the boundaries around these problem areas have begun to collapse […] As a result, old divisions of design practice now appear increasingly inadequate and ineffectual” (Margolin, 1996, p. 23).

The role of the designer is now, more than ever, about adhering to a new way of thinking about problems, one that incorporates a broader research approach in order to fully understand problems as systems, rather than individual parts. By expanding their knowledge designers can then contribute a well-informed solution, matching the complexity of the problem. Evolving far beyond the principles of aesthetics and basic form and function, design thinking is now focused on “form and content,” fundamentally rooted in humanity (Buchanan, 2001, p. 35). Designers must cross multiple disciplines to expand their scopes of knowledge and this approach can now be considered a tool, not solely a profession. Only through this new form of thinking can designers really be able to face current social problems.

2.2 Rittel & Webber’s Wicked Problems

The complexity of problems faced by designers can be best characterized by Rittel & Webber’s formulation of w*icked problems*; those that are far too unique and complex that do not have logical or concrete solutions. The properties of wicked problems are detailed in Table 1. As such, these problems must be looked at more expansively. As social problems tend to be interrelated, they must be looked at it in a bigger context, which “tends to run counter to the more conventional method of trying to simplify problems to boil them down in an attempt to come up with ‘the answer’” (Berger, 2009, p. 206). When a problem is *wicked* it is impossible to fully solve in the way that a mathematician might solve a puzzle. Social problems can never be solved. (Rittel & Webber, 1972, p. 160), and often any one solution may actually “solve one aspect of the larger problem while making another part worse” (Berger, 2009, p. 207). In an example of a current water contamination problem, it is argued that designing a filter is just a quick solution and only identifies one part of the issue. Designers hold responsibility to carefully examine the system as a whole. Only by understanding consequences and impacts such as local culture, water sources, health issues, and cost of implementation, can a solution to a problem as complex as water contamination be approached (Berger, 2009, p. 206).

1	There is no definitive formulation of a wicked problem	The information needed to understand a wicked problem depends on one’s idea for solving it
2	Wicked problems have no stopping rules	There can never be an end to a problem when there are no definitive solutions
3	Solutions to wicked problems are not true-or-false, but good-or-bad	There is no criteria to determine this when there are no definitive solutions
4	There is no immediate and no ultimate test of a solution to a wicked problem	There is no on-the-spot test because it could take years to implement a variety of solutions
5	Every solution is a “one shot operation”	There is consequence to every decision, so there is no room to learn by trial-and-error
6	Wicked problems do not have an enumerable set of potential solutions	There are not only infinite numbers of solutions but infinite combinations of possible solutions

7	Every wicked problem is essentially unique	They can often be similar, but never the same because of individual context
8	Every wicked problem can be considered to be a symptom of another problem	Every problem is interrelated
9	The existence of a discrepancy representing a wicked problem can be explained in numerous ways	Especially in interdisciplinary work, everyone's understanding of a problem will be different.
10	The problem-solver has no right to be wrong	The aim is not to solve, but to improve the problem, so a hypothesis must be given regardless

Table 1. The ten properties of *wicked problems* (Rittel & Webber, 1973).

Put bluntly, these ten properties stress "the social reality of designing" (Buchanan, 1992, p. 16). The concept of *wicked problems* translates to a variety of issues faced in new design thinking because of the "fundamental indeterminacy," of them; that is, lack of answers and infinite combinations of solutions (Buchanan, 1992, p. 16). While problems might not be readily definable, the role of the designer should continue to identify "the actions that might effectively narrow the gap between what-is and what-ought-to-be" (Rittel & Webber, 1973, p. 159). This must first be accomplished by examining social problems as systems, and by following a social model of design.

2.3. A Social Model Of Design

As new design thinking must deal with interrelated and complex social problems, an interdisciplinary practice must be used. Margolin & Margolin propose a social model of design practice specifically for designers, based on the literature of interdisciplinary process used by social workers. Such a model calls for joint projects within disciplines, with the end product designed to satisfy a human need– a six step problem-solving process working "in a collaborative manner with the client system" (Margolin & Margolin, 2002, p. 24). Following this social model, new design thinking can look more holistically at a problem and enlist theory and knowledge from other disciplines. 'Design' as a subject matter "is potentially universal in scope, because design thinking may be applied to any area of human experience" (Buchanan, 1992, p. 16). The magnitude of knowledge needed to formulate strategies when dealing with *wicked problems* is impossible for one designer alone as "individual intelligence is insufficient to our tasks" (Rittel & Webber, 1973, p. 160). Through collaboration, designers can expand the field of knowledge surrounding a problem to ensure that every possible aspect of a system is addressed.

Approaching social problems using an interdisciplinary framework is necessary, as "without integrative disciplines of understanding, communication, and action, there is little hope of sensibly extending knowledge beyond the library or laboratory in order to serve the purpose of enriching human life" (Buchanan, 1992, p. 6). With the primary aim of synthesizing knowledge, interdisciplinary practice is in use by respected organizations, institutions, and design leaders in the field of socially responsible design. Danish organization *INDEX: Design to Improve Life* has implemented cross-disciplinary approaches in their process models and included it in their overall mission statement. Design and innovation firm *IDEO's* roster of multi-disciplinary team members is evidence of new design thinking, and the *Cooper-Hewitt's* affirmation of the need for designers "working directly with end users of their products, emphasizing co-creation to respond to their needs" (Retrieved from the Cooper Hewitt's Design for the Other 90% website, 2009). While these forerunners of design practice set the pace for other designers to adopt a social model for design, the new focus on the human-centeredness of design thinking brings into question the role of the 'user' in the design process.

3. Enter the User: from Participant to Expert

If the consideration of humans at the core of the design process is the "the major tenet of new design thinking" (Buchanan, 2001, p. 37), then what is the role of a particular 'human' in the design process when they are the one(s) potentially affected by the end result? The following sections will examine the application of participatory design practice and explore how users can be effectively involved in order to fully maximize the potential for viable interdisciplinary design practice following a social model.

3.1 Origins of Participatory Design

Participatory design is fundamentally rooted in early Greek Civilization, "where perhaps the first formal citizen forums were held" (Beheshti, 1986, p. 122). While the meaning of the term 'participation' has evolved considerably over the last few decades, participatory methods are founded in the basic tenets of democracy. The egalitarian principles such as freedom of speech, public assembly, and equal representation fed the energy of activism for democracy in the 1960s, and inspired a stronger community consciousness in the early 1970s (Beheshti, 1986, p. 122). These political and social trends were instrumental in growing demands for citizens to have influence in decisions of their communities. Politically, *participatory democracy*, or "collective decision-making" (Sanoff, 2006), has the aim of organizing a society in which "individuals share in those social decisions which determine the quality and direction of their lives" (Beheshti, 1986, p. 122).

Including the perspectives of users in a design project was initiated in Scandinavia in the 1970s. One of the first participatory design projects, using a "Collective Resource Approach," (Sanders, 2008, p. 3) came out of a project where union workers were actively engaged in the development of systems designed to make their workplaces more efficient. This collaboration allowed the computer professionals designing the systems to fully understand the worker's needs and day-to-day issues from the perspective of those "whose work was to be impacted by the change" (Sanders, 2008, p. 4). This realization of the users' intimate understanding of the problem emphasized the potential for active knowledge sharing and mutual benefits by involving people directly affected by the results. In addition, participation research expanded through the writings of Cross, Beheshti, and Sanoff, who supported a model referred to as the *Design Coalition Team*, "simply defined as all those who are involved in, affected by or can exert influence on the process of designing the built environment" (Beheshti, 1986, p.124). This meant equal say from all participants, including users. These writings and initial participatory projects were central in design practice and furthered considerations of user involvement during the design process.

Although participation has been increasingly incorporated into practice, there is still a great divide between the roles of *designer* and *user.* Most recent research methods are conducted through ethnographies, interviews, and surveys. This information is then interpreted by the designer or researcher, who is thought to have an "expert understanding of users of artifacts" (Reich, Konda, Monarch, Levy, & Subrahmanian, 1996, p. 169). While this type of participation in the development process definitely moves the role of the user closer to the designer, the user is still not really a part of the team, but "spoken for by the researcher" (Sanders, 2002), and still through interpretation by the designer. The user is regarded as a *subject*, with little to no involvement further along during the design process. Further participation methods can bridge the designer/ user gap, by involving the user in "ideating, and conceptualizing activities in the early design phases" (Sanders & Stappers, 2008, p. 1), referred to by Sanders and others as the "fuzzy front end" of a design problem. Increased contributions and involvement can possibly shift the view from *user as subject*, to *user as expert*. This can suggest that there must be opportunities for further inclusion of the user throughout the entire design development process.

3.2 Co-Design

Co-design, the "collective creativity of collaborating designers" (Sanders & Stappers, 2008, p. 2), upholds the idea of interdisciplinary practice within the social model. A large part of its potential, especially in socially responsible design, lies in the conviction that everyone is inherently creative, and knowledgeable about their own experiences. With complex social problems, it is necessary to think beyond the obvious solutions, and engage every team member through their skills and expertise. Co-design makes a case for user expertise by enabling the user's active involvement through the design process, who is then able to equally contribute to the solutions.

In co-design, the boundaries of roles between designer and user become blurry, and the user, "who will eventually be served through the design process is given the position of 'expert of his/her experience'"(Sanders, 2002). This is a significant shift in perception from user as *subject* to user as *expert,* now assumed to have an equally valid say in the design process. If expertise is defined as those with "access to special knowledge of a subject which supposedly raises that individual's awareness above that which is obvious" (Sanoff, 1985, p. 180), it can be argued that a user's perception of a problem through personal experiences and memories is in itself a unique knowledge, and therefore an expertise. Because new design thinking is about approaching a problem from every possible perspective, then the experience-based insights from the user are invaluable to interdisciplinary teams.

Users (as co-designers) cannot always clearly articulate their experiences, needs, or desires to relay their expertise. This is referred to as a user's *tacit knowledge,* that knowledge which is implicit, or inherently understood, but may not be able to be expressed through words (Polanyi, 1964). Therefore, it is not enough to simply *involve* users– they must be *enabled* to access and reveal this knowledge in order to "harness the collective and infinitely expanding set of ideas" (Sanders, 1999). Tools are needed to enhance this collaborative communication, in ways that allow people to visually express themselves through tangible means. This paper will focus on two particular generative toolkits.

3.3 Generative Toolkits

There has been much research development in tools for co-designing. To guide communication during the co-design process, the designer must assume the role of *facilitator* (Sanders & Stappers, 2008, p. 11), who can create appropriate tools to enable users to generate tangible, experience-based ideas. It has been established that “people cannot tell you in words about their unmet needs” (Sanders, 1999), so in this sense, by enabling user expression, toolkits can be considered a form of common language through which designers, users and other co-designers can communicate. This language is “built upon aesthetics of experience rather than an aesthetics of form” (Sanders, 1999). Sanders’ *Say-Do-Make* design process model is shown in Figure 1, illustrating that it is through *making* that the tacit knowledge can be made explicit.

Figure 1. Design process model: What people say, do and make. (Sanders, 2002)

These toolkits can be physical materials with which to create tangible artifacts, as in the case of Sanders’ *MakeTools*. Many varieties of toolkits exist, some eliciting cognitive or emotional experiences, stimulated by statements or thought provoking questions. Co-designers express themselves with the materials provided, often able to rearranged and built into artifacts with Velcro or stickers, and refined with pens or markers. Often their created artifacts are in the shapes of words, image collages, prototypes, concept maps or storyboards (Sanders, 2000), from which desires, needs, and “new, experientially-defined categories” emerge (Sanders, 2000). These artifacts reveals users’ clear personal experiences about ideal scenarios, which would probably not have been revealed without the necessary tools.

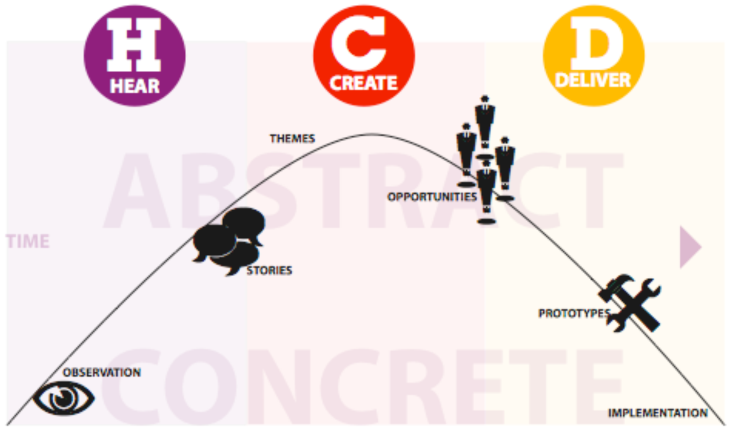

Figure 2. Design process model “Hear – Create – Deliver” (*IDEO Toolkit*, 2nd *Edition*)

IDEO’s *Human-Centered Design (HCD) Toolkit,* and accompanying *Field Guide* were created for particular use for socially responsible design for NGO’s and others, and parallels of the *HCD Toolkit* design process model, shown in Figure 2, can be drawn to Sanders’ design process model in that both aim to generate experience-based ideas through co-design. Both empower users by enabling their expertise. The *HCD Toolkit* guides facilitators through community participation and visual expression. An example of a co-creation workshop from the toolkit is seen in Figure 3. By including notes for the facilitator, and templates from which to build, the kit includes guides for role-playing workshops, storytelling sessions, scenario drawing, and prototyping, this process gives “voice to communities and allows their desires to guide the creation and implementation of solutions” (*IDEO HCD Toolkit*, 2nd *Edition*). This enables their unique expertise in the situation. The toolkit itself functions as much as a facilitator, illustrating how to select participants, and providing ways to deal with differences of culture, gender, hierarchy, and class systems, as shown in Figure 4. These are the same principles underlining interdisciplinary collaboration, as the toolkit reinforces the approach that “one cannot understand the problem without understanding it’s context,” (Rittel & Webber, 1973, p. 162). By enabling co-designers to create a tangible representation of their everyday life, these tools empower community members.

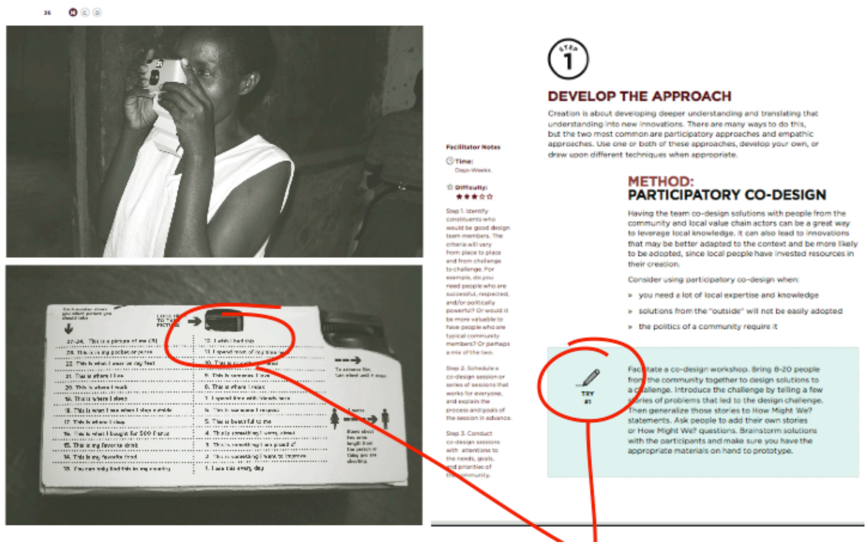

Figure 3. On the right, an example of tips outlined for facilitators to lead the workshops. On the left, co-designers create photographic storyboards using self-documentation and following a list of suggested guidelines– phrases such as *I do this every day* or *This is something I worry about.* (*IDEO HCD Toolkit*, 2nd Edition)

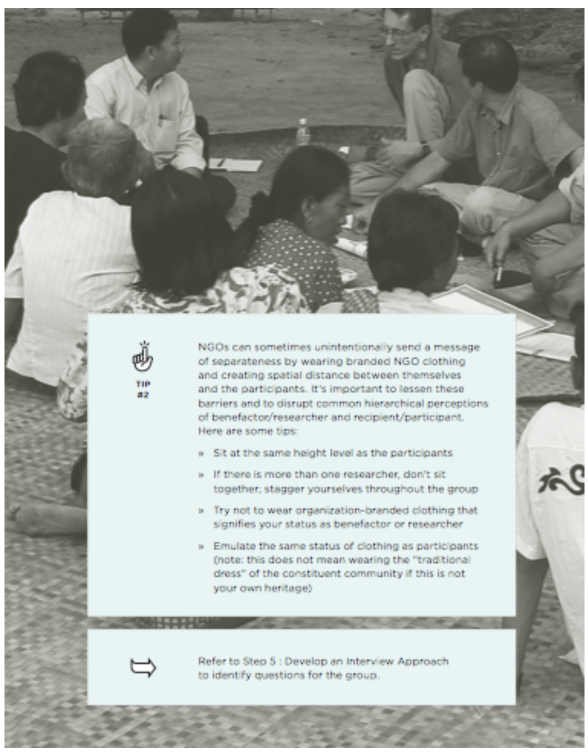

Figure 4. The toolkit explains certain techniques to enable the participant through sitting at the same height, and by not wearing clothing that sets facilitators apart or "separate" from the team, upholding the egalitarian principles of participatory methods (*IDEO HCD Toolkit*, 2nd Edition).

4. Implications on Design Process

Sanders & Stappers write that participatory design has the potential “to arrest the escalating problems of the man-made world” (2008, p. 5). By enabling user expertise through participatory methods, interdisciplinary design teams have a much stronger wealth of knowledge to face problems in the social arena. The benefits and implications of this collaboration are discussed below, as interpreted in Figure 5.

Figure 5. Benefits to co-design practice in socially responsible design

4.1 Empathy

Socially responsible design is especially relevant because of the direct impact it has on quality of life. Because of this, it is the moral responsibility of designers to consider the active involvement of the user in the design process as it determines the quality of *their* life, which the designer has the power to transform. If human rights are at the center of new design thinking, then user participation must be viewed as “a *prima facia* right of all people potentially affected by a design” (Reich et al, 1996, p. 162). The users direct involvement, personal history and unique experiences with the cause suggest a moral obligation for interdisciplinary teams to enable the user’s expertise. There should also be respect for the fact that it is the user whose life stands to be changed the most by the result. Caroll & Rosson aruge for a user’s direct say and meaningful role because users “are morally entitled to have a say in anything that might change everything (2007, p. 243).

Empathy emerges as a success factor in socially responsible design as a result of active user involvement during the design process. Expertise is exchanged between designer and user through co-design as a result of the shared experiences. The user learns design thinking, while the designer gains a deeper understanding of the user experience. Because of this, the designer is able to empathize with the user and greater care can be taken to consider all outcomes. This empathy strengthens the project, as the "awareness of the consequences of the decisions that are taken" (Sanoff, 1985, p. 178) is reinforced. This empathy for the impact on quality of life adds a greater sense of responsibility and consideration to the project. Ideas are developed thoroughly with the shared expertise.

In a case study by IDEO, in collaboration with a VisionSpring team, the tool of role-playing was integral in implementing a solution for eye-screening tests in a rural village in India, where children were terrified of the actual tests. Through role reversal, the team was able to empathize with the children's fear. In the spirit of childhood make-believe games, the team turned it into a game by having the children first conduct the tests themselves on their teachers. By "thinking from the perspective of […] users, and doing everything […] to feel and understand what they are experiencing" (*IDEO HCD Toolkit, 2nd Edition*), the team enhanced the experience by placing the child in a position of authority, thereby making the process playful and the children in control of their lives.

4.2 Empowerment

Co-design toolkits enable users to express their experiences so that within an interdisciplinary framework, they can be perceived as experts, and equally able to contribute to a solution. When the user is actively involved in the design process, "the major source of satisfaction is not so much the degree to which the individual needs have been met but the feeling of having influenced the decisions" (Sanoff, 1985, p. 178). By not only relaying, but also realizing one's own expertise and harnessing it through tools, this new sense of *empowerment* for the user is a critical success factor to the future of collaborative design. Empowerment gives a sense of accomplishment, a sense of pride, and the realization that one has the power to affect change. Most importantly, it gives them the feeling of control over their life and within their community.

In a case study from Africa, a designer worked collaboratively with Ugandan bicycle couriers (called Boda-Bodas) to design and implement low cost utility bicycles that would enable them to carry passengers and supplies to nearby towns. The study examines the design process and experiences of designing with the ten Boda-Bodas. Central to the study is that "including Africans into the design process not only enriched the design but also encouraged the community of their importance" (Morris, 2008, p. 7). Not only did it enable them to participate in their future, their significant contribution to the design process empowered them. There is potential for a much larger impact on social change through community empowerment. By acknowledging that community members have the power to affect change, an interdisciplinary framework could allow members of communities to work together, each of them being experts on local problems.

4.3 Education

Perhaps the shift from *designer* to *researcher* to *facilitator* can continue to transition into *educator*. As co-design continues to evolve as an emerging practice, "participants learn from their engagement in the process" (Sanoff, 2007, p. 214). This implies that there is enormous potential for community action to evolve separately from facilitation of the designer. Empowering community members, toolkits can enable users to recognize their own individual expertise through the design process, which they can then implement through interdisciplinary practice with other members of their community. This would mean that not only is the project "strengthened by the wealth of input, but the user group is strengthened as well by learning more about itself (Sanoff, 1988, 3). Given the proper tools, this could address front-end design problems within their communities and possibly prevent problems from becoming more complex further along.

Designer Bruce Mau refers to "distributed possibility," which is "the widespread dissemination of design tools, useful knowledge, and expanded capabilities- all being downloaded and passed around as never before." (Bruce Mau, queried in Berger, 2009, p. 203) What is noteworthy about IDEO's *Human Centered Design (HCD) Toolkit* is that it is open source, readily available and free access for anyone to facilitate a project. This brings into question the possibility of further refinement of such toolkits so that perhaps users can facilitate their own techniques for working towards solutions in their own contexts. Further discussion on toolkit criteria can include elements specific to certain cultures, or enlisting community facilitators to guide their own co-design practice within their own community.

5. Conclusion

Sanders writes of a "world made up of the dreams of everyday people" (Sanders, 2000). The face of design is changing in consideration of the rights of users and in the face of social problems that are far too complex. The scope of such problems are often interrelated, and because of this, interdisciplinary research methods need to be applied in order to ensure that proper knowledge and expertise from multiple disciplines can be distributed in order to shape solutions for *systems,* not just single parts of the problem. Designers have a responsibility to involve the user in the design process as they are ultimately affected by the end result and are the most knowledgeable about their own individual experiences. This will further enhance the interdisciplinary design process in socially responsible design through the combination of experts working together on a common goal. Using tools and techniques to facilitate the user through the design process, there is much potential for research into how to further involve the user in the whole process. The effect of applying co-design techniques within socially responsible design can have substantial impact on *empathy*, which increases the value of design, *empowerment* of communities through co-design and expertise, and *education* by designers to further empower communities. Perhaps a world made up of human dreams isn't entirely far off.

From ontologies to folksonomies. A design-driven approach from complex information to bottom-up knowledge

Abstract

This paper explores the social challenge posed by the complex environments in relation to knowledge management in which contemporary society and all its activities are immersed. The main question addressed is how information design can contribute to the construction of hybrid, bottom-up and collective ontologies-in-progress and dialogue with the complexity of the practices around the construction of digital knowledge.

We argue that it is necessary for information design strategies to deepen its understanding of the semantic web and the new forms of creation of ontologies. This research seeks to broaden the analysis of the role of information design in this moment of change so that design can find a concrete space of agency in such a scenario.

Information design can develop an essential role in developing more suitable prostheses, more versatile instruments and simpler technologies. That is a great responsibility and a great opportunity. A new design approach is required to dialog with the strategies of a web-based culture, as an example of a complex phaenomenon (Lewin, 1992), among which we can find hybrid, bottom-up and collective ontologies, built *in itinere* with the contribution of users that trace definitions, associations and variations, in a kind of defective semantics, founded on co-tagging, mash-up and syndication.

Design has the possibility to establish a rhetorical of project in order to create a dialogue between the social and the technical tissues. This means not only to produce a toolkit to support new scenarios with sustainable models, but also to suggest a vision of a different cultural apparatus, to offer a new way to online interaction, and new points of access to the knowledge.

Keywords

Design and society; cross, trans, inter, multi-disciplinarity; bottom-up knowledge; creativity.

Introduction: approaching knowledge in web culture

According to Lewin (1992) the web culture can be understood as an example of a complex phenomenon. A system is complex when it displays features like non-linearity (there is no direct relationship between cause and effect), emergence and self-organization, among others. They are open, dynamic, non-mechanical systems that are continuously interweaving and interacting with their surroundings. Although they rarely display long-term periods of stability, they are resilient scale-free network systems. A group directed by Albert-Laszlo Barabasi mapped the connectedness of the Web and found out that the structure of the Web connectivity map conformed to what they called "scale-free network" instead of the more popular model of random connectivity. This approach presents also some features present in fractals and other fields.

> Systems as diverse as genetic networks or the World Wide Web are best described as networks with complex topology. A common property of many large networks is that the vertex connectivities follow a scale-free power-law distribution. This feature is found to be a consequence of the two generic mechanisms that networks expand continuously by the addition of new vertices, and new vertices attach preferentially to already well-connected sites. A model based on these two ingredients reproduces the observed stationary scale-free distributions, indicating that the development of large networks is governed by robust self-organizing phenomena that go beyond the particulars of the individual systems (Barabasi, A. and Reka, A., 1999).

The approach of Barabasi is especially noticeable in the way the propagation and constant growth of the World Wide Web have triggered the development of complex systems to control and manage information. The hierarchical features and ethno-classifications that dominated the first phases in the history of online knowledge are being increasingly substituted by non-linear popular taxonomies (folksonomy) that have been emerging without default relationships among elements nor precise points of departure.

By means of these complex taxonomies social actors self-organize themselves to produce definitions, associations and variations, developing a kind of defective semantics founded on practices such as co-tagging, mash-up and syndication. These practices enable social actors to develop different spontaneous and collaborative forms of "bottom-up" classification (Tapscot and Williams, 2007) according to their own conceptual model.

Among multiple perspectives of innovation and development that sprouted in the last years in relation to that flexible and effective codification of online information there are two perspectives that we would like to highlight. These perspectives (correlated but with independent variables) are the semantic web (Berners-Lee, 2002) and the creation of ontologies (Davies, J.; Fensel, D. and Frank van Harmelen, 2003).

Approaching these concepts, the aim of the paper is to explore the social challenge posed by the complex scenarios in relation to knowledge management in which contemporary society and all its activities are immersed. In this direction the research addresses the question of how information design can contribute to the construction of hybrid, bottom-up and collective ontologies-in-progress and dialogue with the complexity of the practices around the construction of digital knowledge.

Emerging strategies in emergent complexity

Complex systems demand a different attitude that is contrary to the reductionist way that we have been traditionally working within disciplinary borders, by breaking reality into separated parts.

Thus, the emerging strategies in digital reality and the exponential development of the web-based culture, call for a different design approach regarding the spaces of communication, relation and interaction. This implies to listen to different rules in order to create and share information and knowledge that is sensitive to the nature of the system that is complex.

Information design has always tried to deal with this complex field and, as such, should be one of the most flexible and transversal disciplines to respond both to the needs and features of the field, that is to say, to the need of collaboration, creation and sharing of knowledge and the trends in the complex organization of information in the society of knowledge.

This research argues that it is necessary for information design to develop new kind of strategies to deepen its understanding and its approach to the semantic web and to new forms of ontologies definition. The arguments that support this assertion are various. On one hand, the semantic web offers an environment in which all traceable information (pages, files, images, links…) can be associated to specific metadata able to individualize the context and to construct a network of multi-pertinence for each piece of information. On the other hand, ontologies are the structures able to maintain all entities in perfect hierarchical relation (Nirenburg and Raskin, 2004). Both arguments directly relate to the core of design strategies. On the one hand, information design faces the same complex situations that are experienced by the rest of social sectors. Thus it is challenged to broaden its capacity of translating complex information structures and hierarchies into a bottom-up approach to knowledge. This challenge is mostly addressed specially to the areas of conceptual planning and technical implementation. In so doing, information design could transform actual hierarchical structures present in the very categories and relations used in traditional ontologies into flexible bottom-up forms of data classification able to contaminate the whole system, redistributing itself and remapping its own schemas and questions.

Such bottom-up approach supposes a change from a scenario dominated by ontologies into one in which non-linear folksonomies are central and social actors and society shape and classify knowledge.

Semantics and ontologies: a bottom-up design-driven approach

As a result of this research we seek to broaden the analysis of the role of information design in this moment of change so that design can find a concrete space of agency in such a scenario.

We see two basic roles emerging. The first is a role of mediator between the emerging scenario and society. It implies translating the social trend of bottom-up articulation of knowledge into information frameworks that facilitate it and enable social collaboration to increase strongly.

The way information design can do that is by establishing a project's rhetoric that fosters the dialogue between social and technical tissues. That means not only to be able to produce toolkits to support new scenarios with sustainable models, but also to reveal the possibility of a different cultural apparatus, to offer a new way to develop online interaction and to create new points of access to knowledge.

This research aims at showing that information design can be essential in this early phase of a process that sprouted from a communication necessity but turned into a central question in relation to knowledge. Information design can play an essential role in developing more suitable prostheses, more versatile instruments and simpler technologies to improve the possibilities to sustain and support social processes. This is possible to be done in relation to specific practices that consider people as active users or actors in knowledge processes. Processes such as these should be supported by tools, which are designed to enable people not only to define and share personal contents but also the grids that connect (meta-define) information itself.

A design-driven transit from complex information to bottom-up knowledge must consider the different features of the actual scenario that are: (1) people are feeling like being "immersed" in the information flow and not like being only "in front" of it, (2) societies take active part in the process of construction of knowledge and are not limited to the role of receptors of information; (3) all can be "tagged"; not only messages (contents) but also objects (media) and all elements involved in different processes of information construction can deliver contents.

Considering these points social actors/societies change from the passive role of data receivers into the role of active propellers, promoters of information in the net according to social relational ties.

Before exploring how this change could occur, and how the current paradigm enables this variation, it is pertinent to analyse the dynamics of the semantic web and ontologies that make it possible, then to consider the transition towards a bottom-up logic.

Together these two sources of knowledge management are currently the most advanced systems for analysis, creation and distribution of data, but their own structural ideas are based on a monolithic view of organizational hierarchy. This structure should be challenged to provoke a change based on the fact that there are increasingly more possibilities of social interconnection, high-speed feedback, feedback in relation to actions and choices of users and, specially, bottom up management of data classification performed by communities that select, classify and manipulate information.

Semantics is a discipline that, according to various criteria and different approaches, demarcates the parameters of a language, and the conceptual and paradigmatic behaviours of a system. It sketches the formal aspects, but also anticipates the inconsistencies, the displacement field and the extensions of a specific reference domain. In relation to complex scenarios, it reduces the factors to be analyzed by breaking them down and looks for links that constitute the fabric of formal learning. In relation to the world of the Web, and taking into consideration its dimension, it should be noted that the successful implementation of a semantic analysis (and often semiotics) derives, in part, from the fact that the latter practice is concentrated in specific environments[1].

Semantics allows for the understanding of systems and their translation into formal codes that abstracts the fundamental character of their relations, developments and the nature of their behaviour. Serving as a tool it helps spot the merits and logic of a method and also the possible epistemological and systemic misuses of application.

Let's consider the case of semantic web applied to systems like Amazon or e-commerce websites, where each question about a product returns as suggestions relating other similar products that may be of interest to the customer to purchase[2]. There are also cases of search engines that are based on the semantic filtering of information (i.e. Mooter, in Figure 1).

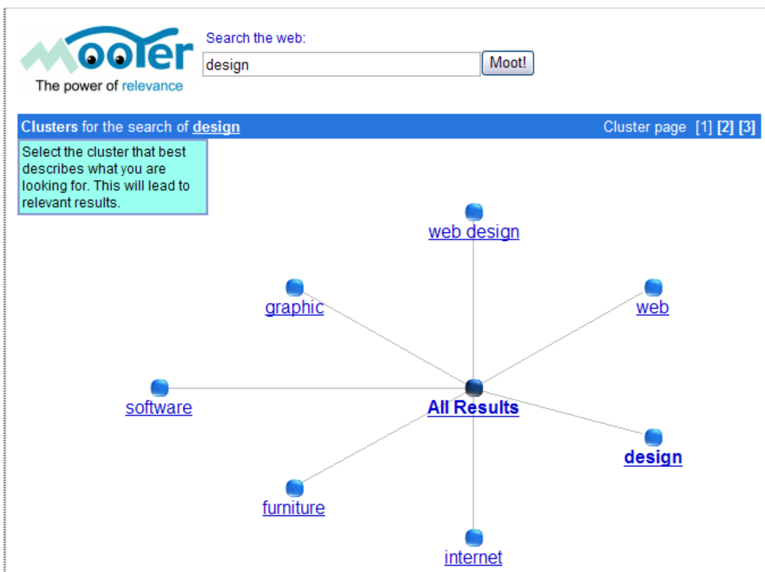

Figure 1. Homepage of Mooter Search Engine, a Website based on an engine for semantic search and content rating.

Thus, when semantics is given the task of outlining the complex linguistic expressions that define the typical or significant features specific to a particular area, it will also mark the content in relation

[1] Cfr. Davies, J., Fensel, D., Van Harmelen, F., *Towards the Semantic Web*, Chichester, John Wiley & Sons, 2003, *passim*.

[2] Do not consider here a similar comparison made by other users and compared with a hypothetical product, but how those products are labelled due to semantic similarities, and how they can be classified and made available to every database query by simply "playing" the characteristics of similarities, themes, quantities, etc.

to which these features are linked, so that they can be associated to "labels" (tags[3]), that are as close as possible to the reality they represent.

The semantic Web, based on the electrical classification of information, thus becomes an environment where information and traceability (pages, files, images, links, etc.) might be associated with metadata[4] that specify the context and build a network of objects that belong to distinct areas.

That process requires a structure able to store and maintain all entities, identified and appropriately "labelled", in perfectly hierarchical relationships. This structure should also provide an exhaustive and rigorous conceptual framework with which to manage relationships, rules, dependencies, symmetries and the specific different domain for which the structure was established.

The configuration logic and substance of a specific domain is called ontology. Although it is a term borrowed from Philosophy[5], in relation to the Web its meaning is no longer focused on the essence and significance of things, but on a particular form of description and classification, which opens and lays out the patterns by means of which things can be incorporated and information reconfigured.

Both ontologies and Semantic Web constitute a unique framework, considered as a complex organism in which information, and the logic that governs information retrieval and archiving, are inseparably united and inter-connected. There are different types of ontologies, all oriented to cover specific needs including some which are constitutive (or higher), disconnected of any application domain, and extended to describe entities in general[6].

What emerges from the consideration of these constructs is the dimension within which they are created, the frame of reference for information management and the very nature of how ontologies have an "embedded" hierarchical scheme developed specifically for self-inclusion. An example of this is the *W3C Semantic Web Layer Cake*, which is not only one of the most popular patterns on the Semantic Web, but also one of the most criticized for having a highly complex and rigorous structure (Figure 2).

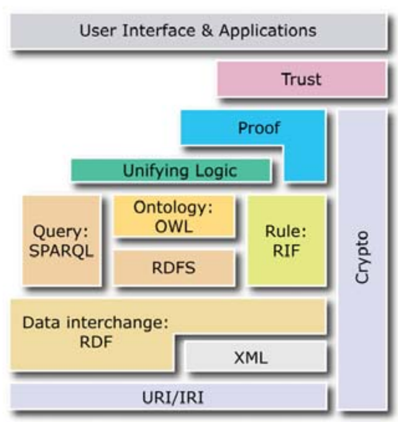

Figure 2. This figure represents the W3C Semantic Web Layer Cake, a very effective scheme based on a rigorous structure for ontologies.

[3] A "tag" is literally a particular label that can be attributed to any item to qualify and create a description outlining the characteristics that distinguish it.

[4] Metadata is literally information about information (*meta*-data, as well as data) used to describe its characteristics. Labels (tags) allow you to identify, locate, filter and get more specific details about a particular item of any type (words, content clusters, files, documents, etc.).

[5] In Philosophy the term ontology (lit. "speech about being") is the study about being as such; for the Web, the term has a branch that involves the construction of an exhaustive and rigorous conceptual framework within a specific domain: a definition that describes with precision the "essence" of a system using the classification and measurement of its key constructs.

[6] Among the most common ontologies is sufficient to recall Cyc, a proprietary system developed as early as 1985 that consists of a constitutive ontology and several specialized domain ontologies; WordNet, a database designed as a semantic network based on the principles of psycholinguistics; SUMO (Suggested Upper Merged Ontology), a project of ontology deployment, which tends to reserve certain words and their meaning for all systems based on the same standard (P1600.1), in the same way that a general ontology (in the philosophical sense) defines "what exists", implying that a hierarchy can be accepted rather than a basic choice.

On the one hand, firstly, the construction of these hierarchical systems ensured the beginning of knowledge formalization in the Web. On the other, different forms of information management appeared: popular taxonomies (folksonomies[7]) allow the development of spontaneous and collaborative forms of "bottom-up" knowledge classification reflecting the conceptual model of users. This is a model free of predefined relationships between elements or specific pre-organized structures.

Redesigning the scenario: towards hybrid ontologies

Considering the idea of the Semantic Web as unattainable, some experts celebrated its death when bottom-up systems of social classification started growing. In fact, the detractors of Web 2.0 are used to consider exhausted the concept of the Semantic Web: the perspective previously outlined shows that the "semantic" approach might be somehow incompatible with the kind of content building process that was considered the original centre of the project.

However, the criticism in relation to the Web 2.0 is not the end of the semantic dimension of information in the network. If fact, it represents the beginning of a challenge related to the re-articulation of the bonds that had been attributed to a "pre-instructed" system of ontologies in order to construct flexible hierarchies, within the limits of specific domains of knowledge.

The change of perspective rests precisely on the imperfect nature of these bonds, which are based on a fluidity that hierarchical systems cannot sustain. This fluidity constantly shapes, defines and translates knowledge processes and practices that occur in social systems of information sharing and has the power to reconfigure the network itself.

Even previous to the assumption of a "collective intelligence"[8], this kind of tag-enabled knowledge management is based on subjective value criteria that reveal the connective[9] shape of people's thinking. That process builds an ontological open form in continuous alteration and semantically flawed.

Information connections, together with the kind of connections typical in social networks, offer a view of how knowledge systems are being organized in the Web: which tools, challenges, drivers and with which forms of technology we are dealing to achieve specific results in empirical applications.

Nova Spivack[10] showed how the current landscape in the Web is not characterized by the decline of the Semantic Web or of an information regimen proper of the system. Spivack says that the Semantic Web is a project to be followed inspired by the position of a society that is aligned with the Web 2.0 but freed from the Semantic Web. It implies a project that points towards a scene in which the systems of semantic search, semantic database, etc., form part of the social web. This is a moment in which we are redefining participation, information and classification tools, and passing from the monolithic and hierarchic system of Web 1.0 to include social networks, media sharing, mash-up, weblog, wiki and all that is redefining the role of the user in the very nucleus of information.

Another element that underlines the role of ontologies in the prospective of "folksonomies" is the actual information management system: designing a process to manage data growth with bottom-up classification methods that reconfigure data without any hierarchies of flow is a natural point of disarticulation between "quantity" and "quality" of information that individuals and groups have to

---

[7] The term folksonomy is derived from the words folk (people) and taxonomy and indicates both a collaborative, popular (bottom-up) mode to classify information using keywords (tags), that emerges from the movement of groups that cooperate spontaneously to organize distributed information in the web. It is also a form of ethno-classification or demo-classification (classification people-driven).

[8] Levy, P. 1994, *L'intelligence collective. Pour une antropologie du cyberspace*, Paris: La Découverte.pp. 205-221.

[9] De Kerckhove, D. 1997, *Connected intelligence*, Toronto: Somerville House Publishing, pp. 73-90.

[10] Nova Spivack is is considered one of the leading voices on the next-generation of search, social media, and the Web. Spivack has founded numerous ventures including Twine.com, EarthWeb (now called Dice.com), and Live Matrix (in stealth). He worked with technology ventures like Kurzweil, Individual Inc., and Thinking Machines in the late 1980's and early 1990's. He speaks widely on the future and has co-authored several books on Internet strategy, collective intelligence, and technology.

manage. This means that with the advent of a truly semantic, ontology-based and bottom-up web, able to process information using a folksonomy-driven approach for classification, we will no longer need to use large amounts of data to obtain better information. Rather we will exploit the most suitable data (qualitatively more weighed, marked and labelled) to obtain a result more aligned to what we want.

Let's consider one of the largest existing search engines, Google. No doubt that if you submit a non-precise search without clear filters, it is difficult to get results without being overwhelmed by dozens of pages, among which it is impossible to navigate clearly for lack of a "policy" guide. They are generated and arranged in precise sequences supported by a structure of referrals. Following a realistic process of development, in this situation it is very difficult to bring what we want to focus.

In the near future, the construction of knowledge in the network -either from the viewpoint of conceptual design or the point of view of technical implementation- should take into consideration the arrangements, structures and social dynamics present in the Web. Having more strategies and recombinant grids to share knowledge empower the way people can contribute and beneficiate of knowledge itself.

This implies to align the current hierarchical structure and the bottom-up processes of data classification, making possible the same categories and relations that are present in traditional ontological systems. This means coming to postulate and implement "hybrid" ontologies based on arbitrary starting structures, according to the domain in which they serve, and incorporating users.

The process of collaborative tagging as a turning point: towards hybrid ontologies

The construction of software systems has always required the adoption of specific programming languages consisting in re-defined or pre-arranged codes. The Web galaxy is no exception to that when considered as a complex environment based on different kinds of software that operates by means of its own codes. However, unlike a programming language, in order to participate in the construction of information in the actual Web galaxy it is not essential neither to build specific processes and to manage and elaborate different languages, nor to have particular technical skills and competencies. There are open-platforms, social software, aggregators, user-generated systems, etc., which allow communities to self-organize in relation to information simply by (re)arranging the structure of pages to be displayed on screens and the relationship between (self-generated) contents.

The uniqueness of this organization, introduced firstly related to a basic language like HTML and then, in the late nineties, radically changed by the social approach to the Web, is to use "labels", known as tags. Tags describe each component on a page, giving it a formal role, functionality or value. From these initial steps related to the dawn of the World Wide Web, many steps forward emerged. In addition to evolution of codes there has been a gradual evolution of classification systems and labelling means, until a change of perspective was brought by the introduction of a new coding language like XML.

The concept of tags, a simple but effective system, not only allowed a profound evolution in programme languages for the Web, but are also emerging as social tools for defining bottom-up information.

In fact, due to its potential, tagging is challenging the traditional channels and methods of construction of knowledge in the network, by making "liquid architectures" of which has always been based on the hierarchy and the predetermination of their own apparatus of incorporation. In fact, these hierarchies are weaker because, by the tagging of one or more elements, people can potentially classify any content. It is possible to create layers between elements and then, meta-layers, and meta-meta-layers, and so on, until the tagging completely re-ontologize the system.

This process suggests another special feature of the labels, namely their strong ability to adapt to contexts of application. In fact, in the Web, with the evolution of the connective participation of users, a tag has a significance that goes beyond simple keywords and page-code structures: labels are directly exploited by users to sort and classify their contents and those of others, without following any hierarchical or scientific rule, but simply by referring to their needs and to an idiographic modus operandi.

Folksonomy, as a method of classifying, refers to communities but is completely personal and customizable. It expresses a form of digital identity of individuals, who, as members of a group (broad or narrow), contribute to shape it according to self-organizing rules, which emerge spontaneously during the connective process of the tagging itself.

Regarding that, David Weinberger[11] offers s a very eloquent example. Weinenberg underlines that if we are in a supermarket, the possible relations between a product and another may be multiple and different for everyone but, because of the fundamental bond of physicality, the products may be placed on one, or a maximum two similar shelves. On the Web, using a tag, and thanks to digital contents, each object can relate to a multitude of others, according to an order that is customizable and scalable.

This characteristic clearly shows how each individual is free to manage and organize information, creating relationships between them and the external sphere of possible links of information. It is interesting to note that categories and hierarchies loose strength and consensus in a social apparatus that tends to overcome them. This self-organizing bottom-up approach to knowledge destabilises the grids of information architectures and substitutes them with liquid forms of relation and different layers of meta-information which are able to create their own order through disorder and emergency.

In fact, different people classify resources in different ways and make different use of them. In addition, similar concepts can be represented with different labels, in many languages and with different kinds of approach.

This property clearly shows that there are languages that can evolve and be structured by the simple phenomenon of tagging, allowing each individual to spontaneously define anything by means of his/her (but shared) language model. The moment this happens all denoted meaning may collapse or evolve, changing the dimension of meaning and significant according to a dynamic logic based on bottom-up understanding, tolerance and trends. In fact, it is enough if a group considers that a new label, or a particular tag is reliable for a specific term to be adopted as common language in the Web.

These considerations suggest that bottom-up classifications are usually successful only when a large number of users tag the same information. The “mass” (*folk*) decides about the most representative and credible keyword and about content in a spontaneous democratic and transparent way, according to a natural and direct principle of self-elimination or collective dismissal.

Thanks to these assumptions, folksonomies are transformed into a fast, distributed and scalable form of information classification, in which the process of indexing not only enables users to produce new forms of aggregation but also questions the validity of any hierarchical ontology. This approach also introduces a change in the method of finding information, -deconstructed and reassembled into descriptive metadata- that goes beyond the original value of a unique and arbitrary classification model. This is changing not only in terms of meaning and significant, but also in relation to the mechanisms of access: social tagging exploits a mechanism of “browsing” that is based on the identification of content through keywords, rather than by index scan, which is established in the “finding” procedure, common to many systems for mapping, tracking and retrieving data network.

The same is valid in relation to information and interaction processes that enable discovery, and possible further classification of information. These processes bring a change in the game of communication which not only alters the message contents but also the paradigm relating to management and meaning, impacting all actors involved.

This change has introduced new forms of visualization and interface, promoting the development of innovative graphical models such as tag-cloud, a visual presentation of labels, which uses a recursion of terms that is measured by the size of a tag-source for determining the level of importance.

---

[11] Weinberger, D. 2007, *Everything is miscellaneous*, New York: Time Books, *passim*.

Another effect of this change has been the phenomenon of serendipity, or the ability to discover something unexpected in the process of looking for something else. This peculiarity shows that tagging is becoming an increasingly essential component of the Web. In fact, the dissemination of folksonomies in various social networks inevitably leads to a different variation of tags in relation to proxemics[12], or distance of interaction.

This means, for example, that the search for a video in a system like Youtube, when we use one or more keywords, may often not give the desired result but is more likely to simultaneously provide a certain number of clips. This process suggests that the very tags trigger greater cross-fertilization and completeness levels in data search, through the variables of relevance, redundancy and recurrence.

In this scenario, contents are enjoyed in a scalable multiple level manner, thanks to the dynamism of bottom-up processes, which are curiously aligned to complex adaptive systems. That means that the structure and connections in the Web display a behaviour that is similar to complex systems. The analysis of folksonomies-in-process can determine and describe this behaviour and processes of change.

Tagging, as noted, has successfully been adapted to the realm of the network and the digital world, and it is important to stress the weight it occupies in everyday life. This process, firstly related to the Web, is now being extended to any process of reality: RFID systems label everyday world, making it possible to identify, through radio frequencies, the objects equipped with RFID-tags. In this way, objects can be recognized and tracked according to position changes. Right now, although RFID-tags are not widely employed they have a great potentiality to be used in marketing and integration. In fact, they represent both the best channel for user profiles and the most effective one for communication between objects (or systems software).

Therefore, it is inevitable to note that labels, whatever the form, are playing a major, if not a decisive role, in the development and creation of new software, hardware, and in new processes in information and knowledge construction.

Conclusion. Design open rules for information: tag mash-up for an “imperfect semantic”

The multiple challenges posed by the successes and failures of the Semantic Web trigger a need to take a new step towards a different approach in relation to online information and its “liquid” shape: it is necessary to facilitate and, in some cases, to provoke a paradigm shift in relation to the hierarchical structure of the system, leading users to a new dimension in the social construction of knowledge.

Based on an user-centered definition of innovation, it is clear that the Semantic Web project -as it is outlined in the manifesto of its inventor Tim Berners-Lee-, brought a gradual change in the concept of knowledge management, especially when it comes to make available and distributed online information.

The development of this new social form of use of the Web seems to result from the permeation of the network’s capillary level, fostered by the distribution of open-source code, the employment of systems that allow for the sharing of any type of resource and a social attitude to create and manage relations by means of online tools. These factors led users to be able to regain possession of a heritage that is theirs by right.

This was not the case in relation to the question of content, but rather in relation to what kind of media and platforms are made available in the phenomenon of social software: everything starts from a need to communicate, not from the subject of knowledge, and then people exploit the most suitable prosthesis, the most versatile tools and the most available technologies to define which tools can be used in the process of knowledge sharing.

The consequences, or the beginnings, of this phenomenon constitute the currently scenery:

---

[12] The term proxemics was created by Edward T. Hall to describe a set of measurable distances between people as they interact (Hall, E.T., *The hidden dimension*, Garden City, N.Y., Doubleday, 1966).

- People are feeling “immersed” in the information flow and not just “in front” of it;
- Users became active parts in the process of knowledge construction, apart from being receptors and distributers (users became actors);
- Not only contents but also all entities and things are involved in the information process (i.e. objects, environments, etc.);
- Unique conceptual hierarchies and classifications can no longer be enough to describe a reality that is constantly changing.

By analysing the implications of that scale phenomena we see that users became not only a patron but also an active propeller in the information network, updating the first forms of co-authoring in the age of hypertext.

This oversized semantic shapes a new way of knowledge building that can no longer rest only on language dimension, semiosis, structural constraints or revived special structural data ties, but should also take into consideration the trends and drivers that have led to specific results, or to evaluate certain goals.

In this moment of indefinite proliferation of groups, which aggregate and separate according to complex and non measurable phases, links built between statements, terms, concepts and data clusters are born and die when the collective attention is focused on them and reconfigure their scope, contents and their very labels. Unstable information links result from these “bottom-up labels” that reflect how online communities accept and determine values. This produces proliferation of metadata and the redefinition of contents according to their cognitive matrix.

The result of all these processes is a form of semantics declined according to the impulses, attractions and polarities that happen between users that reconfigure the very network, since no hierarchical structure can control a process that falls within its same patterns of demarcation and classification.

An imperfect unstructured semantic emerges. It is a kind of semantic that is longer based on models of heuristics and linguistic processes, but on a mash-up of tags and syndication, that characterizes the dynamics of a projective and unpredictable mass collective action based on communities of users on the network.

It is necessary for information design to understand both, the processes present in the semantic web -as an environment in which all traceable information (pages, files, images, links…) can be associated to specific metadata able to individualize context and to construct a network of multipertinence for each piece of information- and the new forms of creation of ontologies, understood as structures able to maintain all entities in hierarchical relation (Nirenburg and Raskin, 2004).

Both dimensions directly relate to the core of design strategies. On the one hand, because information design faces the same complex situations that are experienced by the rest of social sectors and thus is challenged to broaden its capacity of translating complex information structures and hierarchies into a bottom-up approach to knowledge. This challenge is mostly addressed specially to the areas of conceptual planning and technical implementation. In so doing information design could transform actual hierarchical structures, present in the very categories and relations used in traditional ontologies, into flexible bottom-up forms of data classification able to contaminate the whole system, redistributing itself and remapping its own schemas and questions.

In synthesis, such bottom-up approach supposes a change from a paradigm dominated by ontologies into one in which non-lineal folksonomies are central and social actors and society shape and classify knowledge. In this scenario information design can find a concrete space of agency, in special, assuming the role of mediator between that emerging social media and society. This implies translating the social trends into information frameworks to improve social collaboration.

That can be achieved by (1) establishing a project’s rhetoric that fosters the dialogue between social and technical tissues. This requires to develop research that is focused on the articulation of social-technological dimensions; (2) developing more suitable prostheses, more versatile instruments and simpler technologies; (3) being aware of the responsibility that is in the hand of information design to define and discriminate what can start any grid of the shareable knowledge; (4) learning to listen and to be supportive of social processes.

That is a moment of great responsibility and extraordinary opportunity to perform the transit between different conceptions of social information and knowledge. Information design should consider at least these three different dimensions of the actual scenario: (1) how people feel in relation to knowledge (immersed)"; (2) how knowledge is constructed (bottom-up), and (3) what can be included in the process of electronic knowledge (contents, objects, environments, products, etc.).

This challenge can help society to find new ways to create information online: it can redefine systems in order to serve society to create social deals and offer a totally bottom-up knowledge toolkit to empower people.

Author Biography

Matteo Ciastellardi

Senior Researcher in the IN3 (Internet Interdisciplinary Institute - Universitat Oberta de Catalunya), Barcelona. Ph.D. in Industrial Design and Multimedia Communication (Politechnic University in Milano). Bachelor in Theoretical Philosophy (University of Studies, Milan, 2005). Adjunct Professor for the course “New Languages in Information Science”, University of the Studies of Milano. Assistant professor at the University of Studies of Milano for the Hermes_Net Laboratory (telematic course for theoretical writing).

Derrick de Kerckhove

Director of the Research Line Digital Culture, IN3 (Internet Interdisciplinary Institute - Universitat Oberta de Catalunya), Barcelona; Director of the McLuhan Program in Culture and Technology, University of Toronto; Professor in the Department of French at the University of Toronto, and Professor in the Faculty of Sociology at the University of Naples Federico II; Ph.D in French Language and Literature (University of Toronto, 1975); Doctorat du 3e cycle in Sociology of Art (University of Tours, France), 1979.

Cristina Miranda de Almeida

Artist, Architect and Urbanist, Teacher and researcher in the University of Basque Country in Graduation and Doctorate Courses; External Collaborator at IN3 (Internet Interdisciplinary Institute - Universitat Oberta de Catalunya), Barcelona. European PhD in Arts (University of the Basque Country, Spain); Postdoctorate Degree (Advanced Research Associate at the Planetary Collegium, University of Plymouth, U.K); Master in Industrial Design (DZ-BAI Berrikuntza Agentzia); Specialization in Territorial Planning and in Town Planning, (IBAM, Rio de Janeiro, and Fundicot, Madrid).

Dynamique des ambiances lumineuses par relevés vidéo d'espaces de transition

Mathieu Coulombe, Université Laval, Canada, mathieu.coulombe.1@ulaval.ca

Claude MH Demers, Université Laval, Canada

André Potvin, Université Laval, Canada

Abstract

Natural light characterizes architecture in a complex manner, especially when considering its fluctuations and variations whenever we experience a transition or passage from a space to another. It also influences the comfort and the well-being of its occupants. This visual adaptation appears in a process that is translated into a spatio-temporal dynamics implying body movement from space to space. The literature review recognizes the lack of knowledge in the relation light-space-time. This research proposes to study this spatio-temporal relation existing between light and architectural space, to qualify an architectural *promenade*. It proposes to reconsider the design of transitional spaces by the spatio-temporal analysis of light, through *in situ* experimentation including filmic segments. The studied variables of this research take into account the qualitative and quantitative aspects of light such as luminance, time, contrast and brightness. It combines the use of a luminance-meter, a camcorder and the analysis of numerical images as a starting point for the assessment of spatio-temporal qualities of light. The resulting analysis, as well as the visualization of the dynamic experience of visual ambiances, will allow a classification of luminous transitional experiences. The architectural *promenade* is analyzed according to the diversity and relative intensity of luminous ambiances in relation to time, which allows the development of a descriptive analysis of visual perceptions through spatial transitions. This method of analysis and dynamic representation offers a potential to favour the design of spaces while encouraging and applying principles of luminous diversity in architecture.

Transitional spaces, contrast, video, images analysis, visual adaptation, Light, daylighting

Résumé

La lumière naturelle dans un bâtiment avec ses fluctuations et ses variations lors du passage d'un espace à un autre, caractérise de manière complexe, mais importante le design d'un bâtiment. Elle influe sur le confort et le bien-être de ses occupants. Cette adaptation visuelle s'inscrit dans un processus qui se traduit par une dynamique spatio-temporelle impliquant le mouvement du corps d'un espace à un autre. La littérature fait état du peu de connaissances en ce qui a trait à la relation lumière-espace-temps. Cette recherche propose donc d'étudier cette relation spatio-temporelle existant entre la lumière et l'espace architectural, afin de qualifier un parcours architectural. Elle propose de reconsidérer le design des espaces transitions, par l'analyse spatio-temporelle de la lumière, au moyen d'une expérimentation en milieu *in situ* et de segments filmiques. Les variables étudiées lors de cette recherche prennent en compte les aspects qualitatifs et quantitatifs de la lumière tels que la luminance, le temps, le contraste et la brillance. Elle combine l'utilisation d'un luminance-mètre, d'une caméra vidéo et d'une méthode d'analyse d'images numériques comme point de départ pour l'évaluation des qualités spatio-temporelles de la lumière. L'analyse résultante ainsi que la visualisation dynamique des ambiances lumineuses permettent une classification des ambiances lumineuses. Le parcours architectural est analysé en fonction de la diversité et de l'intensité des ambiances lumineuses en fonction du temps, ce qui permet de développer une analyse descriptive des perceptions visuelles d'espaces transitions. Cette méthode d'analyse et de représentation dynamique offre donc un potentiel aux concepteurs désireux d'enrichir le design d'espaces en favorisant la diversité lumineuse dans l'expérience architecturale.

Mots clefs

Espaces transitions, contraste, vidéo, analyse d'images, adaptation visuelle, Lumière, éclairage

Le design d'un espace éclairé naturellement tient à la fois compte de la performance énergétique du bâtiment, mais considère également de la recherche de confort visuel pour ses occupants. Par contre, le design en relation à la lumière naturelle demeure l'un des champs de recherche les moins développés en ce qui a trait à l'analyse qualitative de l'environnement intérieur en relation à des données quantitatives. Par exemple, le facteur lumière du jour (FLJ), largement utilisé pour caractériser les espaces éclairés naturellement, est maintenant reconnu comme mesure déficiente autant d'un point de vue qualitatif que quantitatif [1]. Les défis reliés au design de bâtiments éclairés naturellement dépendent donc de la capacité des architectes à optimiser la performance et le confort visuel des espaces. Cette optimisation doit prendre en considération que la perception de l'architecture se vit notamment par la dimension spatio-temporelle de la lumière naturelle impliquant le mouvement. En ce sens, les espaces de transition sont des lieux privilégiés en architecture puisqu'ils permettent d'expérimenter la diversité de la lumière lors de transitions lumineuses, permettant l'adaptation visuelle des usagers. En effet, s'ils sont bien conçus, ces espaces transitions servent à expérimenter les seuils de caractéristiques lumineuses particulières et provoquer des situations complexes et visuellement stimulantes de diversité environnementale. Les espaces de transition peuvent prendre plusieurs formes et accueillir plusieurs usages, tels foyers, lobbies, atriums, corridors et tous les autres espaces où les gens circulent entre l'intérieur et l'extérieur [2]. Le seuil entre deux espaces devient donc un élément fondamental dans le potentiel expérientiel, car il peut s'exprimer de façon graduelle ou soudaine, rendant la transition plus ou moins confortable. Ce type d'endroit constitue un lieu d'étude important afin de comprendre le processus de perception et d'adaptation visuelles. Si celui-ci est fortement étudié en relation à la notion de temps, peu de recherches ont été développées afin d'étudier le comportement lumineux de manière dynamique. Alors que la photographie, le film, l'architecture et les arts ont toujours reconnu la nature dynamique de la lumière et ses qualités, la communauté scientifique a tenté de simplifier cette relation, en n'arrivant toutefois à aucun modèle suffisant pour supporter l'analyse dynamique de la lumière en architecture. Cette recherche se veut donc une nouvelle approche dans l'analyse de la lumière naturelle, reconnaissant sa nature dynamique dans le contexte d'un parcours architectural, et ciblant de manière expériencielle l'analyse de l'environnement visuel d'un occupant. Les auteurs proposent la mise au point d'un outil d'analyse vidéo qui permettra d'évaluer et de caractériser la qualité lumineuse de façon dynamique des espaces de transitions, et ce, dans le but d'alimenter le processus décisionnel en phase préliminaire de design. Elle s'inscrit dans une volonté d'approfondir les connaissances sur la dynamique des ambiances lumineuses architecturales, un domaine encore peu étudié puisque les paramètres impliqués dans les phénomènes de transition, de perception et de lumière naturelle sont multiples. À cet égard, la méthode digitale proposée permet de simplifier le processus d'analyse et de représentation de ce phénomène complexe.

Lumière, architecture et mouvement

Lorsque nous regardons le monde qui nous entoure, la lumière qui entre par la pupille passe au travers une série de processus mentaux qui convertissent le patron visuel en une perception du monde comme nous le connaissons [3]. Ainsi, ce patron visuel n'est pas statique, mais il est continuellement en mouvement [4]. En fait, Arnheim [5] décrit l'architecture dynamique par : "The visitor experiences not only a sequence of sights but the constant gradual transformation created by perspective and lighting in every wall and constellation of elements" (Arnheim,R.,1974, p.11). L'architecture dépend donc littéralement de la lumière, qui révèle la forme, l'espace, et simultanément dévoile le sens et les intentions qu'ont imaginés les architectes lors de la conception. La lumière peut améliorer l'expérience de l'architecture, en dévoilant la structure, les matériaux, les textures afin de permettre l'orientation, le focus et l'expérience du temps. Le résultat d'une interaction entre une ou des lumières, un individu, un espace et un usage peut ainsi être décrit comme une ambiance lumineuse [6]. Cette interaction influence momentanément ou durablement la perception du lieu éclairé [6]. La caractérisation d'une ambiance lumineuse est complexe, car elle fait intervenir divers paramètres physiologiques, psychologiques et culturels. L'éclairage à l'origine de ces diverses ambiances lumineuses se mesure grâce aux valeurs photométriques (intensité lumineuse, éclairement, luminance, uniformité, contraste). Par contre, la mesure des ambiances lumineuses fait intervenir des éléments de perceptions plus subjectifs qui font appel à l'appréciation individuelle [6].

Afin de qualifier et quantifier cette perception lumineuse, il est généralement admis d'utiliser une sonde photométrique qui mesure la luminance à certains points de l'espace [7,8]. Ces types de mesures statiques constituent un frein à une compréhension de la lumière comme phénomène dynamique, car elles ne permettent pas une visualisation de l'interaction de la lumière avec l'espace. Déjà en 1980, Derrick Kendrick énonçait l'importance de considérer le rôle prépondérant de la nature dynamique de la lumière naturelle dans un bâtiment [9]. Alors qu'en 1997, Fontoynont soulignait que nous atteindrions les limites des représentations statiques en lien avec la nécessité de représenter l'usager en interaction avec son environnement [10]. En ce sens, la lumière naturelle est une lumière très variable qui peut atteindre sur la façade d'un bâtiment, 100 000 lux par journée ensoleillée et diminuer à quelques centaines de lux lorsque le ciel est couvert [11]. Généralement, lorsque la fréquence et l'écart entre les changements de stimulus dans la distribution lumineuse sont trop élevés, l'œil ne suffit pas et s'en suit une confusion dans l'analyse de l'espace. Ceci peut causer : l'échauffement et l'écoulement des yeux, des douleurs, des maux de tête, des migraines, de la confusion perceptuelle et des étourdissements [7,12]. La présence de la lumière naturelle dans un bâtiment avec ses fluctuations et ses variations lors du passage d'un espace à un autre caractérise le design d'un bâtiment ainsi que le confort et le bien-être de ses occupants. Dans un parcours architectural, les variations temporelles et visuellement perceptibles de la lumière qui sont dépendantes du design du bâtiment sont considérées dans le cadre de cet article comme étant des dynamiques lumineuses. Dans ce contexte, les architectes doivent être conscients du rôle qu'ils occupent dans la conception d'espaces qui sont soumis à cette dynamique lumineuse [7].

Il paraît alors improbable d'arriver à une définition d'un espace durable d'un point de vue de la qualité lumineuse en utilisant des facteurs mathématiques qui ne tiennent pas en compte la perception de l'espace. L'adaptation visuelle peut être définie comme étant le changement de sensibilité à un patron lumineux résultant d'une exposition prolongée à ce même patron [13]. Par conséquent, l'habileté avec laquelle les individus s'adaptent aux conditions dynamiques de la lumière est très importante [7,13]. En fait, nous nous basons principalement sur la perception visuelle de l'espace lorsque nous nous déplaçons dans un environnement, car, le système visuel est plus sensible aux changements qu'aux conditions stables [14]. Le mouvement et la vitesse sont des paramètres qui influencent grandement notre perception de l'environnement. Ceci est observable, non seulement selon des caractères spatiaux, mais aussi selon le temps [15]. La vidéo constitue de nos jours, une méthode de représentation des espaces qui se rapproche le plus de la réalité perceptuelle des usagers. En effet, elle permet de comprendre l'espace dans son ensemble, d'avoir une représentation des textures, des luminances (horizontales et verticales), des contrastes, et ce, modulé dans le temps. L'analyse de la vidéo, comme outils de représentation et d'analyse de la lumière, permet ainsi une simplification de la représentation et de l'analyse. De plus, contrairement à la photographie, ce médium offre l'avantage d'un continuum de prises de vue (30 images par secondes), et ce, sans interventions manuelles du cameraman sur les paramètres d'une scène (ouvertures, temps d'exposition, etc.). Ces paramètres automatisés par la caméra, donnent la possibilité d'enregistrer de façon presque impersonnelle une progression dans un espace. La prise de relevés vidéo suggère aussi la potentialité d'aborder la problématique selon une approche d'analyse spatiale différente qui tient compte des aspects qualitatifs (l'image) et des aspects quantitatifs (les valeurs numériques des pixels).

Cette recherche, propose l'intégration des variables qualitatives par l'analyse numérique d'images vidéo et des variables quantitatives qui peuvent y être extraites par la corrélation avec la luminance, le temps, le contraste et la brillance.

Méthode

Le développement des technologies numériques, de nos connaissances sur les espaces transitions ainsi que l'utilisation maintenant courante de la vidéo numérique rendent la création d'une interface d'analyse de l'image en mouvement possible. La méthodologie la plus appropriée pour étudier un phénomène complexe, comme le sont les ambiances lumineuses dans les espaces transitions, est une évaluation impliquant un relevé in situ [16]. Fondamentalement, la méthode consiste à utiliser la caméra vidéo digitale, de filmer un parcours *in situ* et d'en étudier les images calibrées résultantes afin d'en faire un schéma des caractéristiques lumineuses.

Le bâtiment à l'étude est le séminaire de Québec, situé en plein cœur du quartier historique de la ville de Québec. Il est considéré comme l'un des plus anciens en Amérique du Nord et comporte des caractéristiques spatiales particulières. En effet, il est constitué d'une façade possédant un albédo très élevé, des murs très épais (0,75 m.

à 1 m.), une variété élevée de types d'ambiances lumineuses, un hall d'entrée complètement fermé avec peu d'ouvertures ainsi qu'une fenestration répétée qui rythme la façade. Les relevés, présentés aux figures 2 et 3, ont eu lieu le 27 septembre 2009, à 12h00, par une journée de ciel complètement dégagée, afin d'éliminer les variabilités occasionnées par des passages nuageux. Cette date correspond, à la journée la plus près de l'équinoxe d'automne, soit lorsque le centre du Soleil est exactement à la verticale d'un point de l'équateur de la Terre. Cette évaluation *in situ* comporte trois grandes étapes décrites subséquemment, soient :

— Repérage (Prise de données quantitatives)
— Tournage de la Séquence filmique (Prise de données qualitatives)
— Analyse des données

Le repérage (Prise de données quantitatives)

Cette étape consiste principalement à établir un parcours architectural qui débute à l'extérieur du bâtiment à l'étude, se poursuit dans l'espace transition, pour se terminer à l'intérieur du bâtiment. Ce parcours est établi dans le but d'obtenir le plus de variabilité d'ambiances lumineuses. Les figures 2 et 3 démontrent le parcours établi dans le cadre de cette étude entre le point A, situé à l'extérieur du bâtiment et le point F, situé à l'intérieur du bâtiment.

Une fois ce parcours établi, il est alors possible de déterminer les endroits de faible et de forte luminance tout au long du parcours. Cette étape fait intervenir l'utilisation d'un luminance-mètre afin de calibrer ultérieurement les images vidéo en fonction de leurs luminances, une donnée qui permettra de quantifier les brillances relatives dans le champ visuel des images. La luminance d'une source est le rapport entre l'intensité lumineuse émise dans une direction et la surface apparente de la source lumineuse dans la direction considérée, cette mesure s'exprime en candélas par mètre carré (cd/m^2) [17]. Les données de brillance des images seront utilisées pour mesurer le contraste entre des éléments du champ visuel, ainsi que le contraste globalement perçu entre deux espaces. Il s'agit de sélectionner dans la scène, deux zones, une sombre et une seconde plus brillante, tel qu'il est illustré par la figure 1. Il est important de choisir ces zones de tailles raisonnables, d'une luminance constante, utiles et facilement identifiables au sein de l'image. Il s'agit de prendre la luminance de ces zones, les enregistrer et de noter l'endroit exact de la prise de mesure.

Tournage de la Séquence filmique (Prise de données qualitatives)

La seconde étape consiste à filmer le parcours architectural à l'aide d'une caméra vidéo numérique. Cette étape est relativement simple, mais nécessite tout de même une grande rigueur dans sa planification. En effet, bien que la majorité des caméras numériques soient dotées de stabilisateurs d'images intégrés, il est important d'optimiser la stabilité de la caméra, afin d'obtenir une image de plus grande qualité [18]. De plus, le tournage doit s'effectuer avec un pas régulier et standard d'environ 1m/sec [19], afin de représenter le déplacement de la majorité des usagers. Puisque cette recherche se veut également quantitative, le réglage d'exposition automatique intégré à la caméra sera utilisé pour effectuer la prise de données et l'interprétation de la brillance. La brillance d'une image correspond à la luminosité d'une scène qui est un attribut d'une sensation visuelle selon lequel une surface paraît émettre plus ou moins de lumière [20]. À cet égard, il est important de rappeler que l'œil humain possède un temps d'adaptation visuel différent de celui du système numérique utilisé. En effet, dans le diaphragme mécanique, le temps d'adaptation à la lumière pour rendre efficacement une scène s'établit en fractions de secondes comparativement au système rétinien qui prend plus de temps à effectuer le même travail. L'adaptation complète de l'œil passant de la lumière du soleil à des luminances intérieures cent fois plus faible demande environ 20-30 minutes, bien que 70% de l'adaptation soient réalisés après 90 secondes [21]. Mais si l'espace intérieur est éclairé naturellement, l'adaptation y est deux fois plus rapide. De plus, le temps d'adaptation varie d'un individu à un autre [13-21]. Il est aussi possible d'établir que chaque caméra numérique possède un système de capteurs de la lumière différent. Dans le cadre de cette recherche, les auteurs énoncent l'hypothèse que la caméra vidéo représente un système d'adaptation lumineux parmi ceux de l'œil humain.

Analyses des données

Bien que la brillance d'une image soit un phénomène à première vue subjectif, il est par contre possible d'établir une relation entre la luminosité d'une image et la luminance qui elle, est quantifiable [22]. Cette recherche se base principalement sur une méthode qui intègre le contraste et la luminosité afin de permettre un classement lumineux qualitatif et quantitatif de la vidéo. Pour ce faire, la vidéo est alors traitée à l'aide du logiciel ImageGrab41fr. Ce logiciel permet d'extraire des images d'une vidéo tout en conservant les propriétés de luminosité et de contrastes. L'expérimentation requiert l'extraction d'une image toutes les secondes, ce qui équivaut à 1 mètre de distance parcourue, la vitesse de marche étant de 1 mètre par seconde. Une fois ces images obtenues, elles sont alors traitées par automatisation à l'aide de la fonction traitement par lots dans le logiciel Photoshop. Cette automatisation consiste en un changement de la dimension des images à 320(w) x 240(h), la transformation de l'image à l'aide de la fonction isohélie en 5 tons de gris puis finalement de sauvegarder l'image en format RAW. La transformation d'une image en cinq (5) tons de gris permet une décomposition en cinq (5) zones (0 %,25 %,50 %,75 % et 100 %) de la luminosité. Ceci a pour effet d'abstraire une certaine réalité perceptible pour se concentrer sur la composition lumineuse de l'image [22]. L'ensemble des images est par la suite, modifié en utilisant le logiciel Rascal, qui permet l'extraction des valeurs de chaque pixel en valeurs numériques. L'ensemble des valeurs numériques des images est alors analysé par le tableur Excel Culplite qui permet d'attribuer une valeur de luminance à une valeur numérique d'un pixel [23]. L'utilisation de ce processus permet donc l'établissement d'un rapport entre la luminosité d'une image et la luminance mesurée en milieu réel à l'aide du luminance-mètre. L'image résultante est donc calibrée en fonction de la luminance.

Cette série d'images est alors évaluée en fonction des valeurs de la moyenne et de l'écart-type des valeurs des pixels extraites des images. Ce type d'évaluation de l'image est possible en regardant l'évolution de l'histogramme d'une image. La mesure du contraste, qui correspond à une évaluation de la différence de deux ou plusieurs parties du champ observé, peut être extrapolée en utilisant les valeurs de l'écart-type dans cet histogramme alors que la moyenne des pixels d'une image représente la luminosité [24-25]. Les données obtenues par le biais du logiciel Adobe Photoshop et celles de l'analyse des images faite par Culplite sont utilisées pour générer la valeur correspondante à la valeur de la moyenne de l'image (brillance) et celle de l'écart-type (contraste) en cd/m². L'ensemble de ces données est compilé sous forme d'un graphique (voir figure 1), qui exprime l'évolution de la brillance (luminance) et du contraste d'un parcours architectural en fonction du temps.

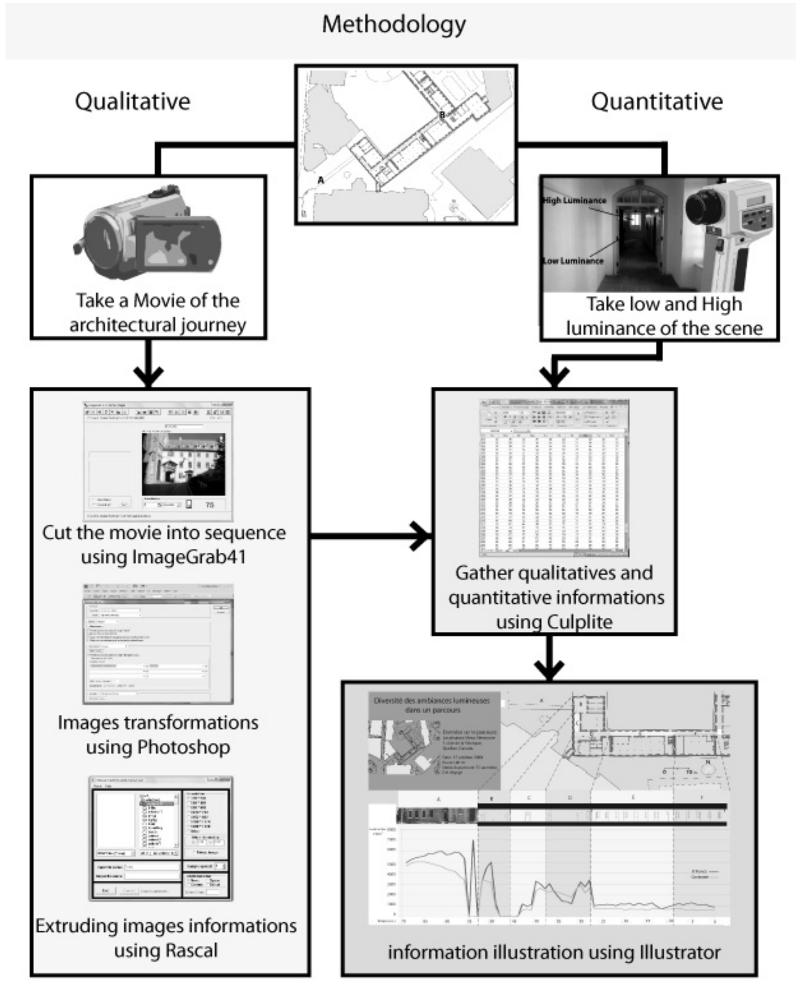

Figure 1 : Méthode d'acquisition de la dynamique des ambiances lumineuse.

Analyse des résultats

La figure 2 illustre la variabilité des ambiances lumineuses dans le parcours architectural effectué de l'extérieur vers l'intérieur, entre le point A et le point F alors que la figure 3 représente un parcours en sens inverse, soit de F vers A. Le parcours a été effectué dans les deux sens afin de comparer la perception lumineuse d'un même espace, mais avec une orientation différente.

L'évolution des valeurs de brillance et de contraste dans la section A, B et C des figures 2 et 3, permet de représenter la relation intérieure-extérieure de manière graphique et offre une analyse globale du phénomène complexe de transitions-espace-lumière. En effet, ces sections du parcours représentent la principale zone d'adaptation lumineuse lors d'un passage entre l'extérieur et l'intérieur. Ces portions du parcours démontrent une plus grande variation dans l'évolution des valeurs de brillance et de contraste, comparativement à la suite du parcours. Si on se réfère à la définition de l'adaptation, laquelle indique un changement de sensibilité à un patron lumineux résultant d'une exposition prolongée à ce même patron [13], l'œil devrait donc s'adapter, dans cette section du parcours, à un grand écart de luminosité et de contraste.

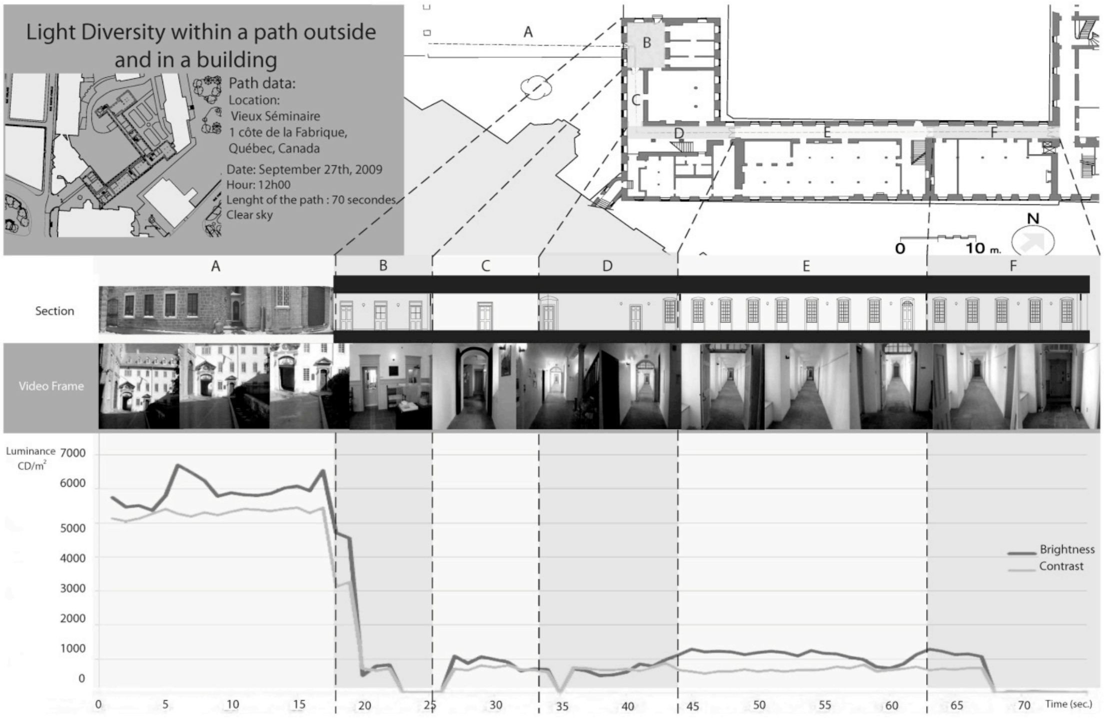

Figure 2 : Distribution de la luminosité et du contraste selon le temps dans un parcours architectural de A vers F.

Les figures 2 et 3 démontrent également que la brillance et le contraste dans les images du parcours varient en fonction du temps. En effet, dans la figure 2, on peut apercevoir que dans l'espace A, bien que nous circulons dans un même espace, nous observons une variation de la brillance et du contraste dans le temps. Les valeurs des moyennes de la brillance des images varient de 6490 cd/m² à 7 secondes, 5800 cd/m² à 11 secondes, à 6555 cd/m² à 17 secondes et 4720 cd/m² à 18 secondes. Ces variations sont trop importantes pour qualifier qu'une seule ambiance lumineuse. On peut donc avancer l'hypothèse que cet espace pourrait contenir 4 ambiances lumineuses différentes. Celles-ci correspondent aux deux pointes, à 7 secondes et 18 secondes, de la courbe de la brillance en fonction du temps dans la section A de la figure 2 et aux deux plateaux qui sont observés respectivement entre 1 et 7 secondes et entre 8 et 18 secondes. Les données précédentes démontrent donc que la variabilité des ambiances lumineuses dans un même espace est importante et qu'elles sont modulées et réparties dans le temps. On peut observer également ces variations avec des intensités et des durées variables dans l'ensemble des autres espaces (B,C,D,E,F) des figures 2 et 3.

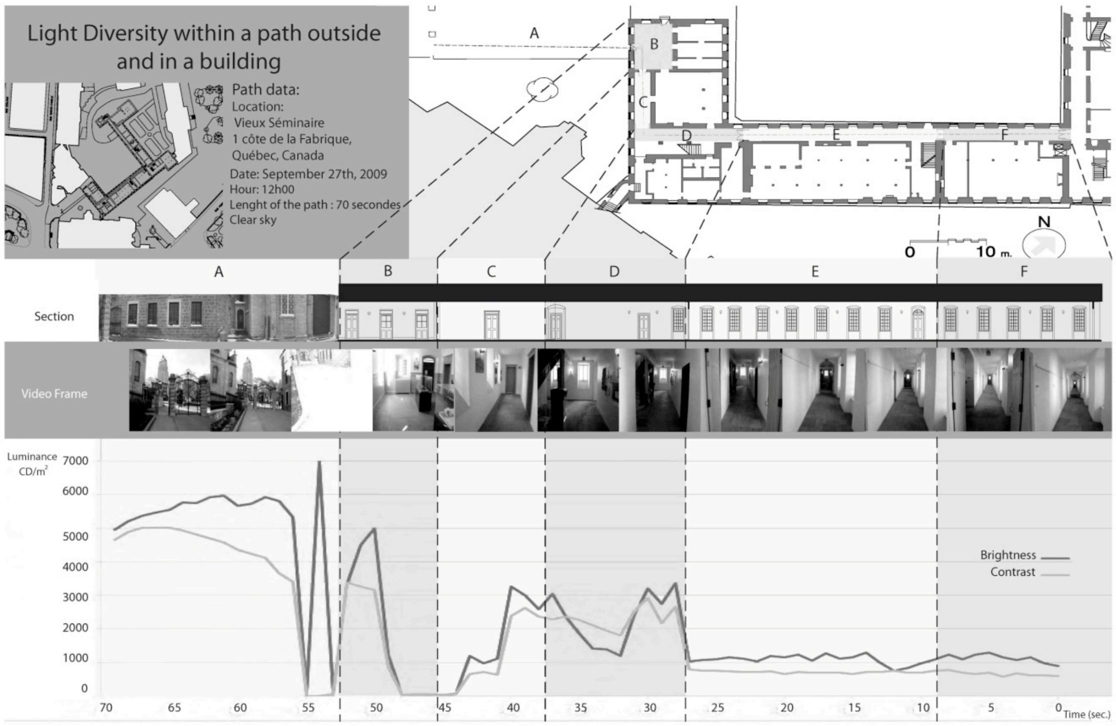

Figure 3 : Distribution de la luminosité et du contraste selon le temps dans un parcours architectural de F vers A.

Dans le relevé présenté, cette adaptation est vécue différemment que l'on sorte (figure 4) d'un bâtiment ou que l'on y entre (figure 5). Ce phénomène peut s'expliquer en étudiant les limites du système visuel lorsqu'il est soumis à des différences de luminosités et des contrastes élevés [7, 21]. Ces situations ont tendance à être plus fréquentes lors de l'entrée et la sortie d'un bâtiment [7,21]. Il semble y avoir un consensus dans la communauté scientifique sur le fait que le processus d'adaptation de l'œil fait intervenir des cellules spécialisées distinctes en conditions de faible et de haute luminosité [21]. Les cônes sont constitués des cellules sollicitées par des luminances élevées alors que les bâtonnets le sont lors de luminances faibles. Cette distinction physiologique amène une discrimination importante dans la perception de l'espace [21]. De par leur évolution, les cônes procurent un meilleur rendement visuel, tant à ce qui a trait aux luminosités, qu'aux contrastes et aux perceptions de l'espace [12-26]. Par contre, les bâtonnets sont plus limités dans la perception des couleurs, des nuances de contrastes et offrent un rendu de l'espace moins performant [21]. La figure 2 illustre que le passage d'un environnement où les luminances moyennes enregistrées sont de l'ordre de 6560 cd/m² à 17 secondes, à un environnement où celles-ci sont de 22 cd/m² à 22 secondes, implique un ratio correspondant à 1 :300 ce qui est drastique. Lors de cette transition, l'œil doit faire le relai entre l'utilisation des cônes, qui sont sollicités à l'extérieur, vers les bâtonnets qui sont utilisés en luminance faible [21]. Ce phénomène amène la perte momentanée d'informations spatiales, qui se traduit par un *black-out*.

On parle alors d'effet de *black-out,* c'est-à-dire d'une perte d'informations dans la lecture spatiale de l'environnement créée par un effet d'éblouissement qui se traduit par la perception d'un environnement beaucoup plus sombre que la réalité. La figure 4 représente l'effet du *black-out* qui a lieu lors de l'entrée dans le bâtiment. La première image représente la façade du bâtiment avec un albédo élevé et où l'œil offre un rendu convenable de la scène alors qu'à la lecture de la seconde image, la scène semble être inexistante dans la partie de droite de l'image. L'image démontre une faible luminosité ainsi qu'un faible contraste (image tirant sur le noir). Il s'en suit une perte de la lecture de l'espace qui est retrouvée par un rendu convenable de l'espace dans la dernière image.

Figure 4 : Images représentant la séquence d'entrée du bâtiment et l'effet *black-out.* 4 a) extérieur au t = 17 secondes et avec une luminance moyenne de 65600 cd/m², 4 b) phénomène du *black-out au t = 20 secondes* et avec une luminance moyenne de 740 cd/m², 4 c) espace transition constitué par le hall d'entrée au t = 22 secondes et avec une luminance moyenne de 22 cd/m².

À l'inverse, la figure 3 illustre le passage d'un environnement où les luminances moyennes enregistrées sont faibles (41 cd/m² à 54 secondes), à un environnement où celles-ci sont dites élevées (5300 cd/m² à 57 secondes). Lors de cette transition, le système d'adaptation de l'œil passe donc du système utilisant les bâtonnets au système utilisant les cônes ce qui génère la perte momentanée d'informations spatiales. On parle alors d'effet de *white-out,* c'est-à-dire d'une perte d'informations dans la lecture spatiale de l'environnement créée par un effet d'éblouissement qui se traduit par la perception d'un environnement beaucoup plus brillant que la réalité. La figure 5 illustre l'effet de *white-out*, qui se traduit par une surexposition de la luminosité et une perte du contraste dans l'image (image tirant sur le blanc). Ces phénomènes sont donc attribuables aux trop grandes différences de luminosité et de contraste qu'il y a entre l'intérieur et l'extérieur. Dans ce cas précis, la différence énorme provoque un éblouissement et une perte de la lecture de l'information architecturale pendant quelques instants (figure 5).

Figure 5 : Images représentant la séquence de sortie du bâtiment et l'effet white-out 4 a) intérieur au t = 52 secondes et avec une luminance moyenne de 1000 cd/m² 4 b) phénomène du white-out au t= 55 et avec une luminance moyenne de 7000 cd/m² 4 c) extérieur au t =57 et avec une luminance moyenne 5300 cd/m².

La figure 5a) représente l'étape initiale de l'effet d'éblouissement, où on peut bien comprendre la perte de la lecture d'information de la configuration spatiale dans la section de droite de l'image. La figure 5b), représente l'effet de la surexposition de l'image vidéo et de la grande brillance, rendant l'environnement avec une perception extrêmement lumineuse. Finalement, la figure 5c), illustre l'espace A, soit, l'extérieur du bâtiment.

La conception d'un espace de transition entre l'intérieur et l'extérieur pourrait donc traiter architecturalement ce type de seuil en ce qui a trait à la luminosité. On peut remarquer une variation importante de la luminosité aux limites des environnements terminés par des ouvrants, soient les portes. Ainsi, à la limite des zones A et B ainsi que B et C, des figures 2 et 3, il est possible de constater une variation importante dans la luminosité et le contraste suite à ces frontières spatiales. Cet effet est amplifié par le fait que l'espace transition est très opaque et ne possède que peu de continuité visuelle avec l'extérieur. Ce phénomène serait moins apparent, éclairage moins contrasté, si l'espace de transition comportait une plus grande continuité visuelle avec l'extérieur, c'est-à-dire plus de transparence dans l'espace de transition.

En comparant, la section D (figure 2 et 3) dans les deux parcours, il est possible de constater une différence dans les variations de la luminosité et du contraste. La façon de percevoir cet espace lors de la migration de A vers F section D (figure 2) semble moins soumise aux variations dans la luminosité et le contraste que lorsque nous effectuons la migration inverse de F vers A section D (figure 3). Ce phénomène peut être aperçu à la figure 6 et s'explique par le champ visuel et la nature de la scène filmée. En effet, lors de la progression de F vers A section D (figure 3), il y a présence, au centre du champ visuel, d'un élément de transparence, une fenêtre, qui est absente du champ visuel lors de la progression de A vers F section D (figure 2). La moyenne de la brillance des images de la section D de la figure 3 est de 2200 cd/m² alors que celle de la section D de la figure 2 est de 664 cd/m². Le même espace est donc perçu avec une brillance de plus de 3 fois supérieures dans le parcours fait à la figure 3 que celui effectué dans le cadre de la figure 2. On peut conclure que la perception de brillance est dépendante des variables lumineuses présentes dans le champ de l'observateur en mouvement et qu'elle pourrait être étudiée architecturalement en modifiant la disposition des éléments de transparence pour minimiser l'inconfort visuel créé par une transition trop brusque entre deux espaces.

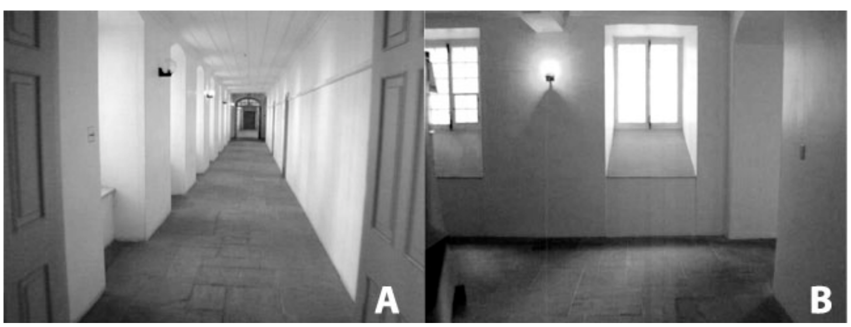

Figure 6 : Images représentant le champ visuel lors dans l'espace D. 6 A) lors de la migration de A vers F de la figure 2; 6 B) lors de la migration de F vers A de la figure 3.

Conclusion

Fondamentalement, la méthode utilisée dans le cadre de cette recherche consiste à utiliser la caméra vidéo digitale, de filmer un parcours *in situ* et d'en étudier les images résultantes afin d'en réaliser une représentation graphique des caractéristiques lumineuses. Les résultats indiquent que la diversité des ambiances lumineuses dans un parcours linéaire relativement « simple » est grandement supérieure au nombre d'espaces traversés. L'exemple présenté dans la section A de la figure 2 démontre, en effet, que 4 variations importantes de la brillance dans le temps ont été enregistrées dans 1 seul espace. De plus, la recherche illustre que l'adaptation lumineuse, lors du passage intérieur-extérieur d'un bâtiment, est vécue différemment que l'on y sorte (figure 4) d'un bâtiment ou que l'on y entre (figure 5). Ces variations dans la perception des ambiances lumineuses sont caractérisées par deux phénomènes, le black-out et le white-out. Ces deux phénomènes, démontrés aux figures 4 et 5, sont le résultat d'une grande différence dans la brillance des images successives et impliquent un ratio de brillance de l'ordre de 1 :300.

La comparaison entre la section D de la figure 3 et la section D de la figure 2 a permis de conclure que la perception de brillance est dépendante des variables lumineuses présentes dans le champ de l'observateur en mouvement. De plus, cette analyse a permis de constater que la perception lumineuse d'un même espace peut être expérimentée différemment selon la direction avec laquelle il est traversé. Il est alors promulgué qu'un même espace peut provoquer des perceptions différentes selon la position du champ de vision de l'observateur. Les auteurs sont conscients que le choix d'un autre bâtiment procurerait une expérience lumineuse différente. Dans cette optique, il serait alors possible d'étudier les transitions lumineuses dans un certain nombre de bâtiments afin d'en comparer les ambiances lumineuses lors de promenades architecturales planifiées en fonction du mouvement des usagers.

La relation de la brillance avec l'espace est proéminente quand il est question d'étudier les ambiances lumineuses. Le mouvement et la vitesse constituent des paramètres qui influencent grandement notre perception de l'environnement. En ce sens, l'utilisation de la vidéo implique non seulement la notion de temps, mais également la relation entre la représentation graphique et l'analyse. La lumière ne possédant aucune échelle, la méthode expérimentée *in situ* pourrait s'avérer très efficace dans le cadre d'une utilisation avec une maquette analogique, permettant de contribuer plus explicitement à la définition des ambiances dynamiques des espaces de transition.

Cette recherche vient appuyer le fait que l'expérience de l'architecture fait partie intégrante de la transformation constante et graduelle, créée par la perspective et la lumière sur un ensemble complexe de variables. Finalement, la création d'un espace devrait impliquer le mouvement des usagers, générant des espaces transitions adaptés à la complexité des ambiances lumineuses. Cette étude établit qu'il est dorénavant possible de qualifier et quantifier le caractère dynamique des ambiances lumineuses pour une promenade architecturale.

Abstract
The studies on consumption experience have gained force not only in the Marketing field but also in relation to the impact that design can have in the construction of those experiences. This paper discusses the role that Design can play in the construction of experiences perceived in road running activities. In order to do so, an exploratory study was conducted through the use of multiple techniques of data collection (in-depth interviews, desk research, and ethnographic essay). The results indicate that the experience generated by the running activity is strongly dependent on external agents, like sport consultancy services and competitions, being Design as an important factor to the promotion of sports practice and the constitution of consumption experience.

Keywords
Experience design; running; tribes.

The road running market[1] is a global phenomenon. Millions of runners practice this physical activity in parks, squares, and streets in big cities all over the world. More than a sport activity accessible to a great public for several reasons (easy to practice, no specific equipment required or no need for other participants), running has gained strength as the fastest growing sport in the world with very expressive figures in Brazil, too.

Practicing alone or in groups, runners have motivated the creation of an expressive number of competitions, from short distances (5km and 10km) to higher challenges (21,097km and 42, 195 km – half-marathon and marathon), or ultra-marathons as the Comrades in South Africa, with 89 km.

The evolution of the practice can be noticed by the impressive figures of the New York Marathon, with more than 100 thousand applications for 43 thousand allowed participants (AIMS, 2009). Marathons as Tokyo, Chicago, Berlin and Paris are big events that attract thousands of tourists and athletes, representing important dates on their tourist calendars. But, why does it happen?

We can speculate on some reasons for this trend, such as the increasing concern with sedentary life style and stress, typical of post-modern societies, or the search for a perfect body and the consequent elevation of self-esteem. However, which factors are really responsible for such figures?

In the 70s, there was a booming in jogging all over the world influenced by the work of Dr Kenneth Cooper and by the beginning of the increasing status of running as a healthy sport. In the USA, there were about 100,000 runners at that time, increasing to 30 million nowadays. In Brazil there is an estimative of 3 million daily basis runners[2], placing it as the second most popular sport in the country's biggest cities (São Paulo and Rio de Janeiro), being soccer the first one.

---

[1] According to the International Association of Atletics Federations (2009), road races are disputed in streets, avenues and roads with official distances varying between 5 to 100km.

[2] Daily basis runner is considered the one who practices this physical activity at least 3 times per week for 30 minute-lenght period.

Sports goods companies have invested huge amounts of money in the development and launching of shoes and accessories for running, focusing on lighter, more resistant to different kinds of ground and weather, and customized products for each type of runner, taking into consideration, for instance, their weight or the way they step and move when running. At the same time, the events organization related to running have multiplied and professionalized. In São Paulo, the biggest Brazilian city, there were 11 official competitions in 2001. In 2009, 174 competitions were carried out, or 3 competitions every weekend (Corpore, 2009).

Once it is realized the relevance of this sportive and social phenomenon, some inevitable questions come to mind: The increasing number of people practicing running is something spontaneous or created? What makes a strenuous and little stimulating activity into something attractive and capable of mobilizing crowds?

The discussion proposed by this paper is guided by these questions: is the experience of running something designed by others or is it something constructed by the user; how can Design influence the practice or the consumption of running; can the racing practice phenomenon be explained by the formation of a subculture proper of this kind of individuals that are sometimes organized in tribes; is the formation of tribes the result of projected actions by market agents? In order to discuss these points, it was defined as research goal the evaluation of experience design influence on consumer behavior of road runners in Porto Alegre, as well as on the tribe's formation process in this market.

The scope of Design action has been broadened since the original conception of product projecting to the constitution of offer and value to the user. Mitchell (1993) used to say that Design should not project only objects butalso functions, contexts of use, systems and environments. This conception is materialized through experience design, which has as its purpose not only in product development but also creating conditions to generate satisfactory experiences for the user.

Recent studies have tried to analyze the role of Design in the development of consuming experiences (Forlizzi, Di Salvo e Hanington, 2003; Freire, 2009), however, there are innumerous theory gaps in the area. In the next section the concepts of experience design will be detailed.

Experience Design

The experience theme has gained relevance in the field of consumer behavior since Holbrook and Hirschman's study (1982). Until then, the discussion about consume wouldn't explicitly consider the role of hedonistic and symbolic elements that products and services had on consumer perception. The authors highlight that there was a flow of fantasies, feelings and fun around consuming processes so far underestimated by organizations in the development of their offers and even when designing their products. Personal experiences would be the result of individual events, full of emotional meanings resulting from the interaction between user and a set of stimuli, either related to products, services, or communication.

Pine and Gilmore (1998) pointed out that the consuming in XXI century would be within the "experience economy", that is, the XIX century industrial revolution that attempted to implement standardization and mass production would be replaced by mass customization (products/services increasingly more adapted to individual needs and desires) which, in its turn, can be characterized by the search for individual immersion in consumer experiences instead of simply buying products or services.

In economies increasingly more dependant on services, the concern is to generate experiences based on the creation of environments capable of absorbing clients in a pleasant, memorable, and unique way, with services working as stages and products as supports (Pine e Gilmore, 1998; Schmitt, 2003). Lusch and Vargo (2006) point out that the dominant logic of services in national economies lead to a new consumer role in the purchasing and consumption process. A passive posture loses space to an individual in search of co-authorship in the creation of consuming value. There is no value in offers until they are used, and the experience is fundamental in determining it. Experience, in that sense, is not an accessory element to the consuming process anymore and it plays a leading role in the construction of value organizations. The consequence of this process is the change in the role of Design that in this new context is not an ability focused only at designing artifacts but to develop user experiences. The challenge is to be capable of generate not just everyday and satisfactory experiences, but outstanding ones. The cognitive psychologist Mihaly Csikszentmihaly says that activities that are intrinsically motivating[3] for the individual, that give pleasure in their accomplishment and take the user to a deep state of involvement and personal joy generate a state of mental flow and are essential for the constitution of outstanding experiences. When in this state, the feelings of pleasure and satisfaction are considered unique and can contribute for a bigger engagement in the continuous realization of a certain activity. The figure 1 shows the conditions for generating flow, which occurs when there is a higher level of challenge to be faced, demanding a higher degree of skill to be accomplished.

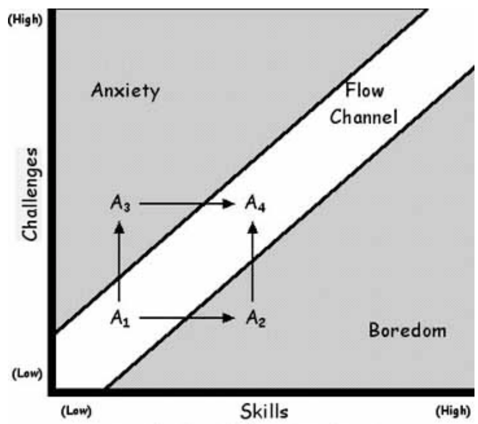

Figure 1. Conditions for the generation of Flow

Source: Csikszentmihaly and Csikszentmihaly, 1988.

Many authors have discussed the nature of consumption experience. Pullman and Gross (2004, p.551) indicate that the experiences are "inherently emotional and personal", and are dependant on individual factors like cultural background, previous experiences, mood and personality traits. Forlizzi, Disalvo and Hanington (2003) as well as Hekkert and McDonagh (2003) point out that experiences are unique, made of small experiences related to contexts, products and people, and the experiences themselves cannot be projected, only the situations of interaction with users.

Caru and Cova (2007) classify consuming experiences within a continuum, according to those responsible for their construction, as visualized in figure 2. There are, on one side, experiences oriented by consumers, which are organized by users and tend to be the result of everyday services and products sold by companies through traditional marketing approaches. On the other hand, there are experiences oriented by companies conceiving all the details of the projected experience, characterized by specific organizational efforts to generate immersion consuming contexts.

[3] Intrinsic motivation can be described for not be focused on the rewards from some activity, but as consequence of its involvement and effort. Extrinsic motivation occurs when an activity is just the way to reach some goal, generating more tension and stress for its achievement (Cszikszentmihaly and Csikszentmihaly 1988).

Fig 2. Continuum of Experience Consumption

Source: Caru and Cova, 2007.

The intermediate position in this context relates to experiences dependable on the construction by companies of an experiential platform as well as on the user's active participation in the development of his/her own experience. Therefore, the results of the projected experience are the outcome of co-authorship between organization and consumer. Playful activities like adventure tourism and cultural events are typically co-driven experiences.

According to McLellan (2000), experience design is intended to "orchestrate" experiences that are functional, engaging, attractive and memorable. It demands designing all the details of content and context for the user, seeking to generate emotional fulfillment and pleasure in use that enhance one's perceived experience (Kurtgozu, 2003). The scope of experience design is beyond the materialization of a service or a product; it is in the set of planning activities of processes and systems that support the occurrence of the experience, besides the earlier stages of its construction, like the full understanding of clients and production contexts.

Method

The study presented here sets out from a phenomenological approach and presents an exploratory character. To generate understanding about the road running market phenomenon it is used data triangulation by employing different approaches of data collecting. The development of a desk research about the running world, either from market data or studies from other academic research fields like Physical Education, Tourism, Marketing and Psychology was the starting point.. Secondary data collecting was carried out at running related institutions like Association of International Marathons and Distance Races (AIMS), International Association of Athletics Federations (IAAF), Corpore (Paulista Road Runners United), Associação dos Treinadores de Corrida de Rua de São Paulo (São Paulo Road Runners Instructors Association), as well as a large research in the different running specialized medias like magazines, sites and blogs.[4]

Primary data was collected through a set of audio recorded in-depth interviews based on semi-structured scripts with agents from this industry.

1. Corpore general manager: the biggest running group (9850 athletes) and the biggest competition organizer in Brazil.
2. Two directors from the biggest running training groups in the country (Run & Fun and MPR, with 1400 and 1300 enrolled athletes respectively).
3. Marketing directors from the two leading sports brands in the running world market.
4. Members from the media specialized in running (Runners World Brazil magazine, and Sprint Final newspaper).

[4] It's important to highlight that the data was collected in two Brazilian cities (Porto Alegre and São Paulo) due to the expressiveness of São Paulo market in the context of road running, being considered the city with the highest number of runners and running races in Latin America.

An ethnographic essay with one of the authors of a sports consultancy service company was developed in parallel, in which he was submitted to three training sessions of 60 minutes each, three times a week for 7 months. The criterions for choosing this company were the number of athletes participating (120 runners) and its structure level in relation to other groups in Porto Alegre. Besides the training, the researcher also took part in 5 annual competitions in the city, with distances of 5 and 10km, as well as of social activities with members of the running group. Notes were taken in field diaries throughout the study and photos were taken during the activities.

Data analysis was performed by the transcriptions of in-depth-interviews, and a content analysis was carried out about the collected material, that was evaluated in conjunction with other obtained data.

Results

The results of this study are presented in two parts: the description of the main agents in the running market, followed by the analysis of the influence of experience design over the consuming behaviour of road runners.

The market of road running in Brazil is made up by the following agents:

1. Runners
2. Sporting goods brands
3. Events organizers (private companies, running clubs, public sector)
4. Sport consultants or training groups
5. Specialized media
6. Business opportunity seekers
7. General public and family members

Unquestionably, the main agent of this process is the one that runs. For many reasons that will further be dealt in this paper, runners get interested in the running activity and in most cases start playing the sport independently. Running, just like walking, is the most accessible sport activity because it can be carried out alone, anywhere, and initially requires little investments. Some studies point out the factors that motivate people to choose running as a physical activity. According to Silva (2009), running improves the physical conditions of athletes (better fitness, less risk of cardiac diseases, weigh control and breathing capacity), the emotional and cognitive balance (stress reduction, better mood, higher self-confidence, enhanced learning, concentration and abstract reasoning), and the social skills (the need to belong to a group, make new friends etc.).

Although it takes little investments to go running, the role of sporting goods labels is more important than it seems. Brands like Nike, Asics, Mizuno and Adidas have noticed that the market of running has a high annual growth rate and that runners look for products that allow higher performance, regardless of their own performance level. Products range from foot wear, with improved technology to bring comfort, cushioning, resistance and stability, to training apparel crafted with smart fabrics that are light and moisture-wicking, and also accessories like heart monitors that measure speed, distance, calorie expenditure, with GPS sensors and other performance display features.

Running shoes are the flagship of brands. They have an outstanding role in the market since there are annual collections being launched globally that bring on technological advancements and are widely advertised in the specialized media (most of them publish running shoes profiles comparing brands, models and performance tests), as well as in the outlets and races sponsored by the labels.

A particular issue from the Brazilian running market is the relevance of the running groups or sport training consultancy services for influencing the runner behavior. There is no recent statistics of the share of runners market which hires this kind of service, but it's an important element to leverage the sport growth in the country. The running training groups, distinctively from the runners groups, are paid services which seek to become the sport experience more pleasure and comfortable. They are compound by training counseling before, during and after the exercise and races (including warm-up, stretching, massage, and hydration), customized training spreadsheets, tents and lounges for athletes in the race. The distribution of t-shirts for the members, the transportation for training in distant sites (most of the practices occur in parks and streets of the cities, according to a previously informed timetable), the race registration service, the web-based platform for communication between athletes and instructors, as well as the organization of running trips (especially for interesting races as prestigious marathons abroad) are extra services which differentiate the companies and the value perception of the runners (the basic cost for this services is US$ 80 per month).

Sports consultants (or running groups) offer services to two segments of the market: individual runners and corporations. Companies, with the objective of improving the health and lifestyle of their staff, have been hiring consultancy services to organize and assist their staff in running activities. Besides promoting fitness among the staff, this kind of initiative also improves corporative life.

The growth of Brazilian running market is due to an increasing number of races in a structured calendar, which can vary according to distances, courses and purposes. Competitions have been more professionally organized, which involves processes and services of advertising (mass and specialized media), application (mostly by the internet), the use of transponder timing systems (which are essential to measure the performance of athletes), the distribution of apparel sets (a numbered T-shirt is the basic item with a variation of accessories and toiletries), the setting of race courses, inspection, lightning, music etc. Application costs are also higher (ranging from US$ 20.00 to US$100.00 for each athlete), not only for restricting the number of participants but also for choosing a target public for the organizers. Races that are up to 13.1 miles have a number of participants that ranges from 2.000 to 15.000 in average.

Another interesting fact which regards to race events is that they are usually related to an issue, a project or a specific public. Besides being organized by their course length, races can be directed to females (Venus Circuit), Kids (Kids Run) or companies' running clubs (Corporate Run). They can be held in the evening, with a clubbing atmosphere (Fila Night Run, Poa Night Run), inside a factory around the assembly line (Volkswagen Run) or in fashion high streets. A common kind of race is the one in which athletes take turns allowing groups with different numbers of participants to run side by side, regardless the performance level of each runner.

Some elements that characterize the studied races are the great number of stands dedicated to sport consultants and running clubs. They usually provide support services to runners that take part in these clubs, like a place to keep their belongings, fruits and drinks. All participants of a running club wear the same apparel as a way of keeping unit, even when race organizers offer a specific T-shirt for the competition.

Analysis of Data and Findings

Considering the analysis of the context for the practice of road running, the guiding questions of this study about the role of Design (specifically experience design) in different forms of consuming associated to running can be discussed. The individuals who practice running were grouped in different segments according to their motivations. It became clear throughout the interviews with the specialized media and sport consultancy services that there are three runner profiles:

1. Group 1: formed by extremely competitive individuals seeking a superior performance. They participate of competition on a regular basis and are heavy users of related services and information.

2. Group 2: formed by individuals seeking a better quality of life. They participate of competitions for the pleasure of taking part in the event and, in some cases, for the challenge to improve performance. They often start practicing motivated by the possibility of being accepted in a social circle or because it is trendy, but as they get involved they realize it is an easy, pleasant and low cost activity.

3. Group 3: formed by individuals who are marginal to the market. They do not take part in competitions and are light users of products and services related to running.

The first group represents a very small percentage of the running population, but works as an aspiring element for the other participants, mainly for the second group. Group 2 has been responsible for market growth, influenced by the increasing number of runners in public places and by the growing number of competitions designed for beginners (5 to 10km).

Based on Csikszentmihaly's flow concept it is possible to notice that practicing running has distinct tones for each runner profile. For those who have as their aim the continuous improvement of performance, the imposed challenges demand the development of skills necessary to achieve their goals, forcing them to use all the necessary resources in order to be able to accomplish their goals. The use of sports advisory services, the constant search for information and the continuous investment in equipment and accessories to improve performance give support for the mental sate of pleasure to be eminent. Besides the elevation of challenge levels, diversity of stimuli has played a fundamental role for the designing of outstanding experiences. This can be confirmed by the constant innovation in the dynamics of competitions, either in racing circuits, services or available technologies for their occurrence. Another trend identified for competitive runners is the called *running tourism*, that is, competitions like the New York Marathon, or similar ones in Berlin, Buenos Aires, and Rio de Janeiro that have attracted tourists/runners willing to face new challenges and, at the same time, visit new places. Tourism agencies, hotels, and flying companies have designed services targeting these specific tourists who usually travel with other runners or with their families.

For individuals from group 2, the initial motivations for running are extrinsic, with goals not specifically related to the act of running. Because of the immersion in the running context, either inside of the structure of running clubs or advisory services or participation in competitions, the motivational nature is altered, and the pleasure and satisfaction with the activity comes naturally. The immersion process, according to Caru and Cova (2006), is not quickly or automatically established, it is progressive and can be accelerated according to the designing and management of services that compose the experience, either in terms of consultancy services or the organization of street competitions.

Running clubs play an important role in the promotion of the running practice because they are behavior inducers. When gathering people with different motivations, level of performance and different socio-cultural backgrounds but united around the same cause (running), the clubs produce positive reinforcements in the individual, like socialization, the necessary orientation for safely practicing the activity with less injury risks, comfort and support to allow for a carefree practice. It can be concluded that *flow* occurs in this context since consultancy services act as promoters of intrinsic motivation characteristics of this mental state and of extraordinary experiences.

Competitions, even if they are not common to all kinds of runners, play the role of generating constant challenges, which is essential for the arising of *flow*. Unlike other sports, road running is essentially a competition against ones own limits, not against other competitors. Competitions assume two responsibilities in relation to competitors: create opportunities to challenge their records and engage individuals in experience sharing communities, a central characteristic of consuming tribes (Cova and Cova, 2001).

There is evidence that runners who actively participate in the practice of running, either using consultancy services or taking part in competitions, tend to get a more significant involvement with sports practices. Stebbins (1992) reveals that the construction of a social identity is relevant for the individual because it creates a sense of fitting in, a valuable place in a social environment, a connection with others and a way to raise self-esteem. Shipway and Jones (2008), in a study on the experiences of the London Marathon participants, pointed out that only what is known as serious leisure can create a meaningful social identity. Since a social identity is created between runners, a new consuming tribe is constituted. According to criteria identified by Cova and Cova (2001), the four elements necessary to the constitution of a new tribe are: the everyday practice (regular training), locations (parks, streets), trends (increasing number of people practicing running) and gatherings (training sessions, competitions, social activities).

It is in this context that the formation of tribes occurs because, besides the natural obstacles to be overcome, the activities demand a high commitment and engagement. This is possible to notice on the structuring of the consultancy services with the institution of a standard uniform (usually a t-shirt), that reinforces the feeling of belonging to a group, sharing affinities and seeking common goals. The perception of the running competition itself is substantially altered when experienced independently and individually or in teams or groups sharing a minimally constituted identity. The group experience revealed itself as being more stimulating, promoting a longer involvement with the running practice (lower rates of quitters). Design can play an important role in the configuration of this projected experience, either in the constitution of services to stimulate the formation of groups or with tangible elements that reinforce the structuring of a collective identity (brand, uniform, communication, facilities).

When discussing the concept of experience design, it was possible to notice that the elements for its structuring, either for competitions or consultancy services, could be found in the constitution of content (central or auxiliary services offered by event organizers or teams), context (development of physical evidences) and processes (supporting systems that allow for advisory and competition operations). The challenge for the people responsible for it is the continuous generation of positive experiences. Not only this, but with an urge to continuously develop innovations that will characterize them as satisfactory and, if possible, extraordinary experiences.

Conclusion

It is possible to observe that the running activity is initially an independent, low-cost and an easy activity to practice by the participants. However, the construction of a more complex experience with the participation of other people and with specialized technical orientation from professionals of Physical Education and related areas brings other elements for the engagement with the sport. The formation of running clubs, with their own identification and sport consultancy service, as well as services like warming up, stretching, hydration, circuit definition, performance control, organization for collective participation in regional, national and international events, transform a consumer-driven experience into a co-driven one, that is, its fruition and development are equally dependent on the user and companies initiatives.

A good example of how organizations may constitute different experiences for a single runner is the realization of theme competitions in different formats, not only in the possibilities of participation (individual or teams) but also in terms of environments and possible external stimuli (Fashion Run, Corporate Run, Disney Marathon, Volkswagen Inside Run). More than just an event for runners, competitions are their goal because it is where they can break records, improve performance, socially interact and try new sceneries, like circuits, services and products offered by organizers and sponsors .

Initiatives in the developing of running related products reveal the efforts in the designing of experiences, like the partnership between Nike, the sporting goods manufacturer, and Apple in the launching of the Nike Plus system. The system integrates Nike running shoes and iPods, making it possible to monitor the runner’s performance, listen to music and participate in a Nike social network on the Web for athletes using the same technology, reinforcing the stimuli for the constitution of a community of users or sports practicing people with tribal characteristics (Cova, Kozinets and Shankar, 2007). Running is not an obstacle to be overcome and it acquires a social, entertaining and pleasurable character from products that free runners’ central activity from the fatigue, discomfort and sacrifice that they normally face.

This study made it possible to verify, from an approach of various perspectives of different participants in the industry, how the running consuming experience is constituted and the role design plays in the transformation of that experience into something more accessible to a common user, not restricting itself only to a performance athlete. The construction of consuming experiences less focused on the user sportive performance and more focused on the providing for their hedonic and functional needs is the fuel for the expressive growing of this market and highlights the importance of design in the constitution of services, experiences and products.

The study has focused on a minor portion of the running experience as consumption. Issues as runner perception process and its relationship with designed experience weren’t discussed on this article. These findings presented on this paper represent the first part of data analysis of this research project. Further data collection and analysis will be conducted focusing on the experience design methods and their application to the service industry.

Author Biography

Filipe Campelo Xavier da Costa

Coordinator and professor of Design Graduate Program of Universidade do Vale do Rio dos Sinos (Brazil), Filipe Campelo has Ph.D. in Business from Universidade de Sao Paulo focused in consumer behavior studies and specialization in Strategic Design. He has experience in Marketing, Consumer Behaviour and Design projects, doing research on experience and service design.

Celso Carnos Scaletsky

Dr. Celso Scaletsky is graduate in architecture at Universidade Federal do Rio Grande do Sul (1982), has a master degree at Modelisation et Simulation des Espaces Bâtis from Université de Nancy I (1999) and Ph.D. at Sciences de l'Architecture from Institut National Polytechnique de Lorraine (2003). He has experience in Architectural and Industrial Design projects. His investigation focuses on the first stage of the design process, more precisely on a kind of research called blue sky research. The blue sky research corresponds to a form of organization of references that are useful to the project. The aim is to identify trends for the development of new artifacts. Dr. Celso Scaletsky is the Undergraduate Design course coordinator and professor of Design Graduate Program of Unisinos Design School

Gustavo Daudt Fischer

Graduated in Advertising from UFRGS, and MA and Ph.D. in Communication Sciences from the University of Vale do Rio dos Sinos. Professor and researcher at the Design Graduate Program Unisinos, teaching courses in Digital Communications (which coordinated from 2004 to 2008) and Design and the expertise of Strategic Design and Graphic Design.

SCENARIO: The User profiles methods applied to Product Design

Dantas, Denise. Universidade de São Paulo (Brazil)

Abstract

This paper presents SCENARIO (System of Speculative Conception of New Environments related to the Individual and the Object), developed in the Ph.D. thesis called "Design future-oriented, focused on the individual and trend analysis",(2005). SCENARIO is a project instrument created with the objective to help the designer to comprehend both the profile and the user necessities, so that the former is capable of designing more adequate objects to the contemporary context. The objective is also to create conditions that allow the verification and validation of the designer's project proposal through the use of metaphors built on trend analysis. The project is composed of three phases: Phase 1 – Identity; Phase 2 – Projections and simulations; Phase 3 – a possible history. Considering theory references from psychology and anthropology, it discusses methods of data collecting and treatment using phenomenological reduction techniques and participative living. The result can be applied to the conceiving of objects more adequate to the necessities of contemporary users.

This research is based on the assumption that the complexity presents today, after so many changes in all segments of society in recent years. Nowadays the user-individual must be considered the centre of the whole projetual process and Design must consider its vocation for innovation and for the future. The approach utilized in this paper considers the object in its scenario and the individual as a character in this story, to be told using multidisciplinary elements which have their origin in psychology, design, marketing, anthropology and sociology. The second assumption is that it will happen starting from the analysis of the social tendencies and the comprehension of the user/consumer's necessities. We believe that only from the understanding of the object's role in society and its participation in the construction of the individual's everyday life is possible to project new objects that will suit both necessities and expectations.

The theoretical framework is established from the summary tables, establishing relationships between areas of knowledge, the authors used and tool projetual proposal.

Keyword

Human-centred design; User-centred design; Phenomenology; Design process; Industrial Design

Designing for other people is a very difficult task, mostly when one does not know whom one is designing for. When commissioned to design a new object, one has the opportunity to meet its future owner, so it is possible to talk to the client and know his preferences. Thus it is possible to make a unique and personal project based on data provided by the subject himself.

Mass consumption opened a gap between the designer and the end user, firstly by mass production itself. When trying to get closer to the end user, the designer realizes how difficult it is to work for whom he does not know. For this reason companies invest on consumer and marketing research, trying to understand who these people are, creating data banks where their tastes, habits and customs, even manias, can be classified. But even then the designer is still left with the same problem described above: the knowledge from the subject obtained through indirect data, mediated by marketing, provides inaccurate information about the users and their necessities.

This present research is based on the hypothesis that, after so many changes in all segments of society in recent years, it is very difficult to continue designing new objects as it was done until the eighties. Nowadays the user-individual must be considered the centre of the whole projetual process and Design must consider its vocation for innovation and for the future. Therefore differently from Marketing, which strives to understand what the consumer wants to buy, the designer, on the other hand, should foresee the product conditions before, during and after the commercialization and ownership of it. For the designer, the commercialization is just one rapid moment in the process of the use of the object, which relates to just one part of the relations between the object and the individual. The approach utilized in this paper considers the object in its scenario and the individual as a character in this story, to be told using multidisciplinary elements which have their origin in psychology, design, marketing, anthropology and sociology.

We believe the development of new products in view to innovation will consider the socio-cultural aspects involved in its production. The second hypothesis is that it will happen starting from the analysis of the social tendencies and the comprehension of the user/consumer's necessities. We believe that only from the understanding of the object's role in society and its participation in the construction of the individual's everyday life is possible to project new objects that will suit both necessities and expectations. It is fundamental, bearing such an objective in mind, the use of adequate instruments that allow us to comprehend and to contextualize the product in its initial stage.

A new methodology for the creation of new products: searching for a new expertise

Baudrillard (1993) said at 1968 in his book *The system of objects* that it is not possible to describe the everyday system of the objects through a purely technological analysis. "*The system of the objects can only be described scientifically as we consider it, in the same movement, as resulting from the continuous interference of a system of practices on a system of techniques*" (Baudrillard, 1993, p.16). When new objects are designed, the classic methodologies consider them as elements isolated from the rest of the world, circumscribed to a briefing given by the client, as if it was absolutely autonomous. People forget that such an object has a complex symbolic function in post-industrial society and that its success will depend much more on its synergy with the society/culture than on its technological possibilities.

Savoia (in De Masi, 1999, p.361) says that

> So does the market change profoundly. The technological development determines the continuous flow of new products into the market and a strong increase in the consumption of similar and alternative goods; the potential users stratify much more than in the industrial economy. Limited and restricted personal choices, of the kind "either this or that one" and the uniform and standardized shopping behaviour which characterize the consumption for the whole post-war period until the mid 60s, gave place to a

> multiplicity of styles and orientations of strongly individualized choices. The consumer's universe is not an indistinct aggregate of society and publicity for the mass market, where few product choices satisfy few homogenous tastes, but a highly diverse system in which it is possible to identify segments of consumption behaviour, of rentability.

The consumer becomes a determining element in the market and a client, not an administered being anymore. In a market where the absolute rapidly becomes obsolete and where there is no time for deeper thinking, the discourse seems to be lagging behind action. This feeling comes in part from some analytical characteristics of design which have remained stable for a long period in modern history and which, differently from advertising or marketing, have not been adapted to the dynamics required to act in our contemporaneous society.

The requisites of a new methodology for the development of products that would consider the user as the centre of the projetual activity could be divided into two: attitudinal and technical necessities. By attitudinal necessities we understand the elements present in the projetual act or in the designer's posture before the problems that lie in the projetual process itself, generating an approach concerned with the way the professional stands before the new object and its context. By technical necessities we understand the instruments used to gather and to analyze the socio-cultural data and the user as well. Such instruments are to be used by the designers during the projetual process.

From the perspective of the concept of attitudinal design, the designer's posture during the project has great influence on the final result. Utilizing an analogy between the designer's relation with the user and of the psychologist with his patient, we can understand that some points proposed by psychology can help to design and to minimize many projetual problems. The main point refers to the distancing necessary to have a critical perspective on the problem to be solved. It is very common, and many authors, including Papanek, Wachsmann, and Munari, that the designer has a natural tendency to get too involved with the project, thus losing the necessary critical perspective to evaluate the solutions proposed, have already emphasized it. Wachsmann goes as far as to suggest, in his method *Team Work*, the change of teams in the different stages of the project, which would allow an external point-of-view on the problem.

Another very harmful tendency for the project is what we call "self-project", in other words, the tendency the designer has to design for himself. In this case, there are two preferable situations: the designer should either work in a segment where he is a designer and also a user or where he does not have any kind of involvement with the segment in question. In the first case, the involvement happens because of the nearness and knowledge of the object to be designed, which make the process of self-project easier. Thus, by a metonymical tendency, the designer ends up believing that what suits him will also suit everyone else. In the second case, the ignorance of the particular field will bring a desirable distance, but it is also a cause of lack of information and of involvement. Without an adequate research, one might be caught in the trap of working with distorted and stereotype information, be it from the common sense or from preconceptions so deeply rooted in the culture that one does not even realize he is using it. In this last example, there is a tendency to make a worse version of the self-project, because more than using mistaken information, one is inspired by the things he would do in that situation without a proper technique to approach the situation.

The elements referred to above indicate the necessity of finding a more adequate reference in theory, one that would permit to minimize such problems, facilitating an empathic attitude from the designer and reducing the problem of self-project. Psychology and Phenomenology have provided concepts and techniques to better understand the subject-user as a unique individual in the design process. How cans one work with the user-centred design if one continues to think about the user only in quantitative parameters? For the last sixty years ergonomics has contributed to enhance the relations between users and objects, their spaces and activities. However, this quantitative analysis has not shown itself adequate enough to describe the complex relations of the contemporary subject with his environment. The greater the number of options offered by the market and the more hedonistic the individual's attitude, the more it will be necessary to have adequate instruments to better understand his necessities.

We shall demonstrate the main concepts utilized to lay the groundwork for the proposal here presented. After the theoretical structuring, the objective will be to facilitate the use of it, translating the abstract concepts into operating praxis.

A multidisciplinary approach

Marketing was the first to study the user psychology, understood by it as the consumer, based on theory references from psychology. However, due to the nature of the discipline itself, the main focus of all the Marketing studies in the last forty years has been to establish behaviours that emphasize product consumption. Consequently, the adoption of concepts from Psychology has not always been the most adequate one concerning the thoughts of the theoreticians in psychology. Design, on the other hand, has studied the user according to his anthropometric and biomechanical relations, aiming at a better adequacy between the objects and the human body in the exercise of its functions. In this case, Psychology has not become adequately present in such activity. However, more than just perform tasks, objects establish emotional bonds with the subject, even to the point of causing emotional dependency. Thus the incorporation of the concepts from psychology, not mediated by Marketing, can afford us the possibility of a better approach to the user's necessities.

Some characteristics of this research have shown the phenomenological approach to be the best indicated, for it allows the understanding of the user's experience from his own point-of-view, utilizing at the same time inductive and deductive processes. Adequate to solve the problem of objectivity in cultural research (Vargas, 1985), Phenomenology is the most suitable method to be used where it is not possible to establish direct relations of cause and effect between the elements of study, as is the case of study in this paper. In the case of cultural research, the author indicates that the evidences take the place of verifications, therefore creating no need for an experimental conclusion, which is actually not possible due to the mutant character of the object of study. Assuming that the comprehension of the user's necessities is more important than its explanation, the truth criterion becomes the evidence of the conclusion, consisting of the understanding of the user and his relation with the world around him. Thus, there cannot be a conclusive answer, but only evident possibilities.

Some concepts and authors of the humanist psychology have also proven to be of special significance, which we shall describe below as a differentiated alternative to work with the user-cantered design methodology.

The user as a character

A designer's claim to know the user thoroughly is at best naïve and derives most of the time either from his arrogance or pure ignorance combined with a superficial approach based on common sense.

This present work is based on the concept of the user as a character in a play, a human being represented according to his multiple facets. We agree with the psychologist C. Bollas (1998) when he says it is not possible to fully comprehend the character in all his manifestations. The author asks: "*will I ever know the character which the other is? Who the other really is? Will I have the means to transcribe the other's subjectivity to a palpable place?*" (Bollas,1998, p.39). For Design, the subject is collective and will become individualized from the moment he identifies with the object, buys it and starts to use it, incorporating the object in his daily life and in his character.

Therefore we shall work with the concept of a "group of psychographic profiles" which can be described as a group of characteristics particular to an individual or to a group. Thus starting off from the personality, that is, from the Real Self, the objective is to find a group of characteristics to compose a profile.

If we understand the real problem present in the individual and in his environment, the object will be the only and obvious response to this well-defined problem. And thus the animated object becomes an extension of the subject himself, representing him. It is important, for that matter, which we work on data that have been obtained from the items presented in this paper. Hence the elaboration of what we call "character profile bank" is a vital step for the correct application of the instrument thus proposed.

Such profile bank aims at grouping the descriptions of individuals obtained from data collecting and transforming them into cards that can be referred to by designers at the start of a project to define a group of desirable characteristics for the user in question. The observation of everyday life in combination with interview techniques allow one to find the necessary elements to see beyond labels and stereotyped views on the user, a major problem for the development of good projects.

This idea is based on the Jungian concept of "persona" (as cited in Fadiman & Frager, 1986, p.53), defined as

> the form through which we present ourselves to the world. It is the character we assume; through it we relate with the others. The persona includes our social roles, the type of clothes we chose to wear and our style of personal expression.

We are also utilizing Adler's concept of the individual as a unified whole (as cited in Fadiman & Frager, 1986, p.76), the visible part of the individual Ego that can be seen partially by means of the analysis of his daily life. In combination with it we utilized the self-concept of Carl Rogers (2001) that represents the view the person has of him or herself.

Considering the concept of character, we can say: "the user are many", in reference to each of the characters the former represents in the scenario of everyday life. Thus, we have established as a basic principle that there is not one person, the user as an individual, a single entity, but a character that plays a role, a part of this individual's history in the contemporary scenario.

Therefore, if there is not an only individual, there cannot be an only description that represents him in his quotidian and neither there is a product that can satisfy all people. Thus, the technique presented below strives to reveal the character in his scenario by means of a phenomenological approach. In this "plot", the missing part is the object, which shall be designed so as to allow the maximum congruency between the three elements, namely the individual, the character and the user, constructing thus a possible history.

The character is, consequently, what he shows to others, and also a point we can start from to understand the user as a person. Originally devised by an author, the character must be capable of being played by many different actors, thus possessing well-defined personality traits that allow the comprehension of his self. The user will play the character, when identified with his profile, and the latter will represent the former as a possible facet.

Instrument Structure

An approach based on the phenomenological reduction and on participative experience

SCENARIO is a project instrument created with the objective to help the designer to comprehend both the profile and the user necessities, so that the former is capable of designing more adequate objects to the contemporary context. The objective is also to create conditions that allow the verification and validation of the designer's project proposal through the use of metaphors built on trend analysis.

The project is composed of three phases: Phase 1 – Identity; Phase 2 – Projections and simulations; Phase 3 – a possible history.

The following summary describes the structure and theoretical basis for the instrument proposed. Subsequently we shall discuss the methods for data collection and treatment.

Based on the premises described above, we have opted to work based on an only structure that can be repeated for all techniques, thus making it easier to organize, understand and utilize the presented concepts. For all instruments a synoptic table is presented displaying the references utilized in each of the techniques and proposed procedures. In this proposed structure, we indicate:

- the objectives and desired results,
- the procedures adopted,
- the techniques that should be used,
- the profile of the best suited professional for the stage (or procedure),
- a content model to be presented at the end of each of the stages.

Thus we understand that the application of the instrument is more easily effected during the project, once all procedures have been displayed in a comprehensible language for the designer and demonstrated through examples, boards and tables. The main point-of-view will be summarized in the item "commentaries". The works of Marconi and Lakatos (1999) and of Chizzotti (2001) have been used as reference for all the techniques and questionnaire structuring.

The four instruments of the Stage 1 – Identity are an attempt at collecting and treating the data that allow us to "go to the things themselves", to reflect the experience "[…] considering that human experience is always the source of all conceptual elaborations"(Forghieri, 1993, p.5-11). To minimize the effects of an analysis based on stereotypes and preconceptions the observer might have in relation to the subject, the "preconceptions" technique has the objective of preparing the observer for data collecting.

In an effort to know objectively the subject and the elements of his quotidian, the observer writes a descriptive text on his impressions about the subject (his quotidian, physical appearance etc). The result of such a qualifying analysis should make evident the observer's prejudice in relation to his subject. By contrasting this text with the subject's description of himself and with a third person's description of the same subject, we can establish the elements which grant us the identification of the self-concept, indicating the three dimensions of the self: who he is, how others see him and how he sees himself. In this stage we can also recognize some elements of the individual's unfoldment, very important for the design of objects.

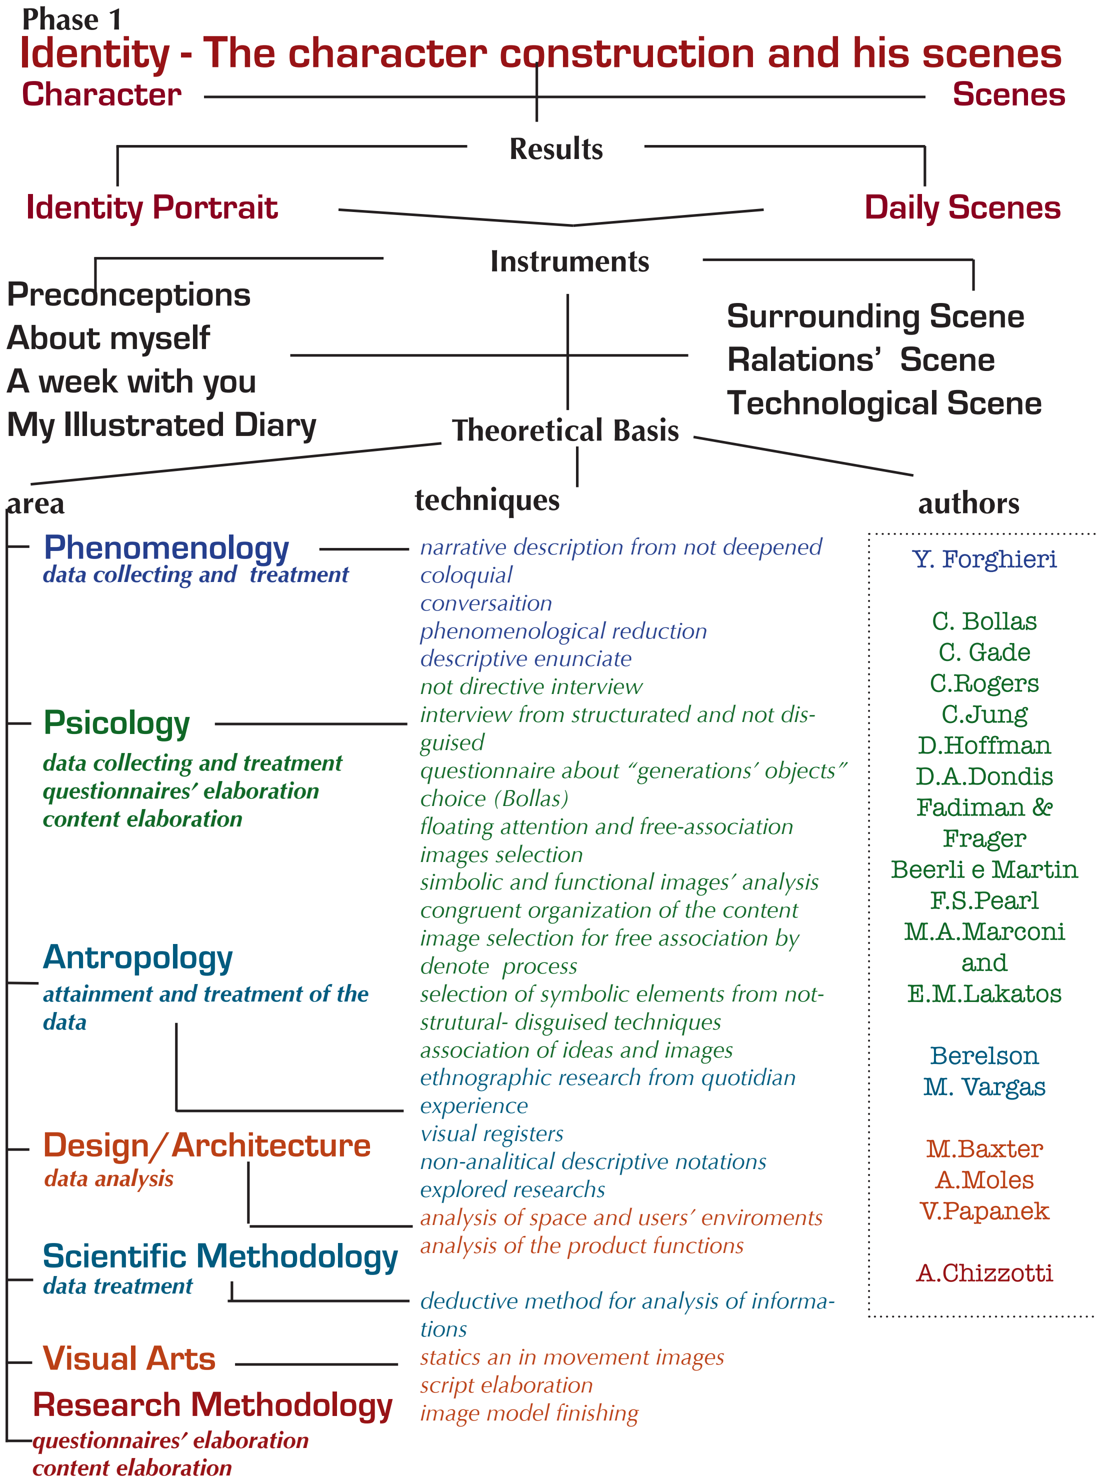

Figure 1: Synoptic diagram: theoretical structure of the 1st phase

About myself

The aim of this technique is to establish different profiles by means of interviewing different people. At this point it is important not to use any directive type of interview so that the interviewee can express himself more freely. A structured questionnaire can be used, mostly in what refers to the individual's cultural values and habits, but as long as the structure is evident. The interviewer should follow a pre-established itinerary. The desired result is a descriptive narrative about the individual and a definition of his socio-cultural profile using client-centred therapy techniques. It is important that the designer works together with psychologists for the objective is not a consumer profile but as said before, a socio-cultural one.

A week with you

This technique aims at building the character's profile from the experience of daily situations, where all aspects of the quotidian can be better observed. As a complementation of the previous technique (About myself), the same person should participate in this second part of data collecting. The underlying principle is that the main difference between the immediate quotidian existence and its theory is that the latter is always partial and limited, which cannot include the totality of the contrasting aspects experienced (Forghieri, 1993). Bollas (1998) says that "*the observation of the subject in his space allows the construction of a metaphor which enables me to come closer to what I want to say about the nature of the human character".* (Bollas, 1998, p.40). The combination of experience and participant observation associated with the fluctuating attention technique is a way not to emphasize any present element and to give the same attention to all presented data. Although it seems to be contrary to all the proposed principles of the participative experience technique with a phenomenological approach, we consider that the use of a directive itinerary will allow the researcher to focus on important aspects for the designer.

This experience shall be done with various different subjects, randomly chosen among common members of society without any privilege or demographic criterion. Following, there must be a detailed analysis of the quotidian habits, establishing a comparison between the information obtained in the "About myself" technique and the ones obtained in the participative experience so that the incongruent point can be found and thus it can be established the difference between the real self, the ideal self and the social self. The identification of the observer's personal characteristics allows the suspension of judgments of value about the user; therefore one should avoid any qualifications. The suspension of the observer's personality characteristics and personal tastes is capital to avoid a subjective reading of the elements present in the quotidian. This must be described following a personal itinerary, a card to be filled where the main points considered detrimental to the observation and the description of the quotidian can be identified.

My Illustrated Diary

The last technique in the construction of the character is called "**My illustrated diary**". Its main goal is to organize the data obtained from the experience "A week with you" and to formalize them to be further consulted and presented. The data obtained by the researcher in the previous technique are organized so as to allow simple reference to the information obtained. The facts and images obtained should be selected and analyzed bearing in mind two main criteria: the search for congruency between the elements present in the observation and their capacity to be representative on the construction of the quotidian (understood here in its two aspects, the connotative and the denotative). The image selection needs special

attention and should consider the semantic and symbolic criteria pointed out by Hoffman (2000), Persi (apud Fadiman & Frager, 1986) and Dondis (1991). The connotative aspects shall be utilized to find the structural patterns that may be visible in the images and which indicates us symbolic or subjective values depending on their repetition in different situations, what configures a pattern to be observed.
No list should be made before analyzing the images. On the contrary, reading the images should be the starting point on the discovery of the elements so as not to look for the confirmation of a previous theory about the individual, but to establish a profile based on a structured provided by the very individual. The data obtained in the experience “A week with you” should be described on paper in details and using colloquial language, with the intention of sharing that experience. After the written description one should try to establish the differences and similarities between what was described and what happened.

Three stages for the process

The first stage is the *Data analysis and interpretation: My Diary*, which is the material collected during that process. The second stage is called *Data verification with the subject: reading the diary*. Presenting the diary for the subject is his ascertainment of the meanings attributed to his objects (both internal and external). The individual should also make observations on the points which he does not agree with the facts occurred and which are consequently not representative of his reality. Thus the user is included in the process in a client-centred approach, from the three dimensions pointed out by Rogers (2001): listen, understand and accept. Firstly, listening to the client’s ideas about his own difficulties; then accepting the client as capable of understanding his own problems and, finally, understanding that the modifications can be directed by him, as well as the goal setting.

It is implicit in the third stage, *Content review and final redaction: My diary – definite version*, a critical point-of-view from the researcher. It is important that he compares his original notes, his first report and the subject’s observation to proceed to the elaboration of a possible description that characterizes what was presented. The material in *My illustrated diary* will work as the basis for the creation of an identity portrait.

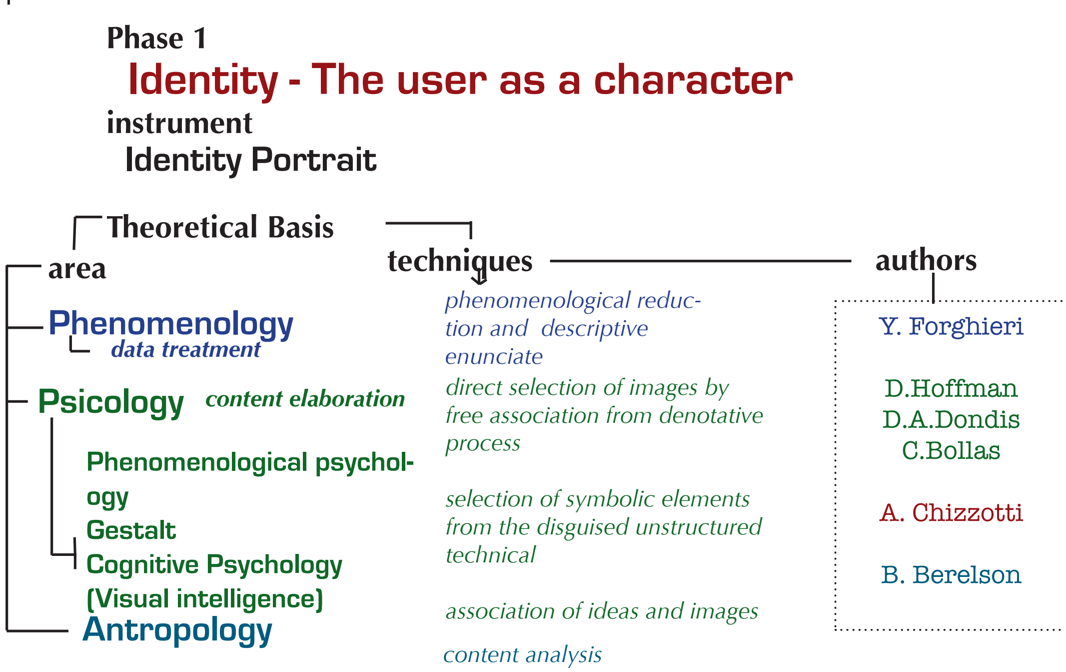

Figure 2 – Synoptic diagram: Identity portrait

Daily Scenes

The instrument **Daily Scenes** aims to put the character in context, from the insertion of images and objects taken of the **Identity Portrait** elements for building scenes and ambient. It is constructed by overlapping the 3 scenarios, the surrounding scenery, and the relational scenery and technological scenery. Work as a database, information that should be considered available and upgradeable to put the character in your environment in order to identify situations the closest to the real.

The overlap of the elements of the 3 previous scenarios, which should contain some descriptive text and visual elements, creating an imagistic model to facilitate understanding of current events and its aftermath

This model serves to mimic what happens in real life, validating the understanding of the theories presented (Vargas, 1985, p.172). The scenario as imagistic model should work also from the use of metaphor, trying to make sense of all the relations that can be established. The creation of a model imagistic daily scene allows us to “specialized” and understands the elements of this so that we can thus understand the future, the construction of the scenario projections.

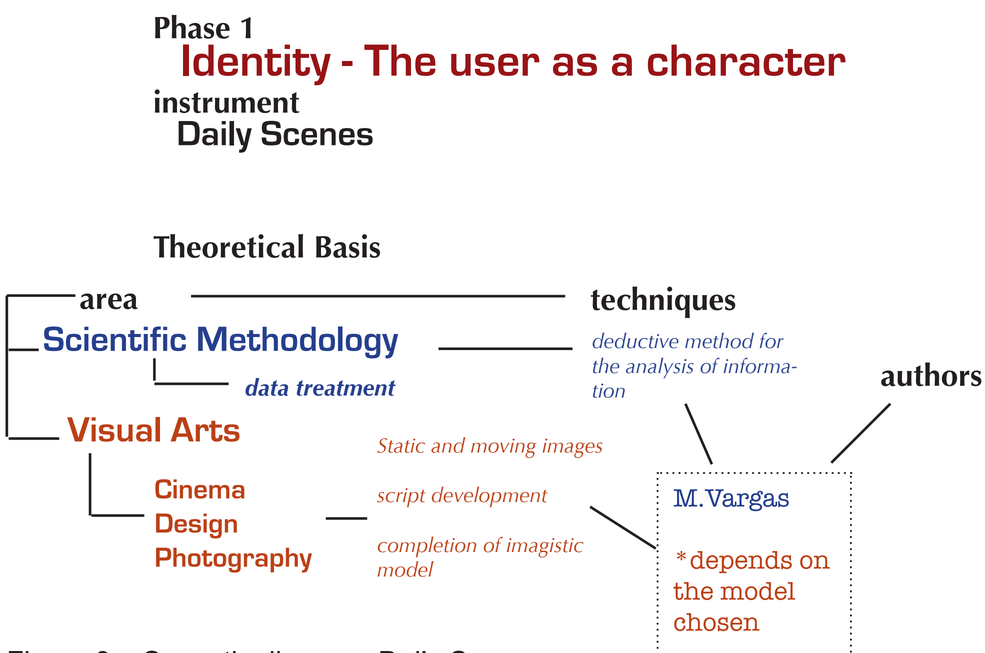

Figure 3 – Synoptic diagram: Daily Scenes

Projections and Simulations

This second stage, called **Projections and Simulations**, provides the application of data obtained in the previous step to create a model that can somehow simulate future scenarios for the implementation of the object. Thus, in one step is simpler because the data has been collected and are available for consultation. Therefore, it is one-step application.

Considering the claims of Bell (1976), Popcorn (1997) and Naisbitt (1998) that this shows us the way of the future, the main work in this step is the analysis of trends and opportunities from the creation of situations of simulation, order to test possible paths chosen by identifying the elements that characterize the changes found in the readings of the daily.

Thus, counter to reality and future prospects in the search, from a close eye on the trends of the components that characterize contemporary changes that may indicate the future directions. Taking advantage of the daily readings, the reconstruction of the repertoire indicates a scenario where simulations are possible and projections from the use of analogies and metaphors. Thus, the object is the result of needs identified in everyday life, and not born a priori.

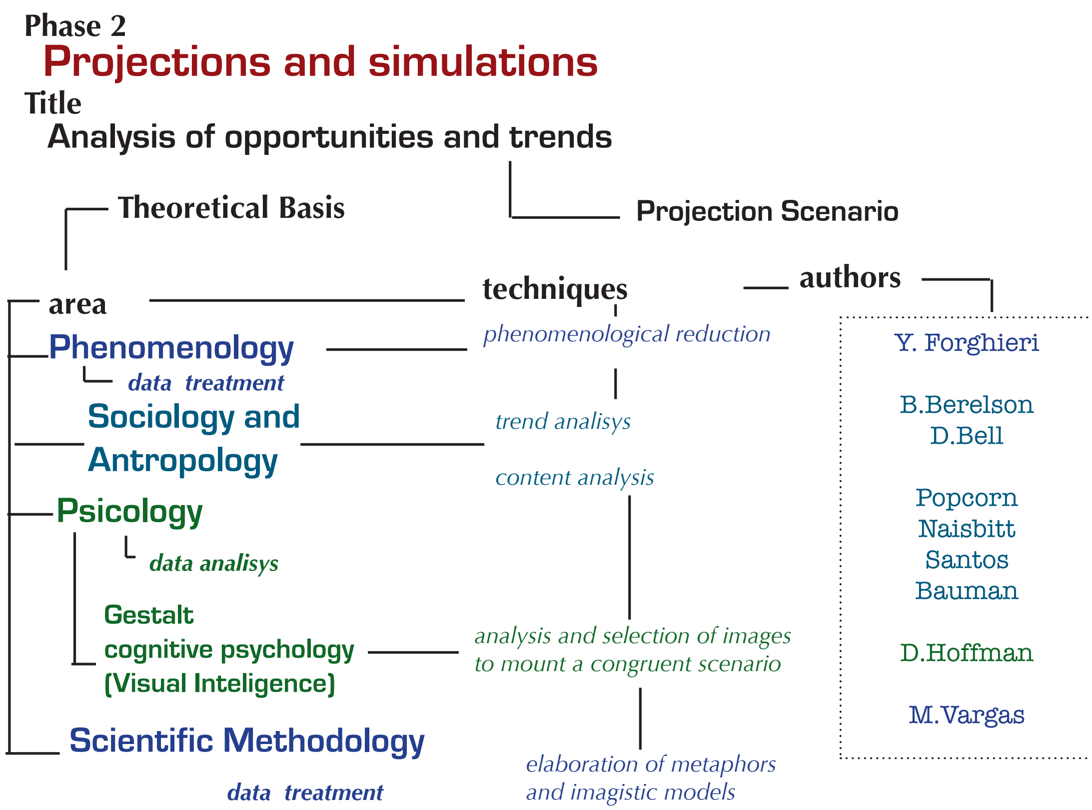

Figure 4 – Synoptic diagram: Projection and Simulation

A Possible History

This third and final stage, called **A Possible History,** is a description of the new daily. This is the synthesis of the whole process, where the application of data from all previous steps, formalized to create a model that can, somehow, describe the everyday future, with all the consequences this may entail.

The main objective of this 3rd. phase is to enable the development of user-friendly material that can describe a new daily life, from the junction of the 3 elements that build: character, settings and objects. We assume that the descriptive narrative format may be the best to assemble the story, which involves the juxtaposition of the various data obtained from previous techniques, so that one can construct a story as possible, and not an element of fiction, where the data presented leave only the imagination of author. Thus, for the avoidance attitudes romanticized in this last step, again to resort to the procedures and mitigation techniques, allowing for greater objectivity to the process to terminate.

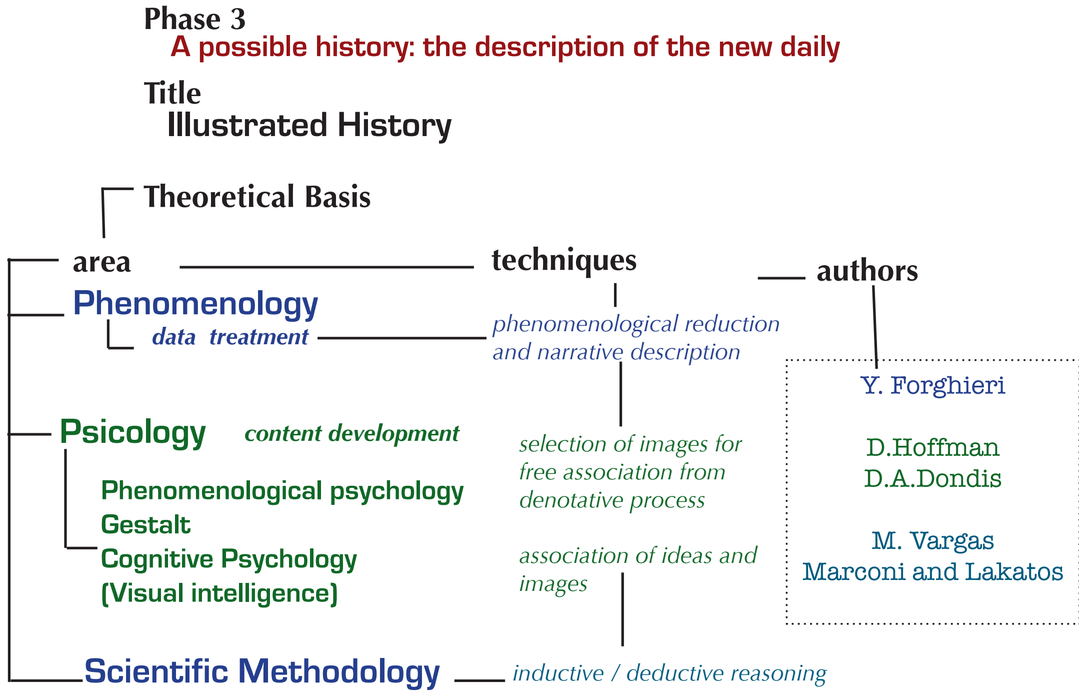

Figure 5 – Synoptic diagram: a possible history

Last considerations

Desirable characteristics for the proposed instrument

Just like a psychologist who adopts a given line of work to help his patient live better, trying to understand all the aspects of the patient's personality, the designer should, more than just understand the user, foresee his necessities, going from the collective subject identified as a consumer to the individual subject, the character that represents him, striving for an empathic relationship that allow the ideal distance to analyze the other, to "*feel what he would feel if he were in the situation and circumstance experienced by another person*" .

The proposed phenomenological approach allows a better understanding of the subject and of his quotidian. Being an inclusive theoretical structure, it also permits an easier updating just by substituting the key elements that are described in the tables used throughout the process.

The examination derived from the distancing using the phenomenological reduction technique allows the rationalizing of the data selection according to the criteria presented by Hoffman (2000), proving itself efficient in the creation of symbolic charts that help to build a history. The proposed structure for the analysis and the description of the elements to be observed favoured the facts of the quotidian, indicated as the most important for an analysis of society.

The organization of a non-linear structure allows you to work simultaneously with the 3 elements, allowing an organization that facilitates synchronous work in multidisciplinary teams.

Thus we believe to have proposed a methodological approach that has granted the final product a meaningful theoretical consistency to be presented, discussed and revised afterwards.

Abstract

Investigating and extracting users' desires and aspirations often conduct design researchers to a great deep challenge. Therefore, the designers usually examine several ways to get closer to these unrevealed feelings. These ways include applying various qualitative and quantitative techniques. Amalgamation of these techniques might be the most desired technique among designers in revealing deep inside feelings. But once a qualitative technique is applied, the design researchers deal with the difficulties of making the outcome data, including verbal and visual expressions, comprehensible enough in order to be used in the subsequent steps of design or to be conveyed to product developers. So, their usage of such qualitative techniques would be subject to misconception and misunderstanding, and here, the expertise of designer will have a crucial effect. Consequently, designers often find qualitative data formats as imperfect reports as they might not be applied convincingly throughout the design process.

This paper presents some encountered complexities of a pilot survey titled "Designing and Implementing an Artificial Design Tool Based on Improved Kansei Engineering" which, due to its concept, involves applying intermingled quantitative and qualitative methods. In addition, this paper is an effort to describe the borderline between quantitative and qualitative methods and their transformation point, and also to describe some practical solutions suggested by the authors.

Within any mixture of quantitative and qualitative techniques, there are two participants: human in one side (both as designer and also the focused and target group) and machine (computer) on the other side. In other words, within any combination of these two techniques, we encounter the qualitative data expressed by the target group and self perception of designers on one hand, and the quantitative data produced or required by the machine on the other hand. And then, the problem will be how to take advantage of these two sources for the analysis and concept generation phases. Surely the future methods of design together with the future design-assistant machines will raise this fundamental question: how can we overcome the rigid borderline between qualitative and quantitative methods and make a seamless concept of co-qual-quant model which will bolster the real human-machine connection. It is one of the design complexities of the time and one of the requisites of the future. We have come up with a solution through a conducted case study, in which we have made a bridge between the human and computer. So, we have used some qualitative methods on the human side (for example PPP and Mood Board) and some quantitative techniques (such as AHP) on the other side and we have tried to infer some co-qual-quant model-based parameters to inject to the design machine as a pure quantitative instrument.

Keywords

User-centric design, qualitative techniques in design, design problem solving, Kansei engineering, AHP in Kansei Engineering, co-qual-quant model in KE

Emotional bonds between users and products are an essential element that can determine the commercial success of a product. Eliciting user desires and emotions often presents a challenge to design researchers. Users can offer a valuable design resource to support the designing process. However, such involvement can be perceived as problematic. This is partly because users find it difficult to conceptualize and express their ideals and wishes, and therefore, they need to be supported. Product functionality as such is closely interwoven with social and cultural values. Users are not always conscious of their needs or may not regard particular pieces of information as useful. Likewise, users are not always able to verbalize their emotions and reflections. Coates distinguishes between the idea of the stereotype (what a typical product is currently like) and the ideal (the imagination of how an object should be like). New designs aim to come reasonably close to the ideal, whilst not leaving the perception of the stereotype (standard) too far behind. Coates criticizes the use of focus groups in market research based on its preoccupation with stereotypes instead of ideals, because the stereotype is what participants know best about and agree most upon. Ideals are “fuzzy” as they vary across people and are not necessarily conscious. *Blue-sky* and *what-if* possibilities are therefore more difficult to reflect upon and verbalize.

So, it is important to give users many different channels through which they can express their requirements and ideals. Several qualitative techniques like Mood Board and Product Personality Profiling have been proposed and employed recently to retrieve peoples' ideals rather than their stereotypes to overcome these shortcomings. A methodological “trick” to trigger novel ideas was employed by encouraging people to consider the “future”. By assisting users in *suspending reality*, new ideas and wishes may emerge. People begin to think more creatively and disclose their wishes and ideals more freely.

These techniques broadly use Images and enable communication of intangible emotions such as happiness, sadness and calm, beyond linguistic restrictions. Images are a powerful resource to convey meanings, particularly emotional values and experiences. Especially, abstract imagery which is applied in Mood Boards is often more successful in this than figurative images which can have strong literal interpretations. As they tend to be purely visual, they transcend linguistic restrictions. Their application can serve as an important tool to communicate values that cannot be expressed easily through words.

As the subject of design becomes more novel and complex, it would be more difficult for the users to think and imagine the hidden aspects of the subject, and also their unrevealed desires. Here, Qualitative techniques play an important role. They are more powerful tools in helping people visualize the current and future context of design and their imaginary and ideal products. Therefore, applying them seems crucial, but also interpreting their result might be a bit of minefield. So, in some occasions converting these qualitative data to quantitative data will bring about confusion and should be solved using combination of appropriate techniques. This is the main approach which will be discussed in this paper.

Framework of the paper:

As a descriptor for the applied technique, we propose a framework which governs all parts of the model. Here, the framework and its basis will be described.

The technique mainly combines AHP, Mood Board and PPP to provide the optimization algorithm with the necessary input parameters (attributes) and also importance weights (final weights resulted from AHP) of those parameters. The novelty of the design subject also made usage of Mood Board inevitable, because we had to reduce the representative objects in the questionnaires (sample products) into more sensible ones for the users. We used Mood Board for simplifying and reducing the representative objects from a complex, concrete and real world object (for example image of some green cars) to some simple and abstract images. Also it helps us to communicate with the unawareness of the users. In addition, we have further used our findings from both Mood Board and PPP in defining AHP criteria. Then, the final extracted weights of importance from AHP were inputted as the coefficients of the fitness function in Genetic Algorithm optimization, the project’s synthesis phase.

We will split the whole framework into some modules and will describe them separately. These segments include “attribute gathering”, “attribute reduction” (includes two sub-segments), “verification”, “importance weight extraction and final quantification”, and “result convergence”.

Case study:

This section is assigned to parts of a conducted project titled “Designing and Implementing an Artificial Design Tool Based on Improved Kansei Engineering” in which we examined application of Mood Boards and Product Personality Profiling as two qualitative techniques in some phases of Kansei engineering parallel to routine exploited quantitative tools. Further, we assessed the results by repeating the procedure with the conventional quantitative approach. The detailed procedure of case study in the first approach is illustrated in the following flowchart. Each block will be discussed separately in the following statements.

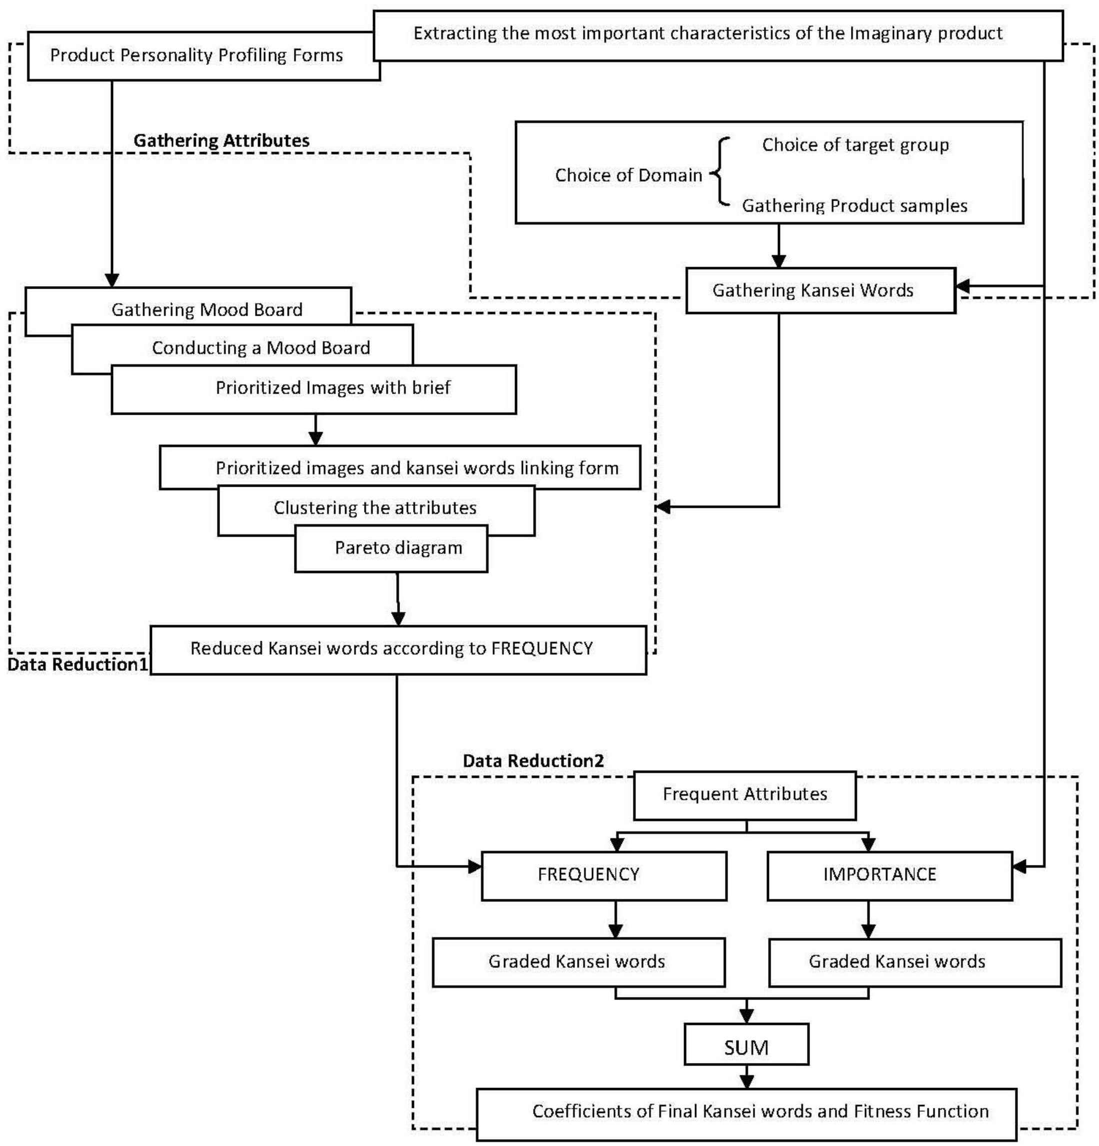

Figure 1. An overview of the whole process

Gathering attributes (Kansei words)

Commonly, the procedure of KE initiates with choice of domain in which the target group and sample products are chosen. The target group included 20-40 Iranian women and sample products ranged from electric and hybrid urban vehicles of renowned manufacturers to some new concepts. In the phase of gathering the Kansei words which is portrayed in the first dashed box in figure1, first all of the related sources such as internet, magazines, pertinent literature, experts, experienced users, relating Kansei studies, ideas, and visions were investigated, also a discussion group was held consist of 20 industrial design girl students in which they were asked to talk about the product samples and choose 3 most preferred ones in accordance with the project. All chosen samples were graded respecting their frequency and 3 of them were applied in the later PPP analysis. Then, we conducted a PPP session which included 20 participants who were shown PPP forms. This form included 3 columns for 3 selected products and also one more column for describing the imaginary product. One sample of this form is presented in figure 2.

Imaginary product	Product C	Product B	Product A	participant	
					sex
					age
					occupation
					lifestyle
					car
					personality
					Family environment
					clothes
					newspaper
					pet
					Favorite TV program
					Music
					Food
					Name
					Role in the family
					Favorite Cartoon Character
					Perfume
					Do you like to buy this product?
					Color

Figure 2. A sample of PPP form

Through PPP analysis we extracted a series of the most important attributes for imaginary products which were useful to be included with other gathered Kansei words. This analysis was also helpful for “data reduction phase”, the next step in KE.

Reduction of attributes, Phase 1:

The outline of this phase is shown in the second dashed box in figure1. Instead of regular application of marketing tools in this phase, Mood Boards was applied. At this point, previous PPP analysis was supportive in helping the design team to have much better visualization while gathering abstract images for Mood Boards. Afterward, one Mood board session consist of the same former 20 participants was held. A variety of images numbered as 778 from various categories were chosen. These images reduced to 271 images in the second classification. Then, all the participants were asked to set a layout of their 7 preferred images and also to prioritize them in accordance to their importance and relevancy to the Mood board question. They were also asked to express a short brief for each of their choices. Some of the advantages of using Mood Board were noticed as high enthusiasm among participants in fulfilling the task, and quicker understanding of the subject. One of these layouts is shown in figure 3.

Figure 3. A sample of a mood board layout used in the case study

The next task was to convert these qualitative responses to some fathomable values for the synthesis phase while reducing the number of Kansei words to the most important ones. Therefore, firstly all the gathered attributes were clustered and then linking forms were planned. This form included a list of all the new attributes and was presented to the participants to be marked for each of their 7 selected images. The list of attributes printed in the form is shown in the table 1.

Lightness	Particularity	Power	Slowness	Fun	Excitation	Complexity	Sensible
Heaviness	Ordinary	Softness	Rapidity	Seriousness	Calmness	Simplicity	Ornamental
Delicate	Sturdy	Sport	Spacious	Kind	Stylish	Compact	Happy
Sad	Mature	Childish	Feminine	Masculine	Smartness	Silliness	Unfriendly

Table 1. List of attributes

In the next step, these data were processed and the most frequent attributes were determined using Pareto diagram. The most frequent attributes in the first three priorities is illustrated in figure 4. These frequency values built the **Frequency** criterion for the second data reduction step.

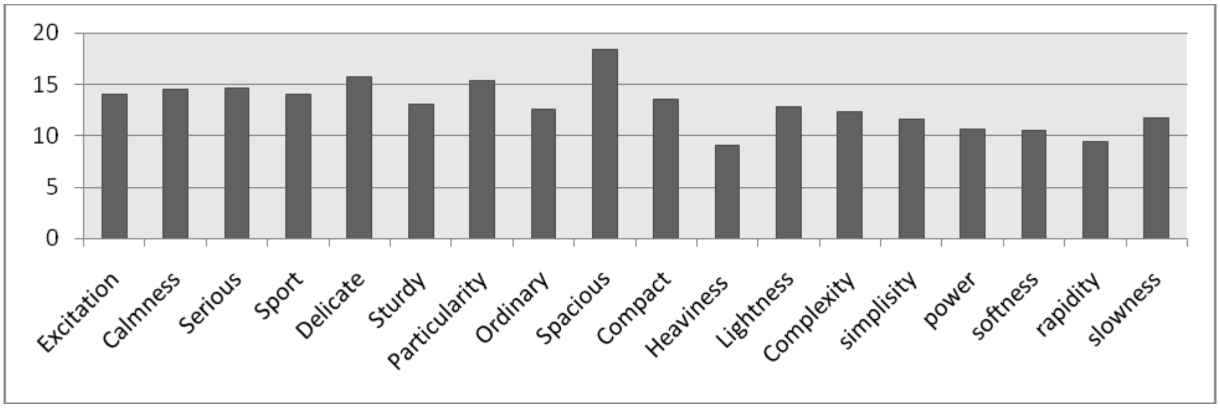

Figure 4. Comparative chart for frequency of attributes

Reduction of attribute, Phase 2:

In order to assign inclusive values to the attributes based on ideas of both participants and design team (the human side of design procedure), another reduction was conducted applying AHP. This phase is shown in the third dashed box of the figure1.As it was discussed in previous section, the output of the first reduction phase was used in defining the frequency criterion in the second step. Also, most of these attributes were in contrast with one another in the meaning; therefore, the attributes were rearranged to polar Kansei words like Spacious-Compact, Excitation-Calmness before being processed.

On the other hand, the **Importance** criterion was defined in accordance to the results gained from PPP analysis based on the designer's viewpoint and interpretation. Within this free point of manipulation, designers will be able to incline the results with respect to the main objectives of the project. For example if designers wish to orient towards a highly delicate final concept, they can assign a greater importance degree to the delicate attribute while processing it in AHP.

Furthermore, the partial scores for each attribute in both criteria were added together and the final scores were determined. Table 2 presents the first 5 attributes with higher final scores. These values were further used as coefficients of fitness function in the synthesis phase based on Genetic algorithm optimization.

FINAL SCORE	ATTRIBUTE
0.17	Spacious-Compact
0.114777	Sturdy-Delicate
0.088467	Particularity-Ordinary
0.083879	Serious-Sport
0.082718	Excitation-Calmness

Table 2. Final score of attributes based on co-qual-quant model

Verification:

In order to evaluate the quantification procedure of qualitative input data, a parallel process was conducted. Within this process all the attributes were graded using seven grade scales, and then the ten highest scored attributes were used in the first step of fuzzy survey. Figure5 shows a frame of the interface of this survey in which all the samples were scored with respect to attributes.

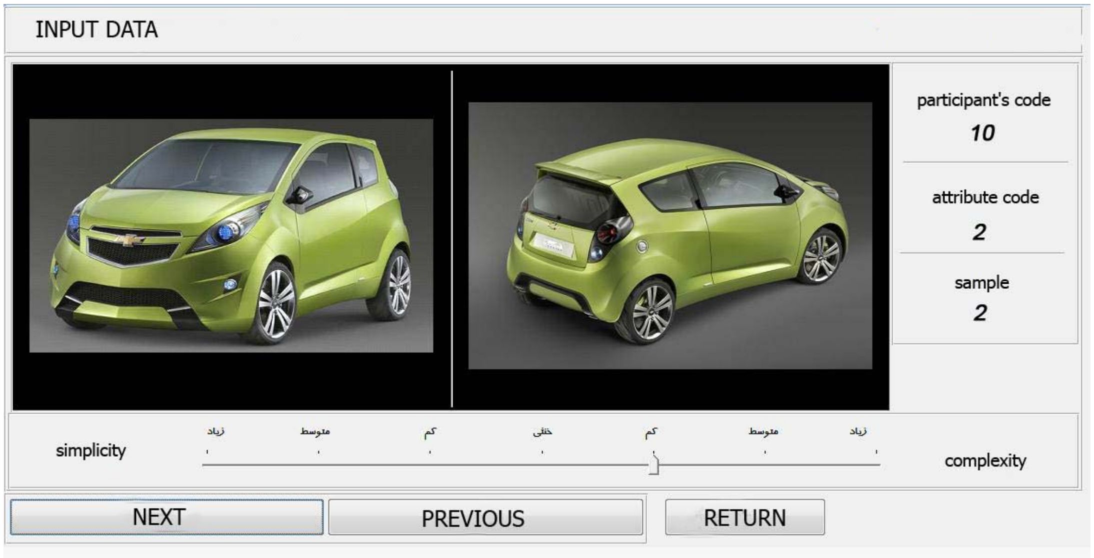

Figure 5. Fuzzy survey interface sample (Phase 1)

The output matrix of the first fuzzy step was categorized and reduced using Factor Analysis. By applying factor analysis the dependant variables or attributes were recognized and merged into one unique group, and then new name was given to this group of attributes. Interestingly, it was possible to categorize and name the main extracted attributes within similar five attributes obtained in the previous procedure like Spacious-Compact, Sturdy-Delicate, Particularity-Ordinary, Serious-Sport, and Excitation-Calmness.

In the second step of fuzzy survey, the data base obtained from the first step was used in order to give the participants a chance for comparing (and making a convergence between the mental concepts of Kansei terms), and also enhancing the accuracy of their choices. A frame of the survey interface is shown in figure 6. All participants were asked to firstly score the vehicle in the left side of the screen and then click the Enter button to see the car with the closer score to her choice. She was then free to change in her assigned scores according to her preference and was able to see the changes in data base accordingly. She was able to continue the procedure as long as she would feel pleased by her scores.

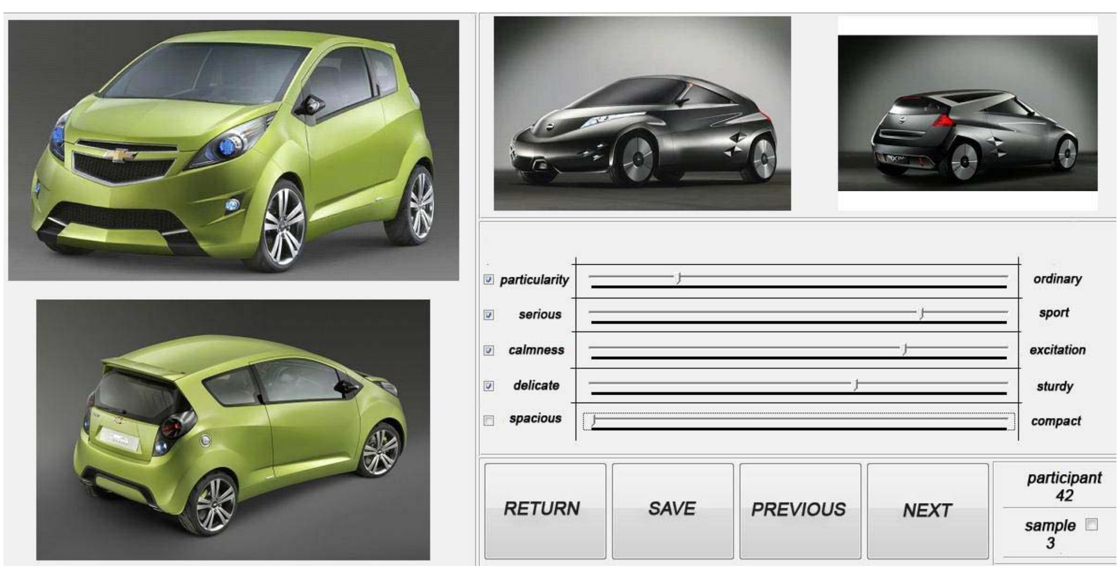

Figure 6. Fuzzy survey interface sample (Phase 2)

Importance weight extraction and final quantification

Due to the overall positive meaning of all of these attributes, in the next task they were all graded based on variance, which means that attributes with lower range of variance are of the most importance and have balanced mixture of both polar attributes, and vice versa. So, the attributes were again prioritized and scored applying AHP based on variance. Table 3 presents the new degrees of these attributes after AHP.

FINAL SCORE	ATTRIBUTE
0.177954	Spacious-Compact
0.088992	Sturdy-Delicate
0.077788	Particularity-Ordinary
0.09352	Serious-Sport
0.06641	Excitation-Calmness

Table 3. Final score of attributes based on pure quantitative procedure

Results Convergence:

After comparing the result of both methods (the pure quantitative method and the new co-qual-quan-titative method), it seemed that there was a meaningful correlation between the two sets of results. It was also expected that there would be such correlation and similarity between the results, because we have had selected a concrete and previously well defined object as the object of the design: a car. But it should be clearly mentioned that for different design objects or methods (for example for pure conceptual or state-of-the-art objects of design or for methodologies which use pure conceptual medium objects) there will be no guarantee for the convergence of the two results, indeed there will be a degree of divergence from a little difference between outputs of two methods up to total different sets of results.

Conclusion:

The new methods of design require the designer to use the numeric and quantitative tools. On one hand the daily developing use of CAD tools and computers and on other hand the need for satisfying the public interest, both force the designer to use computational and quantitative methods. This surely will save a lot of time and expenses in the manufacturing and designing industries, and accordingly will guarantee predicted success for the product.

But on the other hand, this may rise up some new problems in the design area: the designer role will be diminished and the users may show a faulty or unaware response to the quantitative design tool. This requires the methodology designers to revise the methods for overcoming this method.

On of the solutions is to inject some sort of “unconscious” awareness to the tool, and on the other hand there should be always enough role be left for the radical or intended presence of the designer.

As the result of such intention, we have re-designed some parts of a classic “Kansei Engineering” methodology to fulfill these needs. We have added some qualitative methods (as mentioned above, including PPP, MoodBoard and AHP) to the methodology and tried to expose the participants to some fully conceptual aspects and meanings of the object of design. Also we have tested the results in a real-world implementation, a project entitled “Designing and Implementing an Artificial Design Tool Based on Improved Kansei Engineering”.

As the final verification method, and as long as the subject of our project permitted us, we have rechecked the whole results with a pure quantitative and tested method and the result was to a compelling degree consistent. Despite what was mentioned above, in different design solutions or objects, the results might not be convergent like the mentioned project. However, as it seems that the philosophy of the modified methodology is enough reasonable and obvious, we suggest the usage of co-qual-quant techniques in such kind of complexities; for instance, a conceptual and ambiguous object or a culturally unfamiliar one. Not to mention the fact that surely there would be other combinations of such approaches, mixture of qualitative and quantitative approaches, which would yield the appropriate results.

The Success of Designer-producers in Québec

André Desrosiers, Université du Québec à Montréal, Canada

Abstract

The author identified more than 120 designer owned manufacturing companies in Québec. He interviewed 50 designers who owned such companies, and obtained detailed information on more than 75 companies. He examined these companies for: area of activity, size, longevity and economic impact. The companies are highly concentrated in the area of lifestyle products and are of comparable size to other manufacturing companies, show similar revenue per employee and have similar economic impact. They are also much more successful than other Québec manufacturers as far as longevity is concerned. These designer-owned companies create more direct employment than do industrial design consulting firms in Québec. The author proposes several hypotheses for the business success of designer-producers.

Keywords

Professional practice; Industrial design; Manufacturing; Business; Success; Québec

Since the 1960s, the practice of industrial design has been part of the industrial and cultural landscape of Québec. The demand for industrial designers was first felt among design consultancies, but the supply of design jobs within manufacturing companies soon greatly outnumbered that of consulting jobs (Emploi, 2009). This was followed by a new wave of employment in the virtual imaging field, representing a vocational route for a new generation of image-makers especially in the area of electronic gaming (Trépanier and Gosselin, 2007: 22). Other industrial designers began to work in public institutions, research organizations, in the promotion or management of design. A significant proportion of designers have also followed career paths that have led them to hold strategic or leadership functions in companies from a variety of sectors.

In addition, a good number of designers have edited, produced, or otherwise distributed their own creations at one time or another in their careers. Some of these designers have gone on to establish their own manufacturing companies. We call these entrepreneurs "designer-producers"—designers, because design is their field of training or what they claim to be, and producers, not only in the sense of manufacturers, but also in the sense of economic agents who participate in the risk and ensure the financing of their companies, much like film producers. These companies and their performance are the subject of this paper. It is based on a larger study, which was conducted in 2009, entitled "*Les designers-producteurs au Québec"* (Desrosiers, 2009).

The companies we have studied encompass the broad spectrum from craft production to mass production, from local manufacturing to offshore production, from regional distribution to global marketing. Though not common, the practice of designer-producer has nevertheless existed since the birth of industrial design (Choko et al., 2003). Are designers successful in business? Why do they succeed or fail? Are the economic repercussions of designer-producer companies significant? These are some of the questions this paper will address.

Methods used

From January to July 2009, around 50 interviews were conducted with designer-producers, usually at their companies or workshops, occasionally at a café or in their homes. During these meetings, the designer-producers often recommended other designers or identified other designer-producer companies. In this and other ways, our list grew and now includes over 120 companies. If one considers that no more than 3000 individuals practice industrial design in Québec (Emploi, 2009), but more realistically 1500, this list is actually quite extensive.[1] Without claiming that we have identified all companies, we are confident about the representativeness of our study. Since few studies had addressed this issue, we chose to chronicle not only current companies, but also those that were founded over thirty years ago and that are still active, have been sold or merged, or have simply closed.

The interviews were recorded and took place in two phases. A first questionnaire was used to identify the characteristics, motivations, and socio-economic profile of designer-producers, while a second questionnaire produced a description of each company. By combining a number of quantitative and qualitative questions in the interviews, we were able to use both types of information and establish correlations between the two where appropriate. The collected information was then revised, supplemented, and verified by consulting the *Registre des enterprises du Québec*, the database of the *Centre de recherche industrielle du Québec* (CRIQ, 2009) and the biographical notes of designers on their websites or in press kits (Choko, 2004). Several shorter phone interviews were also conducted.

Interviewees were not selected randomly. We attempted to reflect the geographical, historical, and economic diversity of the field. We interviewed in Québec City, Laval, Boucherville, Rigaud, Verchères, and of course, Montréal. We met men and women between 28 and 76 years of age, some whom have been designer-producers for most of their professional lives, and others who have only produced occasionally.

Where possible, and where our sampling permitted, we compared the data with those of similar studies focusing on entrepreneurship (Aramis, 2006) or the manufacturing sector in Québec (Statistiques, 2007).

Definition of designer-producer

In 2007, Michel Trépanier and Pierre-Marc Gosselin (2007:13-15) identified three types of industrial design practice: in-house industrial designers, industrial design consultants, and independent industrial designers or manufacturers. Our study addresses, in part, this latter category. It is our understanding that this last category is quite inappropriate and somehow assimilates practices that are often opposite in the spectrum of practices of industrial

---

1 Data from Service Canada shows 2,950 industrial designers in Québec. A review of this data and their definition suggests that Service Canada uses a broader definition of industrial designer than we do and includes many categories of draftsmen. Their definition is as follows: "Industrial designers conceptualize and produce drawings for manufactured products." A trade definition such as this is at odds with the professional vision that characterizes the industrial design milieu.

design. Leaving the discussion of this typology aside, and to further orient our study, we first define what we mean by “designer-producer.”

The definition of design provided by the International Council of Societies of Industrial Design can be read as follows:

"Design is a creative activity whose aim is to establish the multi-faceted qualities of objects, processes, services and their systems in whole life cycles. Therefore, design is the central factor of innovative humanization of technologies and the crucial factor of cultural and economic exchange." (ICSID, 2003).

This broad definition includes several activities not traditionally associated with industrial design. The design of a chirurgical procedure could certainly fit this bill, yet few would call this industrial design. It also encompasses both goods and services, and considers the aesthetic attributes of objects as part of their "multifaceted qualities.”

In this context, what is the meaning of "industrial"? Does it refer to mechanized or mass production, or simply to the processing of raw materials? How central are materials to this definition when all around us, objects are being defined less and less by their materiality, and more and more by the meanings and values we attribute to them? Furthermore, the definition of “industry” is associated with the production of goods as opposed to the provision of services. This separation between goods and services, already outmoded (Findeli, 2001: 15), is increasingly difficult to maintain. In our modern economies, goods can practically no longer be dissociated from services, and vice versa. Whether we are talking about a bank account booklet, a simple light fixture sold with a guarantee, or software for a video game console, all these products reflect this duality.

We have opted for the broadest and most inclusive notion of industry. We visited designer-producers whose workshops occupy a few square meters, and we visited major industrial facilities. We also looked at companies whose entire production is outsourced, and other companies where every stage of production is conducted in-house, including the manufacturing of their moulds and production tools. In the lighting industry alone, we met artists, craftspeople, technicians, architects, graphic designers, environmental designers, and industrial designers who have started and operated manufacturing companies. In our opinion they are all designers. They define themselves as designers as does the general public. As such, we met designers from a variety of training backgrounds, with different experiences and with various business skills. In this study we did not consider diplomas as the sole criteria for defining professional identity. Rather, we placed an emphasis on the accounts of the participants themselves.

Insofar as we were interested in the practice of designers who have started production companies, our primary concern in this study was the examination of manufacturing companies. Thus, although consulting firms are obviously companies, and their owners and founders entrepreneurs, they were excluded from our area of research unless they comprised a division or branch whose mission was to produce, manufacture, or distribute goods. We also excluded from our interviews those companies whose main activity is trade.

We thus define designer-producers as “designers who have undertaken to produce goods and services (or have them produced) and to market them." This definition encompasses both artisans and more traditional manufacturers, and is one that the people whom we interviewed could easily identify with.

Measure of Success

Early in our study, we wanted to identify factors and markers of success. It quickly became apparent that the concept of success is relative (Chandler et Hanks, 1993). First, success is relative to each entrepreneur and to each entrepreneur’s motivation for transforming his or her project into a company. While money was a primary motivation and a measure of business success for some, it was not the case generally. For many designers, distribution, reputation, the satisfaction of seeing their products sold and therefore purchased, lifestyle, as well as independence were the main motivations. Secondly, success is relative to that of others.

To a large extent, it is the motivation of the entrepreneur that defines his success. Satisfaction changes over time as the motivations of entrepreneurs change. Achieving a goal can sometimes bring about a new one, while for other entrepreneurs, attaining the goal or the original vision is an end in itself.

While all businesses must end, the great majority of entrepreneurs invest time, effort, and money so that their ventures will last. It is interesting to note, however, how the expiration date of a company is a concept that, at least initially, is foreign to entrepreneurs. A few did foresee the end of their ventures, but for the most part, these projects were of indeterminate length (Desrosiers, 2009:21).

In industrial design, longevity is rarely a measure of success. Most design awards, for example, do not recognize the durability or longevity of goods. Instead the organizers request that these products be recent, usually less than two years on the market. There are even awards for products that do not or will not exist. Design tends to celebrate innovation and novelty, not longevity and durability. For the few designers that enjoy license revenues, however, longevity does have its rewards. It is ironic that in industrial design it is easier to obtain an award for a product that does not exist than to get one for a product that has sold for a decade.

In business, it is generally accepted that profits, size and longevity (Dafna, 2008: 305-306) are the ultimate measures of success. Since unprofitable businesses do not endure, we considered profit a *sine qua non* condition for a company’s survival, i.e. it is a means more than an end. In terms of economic impact, job creation, and social utility, a company's longevity is certainly an indicator of its success, and it is the indicator we retained.

Findings

Areas of company activities

The fields of application of industrial design are many and varied. Each year, in Québec universities, a large number of undergraduate projects in industrial and environmental design are related to the fields of transportation, health, sports and recreation, and electronics. Furniture and household consumer goods are also presented, but they clearly do not represent the bulk of the projects of these future designers.

Through their creative input and diverse technical expertise, designers are able to contribute to a wide variety of industries. It must be said, however, that the more a product undergoes transformation and processing, the more designers are involved in its production. Designers are mostly absent from the primary and food sectors. Although it is difficult to classify companies according to the level of contribution of designers, based on the NAICS,[2] we separated industries into two groups: those that are "accessible" to designer-producers and those that are not. In Table 1, industry groups that we considered "accessible" appear in bold. Columns indicate the percentage of manufacturing shipments by year for each industry group.

	1992	1997	1998	2001	2002	2004	2006	2008

Industries not accessible to designers	59,4	55,3	54,2	53,5	53,9	55,4	59,6	61,1

Table 1. Québec manufacturing shipments, by industry group, 1992-2008, in % (Enquête, 2009)

Many in-house designers work in the transportation or rubber and plastic industries, which alone account for 16% of the manufacturing activity in Québec, and about 40% of accessible manufacturing. In contrast, about two-thirds of designer-producers form companies related to household objects (furniture, decorative accessories, lighting, tableware). Out of some 100 companies established by designers, 30 were from the furniture sector, 13 from the lighting sector, and 18 from the decorative accessories or

2 North American Industry Classification System.

tableware sector (figure 1). Therefore, designer-producers tend to operate in areas that represent only about 5% of manufactured goods in Québec. We were thus able to identify the sector of choice for designer-producers (table 2).

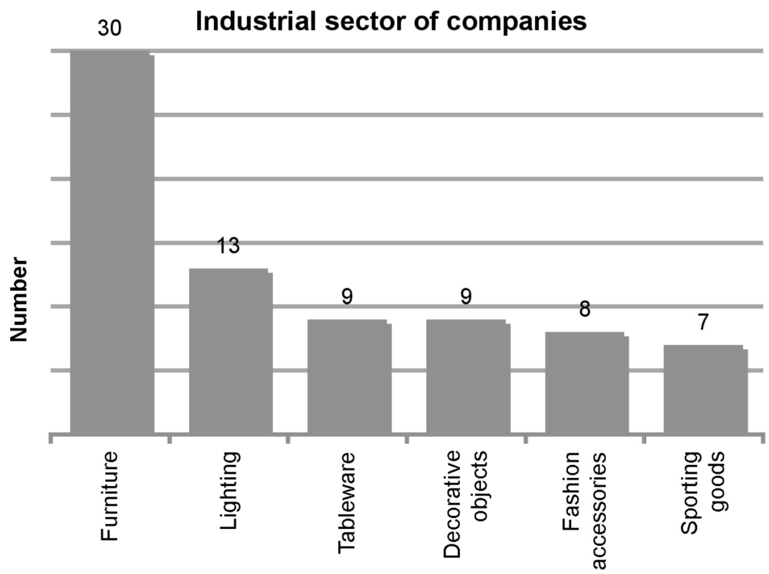

Fig 1. Industrial sector of companies founded by designer-producers

We must be cautious in interpreting these figures, since there is no indication that business opportunities are distributed proportionally to manufacturing shipments. The fact remains that the chosen area of activity of designer-producers is not driven as much by market opportunities as by their love of the activity and the prospects it offers for self-expression (Desrosiers, 2009:19). One could argue that this area requires less investment, or that there are fewer technical and commercial challenges; this is not the case, however. Recent years have been extremely demanding for the furniture sector, with fierce international competition and a particularly difficult economic climate.

	1992	1997	1998	2001	2002	2004	2006	2008
Electrical Equipment, Appliance, and Component Manufacturing	2,6	2,1	2,1	2,4	2,4	2,4	2,6	2,5
Furniture and Related Product Manufacturing	2,2	2,1	2,2	2,9	3,0	3,0	2,5	2,6
Sectors of choice of designer-producers	**4,8**	**4,2**	**4,3**	**5,3**	**5,1**	**5,4**	**5,4**	**5,1**

Table 2. Manufacturing shipments in sectors of choice for designer-producers by industry group, Québec, 1992-2008, in % (Enquête, 2009)

Designers create companies in areas they are passionate about (Desrosiers, 2009:18). For a few designers, this means sports or recreation, but the vast majority opts for the more expressive areas of decorative and household objects. This passion for beauty, for personal expression and aesthetics, is the same motivation that led them to design. This feature of designer-producer companies is important and reveals the underlying motivations of this group of entrepreneurs. It also underlines the historical link between the design profession and decorative arts, here as elsewhere. But does this passion, infused with emotion, prevent entrepreneurs from cogently building their companies, or on the contrary, does it provide the necessary fuel for driving them?

Company size

Some measurements are used to assess a company's size, the most common being the number of employees and sales. These two factors vary considerably during a company's life cycle. From the entrepreneurs we interviewed, we obtained the highest sales and employee numbers on record for each company. We must therefore be cautious about the resulting portrait because it is the most favorable possible. For example, our top company in terms of job creation employed 300 people. However, these jobs were not all in Québec, and the company shut down abruptly in 1982 because of soaring interest rates.

The number of direct jobs is an important economic and social indicator (figure 2). We obtained employment data for 75 companies. About half of these companies had two employees or less. The average number of jobs created, at peak employment, was nineteen.[3 4] About one third of the companies had created no jobs, while nine companies had created more than fifty. The latter are all well-established, commercially successful companies.

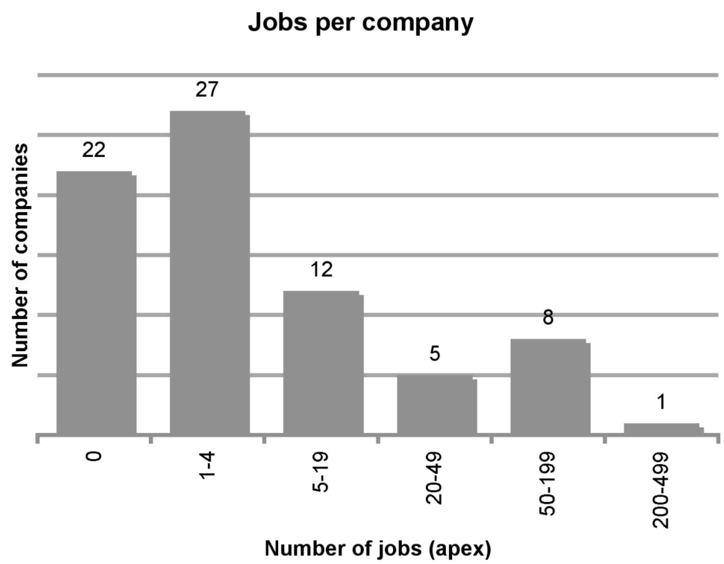

Fig 2. Number of jobs created per company

3 Mean = 18.79; standard deviation = 46

4 If we survey only job-creating firms, the average increases to 27 jobs.

Questions can certainly be raised about companies that create no jobs or whether they can be legitimately considered businesses. A large proportion of these companies were created for specific projects, but were dissolved for lack of income; a few remained active because there was no reason to close them, and some remain at the start-up stage. Nevertheless we chose to consider all of the above as businesses.

Another measurement of a company's size is its revenues. Total median revenues were $100,000 per year. This represents total median revenue of about $50,000 per job. This low revenue per job indicates that these are generally small and not particularly productive companies. It also indicates that a significant portion of these companies are not creating jobs. The chart (figure 3) shows the distribution of companies by revenue. The average maximum annual sales per company were around $2,000,000, with revenues around $100,000 per job. As in most industrialized societies, a high proportion of these companies are micro-enterprises, but a third of designer-producer companies showed sales in excess of $500,000.

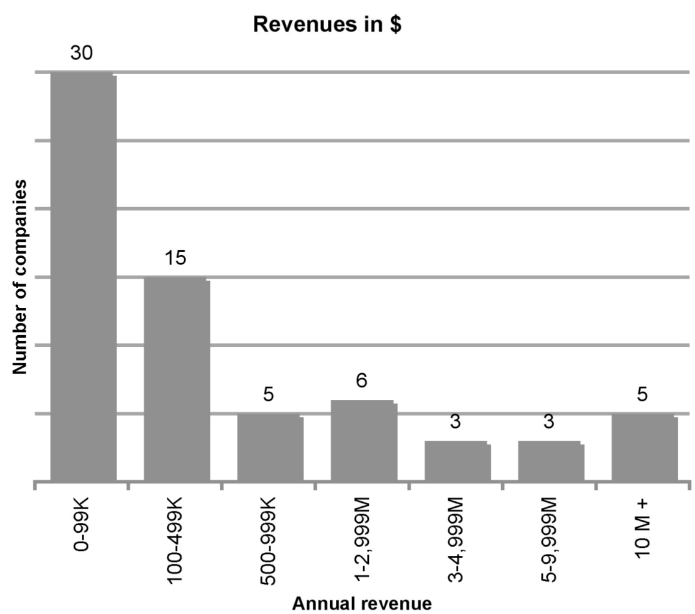

Fig 3. Annual revenue per company

When compared to the manufacturing sector in Québec (Statistiques, 2007), designer-producers companies fared well, creating slightly more jobs per establishment and with slightly higher revenues per employee. When compared to other companies in the sector of choice of designer-producers, their results were somewhat similar to their peers.

Company longevity

One of the main questions this study seeks to answer is whether designer-producer companies are successful. We wish to know how they compare to other companies in Québec. At the beginning of this section, we examined and then defined the notion of success in terms of a company's longevity. In 2008, the MDEIE[5] published a study entitled "*Taux de survie des nouvelles entreprises au Québec*"[6] (Desbiens et al., 2008). Unfortunately, we were unable to compare our results directly with results from the MDEIE study. We did not have access to the data it used, and it was difficult to ask owners about data from their companies' T4 slips (fiscal employment slips) for past years. In addition, we would have had to compare data from the same cohorts and ensure that we had identified all companies of a single and same cohort.

Whereas the authors of the survival rate study define a company as "an economic and social structure having at least one employee working in an organized manner to produce goods or services for its customers" (Desbiens et al., 2008: 88), we did not consider employment as a necessary criterion for inclusion in our sampling. However, we did use this definition in determining the survival and continuity rates of designer-producer companies, so we could better compare them. We have vested significant efforts in identifying the largest possible number of designer-producer companies. It seems likely, however, that companies that shut down abruptly for lack of funding, markets, or perseverance may be underrepresented in our sample. Since these false start-ups rarely generate jobs, we estimate that this has had little impact on the survival rates we have calculated.

In examining the survival rates of all manufacturing firms in Québec, we found that half of them ceased their activities after three years (Desbiens et al., 2008: 43). If we examine the same rates for designer-producer firms, we note that these companies survive, or endure, for a long time. Three quarters of the companies are still operating after nine years (figure 4).

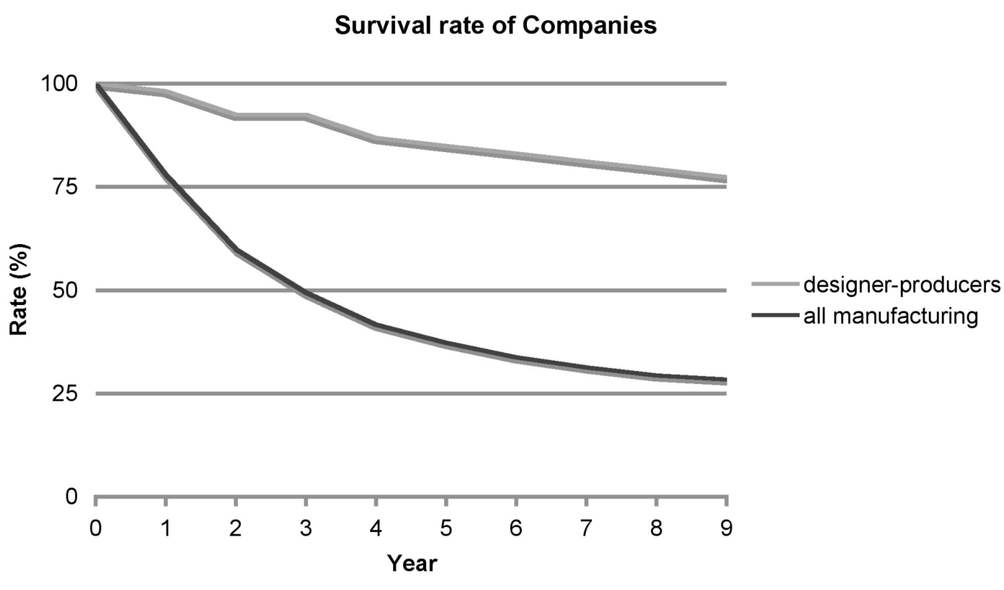

Fig 4. Comparative survival rate of companies in Québec

5 Ministère du Développement Économique, Innovation et Exportation

6 Survival rates of new businesses in Québec

Economic impact

Do the companies we studied have a significant economic impact? Obviously they do for the thousands of people who depend on them for their bread and butter. We estimate at aproximately 13,000[7] the number of job-years created by the 74 firms we surveyed, and nearly 19,000 if we extend our results proportionally to our entire population of companies. It is both a little and a lot. A little, given the millions of job-years represented by the Québec job market, and a lot when one considers the small number of designers trained here and the 125 companies identified in our study.

These jobs are, for the most, productive, wealth creating, unsubsidized jobs, and they have a multiplier effect within the economy.

We compared the number of direct jobs created by designer-producers with those created by designer-consultants. Using the MDEIE directory of industrial design consulting firms (Répertoire, 2009), we were able to total the number of employees represented by this sector. All told, there were 370 jobs for 140 consulting firms or self-employed consultants.[8] Even if we extrapolate these jobs over thirty years,[9] it is clear that designer-producers create at least as many jobs in Québec as do designer-consultants. This is not the only measurement that quantifies the economic activity and impact of designers, but it affirms that the practice of designer-producer is as important as that of designer-consultant in terms of job creation. Both practices, therefore, deserve the attention and support of educational institutions and governments.

There are other impacts of designer-producer companies. Inasmuch as they produce innovative and original products, these companies contribute to the cultural identity of Québec and Canada. The economic value of innovation and its relevance as a business strategy has often been debated, especially in societies in which money and the price of objects are first-order criteria. Despite our passion for design, the answer is not always obvious or rational. What is indisputable, however, is that all societies, to varying degrees, express and identify themselves through the objects they produce. It is a source of pleasure and pride for them. This, then, is an undeniable contribution of the companies we have described.

Discussion

Despite the small size of our sample and the difficulty of comparing the data we collected, nothing leads us to believe that companies formed by designers are less successful or less performing than others. We even dare assert that, in the manufacturing game, designer-producers fare particularly well and have greater staying power than other companies. We offer a few explanations for this.

- Design has been established as a factor of success for public companies by previous studies (Design Council, 2004) and books (Martin, 2009). Whereas several studies have shown that design benefits differentially the companies that use it (Abdel-Malak et al., 2008), our sample used design to the greatest extent of all.

---

7 Job-years = Σ (jobs apex x company duration / 2)

8 We excluded one company that was clearly not an industrial design consulting firm, and two professors of design.

9 340 jobs x 30 years = 11,100 job-years

- For many companies, developing a new product is a costly, risky, and lengthy process involving no revenue and many expenses. For designer-producer companies, such expenses are minimal and are usually associated with the cost of making prototypes. The ability of these companies to last, if only for the time it takes to develop their first products, is greater than that of comparable manufacturers. Designer-producer companies nearly always survive the product development phase. Designers are particularly well suited to making prototypes, building trademarks, and producing their company's image.
- Their founders may unduly keep some companies alive. In many instances, these companies act as avatars for their creators, fulfilling an emotional need to exist as a designer. Whether they generate revenue or not seems secondary to their owners.
- A large proportion of our subjects had university training in design (82%) and the occurrence of entrepreneurs in their families (80%) was very high (Desrosiers, 2009: 15-16).
- It may also be that the project-based training of designers, and thus “the abilities to reconfigure a firm’s resources and routines in the manner envisioned and deemed appropriate by its principal decision-maker(s)” (Zahra et al., 2006: 918), are particularly conductive to starting and maintaining a successful manufacturing business.

We propose that the answer to the manufacturing success of designer-producers lies somewhere within these explanations.

Conclusion

Designers create successful and relatively durable companies that generate economic and cultural wealth. Such companies are heavily concentrated in the areas of decorative objects and furniture, and make original products that stand up well against international competition and contribute in concrete ways to collective wealth. Designer-owned companies vary in size and represent different levels of risk. They constitute attainable and achievable projects. These companies generate more direct jobs than all design consulting firms in Québec put together. Despite this remarkable track record, the practice of designer-producer has been overlooked by design history and education in Quebec.

Whether as in-house designers, as consultants, or as designer-producers, designers could benefit from a more refined and developed ability to recognize business opportunities and the societal changes that underlie them. The university training that designers receive greatly shapes their professional identity. If this training supports and promotes an antiquated, incomplete, and borrowed image of a profession that itself is in constant evolution, this will only lessen the opportunities available to graduates. In Quebec, today’s designers are not only apt at creating new products for business ventures; they are also very capable of creating the ventures themselves.

It is important for the training of designers to be relevant and to better prepare them for the contemporary challenges of economic competition. Insofar as we have shown that designer-producers are an economically viable creative force and that they are numerous, there is ample reason for including notions of entrepreneurship and business in the training of young designers. This single action will, in turn, affect the perception that this profession has of itself.

It would be desirable to compare our observations with those made elsewhere, especially in economies that are the most dynamic and creative in terms of design. Such further research could help to determine the necessary knowledge to better equip future cohorts of industrial designers.

Author Biography

André Desrosiers

André Desrosiers is a designer, contractor, industrialist, editor and professor. After graduating from the Université de Montréal's School of Industrial Design in 1980, he worked as a designer for several design firms on a wide variety of products. Soon after, he launched his own manufacturing company. He has taught industrial design at the University of Montréal, and is currently a guest professor at the School of Environmental Design of the Université du Québec à Montréal. His domains of expertise and interest include Quebec industrial design, intellectual property and the relationship between designers and business.

Design, Democracy and Agonistic Pluralism

Carl DiSalvo, Georgia Institute of Technology, carl.disalvo@lcc.gatech.edu

Abstract

In this paper, the author presents an alternative approach to 'design for democracy,' drawing on the notion of agonistic pluralism. Specifically, the author highlights the differences between politics and the political within agonistic pluralism, and employing examples of contemporary design projects, discusses how these differences can been seen in the objects and practices of design. Through this critical examination, the author contributes a new perspective to the discourses of 'design for democracy' and expands the possibilities for democratic action and critique available to both practicing designers and design scholars.

Keywords

Design, Politics, Political Design, Agonism, Democracy

Over the past decade there has been an increased interest in 'design for democracy.' Not only are these efforts significant for design practice, they also suggest new topics and trajectories for design scholarship. However, within the mainstream practices and discourses of 'design for democracy,' the notion of what constitutes democracy is relatively unexamined. If we study the projects and papers that populate this arena, it seems our familiar notions of democracy are taken as a given good: it is implicitly accepted that democracy is a matter of pursuing consensus through activities of structured deliberation and 'design for democracy' primarily involves improving the mechanisms of participation in politics. Although such endeavours are crucial, they do not express the range of democratic action and critique available to practicing designers or design scholars.

In fact, the concept of democracy is neither given nor fixed. What democracy was to the Greeks is not usually what we consider as democracy today, and democracy in the United States is different is different from democracy in Sierra Leone, which is different from democracy in France. Even within a single nation-state system, the ideals and practices of democracy vary widely. As a thought experiment, we can consider democracy along a spectrum. At either end of the spectrum are governing principles and associated concerns, which serve to characterize democracy and suggest possible courses of action and critique. At one end of the spectrum, the governing principle is consensus and the associated concerns are those of access to information and procedures. At the other end, the governing principle is contestation and the associated concerns are those of revealing and challenging hegemony. Although such a diagrammatic model of democracy is simplistic and exaggerated, it is useful for considering the range of differences within the concept we call democracy.

The diversity of ideas about what constitutes democracy *should* have impact on design and design studies because they suggest different, at times fundamentally different, courses of action, themes for inquiry, and bases for judgment and critique. The trouble is that the exemplars of design practice and scholarship that fall within the context of 'design for democracy' overwhelmingly gather at that end of the spectrum governed by the principle of consensus and the associated concerns of access to information and procedures. Thus, we have a limited notion of what counts as 'design for democracy.' This is a problem because if design is to truly serve democratic ends, and if design scholars are to study the relations between design and democracy, then an understanding of the range of democratic thought and action is necessary in order to better design artefacts and systems that enable or enact democratic conditions, and more rigorously study those products and their contexts of use.

In this paper I will present an alternative approach to 'design for democracy,' drawing on the notion of agonistic pluralism. Specifically, I will highlight the differences between politics and the political within agonistic pluralism, and employing examples of contemporary design projects, discuss how these differences can been seen in the objects and practices of design. In doing so, it is not my intention to dismiss or diminish existing important efforts in mainstream 'design for democracy' projects, but rather, to outline a wider range of possibilities for democratic action and critique available to designers and design scholars.

Agonistic Pluralism: A Model for Rethinking Democratic Action and Critique

Agonistic pluralism is a model of democracy grounded in productive conflict or contest. In theories of agonistic pluralism, democracy is cast as an endeavour of fervent competition and struggle among competing ideals, values and beliefs. This competition and struggle takes place through all forms of social practice and material assemblages, including customs, laws, institutions, the built environment and designed products. In contrast to more familiar notions of democracy epitomized by scholars such as Habermas and Rawls (Habermas 1989; Habermas 1996; Rawls 1971; Rawls 1993), which prize rational deliberation and consensus, theories of agonistic pluralism acknowledge the presence and necessity of radical difference and contentious expression in the practice of democracy. This is not to say that rational deliberation and consensus are impossible from the perspective of agonistic pluralism, but they are not the default or required conditions and qualities of democracy (Connolly 1991; Connolly 1995; Honig 1993; Lalcau and Mouffe 1995; Mouffe 2000, Mouffe 2000b).

For political theorist Chantal Mouffe, the beginnings of an agonistic pluralism reside in recognizing the paradox of democracy: that a pluralistic society is a goal that must be pursued, but can never be fully achieved (Mouffe 2000b). The pursuit of a pluralistic democratic society is characterized by conflict because it is conflict, expressed as tension, friction and dissension, that defends against the erasure of difference. As Mouffe states:

> What is specific and valuable about modern liberal democracy is that, when properly understood, it creates a space in which this confrontation is kept open, power relations are always being put into question and no victory can be final. However, such an 'agonistic' democracy requires accepting that conflict and division are inherent to politics and that there is no place where reconciliation could be definitively achieved as the full actualization of the unity of 'the people'. (Mouffe 2000b, p. 15)

Drawing from Mouffe, one of the tasks of those wishing to support and further democracy is, then, creating and enabling these spaces of contest. In such spaces, difference and dissensus are brought forward and the assumptions and actions that shape power relations and influence are revealed and challenged.

There are a multiplicity of these spaces of contest and a multiplicity of forms and modes of agonism. In fact, one of the characteristics of agonism pluralism that sets it apart from more familiar models of democracy is that it does not require, or even desire, a unified public sphere or uniform set of procedures to enact democratic ideals. Often, and particularly within the academy, the spaces of contest are discursive: lectures, journals and books. Beyond the academy they include the organizing and lobbying activities of social movements, such as those concerned with labour, human rights or the environment. The legislative and judicial systems are also active spaces of contest, as conflicting and competing ideals, values and beliefs are played out through laws and regulations: the contests concerning abortion in the United States being a prime example (see Honig 1993). The questions from the perspective of design then are: *How can we distinguish design in the context of agonistic pluralism from more mainstream objects and practice of 'design for democracy?'* and *How can design objects and practices work in support of an agonistic pluralism?*

Politics and the Political in Agonistic Pluralism

In discourses of agonistic pluralism, politics and the political have distinct meanings. These distinct meaning are useful for distinguishing among designed objects and practices and beginning to describe alternate — agonistic — 'design for democracy' endeavours. In the discourses of agonistic pluralism, politics are *the means* by which a state, organization or other social order is held together: politics are the structures and mechanisms that enable governing. These range from codified laws and procedures to unspoken but observed habits of interpersonal interaction and performances of beliefs and values. Different from these means, the political is *a condition* of society. It is a condition of ongoing opposition and contest. This condition is experienced and expressed in a multiplicity of ways, from debate to acts of provocation, protest and resistance.

Within discourses of agonistic pluralism, the problem with politics is that the structures and mechanisms of governance often hide or mitigate the essential contests of life. In benign forms, this occurs in an effort to lessen public strife and smooth the processes of governance. In less benign situations, politics become the very methods of extending hegemony by feigning to provide opportunities for expression and action, thereby re-directing or sublimating contestation and reinforcing the status quo (Honig 1993; Mouffe 2000). Put another way, politics often functions to *counter* the political. This is a problem because following from the frame of agonistic pluralism, engaging the essential contests of society is an inherent and necessary characteristic of the democratic endeavour. Whether benign or not, diverting attention away from the political by a focus on politics, i.e., a focus on the improving the mechanisms of governance, can endanger the practice of democracy because it draws us away from engaging in the contestation necessary for democracy.

The difference between politics and the political has significance to the practice and study of 'design for democracy' because it allows us to make meaningful distinctions between projects based upon how they engage with the democratic endeavour. Most 'design for democracy' projects fall within the realm of politics, with a focus on improving structures and mechanisms that enable governing. They are 'design *applied to* politics', or 'design *for* politics.' While such projects are important, they are not political in an agonistic sense and they do not represent the range of possible thought and action available to design within the democratic endeavour. If we accept the notion of agonistic pluralism as at least one possible approach to democracy, then we should ask, *What are examples of 'political design' rather than 'design for politics?*' and *How, as design studies scholars, would we describe, analyze and judge such practices and objects?*

Exploring The Differences Between Design for Politics and Political Design

The most direct way to explore the differences between design for politics and political design is by comparison of projects that fall within these rubrics. The Design for Democracy (DfD)[1] initiative within the American Institute of Graphic Arts (AIGA) is emblematic of design for politics. Although it does not encapsulate all of the activities that fall under the general rubric of 'design for democracy,' it is a concerted effort to provide a professional organizational structure to such efforts within the United States, and as such provides a salient example. According their self-description, DfD "applies design tools and thinking to increase civic participation by making interactions between the U.S. government and its citizens more understandable, efficient and trustworthy." (AIGA 2008) The programs within the DfD initiative are indeed broad reaching. They include the *Get Out The Vote* program which solicits non-partisan graphic design to promote voter registration and participation; the *Government Officials: Get Help* program which provides design services to "make government more accessible, transparent, and efficient" (ibid); the *Polling Place Photo Project* which solicits and presents citizen journalism documenting the voting experience in the United States; a design advocacy program to promote the importance of design in government; and the *Ballot and Election Design* program which strives to improve the experience and increase the efficacy of voting through the redesign of ballots, polling place signage, instructional materials and poll-worker training materials.

As a counterpoint, the *Million Dollar Blocks*[2] project provides an example of political design: it is a project that is implicitly contestational and demonstrates one notion of what 'design for democracy' might be like from the perspective of agonistic pluralism. Developed by Laura Kurgan at the Spatial Information Design Lab at Columbia University, *Million Dollar Blocks* uses geographic information systems (GIS) to map crime-related data. Rather than asking, *Where does crime occur?* or *Who are the victims of crime?*, as is the common approach to crime-mapping projects, Kurgan begins the project with the question, *Where does the prison population come from?* The primary product of the project is a series of maps of fours cities (Phoenix, Wichita, New Orleans, and New York),

[1] See http://www.aiga.org/content.cfm/design-for-democracy, access January 24, 2010.

[2] See http://www.spatialinformationdesignlab.org/projects.php?id=16, accessed January 24, 2010.

which graphically depict the distribution of the residences of prison inmates throughout the respective cities. In addition to the maps and related information graphics, Kurgan and her colleagues have produced two self-published books documenting the process and issues, *The Pattern* and *Architecture and Justice* and a scenario-planning workshop (and accompanying documentation) with design professionals and community, civic, and social justice organizations and individuals.

The efforts of DfD in election design have had direct and measurable effect: in 2007 the U.S. Election Assistance Commission accepted the AIGA guidelines for ballot and polling place information design; the *Polling Place Project* has garnered significant participation with thousands of photos submitted and presented; and the *Get Out The Vote* program has produced dozens of compelling posters, replicated in the thousands. This work is exemplary of design for politics: the purpose of the work is to support and improve the mechanisms and procedures of governance. This purpose is clear in the positioning of the work and the stated motivations, e.g., increasing voter participation, making government more transparent and efficient, increasing the efficacy of voting through design.

In contrast, *Million Dollar Blocks* does not work to support and improve existing means of governance. Rather, it strives to critically investigate an issue and raise questions concerning the conditions of that issue. By asking *Where does the prison population come from?,* Kurgan reframes the discussion of crime and the built environment. As she states:

> By focusing solely on [crime] events, the human underpinnings of crime were left largely unaffected. When we shift the maps' focus from crime events to incarceration events, strikingly different patterns become visible. The geography of prison differs in important ways from the geography of crime. (Kurgan 2008)

From this question more questions follow. A key question for Kurgan is, *Is their pattern in this data that reflects a pattern in an underling condition?* and if so, *How might the recognition and interrogation of that pattern bring to light inequalities as they are manifested in the urban environment?* The title of the project — *Million Dollar Blocks* — comes from the recognition that there is indeed a pattern: within any given city, there are sets of city street blocks in which the government is spending more than $1,000,000 annually to incarcerate residents of those blocks. Discovery and articulation of this pattern then raises further questions such as *Who lives on those blocks?*, *What are those blocks like?,* and *How might that money be otherwise spent and perhaps to better effect?* The *Million Dollar Blocks* project can thus be considered as exemplary of political design because it functions to reveal, question and even challenge conditions and structures in the urban environment, that is, it opens a space for contest, and too, it suggests new practices of design in mapping and urban planning.

Agonistic Pluralism and the Work of Political Design

One way to approach the description, analysis and critique of political design in design studies is by examining its purpose, or the work it is supposed to do. Simply stated, the purpose of political design is to do the work of agonism. This means first and foremost it does the work of creating spaces for revealing and confronting power relations, i.e., it creates spaces of contest. This occurs both in and through the objects and processes of design: the objects and processes of design are both the site and means of agonistic pluralism. For example, in the case of *Million Dollar Blocks*, the maps document the existing configurations and conditions of power, and serve as objects through which contestational claims can be made and arguments advanced. It is important to note that the processes of design can be agonistic and political as well. For example, the act of problem definition can be a contestational effort, as when Kurgan inverts the standard modes and directives of crime mapping, by shifting the question from *Where does crime occur?* to *Where does the prison population live?*

We can, however, be even more exacting in describing the work of political design. Through the process of creating spaces for revealing and confronting power relations and influence, political design identifies new terms and themes for contestation and new trajectories for action. Most often, and almost by definition, these terms, themes and trajectories are contra to those of common practices and discourses, and contra to design for politics.

The *Million Dollar Blocks* project engages in precisely this endeavour of identifying terms, themes and trajectories and runs counter to the utilitarian framing of design for politics. Beyond the literal naming of a condition (as 'Million Dollar Blocks'), the project reveals previously obscured configurations in the cycle of crime and incarceration. Through this revealing, these conditions and structures become available for debate and further investigation. In subtle but profound ways, the design artefacts and activities of the project question and challenge how we understand and use crime statistics and practices of mapping, and reveal what understandings, uses and implications we leave out of our analyses and representations. This is exemplified in a quote by Kurgan, describing the maps of the *Million Dollar Blocks* project,

> With this map, we stop talking about where to deploy police resources or how to track individual prisoners for institutional purposes; instead we begin to assess the impact of justice on a city, even a city block, and start to evaluate some of the implicit decisions and choices we have been making about our civic institutions. (Kurgan 2008)

These maps, then, provide the opportunity for an ongoing series of contests and dissensus concerning the relationship between crime, the built environment and policy; the political affects of maps as artefacts; mapping as a practice; and the city as a series of relationships between people and space. With this notion of revealing and contest, we can begin to consider political design as a kind of inquiry into the political condition. That is, whereas design for politics strives to provide solutions to given problems within given contexts, political design strives to articulate the elements that are constitutive of social conditions. Such a notion of political design as inquiry is hinted at when, in being asked about the purpose of the *Million Dollar Blocks* project, Kurgan replied, "I am not trying to find the solution, I am trying to find the right questions." (Kurgan 2008) The purpose of political design generally, and the efficacy of the *Million Dollar Blocks* project specifically, is not to be found in improving usability, extending functionality or achieving a readily identifiable form of change. Rather, the purpose is to prompt and act as evidence in new discourses and practices and as the foundation of new questions.

Conclusion

While projects such as increasing the legibility and use of voting ballots or providing access to the facts of issues ranging from climate change to healthcare are important, they are not political in an agonistic sense. Rather, they serve to support the generally accepted means of politics, and in the process, they may mitigate some of the productive tension, friction and dissension within society. The *Million Dollar Blocks* project provides a particularly useful example of an alternative — agonistic — approach to design. One value of it as an example is its familiarity in form and medium and its relative gentleness in contestation. This is of value because it serves to illustrate that political design that does the work of agonism need not fall prey to common misconceptions about conflict and contestation. Terms such as contestation often garner images of radicals clinging to extreme positions and beliefs, which they communicate in an aggressive and rough fashion, through outsider means. Such stereotypes inhibit taking political design seriously. *Million Dollar Blocks* is thus also a useful example because it demonstrates that political design can, and often does, consist of actions and processes from within, using familiar mediums and forms, to subtly, but powerfully, reveal and question the conditions and issues of democracy.

Although by no means complete, this essay makes a claim for the inclusion of agonistic pluralism in the practices and discourses of 'design for democracy.' Furthermore, it suggests how we might describe design that supports or fosters agonism by way of the distinction between politics and the political, and offers a distinction between design for politics and political design. In contemporary design, projects such as *Million Dollar Blocks* are the anomaly rather than the norm: there is much more work in the realm of design for politics than the political design. However, if we accept a broader notion of democracy, which includes agonistic pluralism as one among many possible conceptualizations of democracy, then we should accept that political design, such as *Million Dollar Blocks*, has a role to play in the democratic endeavour, and is one option of action and critique for practicing designers and design scholars.

The challenge for design scholars is to further consider how we might describe, analyze and judge these works. One possible framing device for design scholars is to consider how political design works to create spaces for the confrontation of power relations and influence by the identification of new terms and themes for contestation and new trajectories for action. We could ask of these works: *What new terms and themes were identified?*, *How do they reveal and challenge hegemony?,* and *What new trajectories for action are set?* The next step for design scholars is to build a discourse around political design, and to explore other alternative conceptualizations of democracy and their implications for practicing designers and design studies. This endeavour will not unfold overnight, but it offers unique topics and courses of action for designers and design scholars interested in the broad context of 'design for democracy.'

An Exploratory Study of Scientists' Perceptions of Design and Designers

Alex Driver, Carlos Peralta and Dr James Moultrie, Institute for Manufacturing, University of Cambridge, UK

Abstract

As part of a wider empirical study in to the potential role of industrial design in scientific research, a series of semi-structured interviews were conducted with scientists to understand how their perceptions of design and designers might influence collaboration.

This paper reports that scientists without prior experience of working with designers may be unclear as to their skills and areas of expertise, and may subsequently be missing out on collaborative opportunities.

Scientists perceive a greater possible impact on applied research through engagement of professional design skills. It was revealed that design interventions could be suitable for many scientists as their range of research activities is likely to include both basic and applied research. Opportunities were identified for designers to play a role in scientific research, especially with issues relating to communication.

Keywords

collaboration; multidisciplinary; industrial design; perception.

There is potential for industrial design to play an important role in the advancement of science and technology as highlighted by Lord Sainsbury in his 2007 Review of Science and Innovation. "Evidence suggests that the use of design helps scientists to develop commercial applications for their work while it is still at a research stage or at the outset of technology" (Sainsbury 2007, p151). Indeed there is substantial evidence of the value of industrial design in the development of new technology in industry (e.g. Kotler & Rath 1984, Lorenz 1994, Black & Baker 1987, Roy 1999, Gemser 2001, Hertenstein et al 2001). This work concludes that industrial designers can help to commercialise technology by becoming involved earlier in the development process. Despite this, surprisingly little academic work has been carried out looking at the role that industrial design might play in scientific research, from which much technology originates. Existing studies in this area are anecdotal and lack first hand evidence of the factors influencing collaboration:

- Chris Rust identified opportunities and barriers for collaborative work between designers and scientists, and outlined 'tentative principles' for designers in collaborative research (Chris Rust 2004 and 2007).
- The MIT media lab provides an environment for 'exploring basic research and applications at the intersection of computing and the arts' (http://www.media.mit.edu/research/ accessed Sep 2007). Similarly, there are a number of multinational firms who have experience of operating these 'sand-pit' environments; e.g. Microsoft, Bell Labs and Google.
- A pilot scheme was supported by the UK Design Council in partnership with the EPSRC and UCL Ventures, to bring design consultancies into scientific research (Design Council 2006).
- A UK Design Council scheme in partnership with Maddison Design and Oxford University brought design consultancies into university technology transfer offices (Design Council 2009).

To address the current gap in empirical research in this area, a study was set up at Cambridge University in which designers worked collaboratively with scientists in supporting their research activities. In addition to exploring the potential role of industrial design in scientific research, this study set out to understand how contingent factors such as the scientific discipline, the status of the research and the type of design intervention would influence collaboration. This paper presents the findings of a series of preliminary interviews conducted with scientists as part of this study, to gain insight into these issues.

The objectives of the interviews were:

1. To explore the scientists' perceptions of the status of their research in terms of how applied it is and at what stage of development it is.
2. To explore scientists' perceptions of design and designers and to understand how these perceptions may influence collaborative work between designers and scientists.
3. To gain scientists' views on the possible roles designers might play in supporting their research activities.

Although the focus of the study was on industrial design, the scientists were asked their views about design in the broader sense so as to capture their views on a wider range of issues.

The paper begins with a description of how a literature review influenced the design of an interview to achieve the above objectives. It then outlines the interview procedure before presenting and discussing the results. The paper concludes with implications for future study.

Literature Review

Classification of Scientific Research

Recognising that 'science' covers a wide range of disciplines and research activities, and that the role of design will likely depend on the context of the research, a method of classification of scientific research is required.

Pierce's outline classification of science illustrates the wide range of activities that employ a scientific method (Vehkavaara 2001). It was decided that participants from this study would be selected from a wide range of scientific disciplines including the physical (e.g. physics, chemistry, and biology), applied (e.g. engineering and medicine), formal (e.g. mathematics) and social (e.g. psychology) sciences.

Linear models have been applied to scientific and technological development in the form of Applied Science Readiness Levels (ASRLs) and Technology Readiness Levels (TRLs), which were developed by NASA to manage their R&D programmes (Millis 2005 p13, DoD 2002 pp204-205,). These models suggest that scientific research can be classified by developmental stages.

It is also important to consider the motivation for scientific research. Traditionally, research has been categorised as either "basic" or "applied", the former being focused on improving understanding of fundamental principles, and the latter focused on considerations of use. Stokes suggests that there is a third category of research motivated by both the pursuit of understanding principles and their application, which he called "use-inspired basic research" (Stokes 1997, p73).

Based upon these views, a model of scientific research was developed to position scientists' work both in terms of the stage of development and the degree to which it is applied. The model shown in figure 1 shares Stokes's motivations for scientific research, and anticipates definable stages of development similar to TRLs.

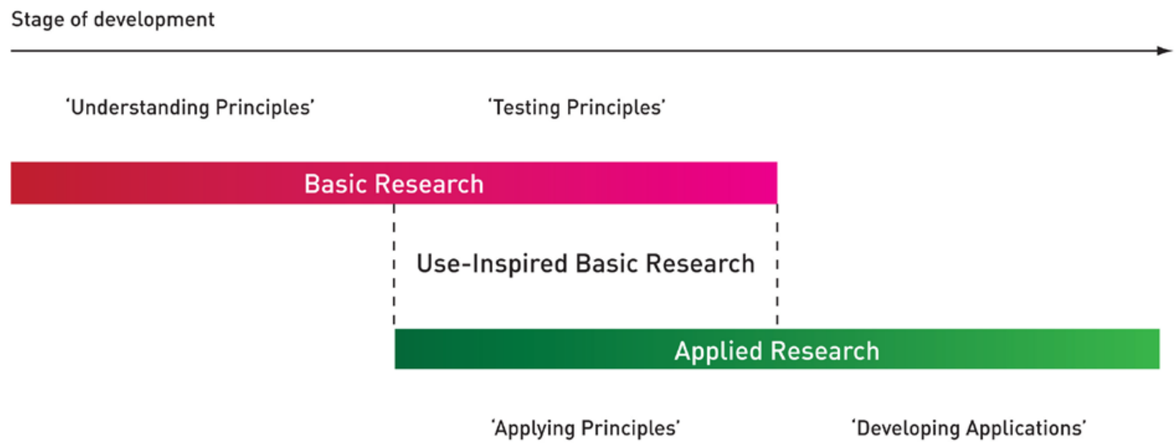

Figure 1 Model of Scientific Research

Designer Characteristics

In order to meet the second objective of the interviews, a list of characteristics was developed which could be used to describe a designer. It was decided that these would be adapted from the Scottish Credit and Qualifications Framework's list of the main areas of learning for students enrolled in higher education (SCQF 2007). This was because these learning areas were developed to reflect what is expected of a professional designer by industry. These characteristics were "Skills", "Knowledge", "Ways of Thinking" and "Role in a Multidisciplinary Team".

Methodology

Potential interviewees were selected following meetings with the head of research at the university's engineering department and representatives from the Research Services Division. Of the 28 scientists contacted, 12 were interviewed, 4 declined, 6 did not respond and 6 sent delayed positive responses. Of those who declined, 2 cited time restrictions and 2 felt that design played a very limited role in their research. Table 1 gives a short description of each of the interviewees.

Scientist	Background
Engineer 1 [E1]	• Manages a research group with a portfolio of projects • Direct experience of collaborating with industrial designers on a research project
Engineer 2 [E2]	• Previously sat on the committee of research councils with an interest in funding design • Previously worked for a group of trusts, one of which funded a collaborative student project with designers and engineers
Physicist 1 [P1]	• Manages a research group • External designers had developed a Graphic User Interface for software his research team had created • Advocate of open innovation in software development and computational science
Physicist 2 [P2]	• No experience of working with designers • Married to a graphic designer
Engineer 3 [E3]	• Experience of working with companies that employ designers
Biochemist 1 [B1]	• Manages a research group • Multiple university spin-out companies • Experience of employing designers in later stages of product development
Clinical Scientists [C1, C2]	• Work in the clinical engineering department of a hospital • Bridge the gap between clinical departments and engineering designers • Experience of working with companies who employ designers • Mostly single patient or single institution use – little commercial activity
Engineer 4 [E4]	• Manages a research group • Previously managed a team including scientists, engineers and designers in industry • Experience in the commercialisation of products
Biochemist 2 [B2]	• Working on a collaborative project between biologists and chemical engineers • No experience of working with designers

Psychologist 1 [PSY1]	• Established a research group into multidisciplinary design • A member of the governing body of a leading art and design university
Material Scientist 1 [M1]	• Manages a research group • A member of a commission that funds student designers
Chemist [C1]	• Working on a collaborative project with an engineer and an architect • Married to an architect

Table 1 Interviewees

Interview Procedure

A semi structured interview was created which was split into three sections to meet the objectives stated in the introduction. The interviews lasted approximately an hour and were recorded for later transcription. The interviewees were informed that they would remain anonymous.

1. The scientists were first asked to describe their field of research, a current research project and their day-to-day research activities. They were asked to try and identify stages of development of their research and to comment on how applied they considered it to be. They were then presented with the model of scientific research developed in the literature review and asked to use it to try and position their work.
2. The scientists were then asked to describe what they understood by the word 'design'. If they had experience of working with designers they were asked how successful the collaboration had been and how they overcame any difficulties that may have been encountered. They were encouraged to list the characteristics of a designer under the headings "Skills", "Knowledge", "Ways of Thinking" and "Role in a Multidisciplinary Team".
3. Finally, the scientists were asked to identify any potential opportunities for the designer they had just described to support them in the research activities they had mentioned in the first part of the interview.

Interview Analysis

Soon after each interview, a summary document was written and emailed to each of the participants for comment. Two of the scientists requested that minor amendments be made to the interpretations. A synopsis of the interview summaries was written including partial transcription. The scientists' answers to each of the questions were gathered and key themes were extracted for discussion.

Results

1. Scientists' Perception of Their Research

All of the 8 scientists who attempted to position their work on the model of scientific research described it as including both basic and applied elements. This was because the scientists were often working on multiple projects at different stages of development with research teams from other universities. Thus, the map was less helpful in positioning the work of senior academics, who managed a complex portfolio of research. The map was more successful however in positioning individual research projects.

One scientist raised the point that what he considered applied research would be considered basic by others:

> *"In order to incorporate my work into the same map with other people's you need to make it hierarchical...if you talk to a person who actually deals with the real world rather than the software, they would say that all of what I do is here [understanding]"* [P2].

Although some scientists made attempts at defining stages of development, no common threads emerged and some commented that the linear process suggested by the diagram was not representative of research practise:

> *"You can go in any direction... I mean a lot of pure scientists say to me 'well, you know what you're doing is you're taking our knowledge we've gained alright?, and all you're doing is applying it', this is a common view and it's total tosh I can tell you...We have one at the moment, a very specific application I'm interested in...we're going to have to generate some new fundamental knowledge...we've got about 5 or 6 approaches we're looking at, I don't know off hand which one is going to come up trumps"* [B1].

Conclusions

- It is difficult to position the work of a particular scientist in terms of how applied it is, particularly when the scientist is engaged on multiple projects. However, it is possible to position individual projects, at a specific point in time
- It is difficult to define common stages of the scientific process, as much science is inherently iterative, with both application and the search for underlying principles occurring concurrently. This suggests that linear development models such as TRLs do not easily apply.
- Following the interviews, a new model of scientific research was constructed which more accurately reflected research being conducted at the university. The model shown in figure 2 illustrates how research, basic or applied, can give rise to applications, and how the development of applications can generate new scientific and technological research.

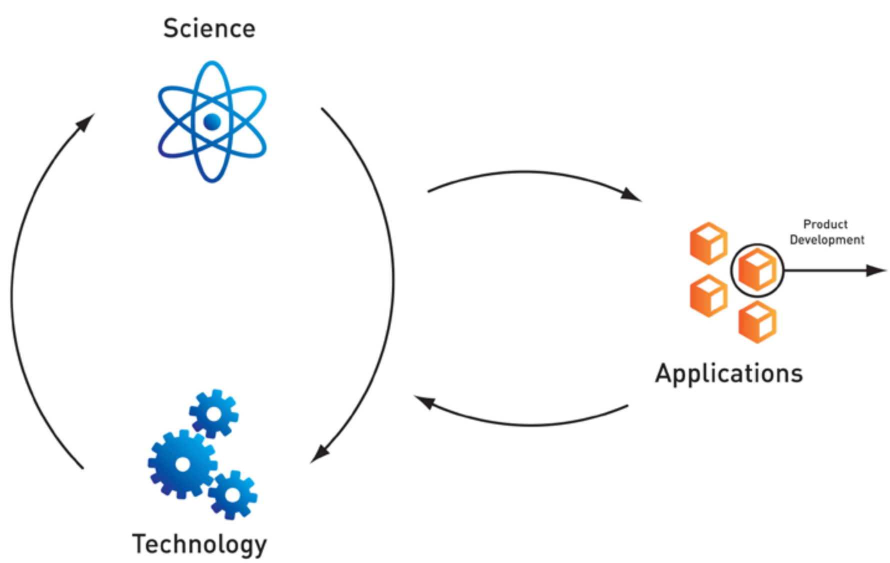

Figure 2 Model of scientific research post interviews

2a. Scientists' Perception of Design

The scientists said 'design' was something they did as part of their everyday work, for example engineering design, circuit design, experimental design, clinical design, survey design, alloy design or composite design.

Three quarters of the scientists interviewed mentioned at least one type of design profession in their answer. These were industrial, product, graphic, architecture and fashion. Those who did not mention specific disciplines said the following about design:

> *"You're talking about a different sort of design [to engineering design], the sort of design in which you bring somebody else along who thinks in terms of the shape and the looks and whether the general public like that colour or not"* [E2].
>
> *"I suppose I would associate it [design] more with the arts and fashion"* [P2].

"It [design] is a creative process... [A designer] is somebody who has a very visual way of looking at the world and who would work with materials and with people to...translate a vision into reality" [B2].

Some of the scientists commented on negative aspects of design:

"What I feel is a dangerous aspect...of design is the sort of making it look glitzy and pretty and calling that design, because I think it distorts what design is about..."The designer comes along with ideas that have no basis in the technology and maybe superimposes them on the design in a way that doesn't...benefit it and may actually detract from it...for me the idea of design is starting from the technical...and the sort of adding on has to be done very carefully" [E2].

"Product design is a bit more airy fairy really isn't it – it tends to be the fashion stylistic sort of approach...an industrial designer is just an engineer in my view" [E1].

"We rough out the ideas and it goes to a professional [designer] who tarts it up" [B1].

"Whether there is an aspect of design which maybe fulfilling the objective of art and beauty which degrades the fitness for purpose is actually very interesting, for example a very clever looking chair that's so uncomfortable you can hardly sit on it" [M1].

Some scientists had a more rounded view of design. More than half of the scientists described functionality, aesthetics and usability as being key aspects of design, with some also mentioning planning. Only one scientist used the word creativity in their description of design.

Conclusions

- The scientists interviewed recognise that design is an important everyday aspect of their work.
- There are fields of design closely linked with science e.g. experimental design, survey design. The scientists did not necessarily make clear distinctions between these and creative professions such as product, industrial, graphic and fashion design.
- Some of the scientist's initial perceptions of designers were as superficial stylists.
- These different perceptions are indicative of the difficulties in establishing consistent definitions of design.

2b. Experience of Working with Designers

5 of the 12 scientists had direct experience of collaborating with designers. A further 2 had indirect experience i.e. they may have worked with companies that employed designers. When asked what issues were encountered during this collaboration, communication was cited as the most common obstacle:

"Conveying the ideas and making sure we all understood what we wanted in terms of the design and the designer understood what was important to us. And that they had to convey to us what they thought was important...in terms of a getting the product in a package that could be used easily" [E1].

"Maybe visualisation is a tough one right? Or the language where I need a little bit of fill-in on some technical terms that might be utilised by him and in my case he would definitely need fill-in on the technical terms because he's not a chemist right?" [C1].

In both cases, these communication issues were overcome by maintaining frequent contact between the participants in the form of brainstorming sessions, meetings and workshops. Chemist 1 explained how problems encountered in interpreting 3D information were overcome by moving to 3D printing. He said "That helps put a lot of things into something I can physically touch and see and get an appreciation for".

Engineer 4 had experience managing a team including scientists and a designer. He said of the designer "He was very dogmatic, so he had very strong views about the importance of design and he would get very upset if people didn't get it or didn't think it was important". This became a problem with one of the designer's engineering colleagues.

Biochemist 1 saw his team as consisting of 'creative scientists'. He said "Creative scientists are few and far between, believe me...where they can see laterally as well as vertically...Most scientists think vertically...a lot of designers probably do think more laterally. If I look in this place in my experience over 30 years I'd probably put about 3 in that category [creative scientists]".

2c. Characteristics of a Designer

The scientists gave a very broad range of answers to this question. For example there were 30 different skills listed by the scientists.

Their answers showed large variation and depended very much on whether the scientist was describing the skills of a designer, themselves (in their capacity as a designer), both or neither. Of the 12 scientists interviewed, 6 described a 'designer', 2 described themselves, 2 described both and 2 did not annotate the graphic. Their answers also depended on the type of designer they had experience of, for example 3 scientists described industrial or product designers, 2 described graphic designers and 3 were not specific about the type of designer they were describing.

A selection of the most common and interesting answers is given in table 2. The numbers in brackets represent the number of scientists who mentioned each point:

Skills	Knowledge	Thinking	Role
Technical: Sketching (1) Model Making (1) CAD (2) Research (1) Engineering (2) Holding Focus Groups (1) Simulation (1) Technical Drawing (1) Project Management (1) Personal: Creativity (3) Communication (3) Observation (1) Patience (1) Listening (1) Restating (1)	Materials (5) Manufacturing Processes (4) Fashion/Styling (2) Graphics (1) Market (1) Technical (1) Regulations (1) Safety (1) Ethics (1) History of Design (1)	Lateral (3) Imaginative/ Artistic (2) Creative(1) Novel (1) Out of the box (1) Innovative (1) User Perspective (3) Curious (1) Holistic (1) Practical (1) Critical (1) Logical (1) Analytical (1) Unrealistic (1)	Integrator (3) Facilitator (1) Project Manager (1) End User Focus(1) Holistic (1) Commercial Focus(1) Inspire (1)

Table 2 Characteristics of designers according to scientists

Conclusions

- The scientists without experience of working with designers did not have a clear understanding of their characteristics.
- Those with experience had a more well-rounded view of designers, recognising their skills are wider than specific technical or materials knowledge.
- Materials and manufacturing processes knowledge were the most commonly recognised traits of designers

3. Scientists' Views on Potential Role of Design in Scientific Research

The scientists were generally sceptical about the role a designer could play during the early stages of scientific research. Biochemist 1 smirked at the question and said "I find it difficult to believe that they [designers] could contribute much round here [understanding] because you'd have to have a really detailed knowledge of the detailed science...You're better coming in somewhere around here [application].

> *"If you want design engagement in the scientific process, I don't see how the designer would have enough scientific knowledge to contribute to the discussion, so they may have divergent thinking, but only in terms of how to put bits and pieces of existing technology together. I don't see how they would be able to help in the brainstorming process of 'what are the scientific reasons why it's not working...I can see all these really strongly in the product development end"* [E4].

However some scientists didn't rule out the possible contribution of a designer in basic scientific research.

> *"How do you access the unknown unknowns, yes? The scientist isn't going to do it because it's unknown by definition yes? Anyone with different viewpoint...different ways of thinking about things, approaching problems can perhaps provide a route into those unknown unknowns. Every bit of science is suffering from this because every real issue in science at the moment is complex"* [P1].

> *"We have learnt so much, by working together between biology and engineering because you need to learn a different language...it's really opened up our horizons. That's why we are keen to work with other disciplines still because it just enriches your way of thinking so very much"* [B2]. When asked if she could see any potential benefits of working with designers, she replied, *"I don't know, it never does any harm to talk and you never know what comes out of it"*.

> *"Perhaps there is a design contribution in that area [scientific principles or understanding], I certainly haven't thought of it"* [E1].

Communication was identified as an important area in which designers could make a contribution.

> *"If someone can help me to see from the outside what the research looks like...that will help me putting my work across"* [P2].

> *"Most scientists have no understanding of what the general public out there actually understand, it's very important to relate it to them...a designer there would come in very well, say a poster for example"* [B1].

> *"I would put that [designers assisting with funding applications] down as marketing again, you're trying to get support from somebody for academic funding...I'm not used to getting money out of the EPSRC or the science funding bodies but they seem to like words...Using words alone is much less effective than words plus images, so I'd add pictures, images and video to the text"* [E4].

> *"Anything to do with public understanding and outreach, I fully agree [design input would be useful]...because that's not to do with functionality of a device it's t do with communication and visual appeal"* [B2].

Some other interesting areas of potential collaboration were identified

> *"Have we left ourselves with less of a development opportunity because we don't engage designers at a scientific level? I think that might be interesting if designers could spot ways of improving that process. And it's largely by not using Heath Robinson toolsets...by perhaps looking at the laboratory equipment, the methods of handling or moving or managing or conveying substances, the methods of testing...it could be design of the space, design of laboratory, design of the bench...that's where I would say the contribution could come in"* [E1].

> *"Lab space design, ha. That is true...thinking about how to lay things out – boy, that just never happens at the moment. It's a good point though"* [E4].

During the first 6 interviews, some of the scientists found it difficult to suggest ways in which a designer might be able to contribute to their research, so it was decided that a list of possible design engagements would be created to stimulate ideas:

- Application Exploration
- User/Market Research
- Concept Design
- Materials/Manufacturing Processes
- Engineering Design
- Prototyping
- 3D Visualisation
- 2D Communications
- User Interface Design
- Lab Space/Equipment Design
- Stimulate Interest/Excite
- Challenge Established Views

This list drew from the recommendations of the Design Council's pilot scheme in which design consultancies worked with scientific researchers (Design Council 2006). It also contains suggestions made by the first 6 interviewees, such as the design spaces and equipment.

Figure 3 Scaled design engagements

Figure 3 illustrates the effect of scaling the list of design engagements according to how many times they were selected by the scientists as playing a potential role in their research activities.

Assistance with communication was picked out by half of the scientists, closely followed by visualisation of products or concepts. Despite some of the scientists recognising that designers know about materials and manufacturing processes, only one of them said their research would benefit from support in this area. Engineer 4 suggested that designers would be of use in assisting with the production of technology 'demonstrators' to pitch an idea to investors or funding bodies. Two of the scientists' work was sufficiently close to market that the assistance they required was more akin to product development than scientific research.

> *"You get an awful lot of people...not far from where I'm sitting now, that actually come up with things...that you'd ever even conceive are going to be useful. And yet they'll spend ages and get research council money for it...They've got their pet project and they're looking for an application for it...There's a lot of pressure on people at the moment to get some sort of application...its government pressure, it's funding, pier group pressure"* [B1].

Talking about open innovation in computational science, physicist 1 commented "I see it [design] no longer divorced from the mainstream development, but sitting at all of the interfaces to make the fundamental science interact with the other bits of development.

Conclusions

- Some scientists perceived that there is scope for design engagement in their research activities, especially with issues relating to communication.
- However, the general consensus was that there isn't an immediately obvious contribution that design can make to basic research but some scientists would be open to exploring this further.

Implications

This research starts with the hypothesis that industrial designers might be able to make a contribution to the early stages of scientific research. Findings from this initial series of semi structured interviews provide some interesting insights into the factors which may affect collaboration between designers and scientists:

- Scientists' current knowledge of and perceptions of designers is limited, and where they have little prior experience, they are often sceptical about the potential for designers to make a positive impact on their research.
- Unless they have previous experience of working with designers, scientists are unlikely to be clear about designers' skills and areas of expertise, and some may perceive them as superficial stylists. Sharing knowledge about the characteristics of the two disciplines should open up more opportunities for collaboration.
- Design interventions could be suitable for many scientists as their range of research activities is likely to include basic and applied research
- Scientists perceive a greater possible impact on applied research through engagement of professional design skills.

Recognising these challenges, in order for design engagement to be successful, the following issues require consideration:

- It may be difficult for designers to persuade a scientific team or individual working on basic science to participate in a collaborative project, as the potential benefits are not immediately obvious. Offering to provide communication support could provide a possible avenue for entry into such a project.
- Designers should be sensitive to the fact that scientists participate in certain design activities as part of their everyday work e.g. experimental design, engineering design, and survey design.
- To overcome the cultural, conceptual and linguistic differences between the different disciplines, collaborative work between designers and scientists should be underpinned by effective communication. This involves frequent contact with the team members to gain a mutual understanding of key issues and to appreciate what each group considers important.

Author Biography

Alex Driver

Alex Driver is a Research Associate in the Design Management Group within the Institute for Manufacturing (IfM) at Cambridge University. Alex has a background in mechanical engineering and industrial design, and worked in industry for several years as an industrial designer for Atkins. He is currently researching the potential role of industrial design within scientific research.

Carlos Peralta

Carlos Peralta is a product designer currently reading for a PhD at Cambridge University, examining the ways in which designers and scientists interact and collaborate. He also teaches at Central Saint Martins College of Art and Design in London on the BA Product Design course and the MA Innovation Management course. Carlos was the head of the Product Design Department at the Glasgow School of Art between 2003 and 2007, and has worked in design education in Colombia, England, Singapore and Spain. His professional design experience includes work for industry, design consultancy and design entrepreneurship.

Dr James Moultrie

James Moultrie is a Senior Lecturer in Design Management. His research interests seek to understand and improve the utilisation of design at project, firm and national levels. James is head of the Design Management Group within the Institute for Manufacturing (IfM) at Cambridge University. James is a Chartered Mechanical Engineer (IMechE) and has many years industrial experience as a project manager, senior engineer and marketing product manager. He has also been awarded a 'Scientific and Technical Academy Award' (Oscar) and an Emmy for previous work on a range of lenses for professional movie making.

Developing a Framework for Mapping Sustainable Design Activities

Bernhard Dusch, Dr Nathan Crilly, Dr James Moultrie, Department of Engineering, University of Cambridge, UK

Abstract

The notion of sustainable design has become increasingly prominent within the design community. As a result, numerous design theories, strategies and tools are available to designers. Yet, limited attempts in the field evaluate these activities by placing them in relation to each other or within the broader context of sustainable development. Based on a literature review this study develops an integrated framework which connects the areas of sustainable development and sustainable design. This framework may be utilised in two ways: firstly, to visualise the interdependencies of sustainable design and sustainable development; secondly, as an assessment tool to measure and compare the potential of sustainable design activities.

Keywords

Sustainable Design; Sustainable Development; Design Strategy; Framework.

Sustainable design is a widely used phrase amongst a number of synonyms which all reflect a contemporary trend in the design community to respond to environmental and socio-economic concerns. The focus of attention is thereby the concept of sustainable development which became increasingly popular over the last few decades. As the idea of sustainable development itself is open to various interpretations it may not be surprising to find a large number of theories, strategies and tools when it is married with design, a discipline similarly regarded as being broad-ranging and hard to define.

So far, sustainable design is rarely conceptualised in direct relation to the bigger picture of sustainable development. Moreover, literature is lacking in appropriate evaluation methods which are capable of classifying sustainable design activities in this multi-dimensional context. In this regard Baumann *et al.* (2000) state that “there are too many tools around, but we should try to use the already existing ones, instead of introducing now ones”. Then they conclude by saying that there is “too little linkage between strategic intent and content [and] too little about the larger context of product development”.

This study aims to develop a criteria-based compound framework which allows both the visualisation of the relationship between sustainable design and sustainable development as well as the classification of sustainable design theories, strategies and tools according to this context. Thereby the study merges appropriate models from both disciplines to generate an integrated framework with aims to be able to:

i) provide understanding of how sustainable design may be seen in the context of sustainable development
ii) allocate a given design activity in terms of its position within this context
iii) classify a given design activity in terms of other design activities
iv) specify the individual ‘sustainability potential’ of a given design activity

In order to create a framework featuring those characteristics the following questions form the focus:

a) How are the areas of sustainable development and sustainable design conceptualised so far?
b) Which visual representations of these concepts may be useful in terms of this study?
c) How can we generate a compound framework based on the existing models?

The study is based on a literature review which is presented in the first half of the paper. The review covers the areas of sustainable development and sustainable design and focuses on the first two questions stated above. The compound framework itself is introduced in the second part of this paper, where we deal with the third question. The paper concludes with a discussion of the framework, which includes the introduction of possible implications of both a theoretical and practical nature.

1. Reviewing the scene

The following review is divided into two parts. The first part discusses the nature and relationship of the concepts of sustainable design and sustainable development, in order to establish clarity in terms of basic definitions. In the second part the emphasise is on visual models of sustainable design and sustainable development. Here innovation models are also discussed as sustainable design strategy is increasingly described with the aid of innovation theory.

1.1 Sustainable design in the context of sustainable development

By nature, sustainable design corresponds with the concept of sustainable development. Yet, as sustainable development is to be seen as a concept emerging from the environmental discourse it is imperative to shed light on the evolution of environmentalism to fully understand the complex and partly conflicting nature of sustainable development. In this sense, the evolution of sustainable development may be traced back to the most fundamental concepts of value which are reflected in the basic world views. The following paragraphs briefly introduce each 'mile stone' of this journey.

1.1.1 The two major world views

According to many scholars (Glacken, 1967; Passmore, 1974; O'Riordan, 1981; Capra, 1982; and Milbrath, 1984) two major world views have been developed in the history of humankind which define the relationship of humans to their environment. Commonly a distinction is made between the '*conservative-nurturing'* and the '*radical-manipulative'* world views. The underlying mind sets of these views are almost contradictory: Favouring the conservative-nurturing world view humans regard themselves as part of nature, considering the environment to be the focus of attention. It follows that "the task of human beings [is] to tend the Earth" (O'Riordan, 1989). The radical-manipulative world view, in contrast, shapes a moral pattern of action which is based on the belief that humankind not only has the right, but also the obligation to shape the world in order to create a better place. In the light of the success-oriented western culture Merchant (1992) suggests a further differentiation of the radical-manipulative world view which finally leads to the following classification:

i) 'Ego-centric' – describing a moral mind set based on ones 'self';
ii) 'Homo-centric' – specifying a moral principle resting upon 'society'; and
iii) 'Eco-centric' – characterising the conservative-nurturing world view.

In literature the categories *(i)* and *(ii)* are often summarised under the umbrella term '*anthopo-centric*', or '*techno-centric*' when the industrial nature of the western culture is emphasised.

1.1.2 The emergence of ecology

As occidental history is closely related to the Christian tradition proclaiming the manipulative world view, the environment has historically been seen as external to humanity (Hopwood *et al.*, 2005). A first step towards environmental awareness was the emergence of the academic discipline of *'ecology'* (Von Haeckel, 1866). This resulted in the discovery of interdependencies of the non-human world and the human world. Finally, ecological matters were seen as an integrated system on a local, regional and global level. As a consequence, environmental awareness began to affect action in many parts of western society. However, 'ecology' is not only a domain of knowledge but also a terminology for movements which aim to change things for the sake of a better (more 'eco-centred') future. Terms such as *'Radical ecology'* (Merchant, 1992) or *'deep ecology'* (Pearce, 1993) may be mentioned in this context and be seen as part of a spectrum of environmental considerations.

1.1.3 About environmentalism

Whereas the early environmentalism in the late 19th century was predominantly concerned with landscape conservation (Kuester, 2009), modern environmentalism since the 1950's promotes a departure from the status quo in industrialism (Dryzek 1997) and takes an all-embracing view of environmental issues. Ultimately, environmentalism developed a broad ranging spectrum of values which all have their origin in one of the basic world views introduced earlier. Therefore, it is evident that different viewpoints may have considerably contrasting beliefs in what environmentalism can be. In his largely used categorisation O'Riordan (1989) tackles this issue and introduces a classification of four different *'trends in environmentalism'*, ranging from the extreme eco-centric to the extreme techno-centric side. Pearce (1993) presents a very similar categorisation but also refers to the discussion of *'sustainability'* by adding *'sustainability labels'* to each of the four categories *(fig. 1)*.

	Ecocentrism		**Technocentrism**	
	Deep ecolpgy	Communalism	Accomodation	Cornucopian
Green Labels	Extreme **preservationist** position	Resource **preservationist** position	Resource **conservationist** and managerial position	Resource **exploitative** and growth orientated position
Type of economy	» **Very deep green** economy, » heavily regulated to minimise 'resource-take'	» **Deep green economy**, steady-state economy » regulated by macro-environmental standards and supplemented by Els.	» **Green economy**, green markets » guided by economic encentive instruments [Els] (e.g. pollution charges etc)	» **Anti-green** economy » Unfettered free markets
Management statistics	» **Reduced** scale of economy and population » Scale reduction imperative » at the extreme for some there is a literal interpretation of Gaia as a personalised agent to which moral obligations are owed	» **Zero** economic growth, zero population growth » Decoupling plus no increase in scale. » Systems perspective – health of whole ecosystems is very important Gaia hypothesis and implications	» **Modified** economic growth (adjusted green accounting to measure GNP) » Decoupling important but infinite substitution rejected. » Sustainability rules: constant capital rule	» **Primary** economic policy objective, maximise economic growth (Gross National Product [GNP]) » Taken as axiomatic that unfettered free markets in conjunction with technical progress will ensure infinite substitute possibilities capable of mitigating all "scarcity/limits" constraints (environmental sources and sinks)
Ethics	**Acceptance of bioethics** » moral rights and interests conferred on all non-human species and even the abiotic parts of the environment » intrinsic value in nature (ie. valuable in its own right regardless of human experience)	**Further extension of ethical reasoning** » interests of the collective take precedence over those of the individual » primary value of ecosystems and secondary value of component funcions and services.	**Extension of ethical reasoning** » 'caring for others' motive – intragene rational and intergenerational equity (i.e. contemporary poor and future people) » instrumental value in nature	**Support for traditional ethical reasoning** » rights and interests of contemporary individual humans » instrumental value (ie. of recognised value to humans) in nature
Sustainability Labels	**Very strong sustainability**	**Strong sustainability**	**Weak sustainability**	**Very weak sustainability**

Figure 1: The sustainable spectrum (Pearce, 1993) [redrafted]

1.1.4 The concept of sustainability

The principle of sustainability was first mentioned by Von Carlowitz (1713), at a time, when the term 'ecology' had not even been coined. In these early days, sustainability was clearly linked to resource management in the forest industry. Current conceptions of sustainability which are conceived of in this way carry the term *'sustainable utilisation'* (IUCN, 1980) and can be viewed as rather anthropo-centric as their aim is to maintain a certain status quo in nature in order to sustain resources. Subsequently, an eco-centric perspective on sustainability has been introduced in literature as well which is normally used in ecology to refer to an ecosystem's potential to subsist over time (Jabareen, 2006). Tonkinwise (in Gregory *at al.* 2008) states: "Sustainability is the measure of the capacity of a system [...] to reproduce itself in the changing circumstances upon which it depends [...] which might involve changing [...] or evolving in form and function." The different arguments stated above clearly show the contradictions in the conception of sustainability and here again, the two basic world views define the positions. However, despite its inherent polarity, the concept of sustainability is to be seen as a key aspect in the environmental discourse (Hopwood *et al.*, 2005). In this context the previously mentioned sustainability labels should be considered which correspond with the environmental spectrum as described before (Pearce, 1993; Haughton and Hunter, 1994).

1.1.5 Towards sustainable development: the evolution of a paradox

Whereas the notion of sustainability can be viewed under the umbrella of environmentalism, the concept of ‘sustainable development’ (Brown, 1982) reaches beyond purely environmental considerations. The so called *‘Brundtland report’* (WCED, 1987) observes: “Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs.” Here it is evident that this concept also embraces social and economic issues. What seems to be a modest statement is ultimately quite remarkable: O’Riordan (1989) points out that sustainable development is “bridging the gap between developers and environmentalists”. A consequence of this is the unification of the techno-centric and the eco-centric world view, which were previously considered incompatible. However, this achievement produces an “ethical paradox” based on the “dialectical relations between sustainability and development” (Sachs, 1993) which is highly problematic as it causes constant contention (Hopwood *et al.*, 2005). Furthermore, many scholars lament the ambiguity of sustainable development (Middleton *et al.,* 1993; Wackernagel and Rees, 1996; Holden, 2007) as it “is open to interpretation of being anything from almost meaningless to of extreme importance to humanity” (Hopwood *et al.*, 2005). However, despite all criticism, to date sustainable development is considered to be the most promising concept to tackle contemporary problems.

1.1.6 About sustainable design

In order to understand the nature of sustainable design it may be helpful to consider a fundamental mode of design. According to McLennan (2004) the action of design is always informed by the mind-set of the person conducting a particular design activity. Furthermore, the activity of design, rather than being an isolated end in itself, is an applied activity which always answers a purpose (Dorschel, 2003). In this light, the following paragraphs may be seen:

The origin of sustainable design is not entirely new. In fact, sustainable action in design has been conducted in many cultures within living memory, as those cultures never abandoned their sustainable life style. McLennan (2004) goes even beyond the human sphere when introducing his four ‘evolutionary stages’ of sustainable design. However, this study concentrates on the modern conception of sustainable design in the industrialised world which might be almost understood as a re-invention of this concept after a time of highly unsustainable development. The renewed interest in this concept had been encouraged by design theorists such as Buckminster Fuller (1963) and Papanek (1971).

Yet, sustainable design should not be understood as a design discipline such as graphic or industrial design. According to McLennan (2004), it is rather to be seen as an underlying notion which has the potential to inform all design activities. On this philosophic level sustainable design responds to the concept of sustainable development by raising questions about the optimal transition scenario for a more sustainable future, the idea of well-being, or the optimal status of goods (Vezzoli and Manzini, 2008). However, it might not be surprising that answers to these questions can diverge considerably, again, according to the basic world view. By trying to overcome these differences, system design approaches become increasingly important (Vezzoli and Manzini, 2008).

Theoretical considerations as discussed above naturally inform decisions on more applied levels such as design strategy and finally the actual design activity. At this point the direct correlation between the fundamental world views and the modern design process becomes evident.

1.2 Models capturing the scene

Considering the ambiguity of sustainable development as well as the diversity of sustainable design, it might not be surprising that literature provides a multitude of models which each aim to visualise either one, or both, concepts. To provide structure, the present study works with a classification of two main categories. Thereby the first category deals with nominative visual explanations which aim to comprehensively display a concept from an overall point of view, whereas the second category is reserved for evaluative frameworks which apply defined criteria to discuss a concept under certain conditions. Furthermore, visual models of both categories may be utilised in two different ways. Firstly, as cognitive maps which visually represent theoretical constructs, and, secondly, as assessment tools which promote the categorisation of further knowledge material (Choucri, 2007).

1.2.1 Models for sustainable development

Although the purpose of nominative models for sustainable development is clearly defined, the variety of attempts is extensive. A further distinction may be made between '*domain-based models'* (which concentrate on the different areas sustainable development is referring to), and '*principle-based models'* (which try to capture the concept by identifying its underlying principles). Generally principle-based models may also be seen 'just as sets of criteria' as their graphical sophistication tends to be limited. However, a classic example for a domain-based nominative model is the well known 'Venn diagram' which introduces the "three pillars" (Sutcliffe, 2009) of sustainable development (environment, economy, and society). Further basic examples are introduced by Giddens *et al.* (2002). In contrast, Choucri (2007) presents a comprehensive nominative framework. Typical principle-based models, on the other hand, are introduced by Jabareen (2006) and Haugton (1999). Finally, Pawflowsky (2008) and Spangenberg (1997) present nominative models which are based on a combined approach, featuring domain-based and principle-based elements.

By looking into the area of evaluative models one is confronted with considerable diversity. This is due to the very nature of this category, as each model features certain aspects of sustainable development according to the criteria applied (*cf.* Holden, 2007). Of particular interest for this study, however, is a model developed by Hopwood *et al.* (2005) *(fig. 2)*. Based on the environmental spectra of O'Riordan (1989) and Pearce (1993) *(fig. 1)* the framework maps different approaches in the field of sustainable development according to their "attitude towards change" (Hopwood *et al*., 2005). Thereby the whole spectrum from eco-centrism to techno-centrism is applied to both the *x*- and the *y*-axis, each respectively describing environmental and socio-economic concerns. The resulting space between the axes enables allocation of any sustainable development principle in relation to its position concerning both directions: the range from eco-centric to techno-centric in addition to the spectrum from environmental preferences to socio-economic concerns. Finally, the space is divided into three zones ranging from 'Status quo' through 'Reform' to 'Transformation'.

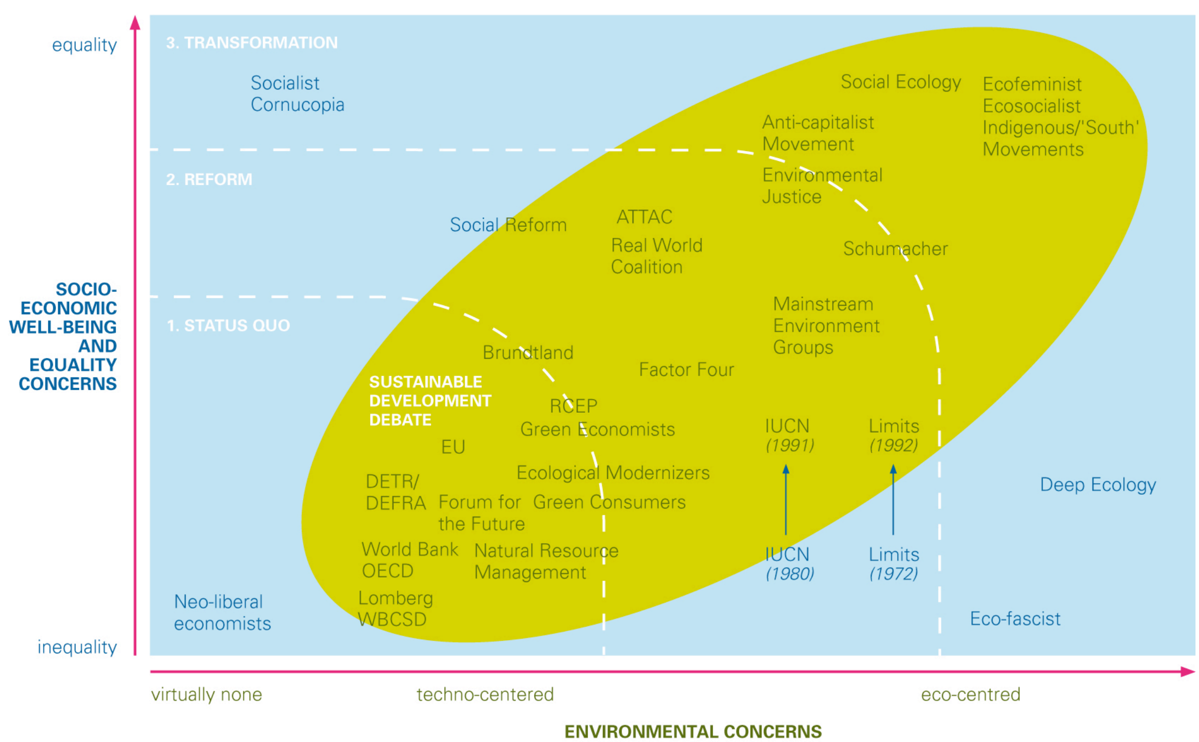

Figure 2: Mapping the views on sustainable development (Hopwood *et al.,* 2005) [redrafted]

1.2.2 Models for sustainable design

Nominative models for sustainable design may be also divided into domain-based and principle-based models. Examples of domain-based models are introduced by McDonough and Braungart (1998) and Fuad-Luke (2009). Here, all authors aim to present a complete picture of what sustainable design might be according to their conception. Principle-based models of different complexity are introduced by Van der Ryn and Cohen (1996), McDonough (1992) and McLennan (2004).

Regarding evaluative models for sustainable design, naturally the situation is comparable with the circumstances already described for evaluative models for sustainable development: Innumerable visualisations are provided in literature which are all concerned with a specific problem (e.g. Porter, 1985; James, 2001). Yet, Vezzoli and Manzini (2008) provide a model which is of relevance to this study. Here, the field of sustainable design is described by four different *'levels of intervention'* with increasing potential to depart from the status quo in the industrialised world. Thus, each of the four levels is connected with a certain stage of transformation in technology and society in order to achieve a more sustainable livestyle:

Level 1: Environmental redesign of existing products
Level 2: Designing new products and services
Level 3: Designing new production-consumption systems
Level 4: Creating new scenarios for sustainable life styles

In essence, the model described by Vezzoli and Manzini is strongly informed by innovation theory, an area which is discussed in the next section.

1.2.3 Innovation Models

Innovation models are increasingly used by scholars to address aspects of sustainable design (Tischner, 2008). Whereas basic models distinguish between incremental and radical innovation, many scholars have introduced more advanced models to be able to better understand the nature of radical innovations (Abanathy and Clark, 1985; Freeman and Perez, 1988; Clark and Staunton 1989). In this context the term 'system innovation' was coined which refers to "far-reaching changes in technology [which may influence] several branches of the economy [or even] give rise to entire new sectors" (Freeman and Perez, 1988). In a conventional context these innovation models are clearly linked to an economic environment. The finite goal of innovation in this sense is therefore economic success (Arrow, 1961). However, when it comes to the issue of sustainable development, additional success criteria of a social or environmental nature play a decisive role.

In order to visualise the sustainability potential of different innovation types Foster's (1986) classic 'S-curve model' is used as a basis by many scholars (Brezet, 1997; Weterings et al., 1997; Halila and Hoerte, 2006). The 'levels of intervention' introduced by Vezzoli and Manzini (2008) may also be seen in this respect. Yet, Magnussen (2001) presents a framework which draws on a different approach. By building on Abanathy and Clark (1985) he introduces a two-by-two matrix which not only allows the visualisation of different types of innovation, but also sets them in context with each other by applying specific criteria on the x- and y-axis of the matrix. Konrad *et al.* (2003), finally, follow this tradition and introduce a framework which aims to highlight the sustainability potential of certain innovation types in the context of product development at a company or industrial level. Thereby "changes in market-actor relations" and "changes in knowledge, technology and organisation" are defined as the criteria which establish the coordinates for the framework *(fig. 3).* As a result, the following innovation types are defined: *'incremental innovations'* (minor changes in both market-actor relations and technology), *'radical innovations'* (minor changes in market-actor relations paired with major changes in technology), *'behavioural innovation'* (major changes in market-actor relations but minor changes in technology) and *'system innovation'* (major changes in both, market-actor relations and well as technology). Regarding this model, system innovation has the highest sustainability potential as it sits on the radical end of both axes.

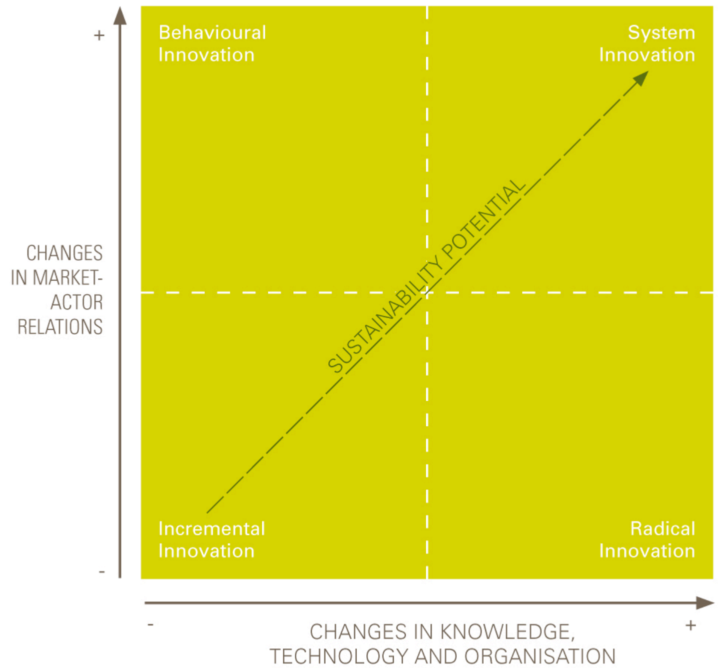

Figure 3: Differentiation of innovation types and their sustainability potential (Konrad *et al.,* 2003) [redrafted]

2. Building the compound framework

After reflecting on the scene, now the compound framework is introduced. The section is divided in two parts. The first part presents basic specifications, whereas the second one finally introduces and discusses the compound framework itself.

2.1 The basic approach

To generate the compound framework this study builds on visual explanations already introduced in chapter one. The following issues are therefore considered:

2.1.1 The nature of the compound framework

Owed to the objectives stated in the introduction of this paper, evaluative models of sustainable development and sustainable design are the core of interest. Moreover the study's focus is on those models which have the potential to accommodate further knowledge material and work as assessment tools (see section 1.2). To integrate models of both spheres a 'frame and picture' analogy is chosen which captures the subject of sustainable design within the wider context of sustainable development.

2.1.2 Specifications of the compound framework

Generally the framework aims to capture the issue of sustainable design in the context of sustainable development on an overall level. As a consequence, different aspects can be covered, ranging from the product development level to matters embracing society as a whole. Naturally the position of the frame, capturing the area of sustainable development may be seen as slightly tuned towards the issues of sustainable design, owing to the very nature of the study. Technically both parts of the compound framework are intended to have the same perspective in order to be compatible. That is achieved by applying equitable criteria.

2.1.3 Criteria applied to the compound framework

The fundamental idea of sustainable development is the departure from status quo towards more sustainable scenarios, although there are different beliefs in how this could be done most successfully. Sustainable design is corresponding to this issue which is particularly expressed in the models of innovation theory. Therefore the criteria applied to the compound framework are designed to measure the potential of any mapped design activity to depart from the status quo in society.

2.2 The compound framework

To build the compound framework different models are introduced and adapted in order to meet the specifications as discussed above.

2.2.1 Building the frame – capturing sustainable development

To establish the frame, the study follows Hopwood *et al.* (2005) *(fig. 2)* and builds on the classifications of O'Riordan (1989) and Pearce (1993) *(fig. 1).* However, in contrast to Hopwood *et al*.'s model, the environmental spectrum established by O'Riordan (1989) and Pearce (1993) is not applied to the full length of the x- and the y-axis. To emphasise the fundamental discrepancies between the eco-centric and the techno-centric world view, the spectrum is divided into two halves which are depicted by one of each axis. The resulting L-section constitutes the frame of the compound framework, representing the two basic attitudes in the environmental debate in terms of how to migrate from the status quo in the industrialised world towards more sustainable scenarios *(fig 4).*

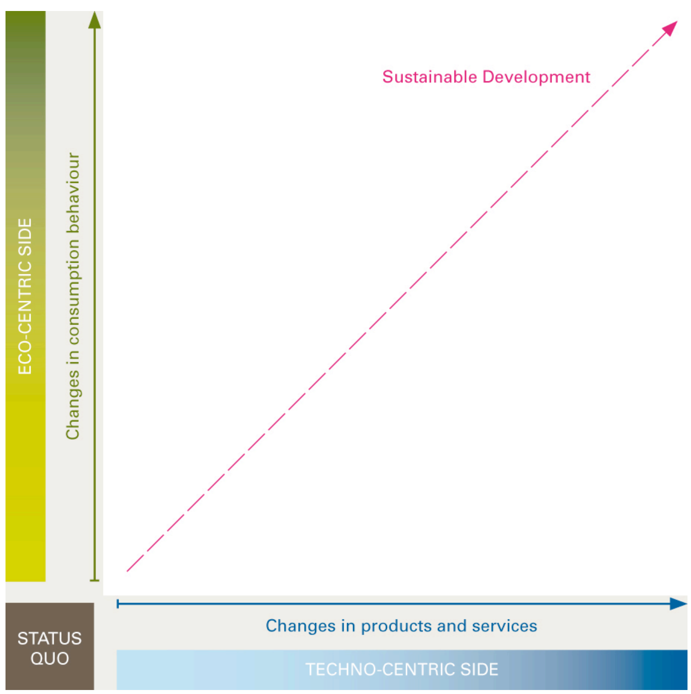

Figure 4: The 'frame' of the compound framework capturing sustainable development

In essence the eco-centric side stands for the conservative-nurturing world view and may be seen as the 'sustainability-side' of sustainable development (Sachs, 1993). Supporters of this perspective believe in the idea that humankind needs to change its behaviour in favour of a more sustainable life style (O'Riordan, 1989 and Pearce, 1993). In the light of consumerism in western society the proposed changes target mainly consumption behaviours, provoking the demand for lower consumption (Vezzoli and Manzini, 2008).

The techno-centric side represents the radical manipulative world view and could be interpreted as the ‘development-side’ of sustainable development (Sachs, 1993). Here, supporters strongly believe in technical sophistication and development to overcome social and environmental problems (O’Riordan, 1989 and Pearce, 1993). So, moderation in consumption may be viewed as a lower priority. However, with ‘doing things better, rather then less’ the basic attitude seems to be appropriately described, resulting in the need to constantly refine production techniques, products and services. (Vezzoli and Manzini, 2008).

According to (O’Riordan, 1989) the notion of sustainable development may be located in between the eco-centric and the techno-centric side trying to marry both spheres. This position is indicated by the pink arrow in figure 4.

2.2.2 Building the picture – capturing sustainable design

The core part of the compound framework mainly builds on the system innovation model introduced by Konrad *et al.* (2003) *(fig. 3)* but is also informed by Vezzoli and Manzini (2008). The choice of this particular innovation model is based on reasoning that it works according to the same criteria as the frame of the compound framework introduced above: It evaluates the potential for certain innovation types to depart from the status quo towards more sustainable scenarios. Yet, Konrad *et al.* (2003) explicitly focus on a company or industry level. As this study is aimed at an overall level the following implications are to be taken into account.

Firstly, the notion of ‘systems’ change as they may not be seen as purely economic structures in future. In the new context systems should be understood as “existing arrangement[s] of technologies and supporting organisational, economic, regulatory, knowledge, and cultural structures” (Vergargt, 1999).

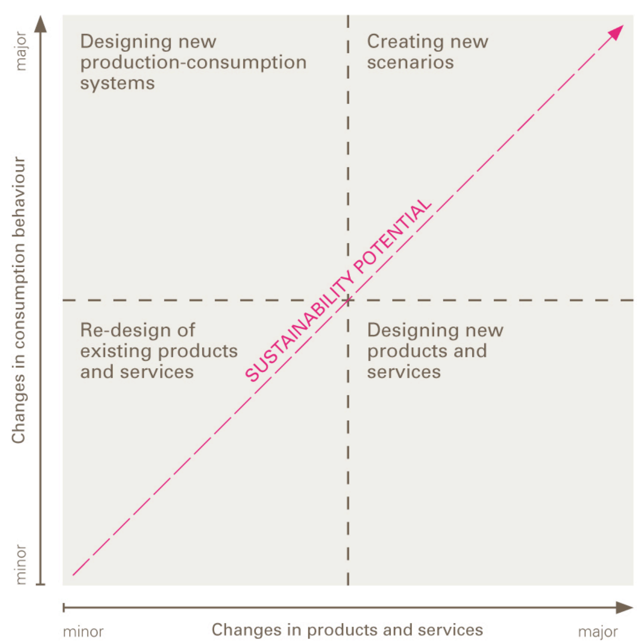

Figure 5: The ‘picture’ of the compound framework capturing sustainable design

Secondly, the criteria of the original framework are modified from ‘changes in market-actor relations’ and ‘changes in knowledge, technology and organisation’ to ‘changes in consumption behaviour’ and ‘changes in products and services’. This step supports both the alignment of the criteria to the more general orientation of the final framework, and a consistent compatibility between the final framework’s ‘frame’ and ‘picture’.

Finally, the four different innovation types introduced by Konrad et al. (2003) are replaced by a set of four 'modes of designing' which are closely informed by the "four levels of intervention" (Vezzoli and Manzini, 2008) discussed in section 1.2.2. These design modes conform with the meaning of the innovation types they replace but have greater potential to represent the issue of sustainable design (rather than that of innovation theory).

The resulting framework *(fig. 5)* ultimately shows a coherent conception of sustainable design: Two fundamental constants of design – the user (or consumer) and the designed product or service itself – determine a set of transition scenarios towards a more sustainable lifestyle. Additionally, the sustainable potential is maximised when both sides are brought together.

2.2.3 Frame and picture – the compound framework

By finally integrating 'frame' and 'picture' the compound framework is built as displayed in figure 6. The following paragraphs discuss the function of the framework as well as its utilisation as an assessment tool.

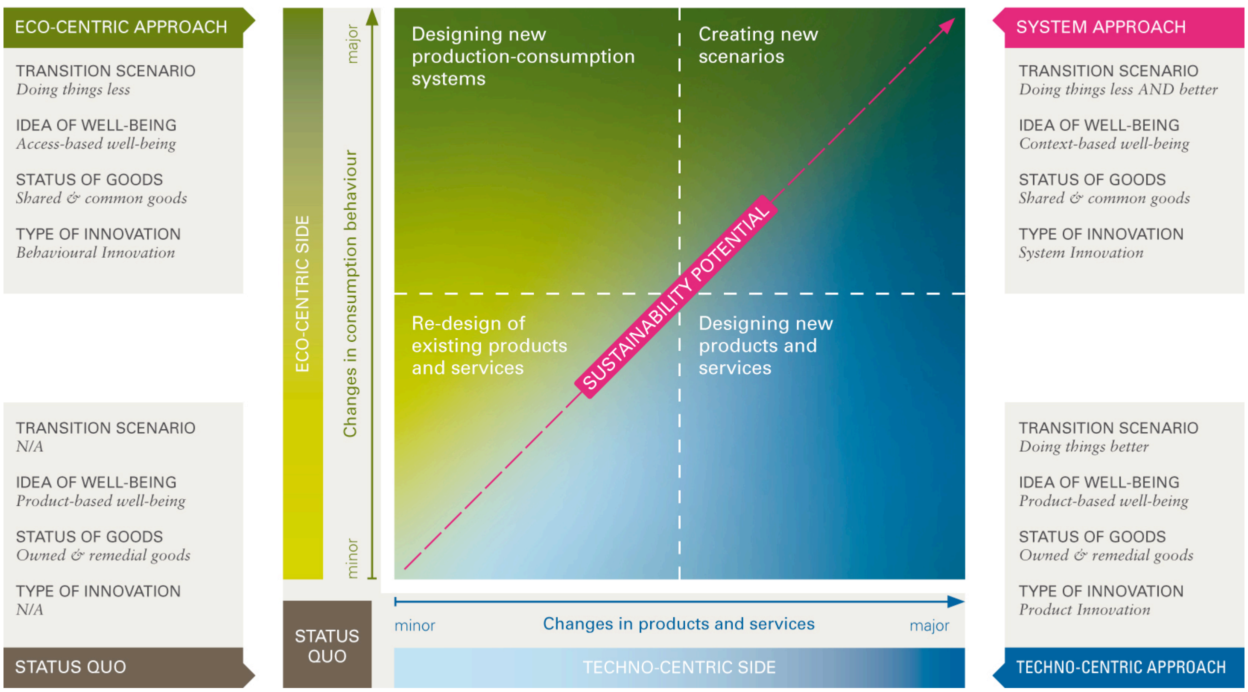

Figure 6: The compound framework – Sustainable design approaches in the context of sustainable development

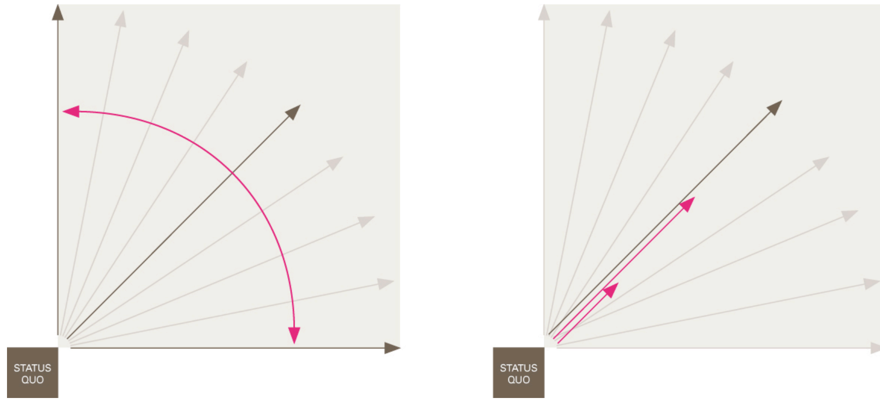
In essence, the L-section of the framework (the 'frame') opens up a space within which the matter of sustainable design is located. Thereby this space covers two different aspects. The first aspect is concerned with the departure from status quo in the industrialised world. As already discussed, this is possible by following different directions. Yet, as illustrated in figure 7 the direction of departure does not necessarily need to follow either the eco-centric or the techno-centric approach, but may take any angle in between both extremes. Thereby the sustainability potential increases as the closer the departure's direction gets into the centre of the spectrum (cf. 2.2.1). The second aspect describes the intensity of the departure from status quo, which would be the equivalent of an innovation's scope in innovation theory moving from incremental to radical (cf. 1.2.3). As the framework does not work with the terms of innovation theory the departure's scope is consequently specified with neutral terms describing a range from minor to major changes *(fig. 8).*



Figures 7 and 8: The departure's direction and intensity

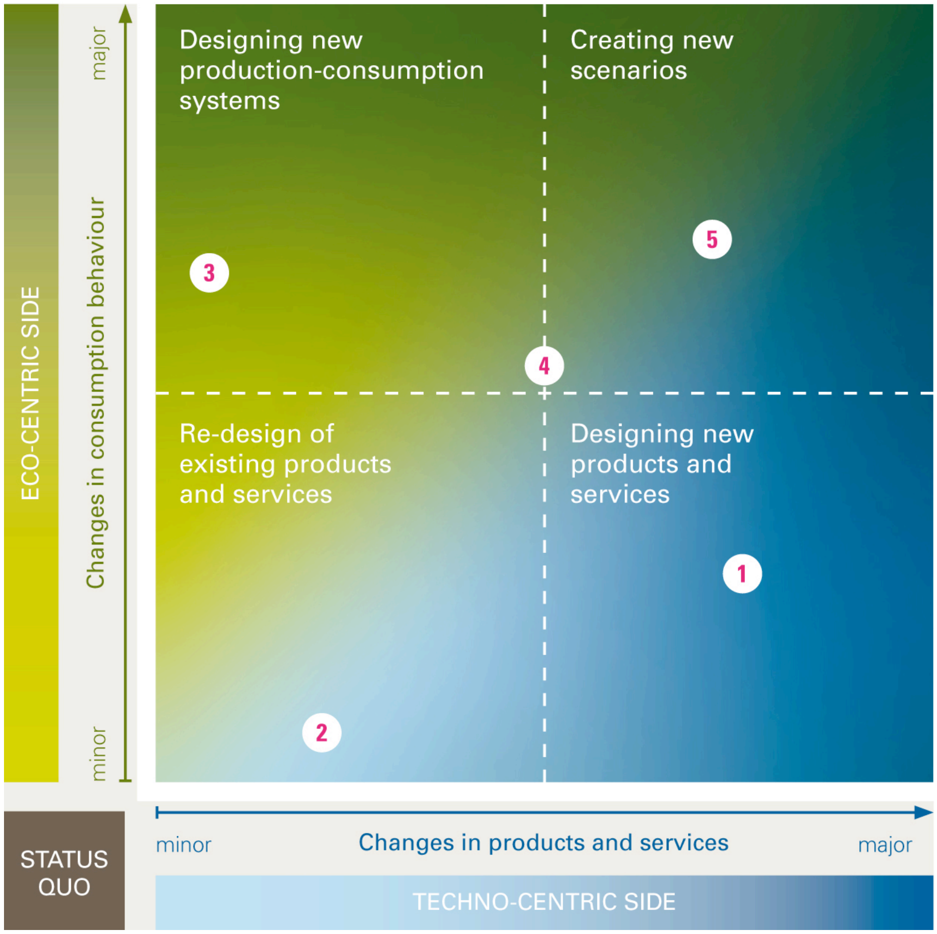
Additionally, the sustainability potential increases as a more determined departure from the status quo is performed. As a result, the framework defines the upper right corner as the area with the highest sustainability potential.

The space described above is populated and further defined by the 'picture' of the framework dealing with sustainable design. The coloured background of the matrix thereby illustrates the relationship of the eco- and the techno-centric approach. In this context the 'four modes of designing' (cf. 1.2.2) appear in a more informed way, as their relationship to the bigger picture of sustainable development becomes obvious: The bottom left corner of the matrix is closest to the status quo. Here it becomes evident that a 're-design of existing products and services' has the lowest potential to depart from the status quo towards more sustainable scenarios. However, the top left and bottom right corners illustrate that even major changes in consumption behaviour or products and services cannot achieve top levels in sustainability performance as long as they are conducted independently. Ultimately, only if both the eco-centric and the techno-centric side are united in order to perform major changes, truly sustainable development can take place. This is reflected by the top right corner and might result in the creation of new scenarios for a more sustainable life style.

As an extension to the framework four text boxes are provided which specify the corner stones of the framework with additional demarcation criteria based on Vezzoli and Manzini (2008). As already discussed in 1.1.6., when it comes to issues such as transition scenarios, ideas of well-being, or the status of goods, the boundaries between sustainable design strategy and the notion of sustainable development become blurred. As a result the text boxes are able to inform the 'frame' and 'picture' providing comparable information for both, the status quo, as well as the three main directions of departure form status quo: the 'eco-centric approach', the 'techno-centric approach', and the 'system approach'.

2.2.4 Mapping sustainable design activities

Beside its function as a visual map which describes the relationship between sustainable design and sustainable development, the framework may be also utilised as an assessment tool promoting the categorisation of further knowledge material (Choucri, 2007). In the latter case the model should be seen as "a sort of skeleton, something like an application form with many blanks or slots to be filled" (Minsky, 1986). In this case the supporting information such as the text boxes or the like is not essential anymore. In figure 9 the framework's mode of operation is illustrated by mapping the following basic strategies based on Fuad-Luke (2009). Thereby the design strategies get evaluated according to their potential to depart from the status quo as well as to their location on the eco-centric/techno-centric spectrum:



Figures 9 The compound framework utilised as an assessment tool

1. Bio-Manufacturing	–	*nature directly supports the fabrication of products (e.g. fruits become packaging)*
2. Clean Production	–	*production's impact on nature is reduced by putting appropriate systems in place*
3. Community Ownership	–	*maximises the product's efficiency through shared usage (e.g. car sharing systems)*
4. Dematerialisation	–	*products are replaced by services*
5. Downloadable Designs	–	*reduces the impact on nature and opens up entirely new scenarios*

Conclusion

Confronted with a considerable variety of different sustainable design activities such as theories, strategies or the development of tools, this study ultimately aims to establish conceptual clarity within the area of sustainable design. In order to provide a solid foundation for the area of sustainable design, it is important to define the context within the notion of sustainable development. However, due to the fundamental nature of sustainable design, it may not be entirely possible to define the field completely.

This study focuses on the relationship between sustainable design and sustainable development. The approach is based on the assumption that sustainable design may not be seen as a normal design discipline, but as an underlying notion, a philosophical approach to almost any design activity (McLennan, 2004). This notion finally responds to the same issue as the concept of sustainable development: At the centre of attention, is the departure from the status quo towards more sustainable scenarios.

To capture the fields and their relationship as described above, a visual approach is chosen. A literature review provided the basis for the conception of sustainable design in the context of sustainable development. Building on this, visual models of both spheres are introduced, classified and discussed to build a data base for the framework to be created.

As a result, a compound framework has been developed which is able to visualise the field of sustainable design in the context of sustainable development recognizing the potential to depart from the status quo as described above.

Depending on how it is used, the framework has the following implications: On a theoretical basis, the framework works as a visual map which describes the relationship of sustainable design and sustainable development. On a practical level the framework may be utilised as a visual assessment tool which promotes a better understanding and evaluation of the growing number of sustainable design activities. However, the mapping process may be debatable as many factors are not finally defined yet. This might be the starting point for future research.

Author Biography

Bernhard Dusch

Bernhard Dusch is currently researching for a PhD with Nathan Crilly and James Moultrie focusing on sustainable design of domestic appliances. Bernhard started his career as a professional photographer for industry and fashion. He holds a Diploma in Communication Design from the Georg-Simon-Ohm University of applied sciences in Nuernberg/Germany and a Master's with distinction in Industrial Design from Sheffield Hallam University. He has been working as a Designer for the German based design consultancy MetaDesign before he joined the Institute for Manufacturing (IfM) at the University of Cambridge in May 2009.

Dr Nathan Crilly

Nathan Crilly is a Lecturer in Engineering Design at the University of Cambridge where he coordinates the Design Practice theme in the Engineering Design Centre. Nathan has research interests in the areas of design, creativity and communication. In particular, he employs an interdisciplinary approach to investigating the relationship between how designers intend products to be experienced and how they are subsequently experienced by consumers. Nathan holds a bachelor's degree in Mechanical Engineering, a PhD in Product Aesthetics and has professional design experience in the aerospace and software industries.

Dr James Moultrie

James Moultrie is a Senior Lecturer in Design Management. His research interests seek to understand and improve the utilisation of design at project, firm and national levels. James is head of the Design Management Group within the Institute for Manufacturing (IfM) at Cambridge University. James is a Chartered Mechanical Engineer (IMechE) and has many years industrial experience as a project manager, senior engineer and marketing product manager. He has also been awarded a 'Scientific and Technical Academy Award' (Oscar) and an Emmy for previous work on a range of lenses for professional movie making.

Understanding the practical challenges of moving from closed to open source collaborative design

Natalie Ebenreuter, PhD, Alcatel-Lucent Bell Labs France

Abstract

This inquiry examines how effective collaborative user experiences can be shaped in open source communities. It focuses on the changing design and development conditions of the prototype computer software application *LabanAssist* (Ebenreuter, 2008). These changes stem from, the project's prior development as a prototype application in a relatively closed collaborative environment. This environment had developed through a human-centred participatory design approach and changed into one that was dynamic and embraced open source collaborative design.

By changing the project's environment and activity of development, it is envisaged that a range of experts will have the potential to participate in the ongoing advancement of *LabanAssist*. The challenge, here, rests in designing a way in which an integrated view of the design situation and the associated activities required to continue the open development of the *LabanAssist* project, can be shared and communicated effectively across different design domains.

In this paper, literature concerning the nature of collaborative activities in open online communities is examined. This is done to better understand the challenges of communicating interdisciplinary ways of working and thinking that contribute to the holistic development of open design projects. To address these challenges, a number of interaction design guidelines for facilitating collaborative action are offered as a means to maintain the purpose and activity of open design projects.

The proposed guidelines offer a way of thinking about the manner in which interactive tools can be designed to assist with the identification of design elements in open design projects and to be able to visualise the relationships between various collaborators from different areas of expertise. An open design environment that has the potential to support collaborative action is shown through various interface designs of a conceptual tool that illustrates how a shared view of the form and significance of evolving ideas may be communicated over time.

Keywords

Open design; collaborative action; participation; guidelines; workflows; open source.

The environment and activity of design

Changing business models, methods of innovation and interaction fuelled by the capacity of the Internet to facilitate communication through emerging uses of technology have introduced alternative avenues in which design products and services can be developed. An example of this can be seen in the increasing number of open source development projects, which potentially involve any number of global participants who contribute to the collaborative development of a product's advancement online. In this way, products are designed to adapt, not to a fixed need, but provide a place for action that expedites the needs and intentions of diverse users, in dynamic situations.

This research is built upon on the understanding that open collaborative design practices have the potential to enhance the exploration of unknown design potentialities and the creation of innovative outcomes (Harhoff et al., 2003). In this (Harhoff et al., 2003) view open design can be understood as a dynamic and complex process made up of diverse people, methods, perspectives, and values. This process is fundamentally different from the design of a product that offers a determinate solution to a particular need or desire. Instead, the unfixed or open nature of design potentialities that can take shape is therefore unknown. The notion of unfixed design potentialities is further enhanced by the dynamic direction of open design projects. These projects are essentially driven by end-user needs and intentions and provide the potential for innovative ideas and solutions to develop (Harhoff et al., 2003).

To support the development of innovative design outcomes, useful and informative resources that inform the practice of designing are needed to communicate the idea, purpose and function of open design projects. Communication of this information should be done in a way that bridges the gaps of understanding between individuals from different knowledge groups and varying levels of expertise. In open source software communities it is customary to offer up existing software systems for iterative development in terms of ‘change requests’ and desired ‘product features’. This is done across a variety of online forums and discussion groups, in the form of ‘to do lists’ and ’bug reports’ which do not offer potential collaborators of the project a global view of the design situation. Ubuntu Brainstorm (n.d.) provides an online forum to support the collaborative development of ideas to enhance its software platform. The environment in which the communication of shared ideas is made possible is problematic. The environment typically does not offer end-users the tools or the useful presentation of ideas in a manner that is either useable or helpful (Ashton, 2009).

The focus of this research concerns the changing design and development conditions of a prototype computer software application called *LabanAssist* (Ebenreuter, 2009). The *LabanAssist* project is a continuing work in progress that is seeking to make the knowledge garnered from its prior development, as a prototype application, into useful and informative resources. These resources can potentially be shared, understood and continued to be developed in an open design environment by a range of experts. It involves the clarification of countless interrelated dimensions of a project together with the variety of information, objects, events and practices relevant to the fields of user interface, interaction and software design. Since many issues can arise when conversations within their respective fields are discussed in terms that are seemingly diametrically opposed to one another, the challenge lies in designing a way in which a shared view of the *LabanAssist* project can be communicated effectively.

In the following sections I give context to this research. I discuss the challenges involved in building the necessary relations between different fields of knowing, doing and making with respect to the active involvement of potential participants of open design projects. I propose a number of interaction design guidelines for facilitating collaborative action in open design projects. Through a series of interface design concepts I illustrate the significance of these guidelines on the design of an interactive tool that seeks to support the dynamic structure and activities of collaborators from three different design domains.

I conclude the paper with further remarks concerning the future potential of this research.

Changing design and development conditions

In light of the changing environment and activity of design Keinonen (2009, p. 64) proposes two emerging fields of design practice: (1) ‘immediate design’ which focuses on various practices of use from a user-centred approach; and, (2) ‘remote design’ which is concerned with facilitating practices that lead to structural change. While the idea of distance is used to differentiate the two types of design practice, the development of objects and events that constitute the elements of the design situation, should be understood as part of an organized integrated system. Dewey (1938, p.72) expands upon this idea when he tells us that “we never experience nor form judgments about objects and events in isolation, but only in connection with a contextual whole”. This is an important distinction because without the capacity to build the necessary relations between diverse fields of knowledge, the elements of the design situation and potential participants of a design project there is no significant foundation for the creation of form as a unified whole.

In terms of the initial development of the *LabanAssist* project, carefully developed task analysis schematics and design rationale (Ebenreuter, 2007), worked to assist the early conceptual development of a prototype tool that enables members of the dance community to document movement as Labanotation scores. In the same way that musicians can document scores of music as musical notes on a staff, dancers can document scores of movement using the vast symbolic vocabulary of Labanotation. Taking a fundamentally ‘immediate design’ approach to the creation of *LabanAssist,* the prototype application was co-created with and for students, and educators of the movement notation system called Labanotation. This work was undertaken, on location, at The Ohio State University’s Dance department. As a result, the interaction design of the application’s functionality is firmly grounded in the practical problems and user experience of documenting movement in a symbolic form.

The ability to build the necessary relationships between different fields of knowing, doing and working with potential participants of a project is critical to an open design project. Building these relationships are central to providing a variety of collaborators with the necessary tools and power to contribute constructively to a project throughout its iterative development. This idea is in keeping with Keinonen’s notion of ‘remote design’. Design that facilitates structural change, however, providing a common ground in which participants can identify opportunities for collaboration is essential to their active involvement in open design projects (Barcellini et al., 2008; Détienne, 2006; Ye & Fischer, 2007). I argue that the project for the ongoing development of *LabanAssist* requires a common ground or basis for understanding where, and how one can take action. This stems from the underlying rationale for design in which the project was initially developed. In support of this Ye and Fischer (2007) tell us that careful consideration should be given to specific design decisions in a way that encourages the potential for participation and collaboration.

Making the rationale for designing explicit is significant as it has the potential to provide an opportunity in which a strategy for assisting others to take collaborative action can be developed. One in which prior knowledge of the design situation can orient a participant's understanding of a particular aspect of a project, in relation to the whole and better equip collaborative negotiations to develop concerning what is useful, usable and desirable to the design situation. This is a strategy for action that revolves around the development of ideas in relation to what could be done, as opposed to what must be done to carry the development of a project further. In this way a participant's perspective, experience, and judgment made during the process of designing is vital to the arguments and subsequent actions taken to shape the direction of a project. As a result, this way of thinking and working becomes central to the formation of the design process in open design projects.

The practical challenges for facilitating a variety of open design processes becomes apparent when the elements made available to participants for iterative development are not necessarily developed in complete isolation from one another. This is because various design elements, which require collaborative development, carry with them interdependencies that span across different fields of knowing and doing. These interdependencies and the complexity in which design problems can occur during the conceptual development of newly formed products or services, gives us insight. We begin to understand the benefit of social creativity practices that leverage the perspectives, expertise and fields of knowledge of a number of different individuals (Fischer, Giaccardi, Ye, Sutcliffe & Mehandjiev, 2004). In doing so, a shared understanding of a design situation and it's potential resolution can be shaped collaboratively by participants involved in the process of designing (Fischer et al., 2004). However, there remains a necessity for open design projects to establish a concrete connection between the elements and activity of design. This must be achieved across a number of domains, to provide a flexible structure in which open design projects can be successfully developed.

Navigating open and collaborative design environments

In order to effectively coordinate and navigate the potential contributions of participants in open design environments, an integrated understanding of the design situation is required. Literature that gives focus to the requirements for participation (Barcellini et al., 2008; Ye and Fischer, 2007) and a variety of issues concerning the collaborative development of tasks and activities in online communities (Détienne, 2006; Carroll, Neale, Isenhour, Rosson & McCrickard, 2003), offer a starting point in which a strategy for collaborative action can be developed. While Ye and Fischer (2007) seek to address end-user motivations in combination with effective tools and management support, the focus of this research is to enhance the design of interactive tools that facilitate collaborative action in open design projects. The ability to do so is based on the creation of an integrated understanding of the design situation, its elements and actions, across different design domains, rather than creating meaningful experiences that seek to encourage existing participants to further extend their collaborative commitment.

Drawing on the literature available (Antikainen et al., 2008; Fischer et al., 2004; Kensing & Blomberg, 1998; Divitini & Farshchian, 1999; Détienne, 2006; Carroll, et al., 2003; Ye and Fischer, 2007; Barcellini et al., 2008), I identify critical aspects concerning the participants of the design situation, the representation of design elements and their associated activities across different design domains as a way to enable the potential for collaborative action to take shape. In doing so, participants of open design projects may better understand: (1) Who their fellow collaborators are and what they know; (2) What design elements are being developed and by whom; (3) Where they can make a contribution to the project's evolutionary development; (4) How the project's design activities are advancing the overall design situation; and, (5) Why particular courses of action have been taken and what future actions will be taken to support the project's development.

I propose a number of interaction design guidelines for facilitating collaborative action in open design projects:

1. *Provide cohesive structures of communication*
   The fundamental structure and operation of open design environments should provide participants with a cohesive system of communication in which they can contribute.

   - Visualise the progressive development of ideas and design decisions.
   - Order and arrange the priority of elements.
   - Give hierarchical form to collaborative discourse.
   - Highlight the steps and stages of interactive processes.

2. *Establish an environment of activity*
   A system of use should derive from a common understanding of the elements and activities of a design situation, across a variety of knowledge areas.

   - Establish a collective tool set of design practices.
   - Illustrate how participants' activities give shape to the design situation.
   - Create independent structures of activity that progressively require collaborative development.
   - Visualise individual and integrated workflows.

3. *Create situational relevancy*
   The ongoing development and relevancy of elements that constitute the design situation should be understood as part of an organized integrated system.

   - Give context to interconnected elements of the design situation.
   - Connect collaborative conversations to design artefacts and the underlying rationale for their development.
   - Build relationships between participants' expertise and activities.
   - Assign interactive characteristics to the changing and unchanging elements of the design situation.

4. *Allow for potentiality*
   The boundaries of a system should work to orient different ways of knowing, thinking and doing in a way that opens up the potential for a variety of concrete possibilities to develop.

   - Enable the possibility for variety.
   - Allow for the alternative arrangement and organization of design processes.
   - Create an environment in which understanding and learning is possible.
   - Provide the potential in which the mutual exchange of diverse perspectives can enhance and cultivate creativity.

Fundamental to forming a foundation for collaborative action is the interaction and interface design of a tool that supports specific user tasks in a way that successfully illustrates its utility. This is because the underlying methods of interaction, designed to facilitate various end-user tasks, directly informs the visual interface design and key elements of support tools (Armitage, 2003). The interaction design guidelines, listed above, provide a basis in which to consider the challenges of enabling collaborative action to take shape in open design environments. They offer a way of thinking about the manner in which these concerns are addressed through the design of an interactive tool.

Essential to the specific purpose of this research is the consideration, of the practical challenges of facilitating open design projects, and the design activities or tasks relevant to the processes and practices of three different design domains.

In this research the design domains and activities include:

- Interaction design
    1. Information architecture
    2. Wireframes
- User Interface design
    1. User interface design concepts
    2. User interface style guide
- Software design
    1. System architecture
    2. Application programming interface

The above design activities work to complement the existing knowledge collected through the human-centred participatory design approach taken to facilitate the early development of the *LabanAssist* project. These activities encompass diverse methods and techniques of design thinking and working that provide a starting point for the collaborative development of *LabanAssist* as a fully functioning software application in an open design environment. While these design areas are represented as distinct from one another, knowledge used to support the wide variety of design practices that exist today, are not mutually exclusive to any single domain of design. Instead, each domain draws on a variety of different disciplinary practices to assist in the collaborative development of new products or services and reflects the transdisciplinary nature of design (Margolin, 1996).

An approach towards facilitating collaborative action in open design projects

A holistic view of the design situation should communicate the evolving product idea, its overall purpose and function to assist the progressive development of open design projects. It is envisaged that by visually illustrating interactive processes and workflows, that constitute the activity of the design project, the user experience of participating in open design communities will be enhanced. The ability for potential participants to gain an understanding of the basic structure and operation of open design projects should assist in establishing an integrated system of use in which they can contribute. This system of use, or way of working, should derive from a general and familiar understanding of the activities relevant to the design situation and the domains of design involved in a project's development. In this research, consistent workflows of connected activities form the basis of open design processes. These processes give shape to the design of a proposed interactive tool that seeks to facilitate collaborative action in open design projects.

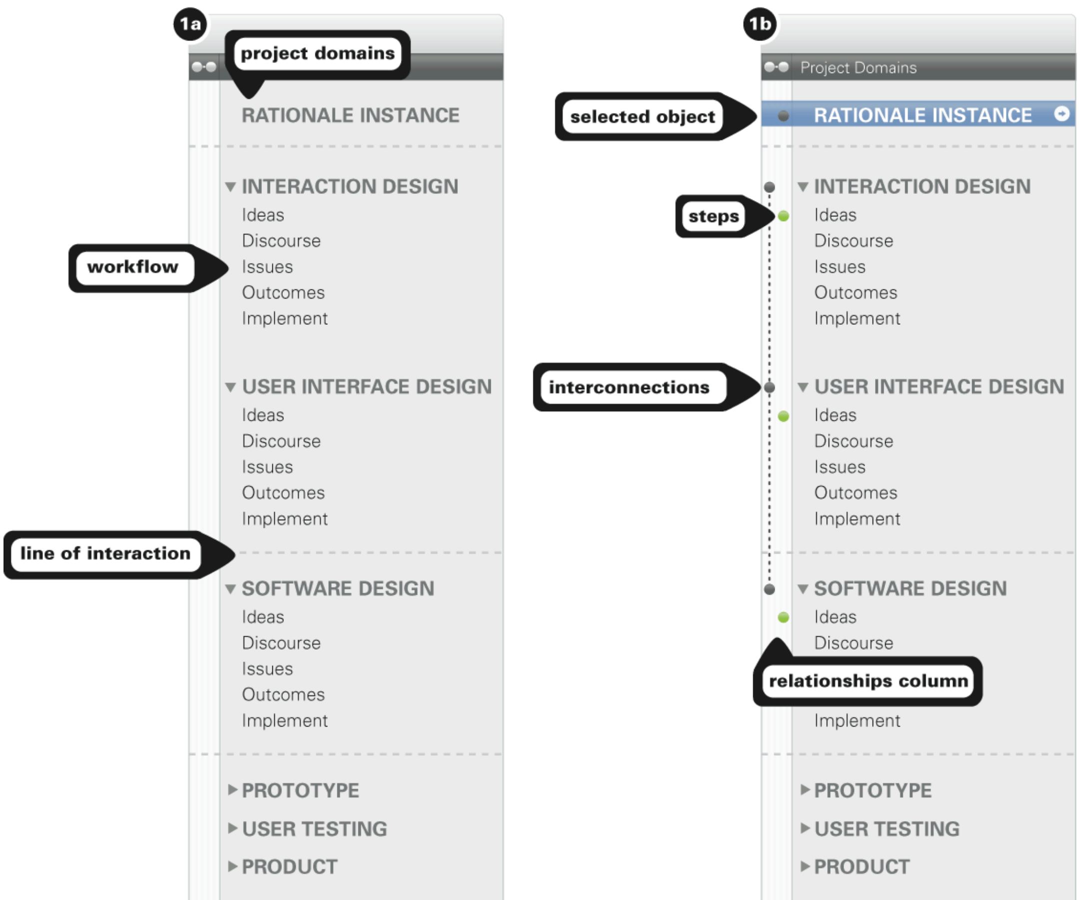

Fig 1. *Workflow structure and relationships across different design domains*

In Figure 1a the interface design of an interactive tool seeks to support the dynamic structure and activities of three different design domains. It illustrates a consistent workflow of connected activities that provide a foundation for the development of ideas as design outcomes and their subsequent implementation as fully functioning products or services. The basic workflow structure displayed in Figure 1a encompasses the ideas, discourse, issues, outcomes and implementation aspects of the design situation, specific to each project domain. Different project domains are made visually distinct in the design of the interface by various horizontal lines of interaction that are placed at the intersection of two closely related domains. In this way, the working relationships between project domains that focus directly on the user interface and interaction design of a software application are highlighted for the work they do in close collaboration. This is because of the immediate impact each human-centred area of design has on one another. Software design, however, is treated differently in the design of the interface because of the technical and supportive role it offers the design of interaction, user interface design and prototype development of software applications. Distinct again from these project domains are the areas of prototype development, user testing and the final product, which hold direct implications for one another during their iterative development. It is envisaged that these areas will also involve end-user participation in both the evaluative stages of a product's early prototype development and the final product release.

The proposed visual distinctions made in the design of the interface are not made to imply that a clear-cut top down approach to designing should be followed. On the contrary, Figure 1b illustrates the interconnections between design elements and various project domains that can potentially exist. In this example (see Figure 1b) the selected object, which is a rationale instance, holds relevancy across three project domains. This is visually represented in the far left of the relationships column, by the positioning of a grey circular marker alongside each relevant domain of the design situation. The relationships are then visually established via a grey dashed line that identifies and unites them. In addition to this, the progressive steps in the design process that connect one activity to another, are represented in the far the right of the relationships column. The following steps of a project are suggested by a coloured circular marker, which is positioned at a lower level in the interface to that of the currently selected object. In Figure 1b the rationale instance is highlighted in blue to indicate that it is the currently selected object. The selected state of the rationale instance is also represented by a circular marker alongside it to suggest that a progressive relationship exists between the rationale instance and the development of ideas across different project domains. In doing so, the structure and stages of interactive processes are highlighted to provide a coherent structure to the communication of developing ideas.

Discovery and Recognition

As an approach to facilitating the inquiry into an open design project, rationale instances in Figure 2 offer potential collaborators of open design projects a way to learn about a particular aspect or object of the design situation, in relation to the whole (Ebenreuter, 2009). They work to provide situational relevancy in open design environments by giving context to the interconnected elements of the design situation. Rational instances achieve this by presenting interdisciplinary design knowledge concerning the development of components, relevant to the design situation, which can be integrated into a larger complex system over an extended period of time. Each rationale instance provides a descriptive account of a component for further ideation and development. They give focus to the relationship between: (1) the specific problems found in the practical user experience that the software application seeks to address; and, (2) the design artefacts created to overcome these issues. The first two points are then further supported with: (3) an explanation of how the function of the design outcome operates; and corresponds to both; (4) the visual attributes found in the interface design of the proposed artefact; and, (5) the interactive elements that the proposed artefact will communicate with, in relation to the system's overall software design.

The design rationale captured within each instance provides a frame of reference in which a variety of designers concerned with the interface, interactive and software elements of a project can continue to shape the development of new products or services. By providing participants with additional knowledge and documentation surrounding each component for development it is envisaged that the potential for creative and innovative design directions can emerge in open collaborative design environments. This additional information is described and illustrated through a variety of documents that are particular to the way in which each domain of design thinks and works. For example the (1) problem; and, (2) design artefact as in Figure 2 hold particular significance to interaction design which contains user-centred design information and documents that are a part of a common set of practices and tools of communication, known to this domain. Alternatively, the (3) functional explanation; and, (5) interactive elements of a rationale instance are relevant to both interaction and software design. Information captured in the system architecture and information architecture documents provide not only a unique view of a component but one that is also applicable to the global view of a software system and it's surrounding interactive elements. Again, this is information that is conveyed within a familiar set of terms and models that communicate this knowledge to individuals who have expertise in these domains. The (4) visual design concept; however, holds specific relevance to the user interface design of a system that is strongly connected to both user interface and interaction design. The method of wireframing, that interaction designers use to visualise general elements in user interfaces, are also significant to the (3) functional explanation of a rationale instance.

Providing potential collaborators of open design projects with various types of design knowledge and artefacts allows individuals, from single or multidisciplinary backgrounds, a specific and general view of the design situation. This is achieved in terms that are relevant to the design domains represented within each rationale instance. It is envisaged that this will help to establish a comprehensive environment of activity that will facilitate collaboration and make understanding and learning possible. By building relationships between participants' expertise and activities, it allows them to focus on independent aspects of a component's design that will progressively require collaborative development as the design process advances. The diverse nature of design knowledge captured within each rationale instance also works to provide a shared view of the design activities that illustrate individual and integrated workflows across a number of project domains.

The relationship between the component for development shown in Figure 2, and the associated design domains for which it holds relevance is also visually illustrated in the interface, on the far left of the relationship column. The fields of interaction, interface and software design are connected with a dashed line and consequent circular markers to indicate their interconnected relationship to one another. This is important as it highlights the different areas of consideration that need to be acknowledged in the resulting ideas and design outcomes that are suggested for integration into a prototype application.

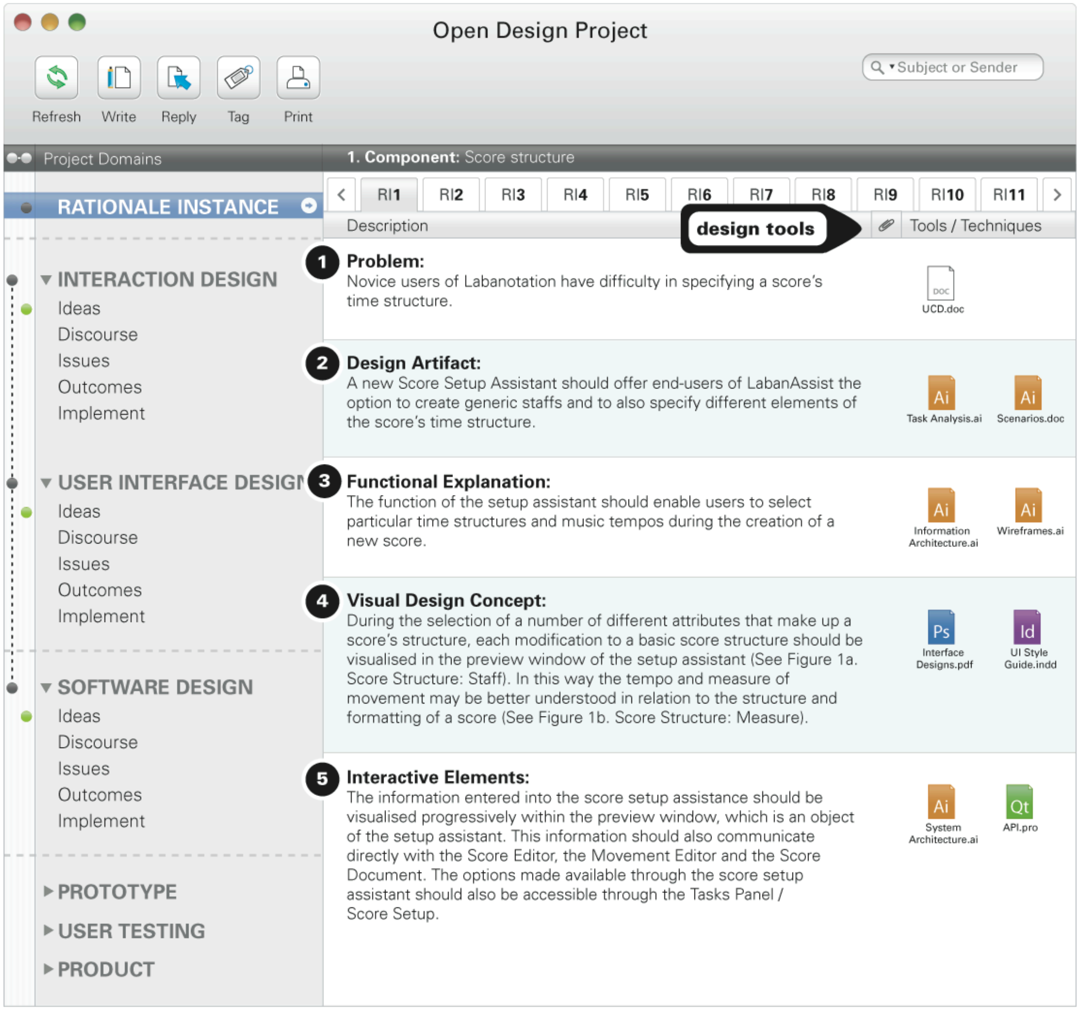

Fig. 2 *Rationale Instance of the component: score structure*

Negotiation and Evaluation

While rationale instances provide a potential starting point for the collaborative development of interactive products, design practices that manage the integration of a project's design elements are needed to ensure that the characteristics of newly developed directions remain consistent with the overall purpose and function of an open design product (Margaritis & Sgouros, 2008). The workflow structures illustrated in Figure 1a give shape to the collaborative development of numerous components that constitute the dynamic design situation. In this way the incremental design and development of each component, over a series of integrated design activities, works to refine the ideas and eventual outcomes suggested by participants to enhance a component's design. This is accomplished as the result of a gradual process of collaborative negotiation and evaluation.

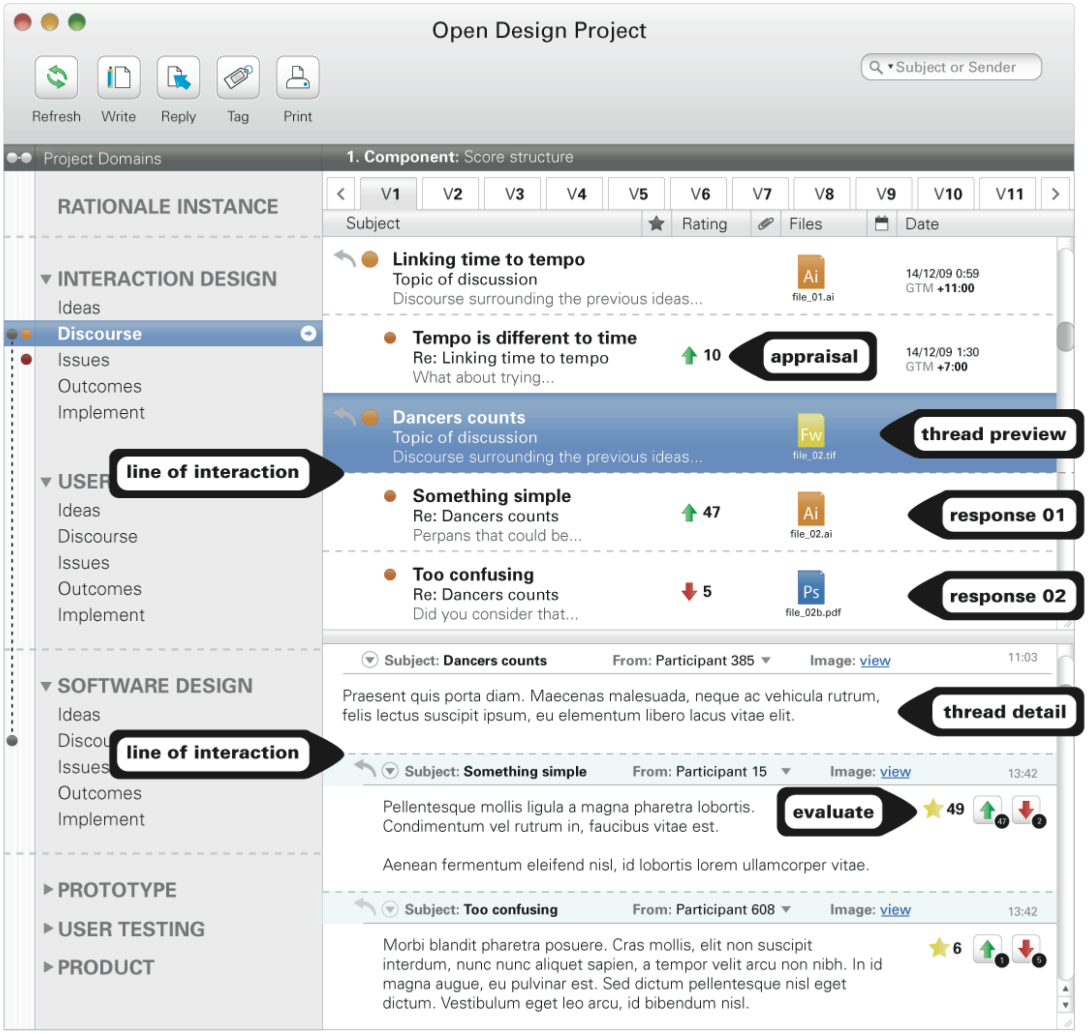

Fig 3. *Threaded discourse*

Threaded discussions, pictured in Figure 3 provide an avenue for collaborative activities and diverse dialogues to develop surrounding the ideas, a discourse (illustrated in Figure 3) of issues and outcomes of the component under development. A visual hierarchy of various subjects for discussion is given to each threaded discussion. This is done through the ordering and arrangement of their representation in the design of an interface by date of appearance or subsequent significance. The priority of each threaded discussion is determined as a result of collaborative appraisal and evaluation during which highly valued design suggestions are positioned at the top of the overview pane. The consequent responses to each thread are visually associated with the thread preview and thread detail by a line of interaction where each response is slightly offset to the right of the original subject of discussion. Individual thread previews and their associated responses work to connect collaborative conversations to design artefacts, whereas, the thread details provide an argument for a particular course of action to be taken. In addition to this, the ability to evaluate the value of each thread response is offered within the detailed view of a threaded discussion and the overall appraisal is illustrated in the thread preview.

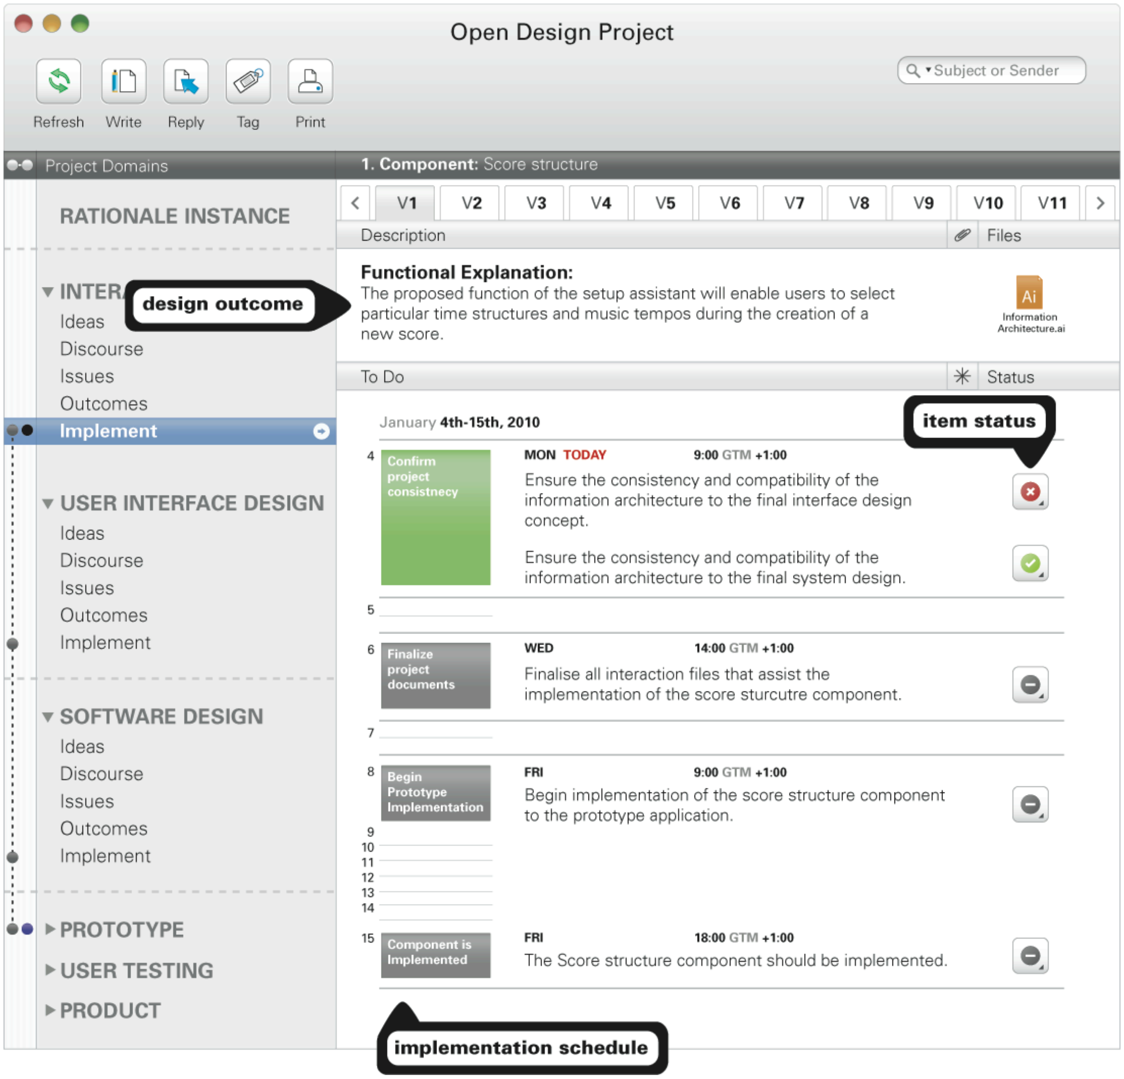

Fig 4. *Implementation to a prototype application*

The application of threaded discussions provides participants of open design projects with a concentrated focus of the design situation, across different activities. These activities are connected to the development of ideas, discourse and outcomes. The issues and implementation process (see Figure 4) of a product's components are fundamentally global in view. A designated site for the development of ideas enables the collaborative development of design components to develop in close relationship to the project domain in which different ideas are formed. Appraised ideas of certain merit are then refined and debated through discourse, for their ongoing value to the utility of proposed design outcome. The further evaluation and appraisal of continuing ideas are then viewed globally, as potential issues across all project domains, to assess if conflicts between the suggested design outcomes could arise. After the evaluation of a suggested component's fit to the overall design situation is corroborated, the potential design outcome is then re-examined within each project domain for its suitability to the purpose and function of the proposed product solution. Successful design outcomes are then offered up for implementation to a prototype application. By visualizing the progressive and collaborative development of ideas and suggested outcomes in relation to the decisions that support their advancement, participants could gain an understanding of how their involvement and activity gives shape to the evolving design situation.

Figure 4, illustrates the implementation schedule for successful design outcomes that have been collaboratively developed and accepted for integration in to a prototype application. It provides participants with knowledge concerning each project domain's contribution to the resulting design component. Interactive icons are used to illustrate the current status of the project's development to assist with the identification of the changing and unchanging elements of the implementation process.

Discussion

This paper focuses on the practical challenges involved in changing the activity of designing from a relatively closed design environment to one that is open and collaborative. A greater understanding of the issues of facilitating collaborative action in online communities enabled the creation of a number of interaction design guidelines. These guidelines shaped the interface design of a conceptual interactive tool that seeks to enhance the user experience of participating in open design projects.

Visually mapping the 'what', 'how' and 'why' of the design process, as a progressive series of connected design activities, can assist to establish an integrated system of use and collaboration across different design domains. However, without the formal evaluation of the proposed guidelines in comparison to the features of other open source projects or an evaluation of the proposed interface designs of the conceptual tool, the key value that the guidelines provide, are as a foundation for designing. This foundation is to assist in the design of interactive tools that seek to facilitate collaborative action. For the specific purposes of this research the guidelines gave shape to an environment in which a design project that embraces open source development as a part of the design activity, could be established. In light of this, the proposed guidelines offer a starting point for designers to further develop and improve upon the manner in which they can assist the design of collaborative action.

A visual representation of an open design project has been illustrated through a number of interface designs, which offers an example of the potential in which a variety of collaborators could better, identify and participate in interactive processes and workflows that constitute the overall design project. Furthermore, the circumstances for developing the design project are underpinned by various techniques and methods that work to supply participants involved in the development of open design projects with a collective tool set and shared vision for it's active formation.

As a continuing work in progress, it is envisaged that the proposed interaction design guidelines will be further developed and refined to address systems of notification that highlight the social status of participants and illustrate the changing elements of the design situation. Moreover, the aim of this research has been to contribute to a growing body of knowledge in design research that seeks to better facilitate open source collaborative action.

Natalie Ebenreuter, PhD

Natalie is a Fulbright scholar who is currently working as an interaction designer at Alcatel Lucent Bell Labs, France and as a lecturer in Interactive Media at Parsons Paris, School of Art and Design. Her experience includes lecturing in design at Carnegie Mellon University's School of Design, Swinburne University of Technology's Faculty of Design and Gobelins l'école de l'image. Natalie has also disseminated various aspects of her research through publications and presentations in Australia, The United States, Canada, Mexico and Europe.

Taylorisme, Fordisme et Toyotisme: comment le design management a construit les principaux modèles productifs de la théorie des organisations

Nabil El Hilali, Université de Nantes & ISTEC école supérieure de commerce Paris

Jean Pierre Mathieu, Audencia, école de management, Nantes

Abstract

Ancrée dans les sciences du management et la théorie des organisations, cette recherche établit un lien entre la recherche en design et les sciences du management. Elle vise à définir, en une perspective inscrite dans la complexité, les fondamentaux de la construction du territoire du design en théorie des organisations. Il s'avère de ce fait que le design est loin de ne constituer qu'un « outil négligé » sous forme d'appendice au service du marketing. Plus que cela, le design structure le champ de la théorie des organisations en étant présent au cœur des trois principaux modèles organisationnels, à l'origine du puissant impact transformationnel de l'économie et que sont le taylorisme, le fordisme et le toyotisme. Une exploration du design située au cœur des principaux modèles productifs montre à travers le récit de F.W. Taylor, de H. Ford et de T. Ohno que le design occupe un rôle stratégique majeur dans le développement, l'essor de ces modèles et l'impact transformationnel qu'ils ont eu sur l'économie. Et que loin d'être circonscrit au produit, le design s'inscrit dans une démarche totale qui va de l'atelier de production à l'outil de travail en passant par le service. A partir de là, il faut considérer différemment le design en management et en théorie des organisations.

Mots clefs : histoire du design; taylorisme ; fordisme ; toyotisme ; sciences du management ; théorie des organisations ; design management

Abstract

Rooted in management sciences and organizational theory, this research establishes a link between research in design and management science in order to define under complexity perspective the construction of design territory in organization theory. Design then is far than being a “neglected tool” and marketing appendix. More than that, design structures the field of organization theory by being present in the heart of the three major organizational models, sources of the powerful transformational impact of the economy, we mean Taylorism, Fordism and toyotism. An exploration of design at the heart of the main productive models shows through F.W. Taylor, H. Ford and T. Ohno narratives that design has a major strategic role in the development, expansion of these models and their heavy impact on economies worldwide. Design then is far from being limited to product design, design was part of a global idea ranging from the production workshop to the work tool and services. From there design should be considered differently within management science and organization theory.

Key words: design history; organization theory; taylorism; fordism; toyotism; management science; organization theory; design management

Cette recherche ancrée épistémologiquement dans les sciences du management et la théorie des organisations, se veut modestement une ouverture vers la recherche en design, de façon à initier un dialogue inscrit dans la complexité entre le design et les sciences du management. Nous entendons le design au sens de (Simon 96) le définissant comme la transformation des situations existantes en situations préférables.

En ce sens, à partir de la théorie des organisations qui structure le champ des sciences du management (Plan 2003 ; Hatch 2006), nous souhaitons montrer que le design est loin de ne constituer qu'un « outil négligé » perçu comme un appendice au service du marketing (Rath & Kotler 1983). Plus que cela, le design est présent dans le champ de la théorie des organisations en étant au cœur des trois principaux modèles organisationnels à l'origine du puissant impact transformationnel de l'économie à savoir le taylorisme, le fordisme et le toyotisme. Précisons ici que les modèles productifs issus de l'automobile offrent un terrain d'analyse privilégié en théorie des organisations de par leur impact sur d'autres secteurs de l'économie (Boyer, Freyssinet 2000)

Méthodologiquement, nous faisons une lecture analytique des récits de Frederick Winslow Taylor, Henry Ford et Taischi Ohno qui ont la particularité d'être tous les trois des ingénieurs impliqués dans la conception de leurs modèles productifs et théoriciens par écrit de leurs propres modèles, écrits que nous mentionnons bien entendu dans notre bibliographie. Nous mobilisons aussi le concept de « Silent design » (Gorb & Dumas 1987) qui développe l'idée selon laquelle le design peut se situer au sein d'une organisation, sans pour autant que cette dernière le définisse et le reconnaisse comme relevant de la pensée et de la pratique design.

Dans la veine des perspectives historiques interrogeant le rôle stratégique du design, des études significatives se sont penchées sur le lien entre industrialisation et design (Quarante 94 ; Sparke 1987 ; Walker 1989), sur l'apport fondateur du mouvement Arts & Crafts en grande Bretagne suivi de l'école du Bauhaus en 1919 (Mozota 2003) ou encore sur les bases de la pensée économique classique avec la pensée d'Adam Smith (Marco 2006).

Toutefois, aucune n'a interrogé les modèles productifs cités ici. C'est donc en une perspective qui porte sur le design dans son lien avec le management, que cette recherche fait le pari de montrer comment une myopie vis à vis du rôle majeur opéré par le design est en mesure de rendre extensible le champ du risque pour les organisations. D'une façon pratique, un tableau synthétisera la problématique design de chaque modèle productif suite à son développement avant qu'un tableau général ne reprenne les trois modèles en guise de synthèse.

Les interrogations qui se posent en ce contexte peuvent se formuler ainsi: Quelle place occupe le design dans le taylorisme, le fordisme et le toyotisme ? Comment celui-ci s'y construit ? et comment la compréhension du rôle du design au sein des principaux modèles productifs aide à repenser le lien entre le design et les organisations à partir de la notion de design management au sens de (Hetzel 93) . Ce dernier définit le design management comme étant un renouvellement des pratiques de gestion, selon une pensée systémique qui favorise la prise en compte par l'organisation et ses acteurs de la complexité et de la gestion de celle-ci.

F.W. Taylor pionnier du design management ?

Réduit à la caricature des « Temps modernes » de Charlie Chaplin, la pensée de Taylor présente de véritables accents de modernité (Hatchuel 1994), celui-ci est le premier à avoir bouleversé pour toujours le fonctionnement des organisations (P.Drucker 2007) et ses principes vont servir à la naissance du marketing. (Cochoy 1993) Or, que nous révèle la pensée de Taylor observée à la lumière du design comme processus inscrit dans la « solving problem theory» (Simon 1997)

L'étude du management selon le paradigme des principes scientifiques portera Taylor à s'interroger sur le modèle productif de l'organisation et à s'intéresser au design de l'outil de travail au sens matériel du terme. L'idée notoire ici s'inscrit dans le fait que l'efficacité du système productif ne peut se faire sans un examen précis et abouti des artefacts manipulés par les ouvriers. Taylor étudiera ainsi les moyens de penser de façon expérimentale les machines en usage à la Midvel Steel company : « (...) the writer (...) obtained the permission (...) to make a series of experiments to determine what angles and shapes of tools were the best for cutting steel," (Taylor 1911p.25)

Soulignons ici, l'attention accordée d'emblée aux angles et aux formes des outils de travail. Ils sont ainsi des constituants paradigmatiques majeurs de tout design liés à la construction de l'offre. Dans le développement de cette même idée, observant scientifiquement l'acte de pelletage, Taylor en vint à la conclusion que le design de l'outil de travail, qui était conçu en un esprit de « rule of thumb » (à vue de nez) ne comportait aucune marge de progression en une philosophie de progrès scientifique. L'acte de pelletage obéissait ainsi avant Taylor à une conception de la pelle complètement arbitraire car un unique fait s'imposait : seule la force physique du pelleteur était en mesure d'assurer une optimisation du travail.

L'observation minutieuse de Taylor démontrera dès lors que la productivité d'un pelleteur ne résidait pas uniquement dans la force physique de l'ouvrier, mais que celle-ci dépendait de la corrélation entre la matière à pelleter, le matériau de la pelle, la forme de celle-ci, sa longueur, le poids de la matière pelletée et enfin la force du pelleteur associée à une gestuelle relevant de ce que l'on appellerait aujourd'hui une ergonomie du poste de travail.

L'étude minutieuse de ces différents paramètres portera Taylor dès lors à repenser totalement le design de l'outil de travail qu'est ici la pelle. Celle-ci ne sera plus une pelle standardisée mais sera «segmentée» en différents modèles qui transformeront totalement le modèle productif objet de l'observation de Taylor : « Instead of allowing each shoveler to select and own his own shovel, it became necessary to provide some 8 to 10 different kinds of shovels, etc., each one appropriate to handling a given type of material (...)". (Taylor 1911 p.26)

La conception et le design de l'outil de travail allait ainsi être recréé en un design visant d'emblée l'efficience. Ayant défini que le poids moyen que peut soulever un homme en une journée de travail, se situait aux alentours de 21 pounds, l'artefact dès lors sera conçu de façon à ne soulever que ce poids. En ce sens, Taylor était parfaitement conscient du rôle majeur que le design de l'outil de travail pouvait avoir comme portée sur la performance de l'organisation: « A large shovel tool room was built, in which were stored not only shovels but carefully designed and standardized labor implements of all kinds, such as picks, crowbars, etc. (Taylor 1911 p.26)

Nous relèverons ici l'intérêt porté par Taylor au design modulaire architectural de l'atelier, ainsi qu'une idée majeure inscrite dans la standardisation, celle là même à l'origine de la rencontre du design et de l'industrie. (Quarante 94) La standardisation de même qu'un design exhaustif de l'outillage de l'organisation constitue ici le point d'ancrage de l'efficience tel que Taylor la conceptualise. Et c'est ici même que se situe le point de départ du modèle productif qu'est le taylorisme et le début de son extension. Il est possible ainsi d'imaginer comment en un vocabulaire actuel, le cahier de charges imposé aux fournisseurs de la *Midval Steel Company* influait et transformait radicalement des outils de travail et construisait de nouvelles offres.

En un autre aspect, il faut souligner que le design de l'outil de travail obéissait à une théorie processuelle du design (Simon 96) qui prend son envol dans la construction du problème (impossibilité d'optimisation du pelletage) jusqu'à la résolution de celui-ci par le biais d'une conception inédite d'un nouveau design de l'outil du travail favorisant une meilleure productivité. Sachant que l'organisation objet de l'observation taylorienne se compose de 600 pelleteurs, cela laisse deviner l'impact productif dû au simple design de l'outil de travail.

Taylor cite aussi en une idée de théorisation une autre expérience propre à la maçonnerie à travers l'étude d'un ingénieur : Frank B. Gilbreth. En ce sens, la pensée de Taylor montre que le design d'un artefact : à savoir l'échafaudage est le résultat de l'éclipse totale en amont du dit objet en maçonnerie. (Findeli & Rabhi 2005). Le travail de construction en maçonnerie sans la présence de cet objet obligeait le maçon à effectuer des déplacements incessants et inutiles vers le point de dépôt du matériel. Le design d'un support de travail sera dès lors pensé dans son interaction avec le maçon assurant ainsi une meilleure productivité tout en étant une innovation majeure :

> He studied the best height for the mortar box and brick pile, and then designed a scaffold, with a table on it, upon which all of the materials are placed, so as to keep the bricks, the mortar, the man, and the wall in their proper relative positions. These scaffolds are adjusted, as the wall grows in height. (Taylor 1911, p.30)

L'idée de l'interaction de l'homme avec les outils de travail à travers le rôle du design est en ce sens une idée capitale. Les formes et la mécanique des machines de la *Midval Steel company* ont été étudiées dans leur dimension ergonomique de façon à définir une harmonie entre le design, le travail de l'ouvrier et sa compétence productive. En une autre mesure, le design de l'outil de travail selon Taylor s'inscrit dans la durée en une idée portée sur l'innovation et le design permanent. Idée au cœur des problématiques actuelles du design et de l'innovation, (Hatchuel, Le Masson, Weil 2006) de la qualité et de l'amélioration continue (Mozota 2003)

> Experiments in this field were carried on, with occasional interruption, through a period of about 26 years, in the course of which ten different experimental machines were especially fitted up to do this work(.......)a very short time was needed to discover one or two types of tools which, though imperfect as compared with the shapes developed years afterward, were superior to all other shapes and kinds in common use...) (Taylor 1911, p.45)

En un autre aspect, Taylor mentionne avec conviction l'inscription du design dans la durée et son lien avec l'innovation. Ce qui offre la possibilité d'une amélioration de l'outil, prélude à de nouvelles formes de standardisation, qui ne peuvent qu'influer sur la productivité des organisations.

Ainsi, la pensée taylorienne dans son lien étroit avec le design, montre comment l'idée qui consiste à repenser avec force le design de l'outil de travail, porte en elle les germes des transformations majeures qui vont affecter pour toujours le management des organisations.

Songeons ici aux implications directes et indirectes de cette pensée, d'autant plus que Taylor est considéré comme le premier consultant de l'histoire (Mc Kenna 2006) et que dans la foulée de sa pensée, des agences conseil en « styling » vont essaimer sur le territoire américain (Mozota 2003) amorçant le design industriel qui connaîtra son apogée avec le fordisme notamment.

N'omettons pas ici, en un autre registre, le fait que les cas présentés à l'appui de l'exposé de Taylor étaient conceptualisés en un souci d'essai théorique. L'idée du progrès de l'organisation est manifeste à travers le lien étroit entre le design de l'outil de travail, le comportement organisationnel et l'efficacité personnelle.

En définitive, le design de l'outil de travail constitue le creuset à partir duquel des transformations majeures vont façonner l'histoire de la gestion. Partant de là, il n'est point possible d'évoquer ces transformations sans prendre en considération l'impact d'un véritable management du design.

En se centrant sur l'outil physique du travail, Taylor allait favoriser une gestion inédite de l'entreprise. Ainsi, il est possible d'affirmer au vu des éléments développés ici que Taylor par sa pratique peut être considéré comme le pionnier par excellence d'un management par le design bien avant que cette notion ne soit développée académiquement par (Farr, 1966 ; Gorb, 1990 ; Hetzel,1993 ; Topalian, 2002 ; Mozota 2003)

Principal apport	Invention du design management Standardisation de l'outil productif Optimisation de la production

Tableau 1 : La problématique design dans le taylorisme

Le fordisme ou l’invention du design total:

L’aspect le plus significatif dans le modèle du fordisme réside dans le fait que la vision du design chez Ford obéit à un design global. Celui-ci s’étend du design de l’environnement du travail jusqu’au produit. Nous verrons l’importance de cette question pour Henry Ford dans son lien étroit avec le produit qu’est la *Ford T* notamment.

Ainsi, selon les principes tayloriens d’observation scientifique de l’entreprise, Ford étudiera l’architecture modulaire de l’atelier. Le design de celui-ci, sera de ce fait pensé dans ses moindres détails. En cet esprit, nous pouvons voir comment l’attention sera portée sur les liens entre construction architecturale, conditions climatiques dans lesquelles l’ouvrier opère, la réduction du risque industriel au travail et sa productivité : « One point that is absolutely essential to high capacity, as well as to humane production, is a clean, well lighted and well ventilated factory ». (Ford 1922, p.30)

D’un point de vue plus étendu, inscrit cette fois dans le design et l’innovation permanente, Ford décrira cette corrélation dans ses ateliers de Ford Rouge plant en ces termes :

> When we put up the older buildings, we did not understand so much about ventilation as we do to-day. In all the later buildings, the supporting columns are made hollow and through them the bad air is pumped out and the good air introduced. (...), during daylight, there is nowhere the necessity for artificial light. (Ford 1922, p.49)

Soulignons ici, le rapport mentionné par Ford entre le design du bâtiment, son éclairage et les économies d’énergie, qui ne peuvent que s’inscrire d’une façon étonnante dans la notion ô combien trop actuelle de développement durable.

Partant de là, l’atelier sera pensé en une vision orientée vers la qualité du design propre à l’espace de production. L’idée de l’assemblage de la voiture, qui a révolutionné à jamais le système productif des organisations, trouve son point de départ dans le design de l’atelier. Et ce, à partir d’une réflexion imbriquée dans le lien entre le déplacement de l’ouvrier, l’accomplissement de sa tâche et la réduction du risque ouvrier au travail.

En ce sens, Ford relate le fait qu’au départ, les pièces nécessaires à l’assemblage d’une Ford composée de 5000 pièces étaient récupérées par les ouvriers en des entrepôts variés. L’assemblage de la voiture était ainsi similaire à la construction d’une maison. Cette forme d’organisation amenait l’ouvrier à réaliser des déplacements multiples au sein de l’atelier, ce qui laisse aisément imaginer une importante perte de productivité.

A partir de ce constat, le design de l’atelier sera repensé totalement de façon à préserver l’ouvrier de tout déplacement superflu. Nous sommes donc devant un événement marquant et fondateur de l’histoire du design en sciences de gestion. Il s’agit de la définition d’une nouvelle construction de la performance reposant avec force sur le design de l’environnement du travail. En gommant les déplacements inutiles de l’employé, grâce à une modulation pointue de l’espace architectural, l’accélération de la productivité ne pouvait dès lors que s’enclencher.

Si le design d’environnement de l’espace de travail est une composante du système fordien, le design de l’outil retiendra l’attention de Ford de la même manière : « None of our machines is ever built haphazardly(...). Sometimes wooden models are constructed or again the parts are drawn to full size on a blackboard.” (Ford 1922, p.44)

Ford évoque ici l'usage du prototypage en recourant aux deux procédés que sont la maquette ou le dessin afin de concevoir un design abouti. Ce qui nous amène, au concept d'assemblage qui est au cœur du système fordien. Celui-ci se résume par ce qui peut s'apparenter à une formule : « The first step forward in assembly came when we began taking the work to the men instead of the men to the work ». (Ford 1922, p.35) C'est sur cette base donc que la célèbre chaîne d'assemblage fordienne sera conceptualisée.

Soulignons ici que le design de la chaîne d'assemblage est pensé en une interaction étroite avec le design architectural de tout l'atelier. Les composants du produit sont ainsi acheminés vers l'employé au point précis où celui-ci en a besoin, sans que ce denier n'éprouve le besoin de se déplacer.

En une autre idée, la surveillance de la température du four allait connaître une simplification déterminante : à la place d'un indicateur classique de mesure fahrenheit/Celsius, le design d'une ampoule s'activant à la bonne température, non seulement simplifiait au maximum la tâche de l'homme sur la machine, qui par un simple coup d'œil s'acquittait de celle-ci, mais surtout rendait la fonction accessible à tout ouvrier nonobstant sa qualification. Le design d'un signal lumineux qui peut sembler anodin vu de notre époque, replacé dans son contexte du début du siècle, est ici à l'origine d'une accélération productive : « We introduced a system by which the man at the furnace has nothing at all to do with the heat. He does not see the pyrometer--the instrument which registers the temperature. Coloured electric lights give him his signals." (Ford 1922, p.44)

L'une des idées les plus marquantes, lorsque le fordisme est interrogé dans sa corrélation avec le design, réside dans le fait que le design de l'outil de travail impliquait une gestion de la sécurité de l'ouvrier et la prévention du risque : « Every accident, no matter how trivial, is traced back by a skilled man employed solely for that purpose, and a study is made of the machine to make that same accident in the future impossible." (Ford 1922, p.49)

La sécurité de l'ouvrier étant assujettie étroitement au design de l'outil de travail, l'outil en question sera repensé en une idée d'amélioration continue, à partir de l'établissement d'une corrélation entre le design ergonomique de la machine et l'interaction de celle-ci avec l'homme et son espace de travail. Ainsi, le design de l'atelier conceptualisera des obstacles et des mécanismes empêchant l'ouvrier de se situer en un endroit présentant des risques : « Over the automatic conveyors are placed bridges so that no man has to cross at a dangerous point » (Ford 1922, p.49)

En une autre dimension orientée cette fois-ci sur le produit, l'optimisation du design dans ses différentes composantes centrées sur l'espace architectural et l'outil de travail s'avère être en corrélation étroite avec le design du produit final. C'est donc le design produit qui rentre en interaction directe et indirecte avec les autres composantes du design de l'atelier. C'est en ce sens qu'il faut situer la conception du fameux Modèle T à travers une réflexion qui place la conception du produit au cœur du projet de l'organisation :

> The big thing is the product, and any hurry in getting into fabrication before designs are completed is just so much waste time. I spent twelve years before I had a Model T which is what is known to-day as the Ford car that suited me. We did not attempt to go into real production until we had a real product. (Ford 1922, p.9)

Comment dès lors concevoir le design du produit ? Ford répondra à cette question en une dimension qui définit avec minutie le concept inhérent au design du modèle T. La théorie C.K. (Hatchuel, Weil & Le Masson 2006) montre en ce sens l'importance majeure de la définition du concept dans tout projet design et son rôle dans le succès du produit. Nous pouvons donc suivre ici comment le projet design de la Ford T qui a révolutionné et transformé en profondeur les Etats unis d'Amérique est pensé en une vision stratégique:

> I will build a motor car for the great multitude. It will be large enough for the family but small enough for the individual to run and care for. It will be constructed of the best materials, by the best men to be hired, after the simplest designs that modern engineering can devise. But it will be so low in price that no man making a good salary will be unable to own one-and enjoy with his family the blessing of hours of pleasure in God's great open spaces. (Ford 1922, p.32)

Cette vision stratégique de la conception (Hamel & Prahalad 1989) de la Ford T s'inscrit totalement dans la théorie projet du design (Findeli & Rabhi 2005) Nous pouvons y déceler la représentation qui a porté la Ford T au succès qui était le sien. Succès qui transforma un large pan de l'économie américaine. La Ford T détient à ce jour le record de la voiture la plus vendue dans toute l'histoire de l'automobile. Cette vision stratégique délimite donc d'une façon totale l'ensemble du design de la Ford T qui devait être pensée en une logique de compression des coûts et d'une certaine idée inscrite dans la simplicité.

La dimension service, en une idée marketing ne sera pas négligée, le design de la Ford T en amont devait donc prendre en considération un aspect très important : la facilité de remplacement et de réparation des pièces endommagées qui devait écarter toute opération complexe et coûteuse pour le client. L'idée donc d'un design inscrit dans la simplicité aussi bien en conception qu'en entretien et en réparation était ainsi au cœur du projet design de la voiture fordienne. Dès lors, il est possible d'affirmer que la pensée design de Ford n'est nullement fortuite mais bien inscrite dans une pensée élaborée et un management par le design qui s'étend à toutes ses dimensions.

De là, la pensée fordienne peut se définir comme un projet design manifeste dans l'accès de la classe moyenne américaine à la voiture. Ainsi, étape par étape, seront dessinés les contours d'un artefact, qui va construire un des plus grands succès industriels de l'époque moderne, sans omettre l'impact indirect de la Ford T sur la construction du réseau routier américain et le développement mondial de l'industrie automobile.

Enfin, le design dans son lien avec le style a aussi suscité d'une manière (logique) l'intérêt de Ford. La Ford T n'était nullement conçue en un produit unique, mais segmentée et positionnée en une gamme de produits selon une perspective ancrée dans le marketing naissant de l'époque. En ce sens, il est possible d'observer une « restylisation » annuelle de la Ford T de 1908 à 1927 marquée par des modifications dans le style de la carrosserie, des améliorations techniques, esthétiques et des différenciations nominales des différentes gammes.

Ainsi, il s'avère à partir de ce développement que le design est au cœur de la transformation qu'a apporté le fordisme en tant que modèle économique. Son idée est inscrite dans un design global qui ne se circonscrit nullement au style du produit mais qui englobe le design de l'environnement depuis la source de la production. Par la suite, il s'étend au design de l'outil de travail avant de porter in fine sur le design du produit final. Et ce en une logique d'interdépendance et de complémentarité.

Tableau 2: la problématique design dans le fordisme

Le Toyotisme post fordiste : le rôle du design :

Si le design s'avère être un paradigme fondateur du Taylorisme et du Fordisme, (l'évolution) du fordisme vers le toyotisme, se fera aussi à la faveur d'une nouvelle perception du design comme nous allons pouvoir à présent le développer à travers son fondateur qu'est Taichi Ohno. Toutefois, la prise de conscience de l'importance du design de l'espace de travail et de l'outil de travail est évidemment une idée dépourvue de nouveauté, puisqu'elle reste l'apanage des deux modèles développés plus haut. En revanche, il est intéressant de voir comment le toyotisme s'est construit en une dimension dialogique avec le design de l'outil de travail et de l'espace architectural et comment cette interaction a contribué à l'élaboration d'un modèle économique dont l'impact perdure à ce jour.

Ce fut donc le choc pétrolier et l'entrée en crise de nombreuses entreprises, qui révéla aux yeux du monde le toyotisme à travers la résistance de l'entreprise Toyota à l'avènement d'une nouvelle économie inscrite désormais dans une croissance terne. Or que nous montre ce modèle dès lors qu'on l'interroge à la lumière des théories sur le design.

Tout comme le modèle fordien dont il s'inspire, T. Ohno pensait fortement que si Ford lui était contemporain, il aurait abouti au « toyotisme » « Je suis convaincu que, s'il était encore en vie, il aurait inventé lui-même le système que nous avons mis au point chez Toyota (...) Henry Ford était visionnaire (Ohno, 1993 p.106).

Le toyotisme a érigé comme principe la lutte contre le gaspillage avec une idée ancrée dans la notion du « juste à temps », il est fort intéressant dès lors de constater que le design de l'atelier toyotien sera un paramètre important de la conception du toyotisme. L'idée ohnienne qui consiste à faire basculer l'ouvrier d'un univers mono-tâche à celui multi-tâche est en partie réalisée à travers un renouveau du design modulaire de l'architecture de l'atelier et des machines.

En cette perspective, lorsque les machines étaient disposées de façon à produire la même pièce en un nombre important d'exemplaires, le toyotisme se fixait comme idée de ne produire la pièce en question qu'à partir du moment où la production de celle-ci répondait au principe du « Just in time » autrement dit, la pièce doit être fabriquée au moment où sa fabrication est justifiée en un principe: ni trop tôt, ni trop tard. Ce qui se traduit immédiatement par de grosses économies d'échelle.

Cet aspect va dès lors contribuer à un renouveau du design de l'atelier toyotien qui va prendre en considération la nouvelle organisation:

> Nous avons mené à bien l'élimination des gaspillages en procédant à l'examen critique des installations disponibles, en réimplantant les machines, en améliorant et en auto-activant les processus mécaniques, en améliorant les outils, en analysant les méthodes de transport et en limitant au strict nécessaire les en-cours de fabrication. (Ohno, 1993 p.106)

A la source donc de la nouvelle productivité Toyotienne, un renouveau du design de l'espace architectural dans son lien notamment avec le design de l'outil de travail.

En un autre aspect, Ohno élaborera une notion intrinsèque à un des fondements du toyotisme inscrit dans la lutte contre le gaspillage. Cette notion, il la nommera « diriger avec les yeux» : « Pour que « l'auto activation » permette effectivement de dénoncer les anomalies, il faut que ce qui est anormal se distingue immédiatement, et à l'œil nu, de ce qui est normal. »

(Ohno, 1993 p.126)

Il s'agit donc d'organiser la production à travers une perception visuelle qui implique une remise en question du design de l'outil du travail, à travers la création de nouveaux objets. Cette remise en question se réalisera dès lors à travers deux principaux artefacts : le premier est « l'andon » constitué d'un tableau lumineux qui utilisant un triple système de couleur: vert orange et rouge fournit à l'ensemble des opérateurs une information utile et stratégique à propos de l'état de la production : le vert pour normal ; l'orange quand un opérateur sollicite de l'aide sur la ligne et rouge en cas d'anomalie. Le second artefact n'est autre que le fameux « Kanban » qui est un moyen de communication des besoins basés sur un ensemble d'indication à la source même du principe du « juste à temps ». La construction du principe de la direction par les yeux se réalisera dès lors à partir d'une forte modification de l'ensemble du design de l'atelier toyotien.

Ainsi, avant que le design ne s'étende à l'artefact qu'est la voiture Toyota, il est possible de constater que dans le creuset du toyotisme se situe une réflexion tournée vers le design de l'atelier et de l'outil de travail. Celui-ci s'avère être un constituant majeur du processus à l'origine du modèle dont il a été question ici. En ce sens, il n'est point possible d'ignorer le rôle que joue le design dans l'élaboration du modèle qu'est ici le toyotisme en une conception post fordiste.

Entreprise étudiée	Toyota
Paradigme à l'origine de la réflexion design	Optimisation pointue des couts de production et de distribution par le principe des « 5 zéros » : zéro stock, zéro délai, zéro défaut, zéro panne, zéro papier Réflexion pointue à propos de toute forme de gaspillage
Problématique design	Optimisation de la production par le design d'environnement et de l'outil de travail « Diriger avec les yeux » : l'anomalie doit être distinguée visuellement par des indicateurs spécifiques
Manifestation de la réflexion design	Basculement du travail mono-tâche à multi-tâche Renouveau du design modulaire de l'architecture de l'atelier et des machines Redesign de l'outil de production Implémentation de 2 indicateurs visuels clefs : *Andon :* triple tableau lumineux assignant la valeur « normal » à vert, « demande d'aide » à l'orange et « anomalie » au rouge *Kanban :* moyen de communication visuel des besoins « juste à temps » et outil stratégique fondateur du toyotisme
Méthodologie / Processus design	Examen de la chaîne logistique (Supply chain) Observation / Expérimentation Calcul du coût
Résultat managérial pratique	Optimisation de l'ensemble du design de l'atelier toyotien adaptable à une « direction par les yeux » Economies d'échelles stratégiques pour l'entreprise Toyota
Principal apport	Invention du modèle juste à temps Le design d'environnement et de l'outil de travail comme fondement du principe « Juste à temps » Optimisation coûts et économies d'échelles d'envergure

Tableau synthétique 4 : la problématique design dans les trois modèles productifs

Conclusion:

Que faut-il retenir de cette interrogation du design à la lumière des trois modèles productifs à la source de transformations majeures en management.

1 Le design est au cœur des transformations majeures de l'économie et des organisations.

2 Le « design produit » est le fruit d'une vision globale du design qui s'inscrit dans le design de l'atelier, dans le design de l'outil de travail et des machines et enfin sur le produit en une idée qui ne pourrait amputer le design produit du design inscrit dans l'architecture de l'atelier et de l'outil de travail.

3. Le design dans son interaction avec les sciences du management ne peut être pensé uniquement en une vision instrumentale, car il ne se situe pas à la périphérie des organisations mais en leur centre. C'est un facteur clef de la performance.

D'où l'importance de la prise en considération du design en une logique ouverte sur les organisations en considérant l'ensemble de la chaîne de valeur en management stratégique. En une acceptation large du risque (Guillon et al 2007), la non prise en considération du design en management est en mesure d'être lourde de conséquences dans un environnement hyperconcurrentiel (D'aveni 94) manifeste par une agressivité concurrentielle d'envergure.

Ultra Low Carbon Vehicles: New Parameters for Automotive Design

Stuart. G. English, Northumbria University, United Kingdom

Matteo Conti, Northumbria University, United Kingdom

Abstract

As the influence of vehicle emissions on our environment has become better understood, the UK government has recently placed urgent emphasis on the implementation of low carbon technologies in the automotive industry through: the UK Low Carbon Industrial Strategy. The overall objective is to offer big incentives to consumers and support for the development of infrastructure and engineering solutions. This scheme however does not consider how the development of functional and experiential user value might drive consumer demand, contributing to the adoption of low carbon vehicles (LCVs) in the mass market.

With the emergence of the North East of England as the UK's first specialised region for the development of ultra-low carbon vehicles (ULCVs), ONE North East, as a development agency for the region's economic and business development, and Northumbria University Ideas-lab have supported a project to facilitate innovation through the collaboration of technology, research and development (R&D) and business. The High Value Low Carbon (HVLC) project aims to envisage new user value made possible by the integration of low carbon vehicle platforms with new process and network technologies. The HVLC consortium represents vehicle manufacturers and their suppliers as well as technology based companies and through an ongoing process of design concept generation the project offers a hub for innovation led enterprise.

Whilst new technological developments in areas such as power generation, nano materials, hydrogen fuel cells, printed electronics and networked communications will all impact on future automotive design, the mass adoption of low carbon technologies represents a paradigm shift for the motorist. This paper aims to describe how the mapping of new parameters will lead to new transport scenarios that will create the space for new collaborative research on user experiences supported by innovative technologies and related services.

Keywords

automotive design; low carbon; transport scenarios; sustainable design; user value.

In the late nineteenth Century the fastest cars in the world were electric. These vehicles reached over 65 mph, speeds not surpassed by fuel based cars until the early twentieth century. Since then over 100 years of improvement and innovation in the automotive industry has been focused predominantly on internal combustion vehicles that are responsible for the production of around a quarter of the UK's emissions of carbon dioxide (*Why is the car industry failing on climate change?,* n.d.). Today's car market, in developed countries, is about to undergo a cultural revolution that will open up new and promising scenarios for ULCVs (hybrid and totally electric vehicles) as we mainly utilise our cars in towns limited to daily mileages of less than 40 miles (*Pininfarina Bluecar*, n.d.).

Since the latest car power trains do not offer yet a significant combined reduction of CO2 emissions and fuel consumption over frugal diesel engines, as proven by some motor journalists (*Toyota Prius proves a gas guzzler in a race with the BMW 520d*, Rufford N., & Dawe J.), global competition remains wide open to create more capable and efficient vehicles to protect our global environment. Due to the massive investment required to create a traditional new vehicle, as Tata invested nearly $400 million in the Nano (*Tata: Still Reeling from Its Jaguar-Land Rover Buy,* Srivastava M.), advanced and economical power train technologies can enable even smaller companies to enter the LCV market by converting mainstream vehicles into the next generation of lean and efficient vehicles. IDTECHEX car analysts state that by 2020, it will be possible for some suppliers to offer hybrid cars and no price premium to conventional cars making a strong case why anyone would want the conventional alternative (*Hybrid And Pure Electric Cars 2009-2019*, n.d).

Within this highly technological and thriving context the HVLC project's drive is to obtain a share of this market as a consortium in order to provide design and engineering solutions through innovation and enhanced user value. It is worth noting that this represents a fundamental step for designers to embrace sustainable design through appropriate industrial collaboration in this emerging field, as the opportunity to innovate and drive the evolution of ultra low carbon vehicles in many aspects is going to modify the way we perceive and use cars, as refined products, but also make a real contribution towards lowering our road transport emissions on a large scale. In fact, it is expected this transportation revolution will account for 1.5-2 million electric vehicles (EVs) introduced in the medium term on the European market alone (*Pininfarina Bluecar*, n.d.).

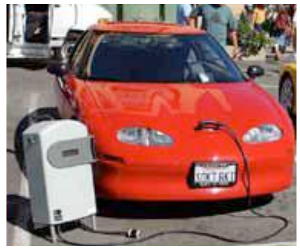
The HVLC's agenda follows the same guidelines that Peter Mandelson, Secretary of State for Business, Innovation and Skills, and Ed Miliband, MP and Secretary of State, Department of Energy and Climate Change (*The UK Low Carbon Industrial Strategy*, July 2009) recently stated: 'The global market for low carbon goods and services is already worth around £3 trillion a year, and will probably grow by half that again by 2015'.

History of Electric Vehicles

Electric vehicles have been a neglected and side lined from the car makers' development and business agenda for nearly a century. This is apparent as EVs rarely feature in car history books. HVLC conducted some preliminary research to comprehend the whole evolution of EVs and then chronologically summarised it in table 1 and 2 by highlighting the most significant EVs' milestones.

1832-1839 First Cell Vehicle Scottish inventor Robert Anderson invents the first crude electric carriage powered by primary cells.	**1891 First Successful EVs** William Morrison builds first successful electric automotive in the US. **1897 First Electric Taxi** The new vehicle hits the streets in this year. The Pope Manufacturing Company of Connecticut becomes the first mainstream American electric automotive manufacturer. **1899 First Land Speed Records** Three records set in one year 57.6mph – highest	**1912 Charging Stations** Thomas Edison and Henry Ford decided to work together to make the electric car the main transportation in the US. Their goal was to have charging stations where people could "fill up" their cars around the country. **1912 First Electric Starter** Charles Kettering invents the first practical electric starter motor for the internal combustion engine, helping the beginning of its evolution.
		
1832-1839 **First primary cell vehicle**	**1899** **First EV land speed records**	**1912** **Thomas Edison`s EV**
	The Global Warming Time Line	
1841 Newspapers report Jean Baptiste Joseph Fourier's theory of global warming. However, many believe that the warming of the earth is a positive development.	**1894** Newspapers reflect on the past decade that brought about a revolution in labour industries. During the c20th, scientists will mark this time period as the beginning of the industrial pollution of the environment	**1913-1914** Swedish scientist Svente Arrhenius coins the term "greenhouse effect" and predicts that the slow warming of the Earth's climate. Many scientists dismiss the possibility of the theory. Arrhenius' prediction sparks speculation about the end of the world.

Table 1 the electric vehicle stepping stones – From its origin until the first world war

1971 Apollo 17 Lunar Rover (19 April) was the first vehicle on the moon. **1972 First Hybrid** Victor Wouk, (Godfather of the Hybrid), builds first full-powered, full size hybrid vehicle based on a 1972 GM Buick Skylark. **1974 Vanguard-Sebring Citi Car** Debuts at the Electric Vehicle Symposium, Washington DC.	**1996 GM EV1** The first modern production electric vehicle from a major automaker and also the first purpose-built electric car produced by General Motors (GM) in the United States. **1997 Toyota Prius** Toyota unveils world's first commercial mass-produced and marketed hybrid car in Japan	**2000** A few thousand all-electric cars (eg. Honda EV Plus, GM EV1, Ford Ranger pickup EV, Nissan Altra EV, Chevy S-10 EV, and Toyota's RAV4 EV) are produced by big car manufacturers, but are mostly available for lease only. **2006** A few pure electric cars and plug-in hybrids are in limited production, with new ones are on the horizon.
		


1974 **Vantguard-Sebring Citi Car**	**1996** **GM EV**	**2002** **Tesla Roadster**
	The Global Warming Time Line	
1950-1970 Development of new technology leads to an increased awareness about global warming and the greenhouse effect. New studies show that the level of carbon dioxide in the atmosphere is rising each year and pollution concerns begin to enter into everyday life.	**1984-1990** Theories about the greenhouse effect and global warming become more prevalent, and gain attention from mass media. However, many people believe the threat is not eminent and some doubt that global climate change is a danger.	**1997-2005** Worldwide conference on Global warming is held in Kyoto, Japan on December 1st 1997. 125 nations sign the Kyoto Protocol, committing to reduce pollution.

Table 2 The electric vehicle stepping stones – from the 1970s to date

Current Context

Global environment

As a result of more than 150 years of industrial activity, the amount of carbon dioxide in the Earth's atmosphere and temperatures have been rising dramatically because of the pollution caused by burning fossil fuels and the unstoppable deforestation process. It follows that glaciers are melting, plants and animals are being forced from their habitats, and the number of severe hurricanes, storms and droughts is increasing (*What is global warming?*, n.d.).

Now that the Obama administration has ratified the Kyoto protocol, whose key aim is to reduce greenhouse gas (GHG) emissions to an average of 5 % against 1990 levels over the five-year period 2008-2012 (*Kyoto Protocol*, n.d.), there is rightly an increasing pressure to embrace low carbon technologies. It must be also pointed out that the global car industry has overtly and covertly delayed the R&D of fuel efficient technology as well as non-fossil fuel based vehicles. Both the government and the car industry have realised that the dependence on non-renewable fuel sources is an area that needs addressing with a certain degree of urgency.

In order to tackle this difficult situation the European Commission has currently proposed to its member states to promote and stimulate the purchase of fuel-efficient vehicles and to invest in more research aimed at reducing car emissions to an average of 95g CO_2/km by 2020 (*CO2 and Cars*, n.d.). This is absolutely necessary since the transportation sector is a major contributor of GHG, as shown in figure 1, and because no nation can avoid the serious consequences of climate change.

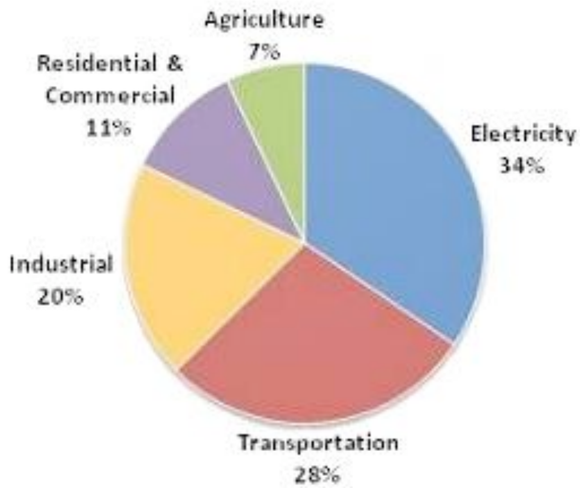


Figure 1 U.S. greenhouse gas emissions by economic sector (2007)

In order to further reduce global warming, in the next few decades, the world's energy systems will have to be transformed so that global emissions drop 50 to 80% (*World Development report 2010*, n.d.). This enormous challenge must be met by the transportation industry as well if we are to minimise the effects of global warming.

Government LCV Strategy

The UK government has recognised the need for research into LCVs technology and has accordingly responded by investing into three main areas:

1. Engineering: £23 million for low carbon vehicle innovation platform - phase 1.
2. Infrastructure: £100 million for low carbon vehicle integrated delivery programme £20 million for LCV public procurement programme.
3. Incentive: £250 million for the DfT EV consumer incentive package encourages consumers to buy electric by providing a £2000 - £5000 subsidy for low carbon vehicles.

The government has also recently released a projected scenario of personal transportation in the UK over the next 40 years, as illustrated in figure 2.

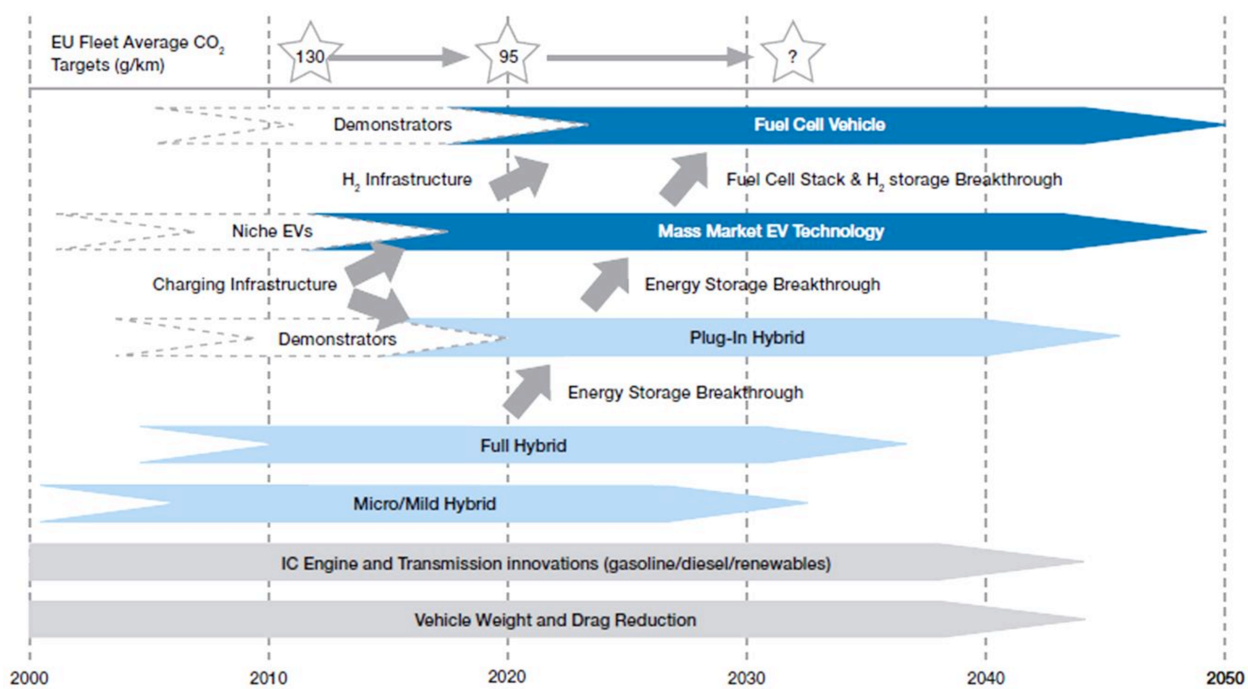

Figure 2 High-level technology roadmap for the UK's decarbonisation of road transport

The chart illustrates an unprecedented parallel development of different power train technologies. It also unmistakably points out how complex, varied and also uncertain will be the future car market, as various advanced LCV power trains will enter the market and become more competitive in terms of low emissions, energy consumption, reliability, and running costs. In addition, another major variable is represented by the subsequent development of adequate infrastructure through local governments to support those alternative means of transport and ensure they are a viable solution to tackle climate change. The complexity of this market will increase as over the next few years more obsolete and less efficient vehicles will be phased out leaving the consumer with a new wider spectrum of cars to choose from based on the user's needs and desires. It follows that styling, safety and branding will not be the only deciding factors in people's mind when it comes to acquiring a new vehicle.

Technology

As in the short term, none of these low carbon vehicle platforms will be resolved and mature enough to emerge from the other alternative power trains and set new standards, a lot of fierce competition between these propulsion systems developed by vehicle manufacturers and component makers will take place. This unusual phenomenon will offer car makers but also smaller design and engineering entities an opportunity to innovate and compete in the market place as the electrification of vehicles will significantly simplify vehicle assembly and procurement of components.

Analysts predict that electric vehicles will penetrate the market rapidly to constitute 35% of the cars made in 2025, 25% hybrids, 10% pure EVs (*Hybrid And Pure Electric Cars 2009-2019*, n.d). As a result, any motor manufacturer without a compelling line up of hybrid and full electric vehicles will be facing serious financial losses.

A recent study by the Swiss Federal Institute for Materials Science and Technologies has dismissed the pre-conceived idea, that driving an EV is simply relocating the problem to the production of electricity, by studying the entire life cycle of different modes of power for individual cars. Figure 3 illustrates the results of a comparison between an EV charged with the European electricity mix (mainly relying on thermal power plants), an EV charged with solar panels (renewable energy) and the usual combustion engine fuelled at the petrol station. Even in the case of the EU electricity mix, over 50% of the CO2 emissions are reduced (*The Bright Green Idea*, D. Rochat).

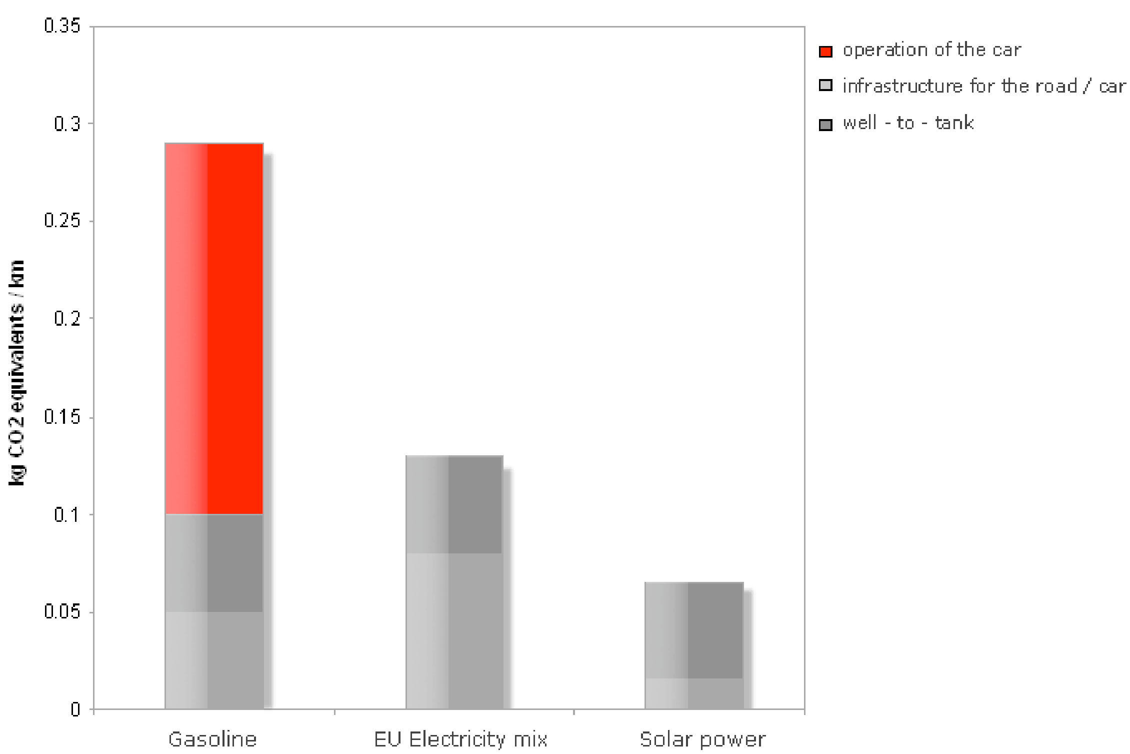

Figure 3 Comparison of greenhouse gas emitted for driving 1 km for three types of car

The High Value Low Carbon Project

HVLC Structure and Objectives

In response to the UK Government's focus on engineering and infrastructure the researchers have initiated a consortium-based project that aims to envisage functional and experiential user value made possible by the development of LCV technologies. The High Value Low Carbon (HVLC) consortium of industrial and research partners includes:

- 4 international automotive manufacturers
- 3 research centres
- 7 component manufacturers
- The regional development agency ONE North-East

By bringing together carefully selected organisations around the theme of LCV innovation, the consortium has enabled companies to interact and as a result a number of 'spin-off' commercial opportunities have been initiated. The aim of the project is:

- To provide a conceptual focus for an ongoing collaborative project involving technology companies and suppliers to the automotive industry.
- To develop high quality interior design concepts for future electric vehicles.
- To demonstrate how printable electronic technology can provide added value concepts in vehicle design.
- To explore the integration of hi-tech on-board info-entertainment equipment such as: screens, Internet enabled computer, mobile phones, cameras, etc.
- To provide a high level of security through the on-board Internet connection.
- To envisage additional user benefits made possible by battery technology.
- To pilot collaborative arrangements prior to the commencement of a substantial LCV project in 2010.
- To stimulate business activity and commercial collaboration.

Research questions

The aim to innovate and tackle the multi-faceted topic of EVs in an unbiased and rational manner led the HVLC team to formalise their reasoning through the identification of key research questions. As a result, the entire research project revolves around 4 fundamental enquiries that explore:

1. New intellectual property (IP).
2. New ideas for new products and services.
3. New methods and ways of thinking.
4. New knowledge about the sustainable future of the automotive industry.

These also represent the motives that drive the development of HVLC in a world where the struggling auto industry needs to seriously reconsider its priorities and product development strategies if it is to survive within future economic parameters.

Research method

The HVLC project is underpinned by a practical knowledge of transportation design and the automotive industry, the researchers being experienced transportation and industrial designers. Three third year BA (hons) transportation design students were employed on placement and the researchers directed their activities in support of the project.

A process of multiple perspective problem framing (English 2008) was adopted, firstly to explore parameters relevant to the development of viable LCV products and services. Secondly to describe potential user value revealed by the interrelationship of these parameters and thirdly, to explore potential opportunities for consortium companies to develop business collaboration (this has already led to a number of commercial 'spin offs' in other fields). Figure 4 shows an initial project-scoping map.

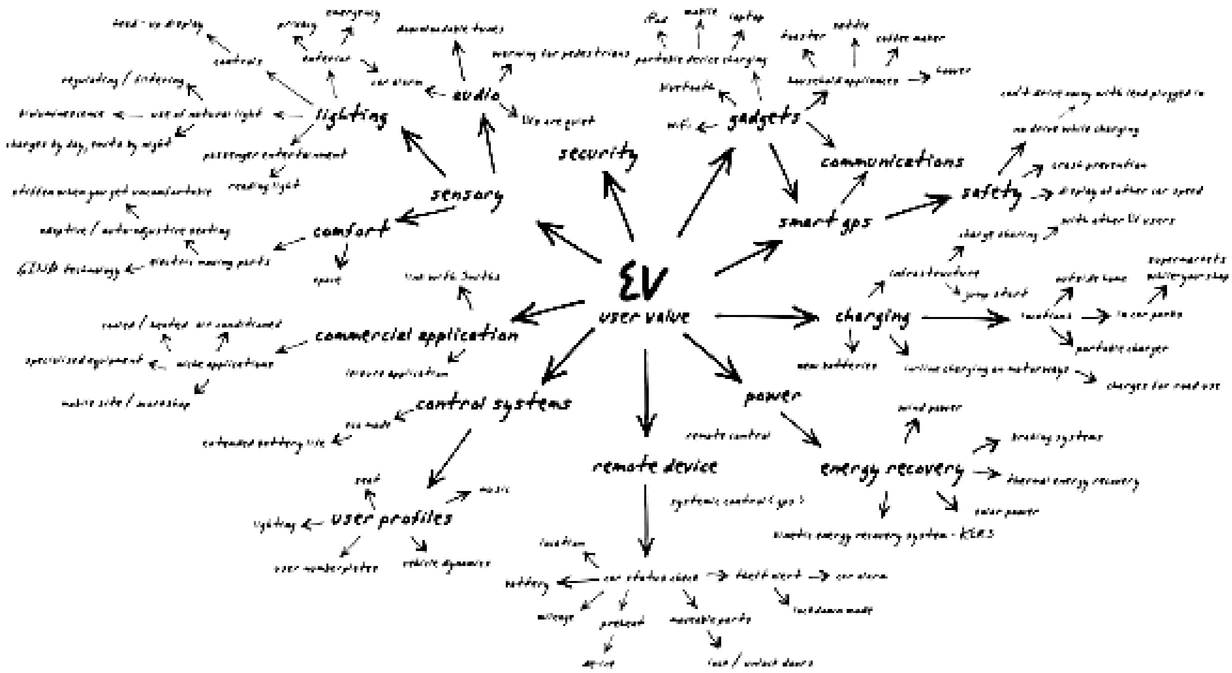

Figure 4: HVLC project-scoping map

This reflective tool was instrumental in the planning phase of the project as it provided the researchers with a clear appreciation of the design terrain and helped to compile the necessary background research to inform subsequent development of the chosen concept themes.

The research team organised regular monthly meetings with key personnel from collaborating organisations. Evolving concepts were presented with a view to stimulating dialogue across the consortium. The ensuing discussion was recorded and the issues arising fed the development of concepts as outlined below.

Project outcome

The following outcomes were achieved at the end of the project:

- A book describing new user benefits made possible by electric vehicle platforms in order to stimulate new business networks and commercial propositions.
- A showcase for new concepts made possible through the collaboration of technology companies and the automotive industry.
- A Presentation package and travelling exhibition used at the CENEX LCV ride and drive conference and exhibition at Millbrook vehicle proving grounds in September 2009.
- A dedicated website (www.highvaluelowcarbon.com) that operates as a hub for a consortium of companies engaged in collaborative low carbon initiatives.

Growth of the LCV market

The dynamics of the car market in developed countries are rapidly evolving as a number of major manufacturers like Honda, Toyota and Renault are launching fully electric (EVs) and hybrid vehicles (HEVs) on the market between 2010 and 2012. Lux Research's ongoing tracking of alternative power and energy storage opportunities found that in 2007, about 500,000 HEVs were sold, accounting for $484M worth of batteries (*Business Wire*, 2008). Plug-in hybrid electric vehicles (PHEVs) and pure EVs are scheduled for introduction in 2010, driving the market for all light electric vehicles, including HEVs, PHEVs, and pure EVs, to 3M units in 2012, leading to a battery market of $3.8B in that year. Although HEVs will continue to grow at 40% annually in the next five years, the next frontier is PHEVs, which need greater energy storage capacities to support longer all-electric ranges.

To further confirm this growth trend, BBC Research - Hybrid & Electric Vehicle Progress Review stated that the global market for large and advanced batteries increased from $8.4B in 2006 to $8.9B in 2007 and it should reach $11.4B by 2012. Research & Markets is projecting a healthy

$200M figure in annual US electric vehicle charging sales by 2015. These predicted figures provide a clear indication of the massive growth of the LCV industry which is still in its infancy and as such requires substantial funding and private investment to support its expansion.

EV Development

The development of the current and future ULCVs is represented by the introduction of EVs. The current obstacle in the EVs' technical evolution is strictly related to a complex series of technical factors which cannot be easily overcome without substantial R&D activities to evolve electric platforms within a well defined and widespread charging infrastructure. Other related parameters such as battery performance, light weight construction, vehicle range, etc. can be separately analysed but they would not necessarily provide a balanced account of the latest trends and challenges that the industry and society are currently facing. HVLC soon realised that the complexity of the EV development and its business success are dependent on a large number of variables which need to trigger other prerequisites in the right sequence to bring technical progress and as a result extensive mass production. Figure 5 shows this evolutionary cycle.

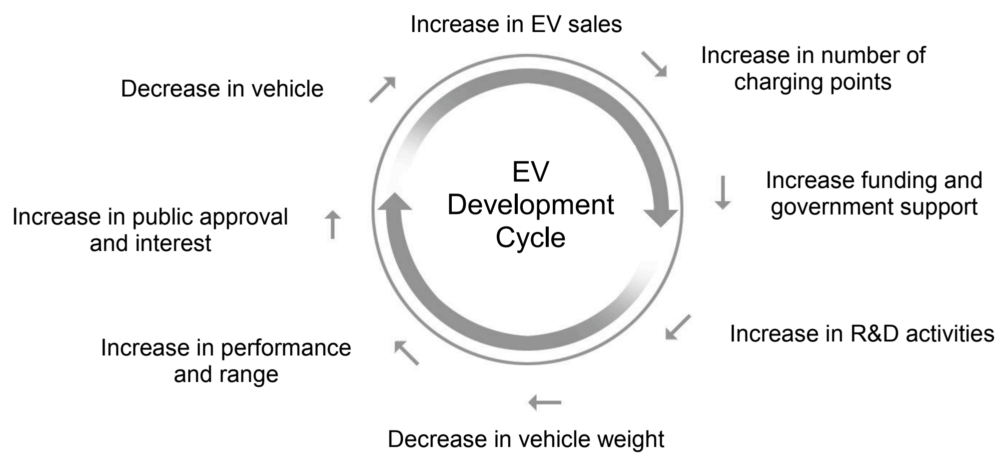

Figure 5 Electric vehicle development cycle

It is apparent that in order to sustain significant EV development and success in the car market some key technical aspects such as the increase of charging points and car range will play a major role. There is delicate balance of factors at play which is not only based on sheer engineering capability but also on design dexterity and marketing strategy to win public acceptance. Based on the government forecast, HVLC started its pilot project in May 2009 by producing a more specific forecast of EVs entering different market segments up to 2025 in order to acquire a better understanding of the whole scenario, as explained through figure 6.

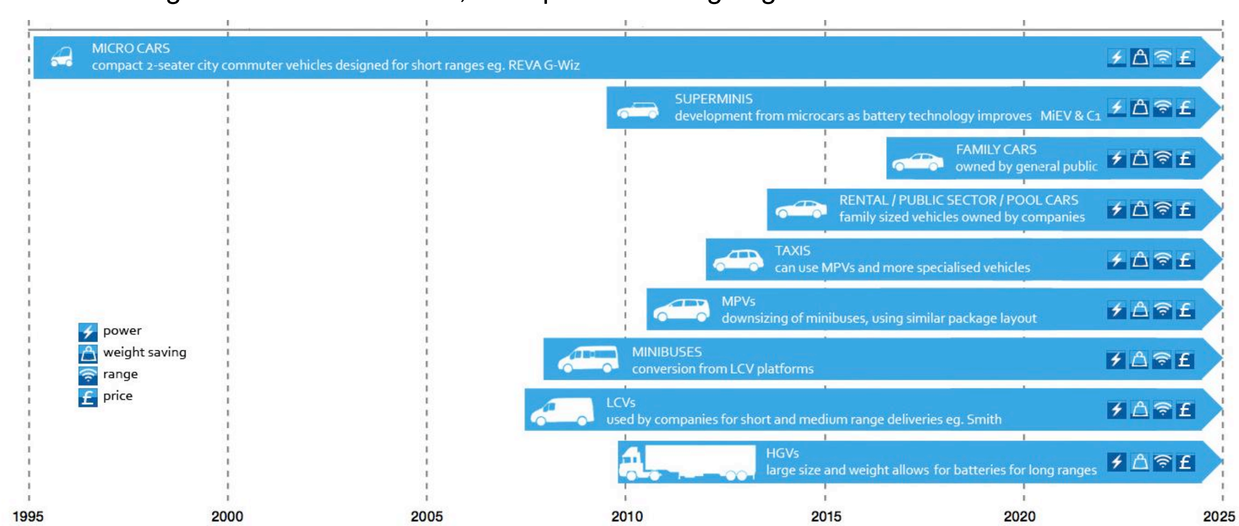

Figure 6 Projected scenario of electric vehicles entering different segments of the car market

Resulting concept themes

The HVLC project was exhibited at the CENEX LCV conference and exhibition at Millbrook proving grounds, Bedfordshire, UK in September 2009 and attracted significant interest from the fast growing low carbon vehicle industry. In order to summarise the project output various design concepts were grouped in the following manner as illustrated in figure 7:

Figure 7 HVLC banner presentation for CENEX exhibition

Battery Intelligence: Range (fig. 8)

In consideration of the comparatively short range of EVs as compared with internal combustion or hybrid vehicles, this concept is an attempt to visually express and better define the distance a given battery charge will allow the car to travel. It presents information to the user in a more meaningful and usable way, as shown in figure 8.

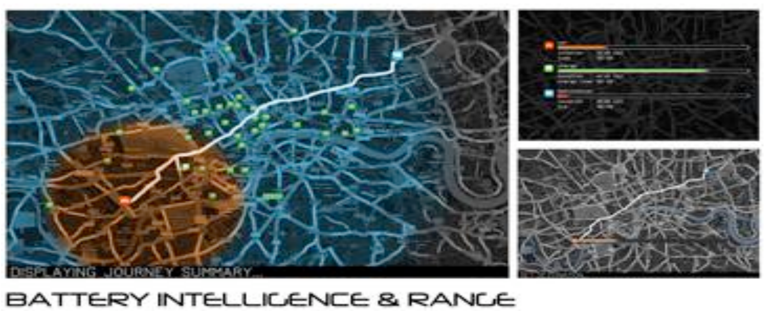

Figure 8 Battery intelligence & range GPS screen shots

Integrated into the GPS system, additional information, such as charge points and destinations, can be incorporated to calculate an optimum route, and recommend the minimum charge time at a given location.

Multi Battery (fig. 9)

This series of concepts explore the opportunities offered by the incorporation of multiple removable batteries inside the car, focussing specifically on recharging, charging away from the vehicle, weight minimizing, efficiency and journey planning.

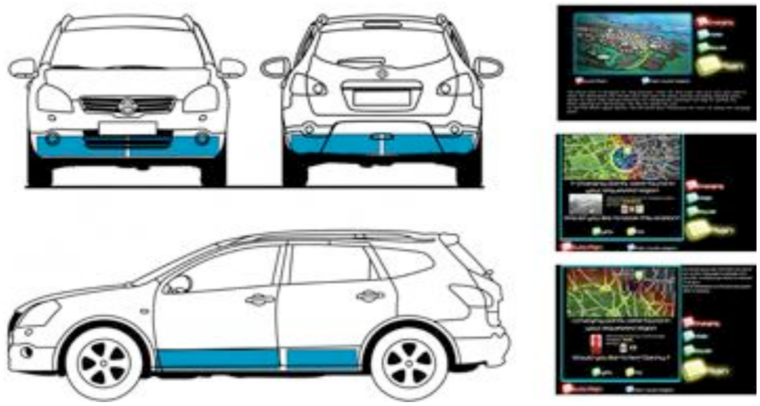

Figure 9 Multi battery concepts

Open Charging Zones (fig. 10)

The principle of Wi-Fi Open Zones is applied to the process of vehicle recharging to envisage possible concepts for new infrastructure. Charging zones for industrial and business use are considered along with possible billing systems and how home users might convert personal fast-charging stations for public use. Figure 10 demonstrates the concept through screen shots of a user-friendly interface.

Figure 10 Open charging scheme

Wireless Charging (fig. 11 & 12)

Nothing would be as frustrating as forgetting to plug your electric vehicle in at night and returning the following morning to find a set of flat batteries. With an emphasis on user interaction on a day-to-day basis, these concepts aim to break free from a reliance on the cable and plug and offer potential static and in-motion charging solutions.

Figure 11 LCV Wireless charging

Motion Charging

Taking wireless charging a step further, as schematically illustrated in figure 12.

Figure 12 LCV Motion charging

Charging point intelligence (fig. 13)

Charging points allow for far greater functionality than just the flow of electricity to replenish the battery. Through the exploration of possible charging scenarios and locations we envisage two-way information transfer between charging point and vehicle. These concepts focus on the content of the data available and the ways in which companies could process it to offer added value to the user, as Figure 13 describes.

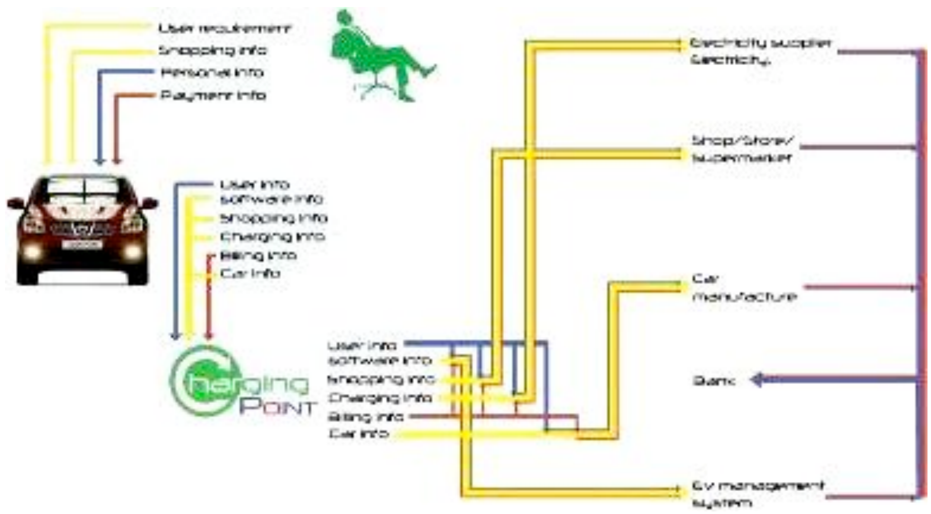

Figure 13 Charging point diagram

Electrolocation (fig. 14)

These concepts have been developed by studying the way that animals such as the platypus use electrolocation to build up a mental map of their immediate environment.

Figure 14 Vehicle's electrolocation

The application of printed electronics to body panels can provide relevant information about a vehicle's immediate vicinity, the driver can make more informed decisions and so drive with a greater degree of safety. By combining this technology with inter-car-communication, the driver can also be alerted to hazards by other road users.

Lighting (fig. 15)

Interior lighting can be developed to offer more than just good visibility. These concepts incorporate technology such as OLED lighting to enhance the experience of both driver and passengers.

Figure 15 OLED applied to vehicle windscreen

EV car rental (fig. 16)

Considering the price gap between comparative conventional engined vehicles and electric vehicles led the team to challenge the concept of vehicle ownership. Should the entire car (bodywork, engine and battery) or only certain parts be owned by the driver?

This group of concepts explores the implications of different states of ownership through the communication of car rental scenarios, these address issues of access, billing, security, duration of use, tracking, user interaction with the product and the service as a whole and integration with existing public transport systems. Figure 16 provides schematic explanation of such a scheme.

Figure 16 EV car rental scheme

Entertainment & sound systems (fig. 17)

By focusing on the user's experience of interacting with the vehicle, these concepts explore the integration of new and emerging technologies into the vehicle interior. The most notable are:

- The impact of the expansion of mobile wi-fi, enabling the vehicle user to access internet based services en-route.
- How the incorporation of printed electronics will lead to new and innovative application of lights, screens, touch-pads, sensors and solar cells.
- 'Audio partitioning' through the use of directional, flat-panel speakers that provide each user with an individual and customisable experience.

Figure 17 On-board entertainment and sound systems

Commercial Applications (fig. 18)

These concepts use printed electronics in the form of printed organic light-emitting diodes (OLEDs) to vary vehicle graphics, branding and advertising displayed on the side of light commercial goods vehicles.

Figure 18 Commercial vehicle featuring different advertising graphics

Conclusion

HVLC's strategic role and its relevance within the LCV field

Whilst political attention is focussed on finance, infrastructure and engineering, the LCV agenda lacks human centred design solutions that will embed low carbon vehicle technology into our society. Engineering R&D activities, while crucial, currently overshadow the potential offered by design to create the machine around the person. This presents us with the need to explore the functional, but foremost experiential user value that must be embodied in LCVs if they are to be considered viable and capable alternatives to petrol and diesel cars.

The HVLC team is concerned with the way users interact with products and systems, and the perceived worth given to this interaction. In addition, HVLC provides a strategic design approach that acts as a catalyst to juxtapose different technologies whilst retaining focus on the experience of the end-user. HVLC aims to seek further industrial partners in order to collaborate by offering transportation and industrial design expertise, as complementary disciplines, which are implemented across the main areas of engineering expertise provided by industry partners.

HVLC's Role as a LCV System Integrator

Ettlie (2006) iterated that the role of a new product strategy in the business unit has a significant impact on performance. This is particularly crucial in the development of LCVs as the auto industry spends 3 to 4 % of sales on R&D. It follows that the HVLC's mission is to assist the future LCV industry by driving innovative collaboration in regional industry as well as nationwide and overseas. This is accomplished by acting as a *System Integrator* for companies and emerging technologies as shown in figure 19.

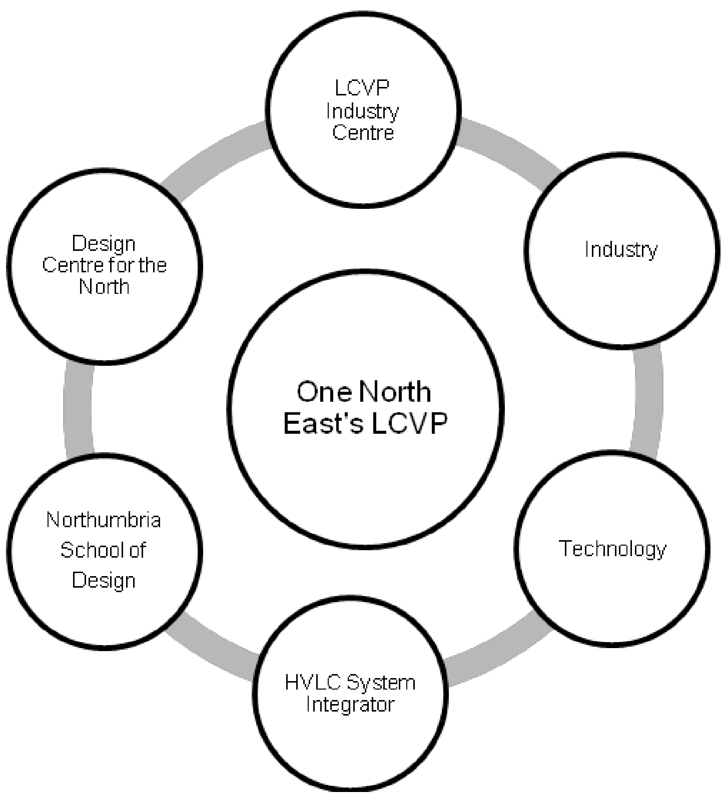

Figure 19 HVLC operating model

The researchers aim to develop HVLC as a creative *technical and design entity* offering value innovation management throughout design, engineering and marketing processes. Apart from the essential involvement of industrial partners HVLC aims to support all engineering and design R&D activities and overall carbon management of the manufacturing process with undergraduate placement students, post-graduate PhD and MPhil researchers to work on specific projects through the Knowledge Transfer Partnership (KTP) scheme and/or CASE Studentships.

To clarify the current nature of the LCV market Prof. Neville Jackson (Group Technology Director, Ricardo UK Ltd and Chairman, Low Carbon Vehicle Partnership) recently wrote that: 'Whilst the key market driver for lower carbon transport is regulatory, consumers have shown an increasing desire for the lower running costs and “greener” image of more fuel efficient vehicles. This has created a demand for new technologies and innovations that are both cost effective and, particularly for passenger cars, attractive, avoiding the perception that fuel efficient vehicles, by definition, are dull and boring. More fuel efficient combustion engines, vehicle innovations, electrification of drivetrains, including all electric and plug-in hybrid systems, are in development and will be introduced to the marketplace in a wide variety of combinations and products. These new technologies drive the demand for new supply chains, providing opportunities for new entrants to the automotive sector’.

Author Biography

Stuart English

Trained as an Industrial Designer, Stuart has worked in the field of Design Innovation for 20 years. He co-founded Glenelg Product Design in 1990 and at Northumbria University has championed design learning innovation whilst leading BA and MA courses in Design for Industry and professional design practice.

Stuart's research challenges the designer's capacity to be both innovative in terms of product designs and design processes. His approach confronts theory with practice and vice-versa. His practice has facilitated new product development through an inclusive approach based on design led entrepreneurship. This addresses multi and cross-disciplinary contexts bounded by clarity of market objectives, and has led to numerous filed patents.

Matteo Conti

Matteo has been a senior lecturer in Transportation Design and an industrial placement tutor for the past 9 years at Northumbria University. During this time he also led the course between 2005 and 2007 whilst retaining his core roles. This Italian bi-lingual academic has been creating various successful industrial partnerships with prestigious design consultancies (Pininfarina, Bertone, IdeA Institute,etc.) to carry out collaborative projects and secure students' placements. His mechanical engineering background led him to initially pursue a career as a robot programmer/engineer applied to vehicle manufacturing and painting.

His passion for design culminated in 1999 when he obtained a first class degree in BA (Hons) Transportation Design from Northumbria University. During his graduate work experience, at Alfa Romeo he was offered an enticing lecturer position at Northumbria which he could not refuse. In 2007 Matteo was appointed External Examiner at Domus Academy in Milan, for the MA course in Car Design. Through HVLC Matteo's intention is to develop further specific design and technical expertise in the EV field by undertaking major industrial R&D projects.

Value innovation modelling: Design thinking as a tool for business analysis and strategy

Stuart G English, Northumbria University Ideas-Lab, UK
Tim Moor, Northumbria University Ideas-Lab, UK
William Jackson, Iconet ltd, UK

Abstract

This paper explores the use of multiple perspective problem framing (English 2008) as a tool to reveal hidden value and commercial opportunity for business.

Creative thinking involves the interrelationship of parameters held open and fluid within the cognitive span of the creative mind. The recognition of new associations can create new value that can lead to innovation in designed products, intellectual property and business strategy.

The 'Ideas-lab' process is based on the proposition that a company's capacity for innovation is dependent on the way the business is able to see its problems and opportunities. In this process the attributes of a company and the experience of the researchers are considered as the parameters of a design problem. It is therefore important to acknowledge the commercial experience of the project researchers, all of whom have a proven track record in helping businesses develop, exploit and protect their know how.

Semi structured interviews were carried out with key individuals in 34 companies. The resulting data was assessed on a company-by-company basis through a process of multiple perspective problem framing, enabling key nodes, patterns and relationships to be identified and explored. A 'Cornerstones of Innovation' report was prepared to inform each company of the observations made by the researchers.

The paper describes the methods adopted and summarises the feedback from participating companies. Case studies are highlighted to demonstrate ways in which the process influenced the actions of particular businesses, and the commercial outcomes that resulted. Finally the researchers reflect on the structure of the Ideas-lab process.

Theory

This paper is founded on two main areas of theoretical knowledge: Multiple perspective problem framing and organisational design. The 'ideas-lab' process described in the paper has been developed through the practical combination of these areas of knowledge in relation to the analysis of 34 companies. We will first summarise key theories and show how these contribute to the approach taken by the researchers.

Multiple perspective problem framing can be considered as a development of the radiant mind mapping techniques pioneered by Tony Buzan (Buzan & Buzan 1996). Buzan's technique involves the growth of a tree diagram from a single centre of enquiry and as such can be used to represent the designer's perception of an issue in context. However because this represents a single viewpoint potential opportunities or other ways of seeing can be hidden. Integrated mind mapping techniques can offer multiple centres of enquiry enabling alternative ways of seeing to be communicated in the same map. English (2008) describes multiple perspective problem framing as a way to 'reveal value by considering a problem or scenario in different ways. This multiple perspective approach to the framing of design problems and opportunities requires designers to acknowledge their own cognitive processing talents and capabilities in order to give form to evolving networks of ideas. In other words, the designer must develop ways to engage with and make sense of interrelated information so that it is not lost in a fog of complexity'. English claims that designers can use integrated mapping techniques to:

- purposefully develop and communicate their cognitive structure in relation to a particular area of investigation
- facilitate reflective self exploration that lifts the level of their own awareness and that of their clients and collaborators
- enrich their understanding of the problem since it considers the design space from different points of view
- 'pick the problem up' from any centre of enquiry - to move around the evolving design space and to envisage new ways of seeing
- reveal potential for agreement by integrating conflicting viewpoints.

Whilst such an approach is not uncommon in design process this paper reports on the use of multiple perspective mapping techniques to reveal hidden value in business, employing a creative process that as DeBono (1996) recognizes 'involves breaking out of established patterns in order to look at things in a different way'. The researchers carried out semi-structured interviews with key executives in each company. Data from the main interview (with a managing director or similar) was where appropriate triangulated with data from interviews with up to two other company executives. The resulting data was used to create 'integrated mind maps' (English 2008) that aim to articulate the 'value arena' of each company. This process involved the researcher who carried out the interviews reporting the data back to another researcher who simultaneously created maps of the value arena occupied by the company. It is important here to note the tacit knowledge brought to the process by the researchers themselves who combined have over 40 years experience in innovation and enterprise. This has implications regarding the replicability of the process outlined, in particular the mapping stage.

The second area of theoretical knowledge to underpin the research is that of organisational design and in particular the design of successful and high performance organisations. Galbraith's 'Star Model' (1995) (Figure 1) provides a framework for organisational design consisting of five policies:

- Strategy - determines direction.
- Structure - determines the location of decision-making power.
- Processes - describe the flow of information; they are the means of responding to information technologies.

- Rewards - influence the motivation of people to perform and address organisational goals.
- People policies - influence and frequently define the employee's mind sets and skills

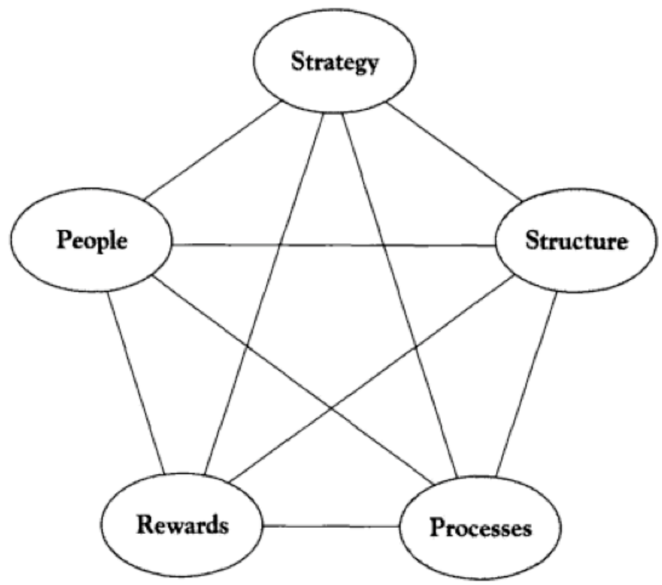

Figure 1: Galbraith 1995 'Star Model'

In Galbraith's model each of these policies can be considered as a separate centre of enquiry, however when they are combined the model can represent an integrated map of the company in question. Thus Galbraith's star model can represent (in general terms) a multiple perspective view of a business similar to the interrelating parameters of a design problem.

Since the aim of the ideas-lab process is to reveal hidden value in companies the researchers needed to be able to make practical judgements within each area of enquiry. It was therefore necessary to relate policies to performance in practice.
De Waal's (2006) analysis of 91 studies identified eight key characteristics of high performance organisations; organisational design, strategy, organisational process, technology, leadership, individuals and roles, culture, environment. De Waal claims that these elements 'seem to influence the ability of organizations to achieve high performance'. De Waal's research was reviewed and distilled leading to the following interpretation where prominent aspects of investigation are highlighted:

1. Organisational design – constantly realign the business in line with **changing internal and external circumstances**, **networked collaboration** across functional and organisational borders, sharing of information and knowledge within a consistent responsibility structure, responsiveness;
2. Strategy – **focus on value**, clear and challenging goals, common understanding of the strategic direction, balancing long- and short-term focus;
3. Organisational process – **innovate products and services**, rewards and incentives for continuous improvement, measure what matters, simplify processes and deploy resources effectively;
4. Technology – **Identify and exploit new technology** to gain competitive advantage;
5. **Leadership** – coach and **facilitate**, grow leaders from within, stimulate change and improvement, allowing experiments and mistakes, action focused decision making, long term orientation;

6. Individuals and roles – master **core competencies**, engage and involve the workforce. Align employer behaviour and values with company values and direction;
7. Culture – **Shared core values** and identity, adaptive performance-driven **responsibility**, transparency and trust;
8. Environment – enhance customer value creation, be part of a **value-creating network.**

Because the ideas-lab process aims to reveal hidden value in businesses and to develop strategies to commercialize this value, the aspect of strategy has been placed at the centre of the ideas-lab star model (figure 2). As Galbraith states (1995) "Strategy is the company's formula for winning. The company's strategy specifies the goals and objectives to be achieved as well as the values and missions to be pursued; it sets out the basic direction of the company. The strategy specifically delineates the products or services to be provided, the markets to be served, and the value to be offered to the customer. It also specifies sources of competitive advantage and strives to provide superior value".

The final theoretical point to make relates to the cognitive span of the investigator. Whilst de Waal has identified 8 possible centres of enquiry Whitehead (2007) suggests that when framing solution space, the designers mind is only able to span a maximum of six or seven concurrent issues and that the choice of these issues is critical to the potential for value innovation. These key issues are described as "cornerstones of innovation" (English 2007) because they represent the most significant parameters of the design arena. English states that *'Cornerstones of Innovation* recognise the designers cognitive 'span' of up to 6 or 7 key factors that in combination frame the problem. By concept mapping cornerstones of innovation the designer is able to model problem space at an optimum psychological size'.

Ideas-lab Centres of Enquiry
Based on Whitehead's (2007) observations the eight characteristics distilled from Waal's research were reduced to six main areas of enquiry orbiting around a central focus on value and strategy (figure 2). By doing this, the researchers were able to cognitively span all six areas of investigation simultaneously. The ideas-lab centres of enquiry as shown in figure 2 are as follows:

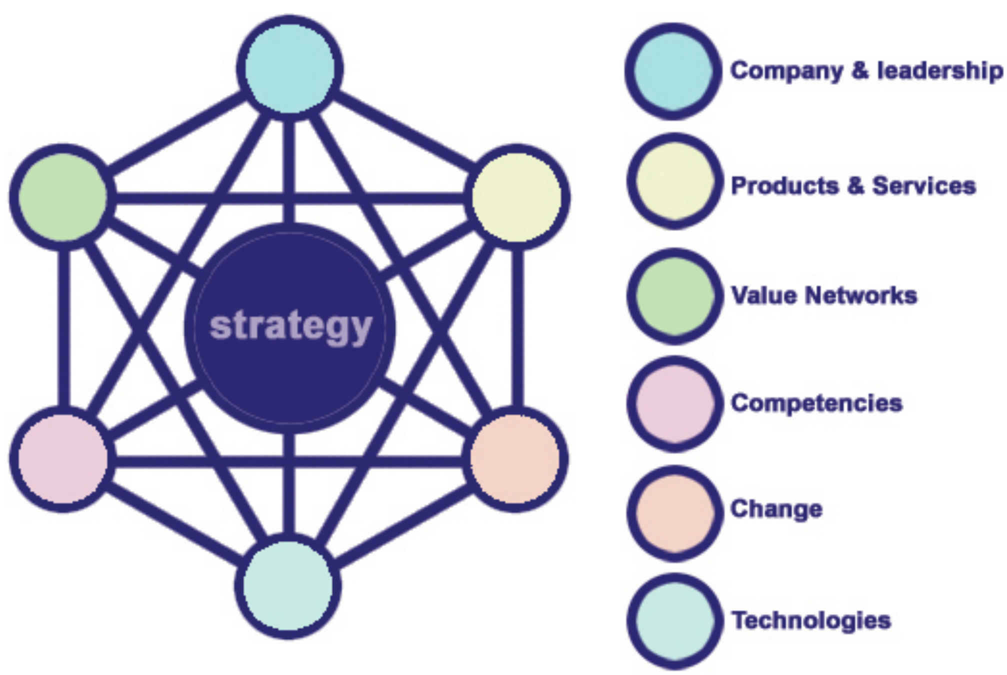

Figure 2: Ideas-lab Star – based on cornerstones of innovation model (English 2007)

(i) Company Leadership - Drive *(de Waal 2006, 5&7)*
History, status, assets and liabilities, turnover, revenue, management, vision, culture, structure, philosophy **(Shared core values).** What drives the company?

(ii) Value Creating Networks – upstream and downstream networks *(de Waal 2006, 8)*
Suppliers, partners, customers, competition, finance, differentiation, market characterization and networks. How and where does the company tap into networks of value to generate revenue?

(iii) Products and Services - Capability *(de Waal 2006, 3)*
Resources, Machinery, Development of products and services, associated costs, contract-work, standards, response, aftercare and value. What is the relationship between customers and products/services?

(iv) Technologies - Intellectual Property *(de Waal 2006, 4)*
Intellectual property portfolio, rights, maintenance, applications, improvements, development of value, marketplace. What does the company technology offer and how is it protected?

(v) Change – Opportunity *(de Waal 2006, 1)*
Environment, context & company, build value, R&D, business threats, market forces and opportunities. What is changing internally and externally and what opportunities does this open up?

(vi) Core competencies *(de Waal 2006, 6)* **- Individuals and Roles**
Expertise, knowledge, know-how, evolution, challenge, future.
What does the company know and what can it do?

The focus of the ideas-lab star model is on **strategy** *(de Waal 2006, 2),* this combines the value proposition with a route to market and can be used to calculate potential revenue. This provides a valuable tool that can contribute to a business plan with a view to securing finance.

Method

The ideas-lab process was initially implemented in 2007 through a collaborative innovation partnership between Northumbria University, Ward Hadaway Law Firm and the regional development agency, One North East. Following the success of this programme the process was made available as a service to members of NetparkNet virtual science park and directly on a company-by-company basis (2008-2009). Most of the 34 businesses analysed as part of this study are SMEs (Small to Medium Enterprises) with 5 – 250 employees although some larger companies were also analysed.
A list of generic questions was prepared to explore the centres of enquiry outlined above. The questions were tailored to each company and each analysis followed the same pattern taking approximately six man-days in each case.

Following initial company research and refinement of interview questions one member of the team (the scout) met with the client company on-site. Semi-structured interviews were undertaken with key individuals and data was recorded for each centre of enquiry. Data from the main interview (with a managing director or similar) was where appropriate triangulated with data from interviews with up to two other company executives. Meeting on-site also provided the opportunity for the researcher to tour the company's facilities and to record any additional data deemed relevant. Following this meeting the scout reported the data back to another member of the research team (the modeller) who, as part of the process, created a 'radiant map' for each centre of enquiry. This was done on a whiteboard or large piece of paper, sometimes using post-it notes, enabling single centres of enquiry to be overlaid using integrated mind-mapping techniques (figure 3).

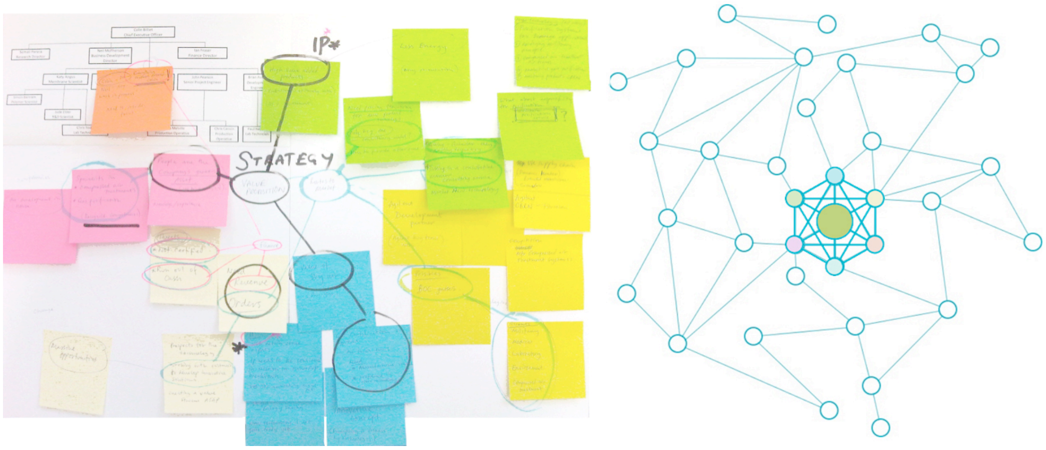

Figure 3: Left - showing an example of the mapping process. Right – showing a theoretical model of this process.

By creating a flexible viewpoint the researchers aim to reveal patterns within the data and relationships between centres of enquiry. The process aims to identify the foundation elements at the core of the company's value, these can include technologies, processes, know how, networks, intellectual property, company culture and structures. We have referred to the relationship of these elements as the company's 'Value Arena' that forms the foundation for any strategic recommendations on how to increase the revenue of the business. The results of the process were reported back to the interviewees in a 'Cornerstones of Innovation' (COI) report detailing:

- the company's value arena
- new ideas on how to increase the revenue of the business
- the value of the company know how and intellectual property, including guidance on its protection and development
- possible sources of professional and academic support that could assist in the implementation of any of the ideas outlined

Results

Table 1 describes the nature of the companies analysed by rating each of the above centres of enquiry from 1-10 (where 1 is the lowest score and 10 is the highest). ***Referring to Table 1:*** Following the mapping process, each centre of enquiry was given a mark out of 10 (columns i-vi); the marks for the six centres of enquiry were then added up and expressed as a percentage (column x). Columns (i) to (vi) represent a current assessment of each aspect of the company, column (x) provides an overall assessment of the value arena. The yellow blocked sections show the significant areas of opportunity identified by the researchers. Column (y) estimates the impact of the process on the value of the company calculated with respect to the following factors as detailed in table 2:

i) Value arena percentage mark
ii) Number of elements ideas-lab would assist
iii) Impact of ideas-lab per element
iv) Size of the company
v) Strength of the value opportunity & feedback

Observations and Evaluation

Through the analysis of 34 businesses the researchers identified 27 value opportunities indicating that the process was 80% successful in revealing commercial value for the participating companies.

2 of the reports recommended that the company in question should not continue on its current path or should terminate further development of certain technologies. On the surface this may have appeared negative but the findings demonstrated that this prevented further funds being wasted and provided an opportunity to utilize the resources in a more focused and productive way.

5 of the reports could be characterized as an assessment of the key issues identified within the value arena. These 'health check' reports were used as an independent appraisal and as confirmation that the company management was on the right course. 2 of these reports included recommendations to contact specific funding organizations.

Company 15 commented *"The report highlighted in writing what the company had already thought which gives Peter confidence from an independent body to work out now how to go about implementing the course of action for some of the points raised."*

Shared responsibility

The ability to reveal hidden value through the process is predicated on the following issues:

i) Other than information available in the public domain, a company and its technology is likely to be unknown to the researchers before commencement of the process.

ii) Value is optimised if there is open communication and a willingness on behalf of the company to disclose all relevant information (under NDA where applicable).

As Company 26 recognised in its feedback *"The very act of discussing what we considered doing made us logically think about the company. Verbalising our thoughts cleared our thoughts."*

There is a shared responsibility for both researchers and company management to capitalise on the enquiry process. Since the researchers enter into the unknown in search of value opportunities it is unclear at this point what if anything will be unearthed. If the company concerned is not willing to fully participate or prevents a free flow of information the likelihood of the process revealing value opportunities is reduced.

Where the focus of the enquiry has been on technologies and change within the value arena, the COI report has always revealed a value opportunity centred on a technology and intellectual property strategy. Where the COI focus has been on company and leadership, recommendations have focused on policy and the means to stimulate change.

The commercial exploitation of the 27 value opportunities mentioned above raises the issue of funding and finance.

Financing the value opportunity revealed through the process
The ideas-lab process has been seen to reveal potential commercial value in 80% of companies. To date, value recommendations have been determined through the experience of the research team combined with the process. Where the opportunities identified have been positively assessed further action has been necessary:

- The researchers have developed a strategy document to support the implementation and development of the value opportunity.

- Where finance does not exist to support the implementation of the value opportunity, the researchers have directed companies to fund and/or grant opportunities or organizations that may be able to assist financially.

This is not an ideal solution as the value opportunity is likely to require support from seed fund or in some cases proof of concept funding. Invariably this leads to the need for due diligence, a costly process in both time and money for the fund bodies concerned. Further research is underway to assess whether the likely impact of a proposed value opportunity can be determined at a pre-investment stage. This work aims to quantify the value created and accurately predict the likely success rate of the proposed opportunity. It is envisaged that this will provide investors with a level of confidence and assist any decision involving a key point of change and any form of due diligence, either internal or external to the company; and would subsequently become a highly valuable tool. The researchers are currently developing networks within the venture capital community to trial such a tool.

Some common attributes of SMEs have already emerged. If the company wishes to progress with an identified value opportunity it should have both a high level of competency in it's specialist field and remain open to third party involvement to create both commercial networks and commercially focused decisions.

The larger of the medium sized companies tended to focus on their 'ordinary activities' and were not able to utilise resources for development activities. The smaller companies tended to have core technology with a clear development path, however management often lacked the ability to commercially exploit the technology. Many of these managers could be described as technical experts in their particular field with a background in research and development.

Implementation of value opportunities
Some of the participating companies have used the cornerstones report to form a strategy to raise finance for the value opportunity. For example, a renewable energy company (6) registered their intellectual property and implemented a commercialisation strategy devised by the researchers; this assisted them in raising a further £10m funding.

Anecdotal evidence would suggest that 1-in-3 companies adopted part or all of the strategy developed by the researchers. Company 20 stated, "We want to action the recommendations made". Companies 26 and 22 both recognised the impact of the programme on their own approach "The purpose of the document was to throw ideas at us and stimulate our thinking which is what it did" (Company 26) "We consider the report to be a contributing factor to our thought processes" (Company 22).
Through informal discussions the researchers are aware that companies (2), (6), (7), (20), (21), (22), (26), (27), (28) and (32) in table 1. have acted on at least 50% of the recommendations, with 3 companies adopting the recommendations in full. The researchers have discovered that the companies who do adopt demonstrate:

- a willingness to change and

- an openness to communicate

These attributes have latterly been incorporated into the company selection criteria.

Placing a financial value on the outcome of the ideas-lab process has been very difficult. On one hand it is easily argued that the process is exploratory and may in certain cases be little other than an independent appraisal, however, in 80% of cases, an opportunity has been identified and this has a monetary value. The value impact demonstrated by company 28 was just 1% however this would equate to £180,000 of company turnover as all recommendations were implemented. In addition to this, the company went onto request a study be conducted into uses of their new technology carbon nano-tubes. In another example identified above, the strategy developed by the researchers contributed to the company's ability to secure a further £10m development funding.

Creating a consortium based value arena for commercial collaboration

Whilst the concept of the value arena has been successfully exploited for the benefit of individual companies the researchers have also explored the use of multiple perspective techniques to frame consortium based problem space. By constructing a value arena that different companies can operate within, the researchers have been able to nurture collaboration and to create business opportunities between companies who might otherwise see themselves as competitors. A working example is the High Value Low Carbon (HVLC) consortium project, developed to stimulate business activity around the theme of low carbon vehicles. The HVLC consortium comprises:

- 4 international automotive manufacturers,
- 3 research centres
- 7 component manufacturers
- 5 technology companies
- The regional development agency ONE North-East

The HVLC project has enabled companies to interact within this particular value arena and as a result a number of 'spin-off' commercial opportunities have been initiated. By bringing carefully selected companies together in this arena, the consortium has attracted the interest of a major power supplier with a view to supporting a five-year collaborative programme.

Reflection and Conclusion

Figure 4 aims to summarise the relationship between the main ideas-lab centres of enquiry and the contribution of the process, described in the two central sections (figure 4) as 'value innovation'. Change creates opportunities for companies to develop both new IP and valuable new applications for their existing IP, however 25 out of 34 COI reports have been concerned with the lack of comprehensive intellectual property coverage, promotion and exploitation. Our experience to date indicates that companies are rarely unable to protect their know how. In fact there is only one COI report that identifies that a company was unable to secure their rights and this was due to market saturation i.e. competitive companies selling an identical product. More often, we have found that companies have the ability and resources to build the value of their intellectual property portfolio if they are made aware of how this can be achieved. In general our observations indicate that smaller SME's and start-ups consider IP to be very important, whereas medium sized companies are less concerned. There seems to be an understanding that the larger they become, the less important IP becomes. Comments include *"who is going to take us on?"* (Company13) or *"it is all about first mover advantage"* (company 5) or *"they* (the competition) *will patent hop anyway"* (company 17). Part of the ideas-lab role has been to reintroduce the importance of IP and the significant value it can generate with particular focus around licensing potential and alternative applications and markets. The ideas-lab research team specializes in this particular area and has an ability to cover a very broad spectrum of patentable technology. We have adopted the premise that, it does not matter what the company technology is, but that the company's core values and the way these values are exploited is critical.

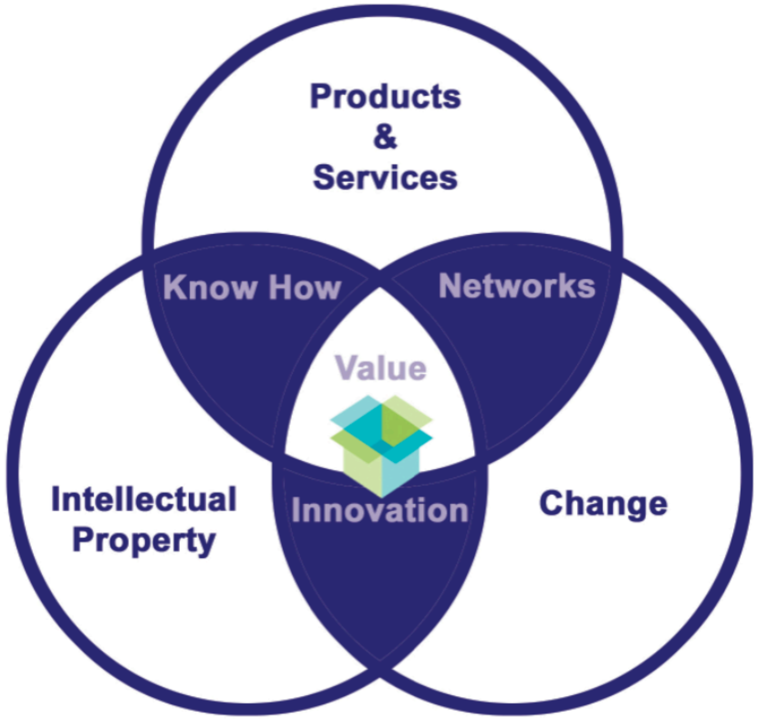

Figure 4: Ideas-lab value innovation model

The ‘fresh eyes’ approach whereby companies are analysed without prior knowledge or understanding of techniques or prior art has proved one of the greatest strengths of the process. A general enquiry question asks ‘What can you do with this technology?’ This question has revealed many opportunities regarding the development of new applications for existing technology utilizing the core IP and company strengths in different ways.

12 of the 34 companies (including 3 businesses with over 100 employees) were encouraged to develop their brand strategy and where appropriate product themes. The researchers found that some product ranges and services were poorly described and promoted to the intended customers, here a clearer marketing message was required to make it easier for clients and customers to see the specific value on offer and remember it. Numbers identified some products and some services were described by obscure names. Company 3 however, created a theme throughout their range, each product being named after a rank in the army, navy and air force such as admiral or colonel. The product range was instantly recognizable and stood out from the competition, more importantly these terms had entered the vocabulary of the company’s clients and the industry as a whole. 30% of companies did not own trademarks for their products and services, this was due to cost or a lack of understanding. Where brand names were identified, trademarks were recommended to prevent ‘passing off’.

30% of companies analysed were found to have issues directly relating to current management and the management structure. In two cases it was difficult to communicate these issues to the individuals involved and the COI report provoked something of an explosive reaction.

The ideas-lab process as outlined was found to be of most significant value to the following categories of company:

- **SMEs** wishing to diversify, expand or maximise the use of their technology and intellectual property

- **Start-up companies** seeking independent appraisal
- **Pre start-up or Spin-outs** focussed on commercialisation of new technology and intellectual property

This is possibly due to the strategic focus of the ideas-lab star model (figure 2) as outlined above. Company 22 summarized the value of the process, stating, "The Ideas-lab process helped us to recognise untapped commercial value in our technology and our expertise" whilst Company 28 endorsed the process describing it as “a valuable service which we thoroughly recommend". Many of the businesses analysed responded to the cornerstones of innovation report by asking the researchers for further assistance to capitalize on the value opportunities revealed by the process. In some cases this has led to the development of a second stage of involvement focusing on the implementation of strategic recommendations and in particular the relationship of the value proposition and route to market. Whilst the initial ideas-lab enquiry stage 1 (figure 5) is typically 6 researcher-days, stage 2 requires around 30 researcher-days over 2 to 3 months to develop a strategy that can be implemented.

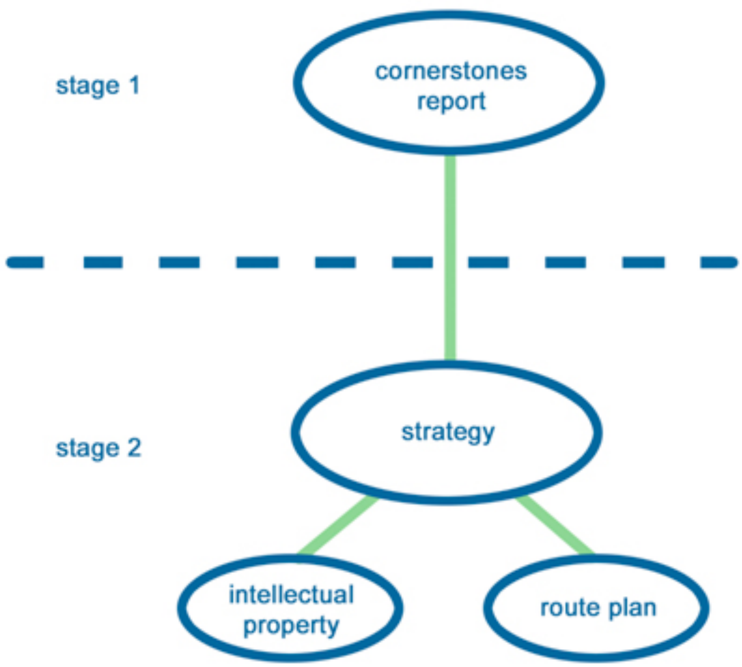

Figure 5: Ideas-lab two stage proposition.

This investigation has been focused on the commercial needs of business to capitalize on technology and know how in order to generate revenue. Through the process described the researchers have endeavoured to connect company technology and know how to commercial opportunities based on value proposition and route to market. The individual strategies were constructed around the ideas-lab framework and whilst every company was different, patterns and common attributes are beginning to emerge. The team aims to carry out further investigative research in this area.

Looking to the future; a response to the challenges of design education in the 21st Century using C&IT

Elaine Evans, University of Leeds, United Kingdom

Abstract

In response to increasing student numbers in practice based subjects, an ongoing project to develop online learning support materials for a BA (Hons) Fashion Design programme is exploring ways in which video based resources, in conjunction with virtual learning environments, can support practical demonstrations. Intended as complimentary learning support materials, rather than replacing face to face demonstrations in taught sessions, this project investigates the ways in which students respond to the learning materials, and preferences they show for the different methods of learning used within a practice based setting.

Keywords

Pedagogy, Fashion, ICT, Virtual environment, Usability, Experiential knowledge, Learning, Project-grounded research

Today, universities in the UK are experiencing new challenges in the face of increasing student numbers; traditional methods of learning and teaching are being reappraised in a context of higher staff: student ratios and the drive to increase efficiency. Universities UK (online 2009) state that there was an increase in student numbers of 47% between the academic years 1994/95 and 2007/08, and that the average staff: student ratio in UK universities is now 1:16.8 (online, 2010), and likely to increase. This is not a situation that is exclusive to art and design subjects, but it does raise some interesting challenges in subjects where traditional methods are undeniably staff intensive. In response to this, there is a necessity to re-evaluate these traditional learning and teaching methods, and to develop the future of design education.

There has been a significant amount of work done concerning the variety of ways that people learn in the broader context, notably seminal texts by Kolb (1984), Honey and Mumford (1982), Entwistle and Ramsden (1983), but there is also a developing field of interest in the pedagogy of art and design subjects in particular; studies discussing and analysing the particularities of the methods used in these disciplines have been conducted by a growing field of researchers, including Davies (2000), Drew (2002), Jackson (1997) and Swann (2002) to name but a few. Indeed, Swann's article *Nellie is Dead*, originally published in 1986, highlights the fact that the challenges facing design education today are not a recent phenomenon, but have been developing over the last few decades. Phenomenographic studies have been conducted by both Davies (2000) and Drew (2002) to assess design students' approaches to learning, and also to compare or contrast these approaches with students' approaches to learning in other disciplines. Davies and Reid (2000) draw comparisons with Gibbs' (1992) conceptions of closed (surface) or open (deep) approaches to learning and to teaching, and also question some of the methods used in design teaching as not explicitly encouraging an 'open' approach to learning. Clearly, in the context of the higher staff: student ratios of contemporary university life, there is a necessity to promote a greater degree of independence from design students than in the past, rather than continuing with the 'sitting by Nellie' approach that Swann (2002) questions. It is in this context that a pilot project began, with a view to enhancing the student learning experience within the Fashion Design BA (Hons) programme at the University of Leeds, by developing online resources to support student learning, while addressing the issue of reduced staff contact time per student in a practice based subject.

Rationale

With the ethos of "facilitating learning" rather than 'teaching', the idea of this project is to provide supporting information in an accessible environment that the students can use as and when they require it. It was deemed essential that the resources tied in directly with what was being taught in class, but also needed to be more 'flexible' than the traditional demonstrations. The emphasis of the project is that the online materials provide additional support material for students in practical modules, and are not intended to replace face-to-face demonstrations in taught sessions. The project also aims to address the need for students to acquire certain skills in order to be competent in their understanding of the design process, but also to promote a degree of independence in their approach to skill acquisition and practice.

Key to understanding the practice of Fashion Design, students on this programme undertake a module (in years one and two) in Garment Technology, which encompasses flat pattern cutting and sample or garment construction. Practical demonstrations form an important part of the learning process in this module, and are the basis of both the pattern cutting and the garment construction work, in conjunction with using worksheets developed for the module and textbooks. As the garment construction demonstrations traditionally take place around a sewing machine, space and visibility can be a problem, so students can fail to benefit from important details because they cannot see or hear clearly. Due to the nature of these demonstrations, they cannot be quickly or easily repeated due to the need for preparation time. The rationale for change in this project was therefore to improve support for these practical demonstrations by using C&IT to enhance the student learning experience.

Methodology

Initially a small number of video based learning resources were created to support student learning in studio based modules in Fashion Design, particularly at level 1. Initial experiments with videoing the demonstrations highlighted the need to modify the way that these demonstrations were carried out for video; it was very difficult to see what the operative in the video was doing in detail as thread and interlining colours blended in with the fabric, whereas on video the visibility of detail was crucial. Strong colour contrasts were found to work effectively on camera, so matching threads and interlining were substituted with contrasting colours. There also needed to be detailed planning of camera angles and close ups to highlight important points in the sample construction process. Professional help was sought to edit the videos, meaning that technical issues such as matching the pace of the visuals with the voiceover (recorded separately) were easy to overcome, as well as being able to enhance the video footage with effects and graphics, for example being able to highlight important aspects of the demonstrations.

The videos are viewed through an "accessible multimedia player" called Webducate AMP. Of particular interest with regards this project was the option for students to see and print a transcript of the audio script, as this provides a good level of support for a variety of learning styles as well as addressing accessibility issues. The videos can be paused, rewound and replayed as many times as each student requires, and can be viewed full screen if the text is not required by the side of the video. Taking into consideration the different learning preferences of the students on this module, it is intended that the online video demonstrations provide support for as many of these preferences as possible. VARK (Fleming & Mills: 1992) is an interesting tool which provides users with information on their learning preferences through a series of questions based around learning styles. VARK describes people as having learning preferences under the following headings:

- Visual (learning by videos, pictures, diagrams, graphs etc)
- Aural (listening to information)
- Read / Write (list-making, note-taking, essays etc) or
- Kinesthetic (trial and error, hands on practice, learning by doing)

Someone with a mixture of some or all of these preferences, is said to be 'Multimodal' (and 60% of the population are said to fit into this category). In the context of this project, students with Visual learning preferences will be well supported both in the traditional practical demonstrations in this module and also by the additional visual information in the videos (with the added advantage of being able to pause and replay the videos). Those with Aural preferences will benefit from verbal instructions both in class and also with the carefully planned audio script that accompanies the videos. For the Read / Write students, the online videos will be a real advantage, as there is no written information given with demonstrations in class, but there is a clear transcript of the audio which accompanies the videos. The students with kinesthetic preferences will benefit most from putting their knowledge into practice by making up the samples themselves.

The video demonstrations were made available to students through the University's Virtual Learning Environment (VLE) alongside other module learning resources, enabling them to become part of a package of online materials to support student learning in this module. Virtual Learning Environments are increasingly being used by universities to make module materials available to students online, as well as allowing tutors to provide materials in a range of electronic formats. An article in the Guardian newspaper (Hoare: 2006) states that *The distinction between distance learning and studying on campus is becoming increasingly artificial. While providers of distance learning such as the Open University are boosting the quantity and quality of face-to-face seminars, traditional bricks-and-mortar institutions are supporting students on and off campus through virtual learning environments (VLEs) based on commercial or open access platforms.* Certainly, in the context of higher student numbers, using C&IT to provide additional support to learners makes sense on a number of levels. Furthermore, in this digital age, these resources may be key to ensuring that students' expectations of support are being met.

The questionnaires

After the initial trial period of the pilot project, students were asked to complete a questionnaire during a taught session to gain feedback on their responses to the online learning materials. This method was chosen because of the ease of dissemination, and the higher likelihood of questionnaires being completed and returned during a taught session. The questionnaire allowed students to reply anonymously, and 29 students completed and returned the questionnaire. The questionnaire itself comprised a series of eight short sections, the majority of which required scaled responses rating difference aspects of the online materials, such as how easy the resources are to find, how the different methods of delivery for the module compare with one another, and how useful the different functions on the site were. There were also opportunities for further comments during the questionnaire to encourage students to share their experiences of using the resources, and therefore inform future practice.

Initial feedback from students using the online materials was generally very positive, indicating that students made good use of the online resources. When asked about whether the students had made use of the video demonstrations, 76% said that they had and a further 10% said that they were aware of the online resources but had had difficulty using them. Students' overall impression of the site where the video resources were accessed was generally good to excellent, with a strong positive trend. Again, there was a strongly positive trend when asked how easy it was to find the resources within the VLE site, with 36% saying that this was 'very easy' and a further 44% saying that it was 'easy'. Students were then asked about how useful they found each of the four video demonstrations available to them. Again, there was a strongly positive trend towards 'very useful' and 'quite useful', but with distinct preferences towards two of the four videos, as is seen in Figure 1 below.

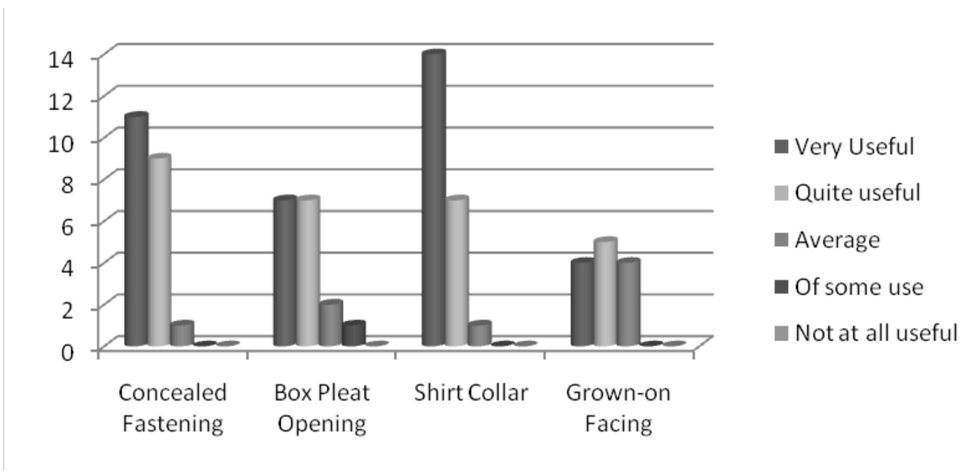

Figure 1. Student preferences towards the video content available to them

It is thought that this is because these two videos dealt with concepts that student found more difficult to grasp, therefore the opportunity to replay these videos helped them to understand the manufacturing processes involved in these samples. Indeed, when asked to give further comments in this section of the questionnaire, the following responses were given:

'Maybe more of the more complex methods could be added'

'Shirt collar was especially good'

'Shirt collar was useful'

Students were then asked about their learning preferences for the following forms of delivery: a) demonstrations in studio, face to face; b) video demonstrations, online; and c) text / voiceovers from the videos online. There was little distinction in the preferences shown between the different methods of delivery, as can be seen in fig. 2 below, but it appears that there was a slight trend towards students finding the video demonstrations easier to use than the demonstrations in taught classes.

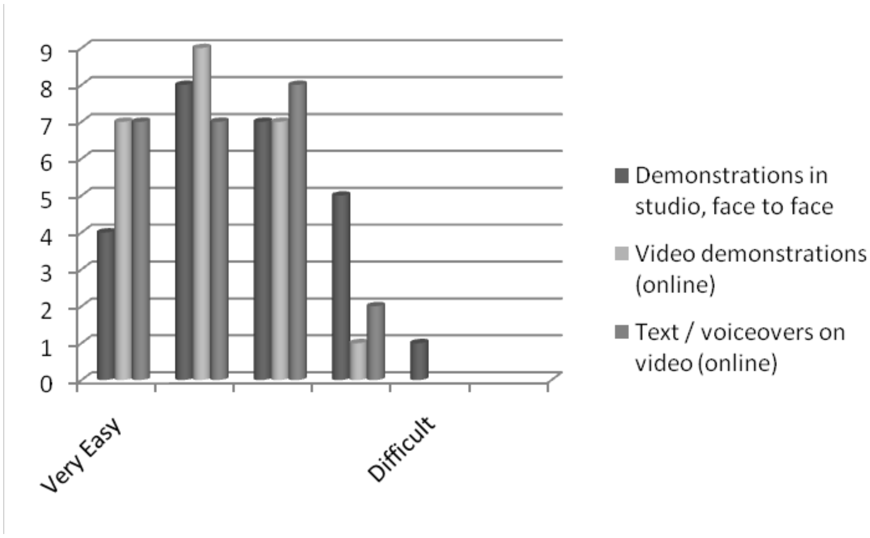

Figure 2. How easy do you find it to learn using the following forms of delivery for this module?

The transcript of the videos was thought to be ‘very useful’, with 73% of students selecting this option. A further 23% thought the transcript was ‘quite useful’ as seen below in Figure 3. However, when asked whether they used the option to be able to print this transcript, only 4% of respondent said that they used this option. This could indicate that written instructions are of most help when accompanied by visual information, but are not deemed to be as useful in isolation.

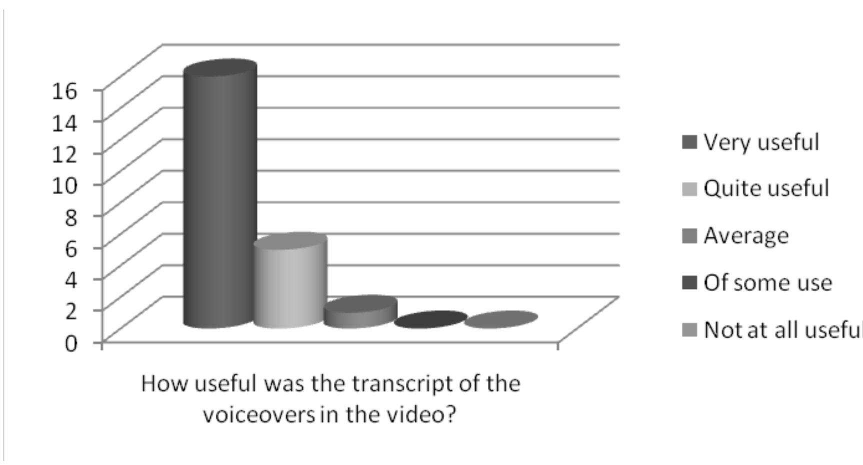

Figure 3. Students’ views on the written transcript of the audio voiceover.

When asked for comments about how the video demonstrations compared with face to face demonstrations in class, some of the comments given were as follows:

‘Able to go back and listen / watch again, so better in that respect’

‘You obviously couldn’t ask questions, but being able to replay parts was helpful’

'Much easier because during class demonstrations it's difficult to see an sometimes hear'

'Can go at your own pace, can repeat if unsure'

'It was easier to see what was being done'

'There was a clear view of what needed to be done. Detailed'

'Not as good as face to face but still useful'

'It was easier to understand as it seemed like a one on one demonstration'

'I prefer to watch a real demonstration'

Indeed, when asked for further comments about the advantages or disadvantages or problems that students encountered with the videos, responses were again very positive, with some students stating that they would like there to be more videos, or videos added on pattern cutting as well as the make-up of samples. Within this cohort of students, only one student stated that they had a visual or auditory impairment that might affect their ability to use web based resources. The student gave no further details about this, but did state that they found the site easy to use. Lastly, students were asked for any final comments about what they would like to see added to the online resources. Examples of the comments received include:

'more demos of different products'

'notes on techniques'

'larger videos'

'more written instructions for all'

'examples of [research] boards and some construction notes'

It is clear from the responses received that students made good use of the additional resources available to them, and that they wished to see the video resource expanded to include further demonstrations, as well as other online resources to support their learning in the garment technology module.

Due to the positive nature of this student feedback, further work was planned on the project. In the second stage of the project Health and Safety training videos were developed to improve Health and Safety provision for practice based modules at all levels of the Fashion Design programme, and with a view to improving students' understanding of how to safely use the three key pieces of equipment in the practical studio. Using the same format as the previous video demonstrations, three videos were planned, then filmed and edited with professional help. One feature of the VLE where the videos are accessed is that tests can be linked with the video files, to assess students' understanding of what they had just watched. In order to promote the use of these videos, 'adaptive releases' were set on the video files and the tests, so that students would not be able to access all other learning materials for the module (including video demonstrations which accompanied the garment construction demonstrations in class) until the videos had been viewed, and the tests completed. Students were asked to watch these videos and complete the tests during the first two weeks of the semester, with instructions on how to do so being given verbally in taught sessions.

At the end of the semester in which the second stage of the project was launched (2 years after the initial pilot project), the group of students involved were asked to complete an updated version of the original questionnaire, and 33 students responded on this occasion. This was a different cohort of students from the students questioned about the pilot project; they had no previous experience of the resources that pre-date the health and safety videos, tests and adaptive releases. In this cohort of students, only 56% of students stated that they had used the resources, 28% said that they had had difficulty using the resources, and 16% said that they had not used the resources. This is a lower uptake than in the first stage of the project, with significantly more students having difficulty using the resources. It is thought that the 'hurdles' put in the students' way, through the use of adaptive releases for the videos files and tests discouraged the use of the resources in some cases. It is worth noting that the ease of access to the 'learning support' files (which related directly to content in class) does seem to have had a significant impact on the percentage of students choosing to use the online resources; this should inform future practice, where more guidance will be given to students when introducing the resources.

Students' overall impression of the site where the video resources were accessed was generally average to good, with a slightly positive trend. Again, there was a slightly positive trend when asked how easy it was to find the resources within the VLE site, with 9% saying that this was 'very easy', 52% saying that it was 'quite easy', 27% saying it was 'average', 12% saying that it was 'quite difficult', and no students saying that it was 'very difficult', as seen in Figure 4 below.

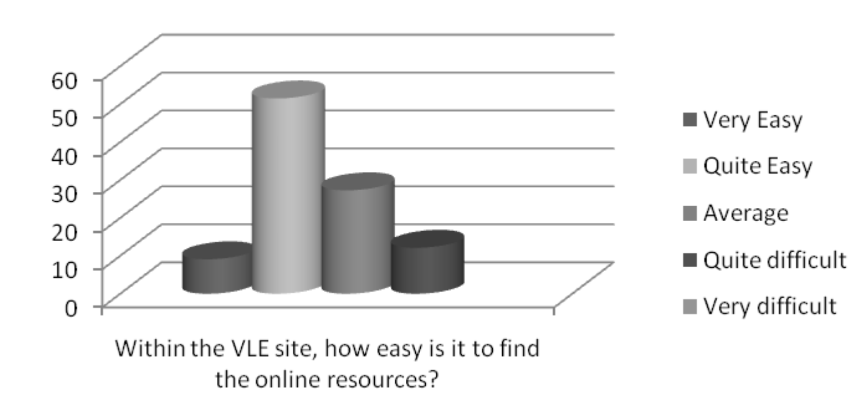

Figure 4. Students' opinions on ease of locating the resources online

Some comments received in this section of the questionnaire are as follows:

'Should be made easier to access and look for'

'Clearer layout and clearer instructions on where to go to find what you are looking for'

'More obvious links to online demonstrations'

It is thought that clearer signposting within the VLE itself, as well as written instructions offered to students in class on how to access the online resources could quickly resolve the problems that students have experienced. Students were then asked about how useful they found the four garment construction video demonstrations. As in the previous cohort of students, there was a positive trend towards the videos being 'quite useful', but the responses were slightly less positive than in the previous feedback. Again, the same preferences were shown towards two of the four videos that had been favoured by the previous group of students, as seen in Figure 5 below.

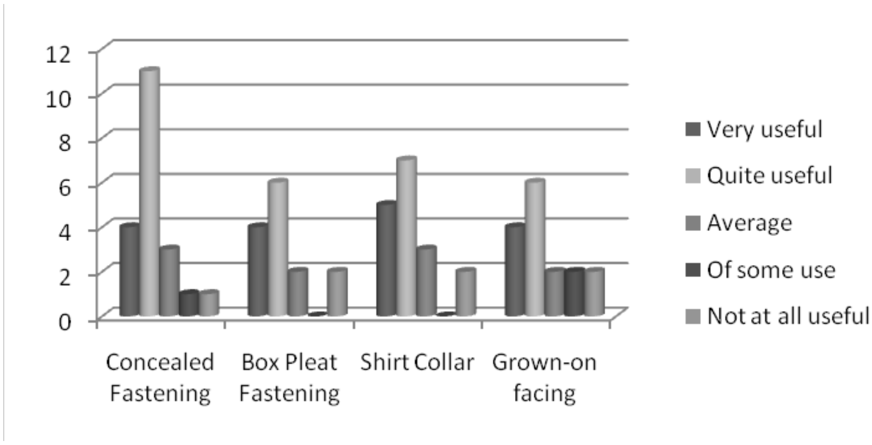

Figure 5. Students' preferences towards the video content available to them (second cohort of students)

In this second set of feedback, when students were asked how easy they found it to learn using the following forms of delivery: a) demonstrations in studio, face to face; b) video demonstrations, online; and c) text / voiceovers from the videos online, there was a slight preference for face to face demonstrations, followed by video demonstrations, and lastly text / voiceovers on the videos, as seen in Figure 6 below.

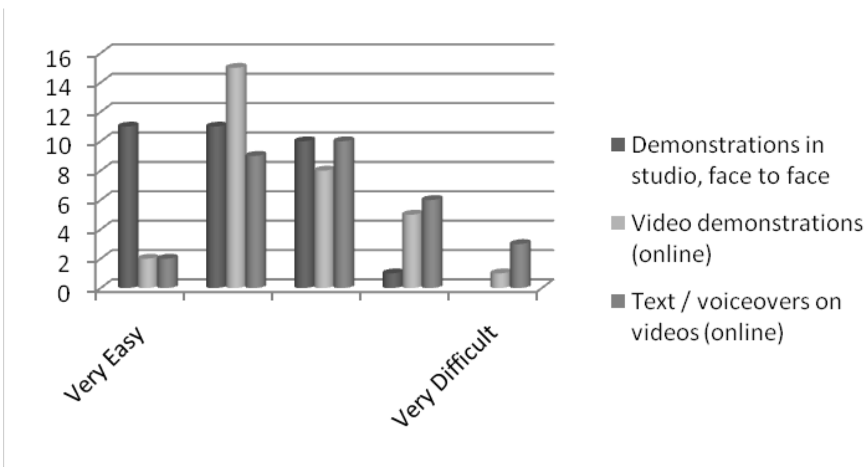

Figure 6. How easy do you find it to learn using the following forms of delivery for this module? (second cohort of students)

More students used the option to print the transcript in this set of data than in the previous set, although this was still only 23% of respondents. The transcript of the videos was thought to be 'very useful' by 33% of students, 'quite useful' by 41% and 'average' by 22%, with 4% of respondents finding the transcript 'not at all useful'. Again, this is a less positive trend than in the first set of feedback on the resources, as shown in Figure 7 below.

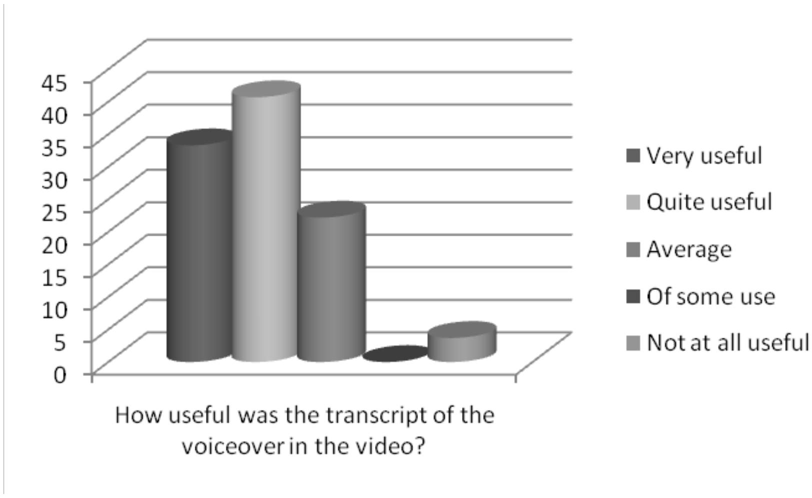

Figure 7. Students' views on the written transcript of the audio voiceover (second cohort).

Comments received from students regarding how the video demonstrations compared with face to face demonstrations in class include:

'It was good to have the transcript to remind me of the face to face demonstrations, but not as good on its own'

'Face to face was more applicable – mentioned problems that might occur etc'

'Easy to read and recap in case I missed anything during the tutored sessions'

'Was only more useful because you can follow it in your own time'

'I prefer face to face demonstrations as I can ask questions'

'I preferred the face to face contact however it wasn't always easy to see as everyone crowds round'

No students in this cohort stated that they had a visual or auditory impairment that might affect their ability to use web based resources. When asked for final comments about what students would like to see added to the online resources, these included:

'Examples of previous work'

'The construction of patterns as well as garments'

'Need all demonstrations on with written instructions'

'Access to all without having to complete tests'

In general, the second set of responses received from students was less positive than the first set. This may partly be due to students feeling that obstacles, in the form of the health and safety videos and tests, had been put in the way of them accessing the learning materials for the module. There were also some technical difficulties during the semester concerned in the second set of feedback, which limited access to the resources for some students. However, it is expected that by providing more explicit instructions to students on how to access the video demonstrations, these problems can be at least partly resolved. One important, and somewhat expected, point that comes from the student feedback is that students see the value of these resources as a support mechanism for the instruction they receive in taught sessions, and not as a replacement. The students seem to value the significance of having face to face contact with staff, and the two way discussion that this can and should promote. It is also important to note that there is a balance to be struck with any such web based resource; the materials should support and engage student learning in an independent and active way, rather than encourage passivity towards the learning process. Some students suggested that all of the demonstrations for the module should be made available online to support them, but conversely, by making only selected learning resources available to students, possibly by facilitating learning of the more complex concepts, this may promote a better learning environment, as students will need to make some leaps of understanding for themselves.

Conclusion

Using VLEs to support the learning experience of students in any discipline has clear advantages, but particularly in practice based subjects, where blended learning resources would seem to be particularly applicable. Using C&IT in this way can help to manage the need for additional student support outside of taught sessions, as information is available to students in an accessible and flexible environment, enabling them to take responsibility for their own learning. However; video based learning materials can be costly and time consuming to produce, so careful and strategic planning is needed to produce resources which will be of most use to the target audience. If the correct balance is achieved, then the resource can be of use year after year.

Work on this project is ongoing, with a view to developing a more comprehensive resource to support delivery of practical modules at all levels of the Fashion Design programme, and move towards a more contemporary and innovative approach to teaching practice based modules which are traditionally staff intensive.

Influential Elements of Creativity in Art, Architecture, and Design Creative Processes: A Grounded Theory Analysis

Ahmad Fakhra, IIT Institute of Design, Chicago, USA, ahmad@id.iit.edu

Judith Gregory, PhD, IIT Institute of Design, Chicago, USA, judithg@id.iit.edu

Abstract

Creativity in art, architecture, and design was investigated in this analytical study through the qualitative research methodology of grounded theory. A data set comprising published interviews with eighteen eminent creative artists, architects, designers, and leaders of creative organizations was analyzed to generate an initial grounded theory model for the creative process phenomenon of generating creative insights. Five influential elements to the creative process were identified from the analysis: sources of creativity that yield creative insights; strategies that instigate creativity; influential factors that drive creativity; individual and collaborative modes of working; and characteristic qualities of creative results. The analysis presented is part of doctoral research in progress in its early phase.

Keywords

Creativity, Design process, Design pedagogy, Art, Architecture

Creativity has been defined by cognitive psychologists as "the result of convergence of basic cognitive processes, core domain knowledge, and environmental, personal, and motivational factors which allow an individual to produce an object or behavior that is considered both novel and appropriate in a particular context" (Ward & Saunders, 2003, p.862). It is regarded as the quintessential element to the process of innovation, which is where creative ideas are actually implemented (Mumford and Gustafson, 1988; Amabile, 1996). A common approach to the study of creativity was presented by Runco (2004) in his review of creativity research in the past twenty years through the discussion of four creativity elements: the creative person, process, product (results), and press (pressures on creativity). In this study, creativity in art, architecture, and design is investigated with a primary focus on creative processes following grounded theory methodology and a generative research approach in the early phase of doctoral research that aims to foster creativity in design process and design studio pedagogy.

In cognitive psychology literature on creativity, creative processes have been approached through various theoretical and scientific models of cognitive processes. Some cognitive models include the generative and exploratory sets of processes of the Geneplore model (Finke et al., 1992, Ward et al., 1997) and the analytic-evaluative processes of Basadur (1995), Houtz et al. (1979), and Perkins (1981). Other cognitive models are concerned, variously, with the idea formation processes of random variations and combinations and the evaluation processes of the chance-based theories of Campbell (1960) and Simonton (1988), the interaction between the primary processes of problem finding, ideation and judgment and the contribution of the secondary components of knowledge and motivation by Runco and Chad (1995), and other processes involving perception and information encoding discussed by Mumford, Baughman, Supinski, and Maher (1996) and Smith and Carlsson (1990).

In contrast to cognitive psychology, Demirkan and Hasirci (2009) argue that creative processes in design research have not been investigated as much as would be expected. They remark: “Although creativity is considered as one of the key concepts in design, designers neglected to make research on creativity for many years” (Ibid., p.294). Christiaans and Venselaar (2005) suggest that reliance on concurrent verbal protocol analysis in mainstream design research poses difficulties for inquiry into processes of creativity. They also point to the need for design research methods that can correlate the performance of designers - creative results - with the nature of design activities - creative design processes.

In this research, grounded theory methodology was employed as a qualitative research approach in this early phase of research of creative processes by examining commentaries and perceptions of exceptional creative achievers. Grounded theory is defined as theory generated from data systematically obtained and analyzed through the constant comparative method (Corbin & Strauss, 2008). The creative process phenomenon of generating creative insights is interpreted from grounded theory analysis of the initial data set comprising texts of published interviews with eighteen eminent creative artists, architects, designers, and leaders of creative organizations. Five interrelated elements of creativity that have influence on the creative process were identified through the analysis. The five elements are: sources of creativity that yield creative insights; strategies that instigate creativity; influential factors that drive creativity; individual and collaborative modes of working; and characteristic qualities of creative results.

Research aims and questions

This discussion presents a grounded theory analysis of reflections on creative process by well-known creative achievers currently active in the domains of art, architecture, and design. This initial study is part of the early phase of doctoral research that aims to develop a theoretical and conceptual understanding of creativity in design and design processes and to propose creativity-informed methods and strategies to foster creativity in design processes in the context of design studio pedagogy.

This grounded theory analysis is guided by three research questions: What are the major sources of creativity in creative practices? What are the common influential elements of creativity in the creative processes of artists, architects, and designers? How could better understandings of creative processes from creative practices help inform design pedagogy on how to foster creativity in design studio environments? Although the doctoral inquiry is focused on understanding the creative process in design, the creative processes in art and architecture are also examined based on the assumption that artists, architects and designers employ similar cognitive and creative processes as they produce creative results.

Research Approach and Methods

Data set

Published interviews with eighteen creative individuals and leaders of creative organizations well known for their creative achievements in art, architecture, and design domains were selected for this grounded theory analysis. The data set presented in Table 1 includes five artists, nine architects and designers, and four leaders of creative organizations. The creative individuals and organizations were selected by the process of theoretical sampling (Corbin & Strauss, 2008), which is achieved by constituting a heterogeneous sample of people who have experienced the phenomenon (of creative processes, in this case) and thereby best contribute to the development of its theory.

Data sources

The data sources from which the data set was constituted are published texts of in-depth semi-structured interviews and reflective writings of eminent creative individuals. Table 1 lists the creative individuals, their creative domains, and their data sources. Funtagawa (2002) and Meyers and Gerstman (2007) are the two major sources of most of the interviews with the selected creative individuals. In addition to these collections, Lindsey (2001) provides a second source for Frank Gehry, and Catmull (2008) is the source for Ed Catmull's own commentary.

The published interviews are a feasible alternative for what could be a very challenging task of scheduling on-site and/or in-person interviews with these hard-to-reach creative individuals. In Funtagawa (2002) and Meyers and Gerstman (2007), it was advantageous to have a group of diverse creative individuals responding to a similar set of questions so that answers could be easily compared and analyzed for patterns. It was possible, for example, to compare the creative process of a photographer and a sculptor to that of an architect or an automobile designer. Another advantage is that the content of these books provides appropriate quantity and quality of creative individuals' reflective commentaries in response to the research questions.

Category	Name	Creative domain	Data Source
Artists	Chuck Close	Painting	Meyers & Gerstman, 2007
	Dale Chihuly	Glass sculpture	Meyers & Gerstman, 2007
	Julie Taymor	Film, opera, & Broadway-show directing	Meyers & Gerstman, 2007
	Ilana Goor	Sculpture & jewelry design	Meyers & Gerstman, 2007
	Ken Heyman	Photography	Meyers & Gerstman, 2007
Architects & Designers	Karim Rashid	Industrial & interior design	Meyers & Gerstman, 2007
	Milton Glaser	Graphic design	Meyers & Gerstman, 2007
	Roland Heiler	Industrial design	Meyers & Gerstman, 2007
	Arata Isozaki	Architecture	Funtagawa, 2002
	Daniel Libeskind	Architecture	Meyers & Gerstman, 2007
	Frank Gehry	Architecture, interior, & furniture design	Funtagawa, 2002

	Pixar - Ed Catmull	CGI animated motion pictures	Catmull, 2008

Table 1. Data set of eighteen creative individuals and data sources

Grounded Theory Procedures

The research methodology employed to analyze this initial data set is grounded theory. In this qualitative method, the analytic process is based on immersion in the data and repeated sortings, codings, and comparisons that characterize the grounded theory approach. Analysis begins with open coding, based on the examination and sorting of text into categories. Corbin and Strauss (2008) describe open coding as the process of "[b]reaking data apart and delineating concepts to stand for blocks of raw data. At the same time, one is qualifying those concepts in terms of their properties and dimensions" (Ibid., p.195). Analysis of key quotes guided the development of code, category, and subcategory labels. Open coding ends when categories are saturated, i.e., when no more new information can be added to categories. In this study, 12 major categories were developed: expressions of creativity; perception in creativity; creative process; creative habits; creative work environment; motivations; inspirations; influences; characteristics of creative results; individual and collaborative modes of working; and creativity contexts.

Open coding is followed by axial coding, which is the process of relating categories to their subcategories and testing their relationships against the data (Corbin & Strauss, 2008). Derived from the analysis, axial coding is presented as a diagram that identifies: 1) the core phenomenon of the creative process of generating creative insights; 2) the sources of creativity that yield creative insights; 3) the strategies or actions that stimulate creativity; 4) the contextual and intervening conditions that affect creativity; and 5) the attributes of the creative results as qualities ascribed to creative processes.

The final step is selective coding. It is the integrative process of selecting the core category, systematically relating it to other categories, validating those relationships by searching for confirming and disconfirming examples, and filling in categories that need further refinement and development (Corbin & Strauss, 2008). Alternatively, propositions or hypotheses may be specified to state predicted relationships. In this study, selective coding is represented through the narrative descriptions of the five elements identified earlier through axial coding.

Throughout the grounded theory process, analytic and self-reflective memos are generated in response to the process of open, axial, and selective coding. Analytic memos are related to the process of writing down questions, ideas, and speculations about the data and the emerging theory. Self-reflective memos are related to writing personal reactions to the narratives found in research data (documents, texts, other kinds of evidence). During the writing process, memos provide a firm base for reporting and reflecting upon on the research and its implications (Corbin & Strauss, 2008).

Results of Grounded Theory Analysis

Figure 1 presents the grounded theory model for the creative process phenomenon of generating creative insights, based on analysis of the data set. The model presents five interrelated elements that play important roles in the creative process. The five elements include sources of creativity that yield creative insights, strategies that instigate creativity, influential factors that drive creativity, individual and collaborative modes of working, and characteristic qualities of creative results.

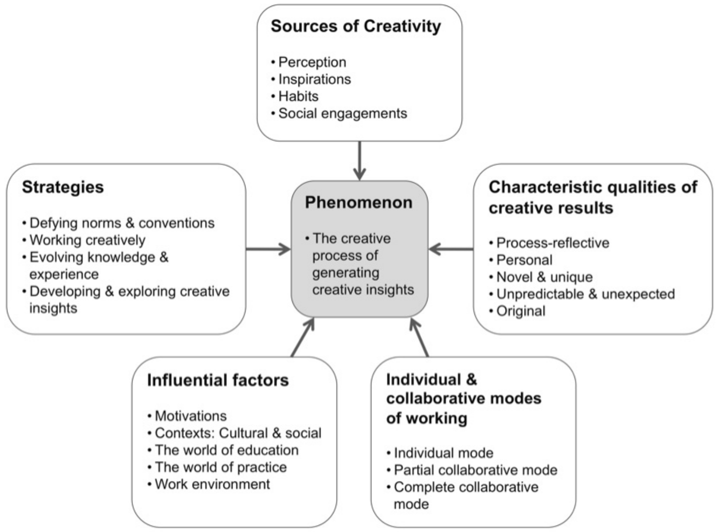

Figure 1. Five influential elements of creativity in art, architecture, and design creative processes derived from grounded theory analysis

The creative process phenomenon of generating creative insights

There is a general consensus among the creative individuals about what characterizes and constitutes a creative process. In general, the creative process is characterized as open ended, where anything is possible, and organic and non-linear, in which the process is not precisely planned and does not follow any pre-existing path. Creative process is perceived to be unpredictable where insights can emerge unexpectedly through mistakes or what Ilana Goor, a multi-media artist, calls "happy accidents." Dale Chihuly, a glass sculptor, considers accidents to play an important role in his creative process. He reports: "What may start as an accident sometimes becomes a valuable exercise and, by trying it over and over, can turn into something that you can control. So you might say that a lot of our work is the result of sort of controlled accidents" (Chihuly quoted in Meyers & Gerstman, 2007, p.38). This kind of work requires not only the ability to have a prepared mind to "see" or recognize the precursors of insights, but also the ability to choose what is important and worth pursuing as well as the ability to take risks.

The creative process is also perceived as a gradually evolving process where insights at the beginning of the process are not pre-conceptualized but rather emerge and constantly evolve – and are sometimes transformed into something completely different towards the end of process. This is expressed in relation to the process of iterations and reiterations with constant editing and refinement that requires lateral thinking, open mindedness, and flexibility for adapting to constant changes. Chuck Close, a painter, explains: "As I move along, I may do something that is wrong before it is right. Then I say to myself, 'Well, what do I need to do to move it closer to what I want?'… I put some color down, do something to it, and if I don't like those colors, I put in some other colors so my paintings gradually evolve to what I want... This is a very different thought process than conceptualizing something and then just executing it" (Close quoted in Meyers & Gerstman, 2007, p.140).

Sources of creativity that yield creative insights

Four sources of creative insights emerged from the data as major categories. These categories are perception, inspiration, habits, and the social engagement. In *perception*, creativity is conceived though the ability for the creative person to see, literally, more than what others see and the ability to perceive problems, challenges, projects, reality, and future, among others, differently than other people. These abilities are derived from the creative individual's cognitive capacity to break out of the habitual and preconceived ways of thinking, to see patterns of potential opportunity across many disparate things, to visualize a future by bridging gaps between different things that are unrelated, and to imagine and envision something new that is beyond the given for a particular project.

Other accounts for having different perceptions are related to the sudden acquisition of insights through new experiences of places or people. Daniel Libeskind, an architect, reports: "It was that instant encounter with the physical wall (of Ground Zero), with the sky, close to the bedrock, close to the space where thousands had died, and I saw the world in a different way" (Libeskind quoted in Meyers & Gerstman, 2007, p.52). Libeskind also comments: "It is often that I meet people by accident, or by chance, who give me a new way of seeing the world" (Ibid., p.51).

Inspiration is found to be another source for creative insights. Creative ideas, concepts, visions, and solutions are oftentimes stimulated as a consequence of either changing one's perception in response to experiences or meeting people – as mentioned above – or receiving new information from sources of inspiration. Three sources of inspiration are expressed by creative individuals in the data set. The first source is *process driven* where insights are surfaced through the incidents of mistakes and accidents. These incidents usually result through experimentations; drawing and prototyping; working with others; and from what annoys and what does not work during the process. The second source is *project specific* where insights are inspired through the discovery of a current project's sets of signs that are found, for example, in an architectural site or product constraints. Creative insights are also inspired by the knowledge and experiences gained from previous projects on which one worked or from successful precedential projects developed by other designers and artist.

The third source of inspiration is realized through the *direct encounter with the world.* This includes what creative individuals see or experience by coincidence such as objects, light, people's names; what they experience in their profession such as buildings, spaces, and products; what they engage with themselves, such as art galleries, music, reading a poem; and also what they experience through travel. Thom Mayne, a creative leader at Morphosis, remarks: "Traveling became a continual source of insight… there have been so many important moments for me… visiting the Mayan structures at Chitzen Itza and Coba… La Tourette… the densely layered spaces of the Saone House in London… this is the first time I had ever experienced architecture through smell and sound prior to vision" (Mayne quoted in Funtagawa, 2002, p.400).

The third source of creative insights is found to be originated through different *habits*. Ideas, concepts, visions, and solutions that sometimes emerge through the habit of externalizing ideas and first creative impulses through either intensive project-specific sketching at early stages of a process or through routine drawing such as the architect Steven Holl's one-hour morning paintings; open-ended drawing of ideas and observations from real-life experiences and thoughts, or from imagination. Chris Bangle, a creative leader at BMW, gives an example: "Like any designer, I take notes on what I see and think and make a lot of drawings. I fill my sketchbooks on what I see in life, what I think of and what I hear. I often sketch an idea that I think relates to something important at the moment and then I go back into the sketchbooks to refresh myself years later" (Bangle quoted in Meyers & Gerstman, 2007, p.168). These paintings, drawings and sketches are all considered second-memory banks of insights as well as references for future projects.

Other insights are developed through the habit of regular involvement and immersion in different creative cultures such as visiting art museums and galleries; attending concerts, theatrical performances, public lectures, and conferences; and experiencing buildings, spaces, and products. Other habits include collecting things of interest, being curious by reading about everything, and keeping busy with work as well as escaping time from work to do different things such as speculating, traveling, and meditating.

The fourth source of creative insights is rooted in the *social engagement* with other people. Different types of people reported as sources of insights. These are creative individuals admired by the artists, architects, designers and leaders of creative organizations who are influenced by throughout their careers; people they work collaboratively with whether in their own work environment or work environments of others; people they design for, such as clients and end-users; people they leisurely hang out with such as artists, musicians, and writers; and other people randomly encountered from life.

Strategies that instigate creativity

The phenomenon of the creative process of generating creative insights is explored here in relation to the strategies that the creative individuals developed to instigate creativity. Four core strategies were identified: 1) defying norms and conventions; 2) working creatively; 3) evolving knowledge and experience; and 4) developing and exploring creative insights.

Defying norms and conventions consists of three groups of strategies. The first group involves following and searching for new paths. Creative individuals expressed the importance of stepping beyond existing boundaries and rules to develop their own creative paths, alternatively defined as a different track of thinking and approaching problems and challenges marked by unconventionality that distinguishes the creative individual from others. One of their strategies includes not imitating others and staying away from influences that could blind the mind from thinking differently. Close explains: “The people who have been the biggest influence on me have contaminated my work, have contaminated my life and they have been hard to purge. When you love something, you want to incorporate it into your work. But then it’s not your work – it’s that other person’s work” (Close quoted in Meyers & Gerstman, 2007, p.137).

The second group of strategies is focused on challenging perception. Having the ability to be creative by “seeing” things differently involves the ability to break out or escape from the habitual or preconceived ways of thinking and working to discover things that are not apparent; and the ability to have a “prepared mind” to recognize and take advantage of accidents as they often lead to new insights. Perceiving differently also involves an ability for “visualizing a future that others don’t see.” Nandan Nilekani, a creative leader at Infosys, continues to elaborate: “In business, success comes when you see something – you see a pattern, and maybe you look at different things that are not really related – and when you look across those things you suddenly see a kernel of an idea” (Nilekani quoted in Meyers & Gerstman, 2007, p.55).

The last group of strategies under the core strategy of defying norms and conventions are related to having the courage to do what others normally avoid doing. These strategies involve audacity for taking risks; making mistakes; working with new, unconventional, or unfamiliar things; discarding used-up ideas even after spending a lot of time on them; and breaking rules. Strategies for dealing with rules include reinterpreting, ignoring, challenging, moving around, and not learning rules. For, example, in design creative processes, some individuals break the rules first to free their minds from conventionality, to discover new ways for approaching a challenge, and to find a creative insight; and then, they solve pragmatic problems later.

Strategies for *working creatively* represent the second core strategies that emerged from data analysis and they consist of two groups of strategies. The first group is related to the general means of approaching creativity in design practice. These strategies include combing and finding a balance between instinct and logic; experimentation and practice; and inspiration and pragmatics. They also include developing universal codes and guiding questions, those which help stimulate creativity without controlling the creative process, such as asking open-ended questions to locate the problem and asking questions nobody else can answer to generate a problem rather than to solve it. Other strategies also include taking time off from work allowing for incubation. Libeskind comments: “It’s not a time of escapism, but a time that I use to create buildings – which I do when delving into a poem, doing some music, walking on a street or just lying under a tree” (Libeskind quoted in Meyers & Gerstman, 2007, p.55).

The second group of strategies, however, involves specific strategies for working creatively with others. These strategies include forming teams with individuals that complement each other with balance in talents, skills, and in some cases gender; assembling interdisciplinary incubation teams that work well together; forming committees of creative peers that help teams with feedback on work in progress; and forming daily review sessions where everyone can share their work and comments and feedback on others in a positive way. Ed Catmull, a creative leader at Pixar, describes some benefits for the daily reviews: “Showing unfinished work each day liberates people to take risks and try new things because it doesn’t have to be perfect the first time” (Catmull, 2008, p.70).

The third core strategy is focused on *evolving one’s knowledge and experience*. Domain-specific as well as other types of knowledge and experience are found to play an important role in creativity. Across all creative individuals; some strategies include learning from bad work; immersing oneself in the field to gain up-to-date knowledge; learning through the bodily experience with buildings, spaces, products, music, and art, among others; and exposing oneself to different cultures, societies, and domains through travel and forming relationships with others such as artists, designers, and musicians. Some creative leaders such as Mayne from Morphosis and Catmull from Pixar stress the importance of maintaining strong academic contact for many reasons including staying close to innovations happening in academic research communities and attracting exceptional talents.

Strategies for *developing and exploring creative insights* constitute the fourth set of core strategies emerged from the grounded theory analysis. Some strategies for developing creative insights include working with initial gut ideas and other ideas generated through the different sources of creative insights. This includes, for example, ideas from the unconventional perception of “seeing” beyond the given; the habit of collecting interesting things and going to museums; the social engagement with artists, musicians, and co-workers; and the inspiration from an “angle of light that fell on a wall at a certain time of the day” (Libeskind quoted in Meyers & Gerstman, 2007, p.46).

Strategies for exploring with ideas, on the other hand, include testing and experimenting with the initial gut insights and selecting the ideal concept(s), idea(s), or solution(s) after developing a large number of alternatives. They also include discarding insights that do not work or evolve into creative ones even at later stages of the process; exploring insights through iterations; and involving others in the process.

Influential factors that drive creativity

Three types of interrelated factors were identified from the data analysis to have influences on creativity. These factors are: motivation; the contexts of culture and society; the contexts of the world of education and world of practice; and the work environment. The three factors are discussed here in parallel, for their possible mutual influences.

Three types of motivations emerged: intrinsic, extrinsic, and a combination of both. Intrinsic motivations are considered as the inner drive of passion, desire, curiosity, joy, thrill, and excitement for creating new things, seeing things manifested, and "living the dream." Extrinsic motivations include gaining confidence and support from others whether through public and private commissions, social acceptance, validations and acknowledgments, or success. The third type of motivations, however, emerges as the inner impulse and desire triggered by something in the culture or someone in society. This includes the pride and original contributions to the domain culture and society, the new experiences and positive influences on people's lives, and the creation of value whether business or social.

The three motivational factors of creativity can be nurtured or diluted through the three contextual factors of culture, society, and the world of education and practice. Some contextual examples given by the creative individuals include market and business support or resistance, in some situations, to innovation; society's conformity in schools, work, and the way of life; society's misconception and lack of understanding of the importance of time and fund investments in creativity; and the social consensus among creative communities for innovation. From the context of education and practice, there is a common agreement among many creative artists, designers, and leaders that the cultural context peripheral to education is as important as education itself. Motivations in this context can be nurtured through the students' exposure to different disciplines in and outside of school and the students' involvement with design practice culture and society.

In the work environment, however, a supportive environment is considered one that prioritizes creativity over authority of precedents, encourages interdisciplinary and democratic engagement and collaboration with others, and inspires learning and exploration. In Pixar, for example, Catmull explains: "What we do is to construct an environment that nurtures trusting and respectful relationships and unleashes everyone's creativity. If we get that right, the result is a vibrant community where talented people are loyal to one another and their collective work, everyone feels that they are part of something extraordinary, and their passion and accomplishments make the community a magnet for talented people coming out of schools or working at other places" (Catmull, 2008, p.66-67).

Individual and collaborative modes of working

Three types of modes of working emerged from the grounded theory data analysis: individual mode, partial collaborative mode, and completely collaborative mode. In general, working individually or collaboratively with others depends on several factors such as personal preference of whether collaboration can to be perceived as productive; the desired type of contribution whether it is for a task or idea contributions; and the nature of the process itself whether it requires one or several individuals. It is more common for artists to work individually than designers. In some cases, working individually is perceived to be more productive, e.g., Goor comments that "[w]hen you're with other people, it's wasting time. It's alright to talk and laugh and eat with them, but when you do something on your own you start really thinking and new ideas are developed" (Goor quoted in Meyers & Gerstman, 2007, p.210). For others, it does not make any sense to collaborate, for example, in taking photographs, painting, or sculpting except for collaborative type of projects and labor-related tasks and assistance.

In contrast to artists in general, designers tend to work more collaboratively with others. This collaboration, however, is partial for the majority of designers and the extent to which others are involved in the process varies. Most designers prefer working individually at the beginning of the process to focus and generate their own ideas through what they do best such as experimentation, sketching, and rapid prototyping and then involve others throughout the different stages of the process. Karim Rashid, an industrial designer, explains: "After the sketch stage, I sit with my senior staff, show them my sketches and tell them about my ideas. Then after listening to their opinions and their feelings about them, we edit them down to maybe five, six, or seven best ideas… Their [the interdisciplinary team's] contributions include defining and refining my ideas, doing the computer aided drawings, handling the presentation renderings and a lot of other follow-up tasks" (Rashid quoted in Meyers & Gerstman, 2007, p.232). Other designers, on the hand, only collaborate with others at certain stages such as the initial idea generation and problem definition stage or when there are specific needs or goals to be accomplished at different stages.

In creative organizations like Pixar and BMW and for some designers, on the contrary, creativity is always produced through a completely collaborative mode of working. Roland Heiler, an industrial designer, contrasts himself from other solo designers: "As for myself, I've always been a team player. I'm not one of those designers who like to point to a product and say, 'Hey, look what I've created'" (Heiler quoted in Meyers & Gerstman, 2007, p.118). The creative individual's role in this mode of working, however, is shifted from being the individual sole creator to more of a creative leader. Some of the leader's roles include bringing a fresh set of eyes to the team; providing the means for ideas to propagate and grow; building common understanding in the work place with a consistent design strategy and a clear vision; establishing clarity, accuracy, and coherence between designers and the others; and being sure to acknowledge the effort of everyone in the team.

Characteristic qualities of creative results

"Embedded in the work itself are indications of the process. You can see what colors are underneath and you can see what colors are on top… You see it unfiltered and untranslated, as decisions being made in front of your eyes" (Close quoted in Meyers & Gerstman, 2007, p.140). Close is reflecting on the qualities of his creative paintings. Process-reflectiveness emerges as one of the qualities of creative results that mirrors the creative process through which it is conceived. Other qualities are expressed as being individual or personal, in which the work reflects the unique thoughts and feelings of the creative individual; novel and unique, in which the work does not resemble anything that existed before; and unpredictable and unexpected, which reflect the expectations that drive the process. It includes the 'nuance of originality' as Rashid expresses it: "My agenda is that I need to do something original or I don't sleep at night… Every project I work on must have some nuance of originality. The nuance could be that I find a new production method, or a new function, or a new material, or a new book. But for me, there needs to be some level of originality" (Rashid reported in Meyers & Gerstman, 2007, p.229).

Conclusion

The phenomenon of the creative process of generating creative insights in art, architecture, and design was investigated in this study through grounded theory analysis of data set of published interviews with well-known creative individuals. The creative processes of eighteen creative individuals were examined in relation to the different elements that play influential roles in creativity. Through the systematic qualitative research methodology of grounded theory, five influential elements of the creative process were identified: sources of creativity, creativity-oriented strategies, contextual and intervening conditions, individual and collaborative modes of working, and the attributes of the creative results.

This initial study is part of the early phase of a doctoral inquiry on fostering creativity in design pedagogy and design practice. The findings from this analysis of the commentaries and reflections of well-known creative individuals in art, architecture and design, and creative organizations will be brought together with future studies to originate creativity-informed methods and strategies that foster creativity in design processes and design studio pedagogy. The grounded theory analysis contributes to the basis for discourse analysis regarding creative processes, that will be developed based on synthesis from the interdisciplinary literature on creativity. The discourse analysis framework will inform empirical research protocols and analysis to understand creative processes in design pedagogy as well as foster creativity.

Author Biography

Ahmad Fakhra

An architect and interior designer currently pursuing his Doctor of Philosophy in Design degree from the Institute of Design, Illinois Institute of Technology, Chicago, Ahmad Fakhra is a scholar employed by Kuwait University College for Women as a prospect interior design educator for the newly established Art & Design Department.

Judith Gregory, PhD

A member of the Design Research Faculty of the Institute of Design, Illinois Institute of Technology, Chicago, Judith Gregory is Faculty Co-Director of the Doctor of Philosophy in Design Program.

Epistemological Positions Informing Theories of Design Research: Implications for the Design Discipline and Design Practice

Luke Feast, Swinburne University of Technology, Australia

Abstract
Design research is not simply concerned with speculations regarding the relationship of theory and practice. Design research also brings out significant questions regarding the nature of research and the position of the doctorate in university education. This paper presents analyses of examples of objectivist, constructionist, and subjectivist theories of design research. The assumptions that underpin their perspectives are outlined, their powers of generalisation considered. The implications for the position of the design discipline in relation to the greater academic community, and the characterisations of design practice that they contain, are drawn out. The paper concludes by considering the pedagogical implications of the role of disciplines in the knowledge building cycle between research and professional practice.

Keywords
Pedagogy; Philosophy;

The issue of designing in design research is significant because it poses questions about the nature of research in general. This aspect of design research is centred on the question of the relationship between what we do and what we know. There are many different ways in which this question is raised in the design research literature, and many useful answers have been given. However, the significance of these answers is difficult to establish because their terms of reference are often unclear. A large number of different terms have been used to refer to designing in research and these terms are often used synonymously as methodologies, approaches, perspectives, and philosophies as if they are all comparable (Niedderer & Roworth-Stokes, 2007, p. 7). A framework that organises the epistemological aspects of design research is needed to make meaningful distinctions between the different positions.

A Knowledge Framework

Michael Crotty (1998, pp. 2-9) frames the research process by epistemology, theoretical perspective, methodology, and methods. Epistemology is the theory of knowledge that defines what kind of knowledge is possible and legitimate. Theoretical perspective is the philosophical stance that grounds the methodological logic and criteria. Methodology is the strategy that links the choice of particular methods to the desired outcomes. Methods are the techniques used to gather and analyse data related to the research question or hypothesis. The four parts of the framework are arranged hierarchically so that all the different methods are contained within three epistemologies: objectivism, constructionism and subjectivism.

Each epistemology contains assumptions about nature of the world and these assumptions are in turn embedded in the particular methods. For example, research conducted using the method of participant observation is one of many embedded within the methodology of ethnography, which has been adapted by symbolic interactionism, which is one theoretical perspectives within constructionist epistemology. It follows that the assumptions about how we know what we know that are embodied within constructionist epistemology are also embodied within the findings collected through the method of participant observation.

Crotty's knowledge framework suggests clearly defined distinctions between the three epistemologies, but it is important to recognise that within each category there are strong and weak versions. For instance, phenomenological research is categorized as constructivist; however, it is a broad term that can encompass approaches that range from thoroughly objectivist to thoroughly subjectivist. Consequently, it is important to note that each epistemology represents a spectrum of approaches rather than a homogenous class. With this qualification in mind, it is useful to identify the assumptions that underpin each epistemology.

Objectivism maintains that a meaningful reality exists independently of the mind, that entities carry intrinsic meaning within them as objects, and that we can discover this objective truth if we go about it in right way. Constructionism maintains that meaning is constructed through our minds interacting with the world, which implies that people in different cultures or eras construct meaning in different ways even in relation to the same phenomenon. Subjectivism maintains that meaning is imposed by people's minds without the contribution of the world, there is no truth or meaning independent of the mind. Crotty's framework usefully connects the theory of research to the practice of research, places the opposition of quantitative and qualitative procedures at the level of methods, reveals the assumptions that underpin particular research models, and identifies the limits of their generalizations.

Epistemological Positions in Design Research

In our recent literature review (Feast & Melles, 2010), we analysed a series of articles concerning design research using Crotty's framework as a reference point. The articles included in the review were selected from a bibliography of approximately 300 journal articles, conference papers, book chapters, and state of the art reviews. The bibliography was developed from database searches, existing design research bibliographies sourced from the World Wide Web, and from research and teaching experience. The articles listed in the initial bibliography were then verified and their ability to be accessed checked. The remaining 150 articles were then ranked by relevance according to key words, and then by the number of times each article had been cited in www.google.scholar.com. Twenty-eight articles were reviewed with the aim to explore the complexity of the issue, rather than seek statistical generalization. We identified articles presenting broadly objectivist (Bayazit, 2004; Durling, 2002; Durling & Friedman, 2002; Friedman, 2003; Langrish, 2000; Melles, 2009; Mullins & Kiley, 2002; Owen, 1998), constuctionist (Archer, 1995; Biggs & Buchler, 2008; Biggs & Büchler, 2007; Cross, 2001; Dorst, 2008; Frascara, 2007; Hockey, 2003; Hockey & Allen-Collinson, 2000; Margolin & Margolin, 2002; Pedgley, 2007) and subjectivist (Candlin, 2000; Cazeaux, 2008; Dilnot, 1998; Frayling, 1993; Gray & Pirie, 1995; Newbury, 1996; Prentice, 2000; Rust, 2002) models of design research.

The objectivist position is illustrated by Ken Friedman's outline of the conditions for theory construction in design (Friedman, 2003). Friedman maintains that theory construction involves systematically building knowledge through converting tacit knowledge into explicit knowledge. The constructionist position is illustrated by Nigel Cross's model of designerly ways of knowing (Cross, 1999, 2001). According to Cross, this model of design research is concerned with developing design knowledge through intellectual reflection upon making and using artefacts. The subjectivist position is illustrated by Christopher Frayling's model of research for art and design (Frayling, 1993). Frayling claims that a cognitive tradition of direct making which constitutes research can be identified and that research following this autobiographical approach is concerned with personal development. Each model contains epistemological assumptions (Crotty, 1998, pp. 7-9). Objectivist research distinguishes facts from people's everyday meanings. Constructionist research places all meanings, scientific and non-scientific, on an equal basis; all are constructions and none is truly objective or generalizable. Subjectivist research concerns personal expression and its claims cannot form significant generalizations. In addition to affecting the status of research claims, epistemological positions locate the research in relationship to the greater academic community.

The epistemological positions locate design in either Isolationist or Situated relationships with other disciplines (Biggs & Buchler, 2008, p. 6). The Isolationist position claims that design research is somehow special and should be granted special criteria and regulations. In contrast, the Situated position maintains that because design is positioned in a comparative competitive environment, it must place itself in relation with its peers by finding commonalities with the academic community as a whole. By arguing that direct making is research, Frayling (1993, p. 5) separates design research from established paradigms of research, therefore, research following his model of research for art and design takes the Isolationist position. Cross's emphasis on individual reflective practice would appear to place his model of design research within the isolationist position; however, Cross (2001, p. 55) explicitly acknowledges that the design discipline must embed itself within the intellectual tradition of the university and demonstrate standards and criteria match those of the other disciplines. This model takes the Situated position. Friedman's (2003, p. 520) model of theory construction based on explicit statements as the basis of research in all disciplines aligns his perspective with the Situated position. The relationship between research and the academic community also implies particular pedagogical forms within doctoral education. Doctoral research undertaken in a subjectivist mode emphasises research as a personal journey that gains knowledge for an individual, while objectivist oriented research places emphasis on training in transferable research skills.

The three models of design research also imply characterisations of design practice. Friedman's designer is a professional knowledge worker who addresses problems in many different knowledge domains. For Cross, the designer is a reflective practitioner who attempts to understand the meaning of her own work. Frayling's model envisages the designer as a lone creative genius. The models characterise designing as problem solving, reflective practice, or direct making. Problem solving and reflective practice focus on designing as a process, whereas direct making concerns the crafting of objects.

Design practice and design research

The object-centered approach grows out of the guild tradition, which transfers a rich stock of tacit knowledge embodied in the skills and techniques passed down from the master to the apprentice through many years of ritual and imitation. This tradition produces a form of habituated know-how that allows the individual craftsman to respond intuitively to specific situations. This form of tacit knowledge remains an aspect of professional practice today, however, modern education can not afford the decades of training that are required for traditional guild style craft education (Friedman, 1997, para. 66). Today, design education is changing from the object-centered master-apprentice model of the guild tradition to the theory driven problem solving approach characteristic of a university discipline.

Recent ethnographic research into modern design practice has revealed that designers do not work as lone creative geniuses, more often designers work collaboratively in interdisciplinary teams (Arias, Eden, Fischer, Gorman, & Scharff, 2000; Bucciarelli, 1994; Chiu, 2002; Guinan, 1986; Lauche, 2005; Minneman, 1991; Olson, Olson, Carter, & Storrosten, 1992; Sonnenwald, 1993, 1996, 2007; Walz, 1988). This change in design practice implies that the object-centered approach to design that underpins Frayling's subjectivist model of design research, no longer represents the reality of professional design practice. Design research concerning design "practice" undertaken within Frayling's subjectivist approach would then be subject to a series of misunderstandings (Krippendorff, 1995; Poggenpohl, 2009, pp. 15-16):

- Designers are lone craftsmen that create an autobiographical design. This myth denies the history of design as well as undermining teamwork and collaboration. In addition, challenges that fall outside the craft education paradigm are neglected.
- Designers are not analytical and aim at holistic responses. This implies that designers cannot break problems into sub-problems, so tend not to ask interesting questions and are unable to criticise existing research.
- Designers do not write. This has the consequence that seminal ideas and prototypes are not recognised, literature on design remains disconnected and that the domain of design knowledge becomes colonised by other disciplines.
- Designers endlessly search for the "new". Without a robust foundation of disciplinary knowledge, ideas are endlessly repeated, the process of knowledge building is not understood, and the accumulation of knowledge is impeded. In addition, science in misunderstood as expounding truth and certainty rather than as an evolutionary process.
- Designers should be competitive both inside the design profession and outside it. This misunderstanding resists community building and isolates design from other disciplines.

- Designers focus on the practice of doing design. This focus on doing design means that designers tend not to analyse why or how they do what they do.

Object-centered design work has been concerned the aesthetic aspects of products and so has tended to work towards the end of the development process after many of the key decisions had been made. Design as a process is more complex and requires knowledge and greater depth of expertise than a solo designer can ever individually possess. This forces designers to move beyond surface concerns with aesthetics to investigating what people actually do, what they value, and how they understand things (Poggenpohl, 2009, p. 19). This human-centered approach requires that designers work with sociologists, anthropologists, psychologists, engineers, and other stakeholders to understand the interaction between people and their environments. This also requires that designers participate in decision-making at the beginning of the development process, where the parameters of design problems are still undefined, and collaborate with different stakeholders. This change towards collaborative work implies that the skills and knowledge that designers need in order to collaborate effectively with stakeholders are different than those that characterize the object-centered craft tradition. The necessity of collaboration requires designers to possess the analytical, logical, and rhetorical skills that form the basis of a profession supported by a discipline.

Disciplines support professions by providing analytical tools to question assumptions and by developing generalized explanations, principals, and theories that can be put to use by people in other times and places. Disciplines work by building knowledge within the domains of their inquiry by scaffolding new knowledge on previous knowledge though criticism, application, and reflection. This process requires a cycle between tacit and explicit knowledge (Friedman, 2003, p. 520; Wenger, 1999). Because tacit knowledge is embodied in craft practices and habitual behavioral patterns, it must be converted into articulate statements in order to allow the construction of theories that can be shared, contrasted, tested, and reflected upon. Generating empirical evidence and developing generalizable answers allows designers to address timely problems rather than repeat past mistakes (Poggenpohl, 2009, p. 14). Building a rich stock disciplinary knowledge is essential to design because it forms the foundation from which collaboration can proceed.

Michael Middleton (1967, p. 103) identifies a number of different forms of collaboration in professional design practice including: forms of association between individual people; forms of association between independent firms within a single profession or independent firms in different professions; single practices in which different skills and disciplines are associated; single firms that practice a large measure of devolution, either geographically among their various offices or in the creation of semi-autonomous teams within one office; and offices organized democratically rather then hierarchically, in which decisions are reached through discussion by the group rather than passed down through a chain of command. These different forms of collaboration can be differentiated in terms of their relationship to disciplinary knowledge as multidisciplinary, transdisciplinary, or interdisciplinary.

Multidisciplinary work involves different disciplines approaching a problem in parallel or sequentially without challenging their disciplinary boundaries; transdisciplinary work seeks to unify disciplinary differences in a holistic way; interdisciplinarity works by integrating different disciplinary insights and confronting their differences with the aim to produce a new understanding that takes those differences into account (Choi & Pak, 2006, p. 359; Repko, 2008, p. 20). True interdisciplinarity is very difficult to achieve and many self-styled interdisciplinary enterprises actually work at the multidisciplinary level. Multidisciplinary collaboration occurs, for instance, when a group of people from different disciplines cooperate by working together on the same problem toward a common goal, but continue to do so using theories, tools, and methods from their own discipline while occasionally using outputs from each other's work. While they work together, they remain essentially within the boundaries of their own disciplines, both in terms of their working practices and with respect to the outcomes of the work (Rogers, Scaife, & Rizzo, 2005, p. 266). Design practice that seeks to solve complex problems and develop new knowledge is necessarily interdisciplinary.

Interdisciplinarity is not anti-disciplinarity even though it recognizes the limits of a single discipline's power to solve complex problems. Because interdisciplinary work integrates different perspectives it is characterized by negotiation and argumentation, and so a strong foundation of disciplinary knowledge is needed in order to support effective communication, sharing, contrast, and evaluation of insights. Without a strong disciplinary grounding, designers working in interdisciplinary collaborative situations are disadvantaged because their ability to contribute lacks rhetorical strength (Poggenpohl, 2009, p. 13).

Conclusion

The increasing need to produce research in design is also influenced by economic necessity. Many university departments in Australia, New Zealand, and the UK, for instance, receive funding based in part on the levels of their students. Undergraduates count little, Masters students more, and Doctoral students most of all. Budgets are also affected by the amount of research each department produces, defined by the number of conference papers, journal articles, books and other outputs that each faculty member publishes. Accordingly, the demand to publish and supervise research has seen the concept of practice-based research quickly become embraced within many design departments. However, there is considerable variation, disagreement and misunderstanding across universities internationally regarding the nature of practice-based research and in particular how it relates to doctoral education in design. Consequently the rigor of practice-based doctorates has become the subject of significant debate and an important topic of major international conferences and publications.

The subjectivist position that all practice is research and that written text is unnecessary is often based on the idea that all designing is a form of creative investigation, therefore, a designed object can make an original contribution to knowledge in its own right. This corresponds to the understanding of the practice-based doctorate as a personal journey that gains knowledge for an individual. Arguably, a limited understanding of the nature of research coupled with a tradition of object-centered design practice has seen an attempt to elevate the designed artifact to the status of research and to accentuate the practice-based nature of design as the distinguishing characteristic of the discipline. The problem with the rush to legitimize practice-based research as the defining trait of the design discipline is that it may appeal to students and academic staff who have limited exposure to academic scholarship and an impoverished view of research methodology. This desire for disciplinarity through the emphasis on object-centered design in fact introduces a vicious cycle that undermines the legitimization of design through producing poor research and under-theorizing design.

Focusing on personal expression short-circuits the knowledge building cycle between research and professional practice. Unless research develops knowledge that can be tested, applied, and reflected on by other people in other times, it creates a gulf between research and practice, and reduces design to concerns with surface aesthetics. Subjectivist design research is based on the mistaken idea that design practice is opposed to the application of systematic methods and the erroneous belief that systemic inquiry is at odds with creativity. These factors contribute to limiting design practice to unique cases and the simple repetition of past knowledge. In order to move beyond ad hoc approaches to collaborative problem solving, research and theory is needed that develop broad explanatory principles that can meet complex, large-scale needs in comprehensive, sustainable, cost-effective, predictable and measurable ways.

Further research

Research concerning interdisciplinary collaboration in design practice has been a concern of the tradition of second-generation design methods, in particular regarding Horst Rittel's argumentative model of approaching wicked design problems (Rittel, 1984; Rittel & Webber, 1973). Rittel (1984, pp. 323-324) mapped out three paths for further research in developing the argumentative model of the design process: 1) Refinement of the argumentative model of the design process and the study of logic of the reasoning of the designer in terms of the rules for asking questions, generating information and making decisions; 2) Practical procedures for implementing the argumentative model, such as how to foster the process of group argumentation, how to select the group, and problems of the decision rules; 3) The technical manner of supporting the instrumental version of the model through administrative and computer based aids. Research into the second and third paths mapped out by Rittel has been particularly strong. Co-design and participatory design have developed significant research and techniques for implementing the argumentative model, with emphasis on incorporating users input into the design process (Sanders & Stappers, 2008).

Research in human-computer interaction has contributed to developing the technical means of support for the instrumental version of the argumentative model through software for the systematic management of information and computer supported cooperative work (Arias, et al., 2000). Arguably, empirical research within the first path concerning the study of the ways in which designers ask questions, generate information and make decisions has been less focused and comparatively underexplored. While there has been research on similar aspects in the fields of cognitive science, knowledge management and organizational studies for instance, there has been less research with a specific focus on design.

Luke Feast is a PhD candidate at Swinburne University of Technology, Melbourne, Australia. His doctoral research investigates the decision-making process within collaborative designerly work in interdisciplinary design teams.

Innovation Methods in Story-Driven Games: Genre Variation

Clara Fernández-Vara, Massachusetts Institute of Technology

Abstract

The paper proposes a method for game design innovation in story-driven games, as exemplified by the development of the adventure game prototype *Rosemary*. This method selects a game model in which a specific variation is introduced. Developing a game where the interface, interaction design, rules, goals, and themes are all new can be overwhelming for the user as well as the developers, so using a pre-existing model can ground the development and help evaluate the success of the innovation introduced.

The design method proposed is called Genre Variation. This methodology relies on a particular story-driven game model as the foundation to introduce new mechanics. After selecting the model, the next step is identifying a design problem that has not been tackled before. Then the variation is implemented as a game prototype and evaluated, following the principles of iterative design. In this case study, the problem was designing the mechanics of memory, and how to turn remembering into a core mechanic of the game. This method is intended at facilitating game development within the limited resources of academia.

Keywords

videogames, game design, story-driven games, methodology, experimentation, innovation

Academic games research can take two basic approaches: critical and development-driven. The critical approach means studying pre-exisiting games, their formal qualities as well as their socio-cultural environment. Games research can also be integral to game development. Rather than expecting games (commercial or not) to bring about innovation, games researchers can work on expanding the design space of digital games. As Mateas and Stern (2005) put it:

"[... M]aking games is required to discover new regions in design space, to understand the relationship between the game architecture and design space, and to probe the local islands that have already been partially explored through previous desings".

The motto proposed by Mateas and Stern (2005), "build it to understand it," is useful to learn more about the dependencies of videogames on the technology (the game architecture), as well as to find the gaps in the design space where innovation can take place. A hands-on approach does not discount the value of theory and criticism. In fact, a well founded understanding of current game design helps identify possible avenues of innovation as ways of expanding the pre-existing islands within the design space.

In an academic setting, videogame innovation depends on a series of trade-offs. Academia has the freedom to choose what aspects to explore, without the time constraints that commercial developers have to deliver a product. Even when game researchers fail to produce a successful game, they can still learn something from the process and apply it to the next project. While academics do not have a large monetary investment to lose, they usually lack the resources commercial developers have. When the technology is available to universities, researchers cannot have as much time and people working on a single project as a commercial developer. Therefore, game research projects tend to be smaller in scope than most mainstream commercial games. If the scope of a game for research is not adequately defined, the projects are usually unfinished and unreleased, so the results of the research may either be incomplete or only available on paper, so that it is not possible to contrast them with the actual artifact.

An additional issue is developing games with a story component, which can be more resource-consuming than other videogame genres. Story-based games, such as computer role-playing games or point-and-click adventure games usually require a larger amount of assets: graphics, animations, sound and text.[1] The audiovisual aspects are essential to represent the story components, and the story is usually inextricable from gameplay—the plot unfolds as the player advances in the game. This also makes it difficult to use methods of rapid prototyping, since even a paper prototype (e.g. a pen-and-paper roleplaying game) can demand more preparation than an arcade game, for example, for which a few game tokens and a board may be good to start playing a first version of the game (see Fullerton, Swain & Hoffman, 2004, pp. 187-182).

The intersection of story and game in story-driven games has the potential to generate new narrative forms and novel gameplay experiences. Much has been written about the limitations of story-driven games and how they restrict the player for the sake of having the player complete a linear sequence of events (Aarseth, 2004). However, there is also the potential to generate new games that defy those limitations. Building experimental games can expand the design space of videogames, and story-driven games in particular.

This paper proposes a methodology to foster innovation in story-based games through development in an academic setting. The method is called Genre Variation, because it incorporates a new set of rules or system within the pre-existing conventions of a specific story-driven genre. This method is evaluated by examining the development process of the adventure game *Rosemary*. This game was made by a team of undergraduate students led by a researcher, and is available online (http://gambit.mit.edu/loadgame/rosemary.php). The method here expounded covers the process of inception, development and assessment of the game through playtesting.

Method: Genre Variation

The method consists of choosing a model within a story-based genre, and introducing a new set of rules within that game. Modifying a game is a known exercise to design games (Salen & Zimmerman, 2004, pp.18-19; Brathwaite & Schreiber, pp. 253-4). To turn the exercise into something productive, developers must have a design focus, defined by a series of parameters that delimit the design issues that they will be addressing (Salen & Zimmerman, 2004, p.16). The two main parameters that help define the design focus in the Genre Variation method are the game model and the design problem.

The Genre Variation methodology consists of three steps: defining the model, specifying the variation, and iterative development.

Defining the Model

The game model in which the variation is introduced must be very specific, usually defined by a game or series of games. In the present case study, the model chosen by the researcher was point-and-click adventure games which used the SCUMM engine (Script Creation Utility for Maniac Mansion), such as *Maniac Mansion* (Lucasfilm Games, 1987), *The Secret of Monkey Island* (Lucasfilm Games,1990b) or *Full Throttle* (LucasArts,1995). Other possible ways to define the model can be a role-playing system such as *Dungeons and Dragons 3rd edition* (Cook,Tweet, & Williams, 2000), or choosing a single pre-existing game.

One of the advantages of using a pre-exisiting model is that it is associated to a series of conventions, which players may already be familiar with. It also saves time in the inception of the game, since the model brings a set of design decisions that researchers can build on, such as the user interface, the navigation in the space, or the standard actions to interact with the game.

The SCUMM model uses a point-and-click interface (see Figure 1). The player selects an action from a list of verbs in a menu, and then selects the object or character on the screen in which to perform it, such as "take key" or "open microwave". The player thus constructs a sentence, which is a command for the player character. The player character then carries out the action or responds that it was not possible to do it (e.g. "I don't think that's a good idea").

Figure 1: The SCUMM engine model: *Maniac Mansion* (Lucasfilm Games, 1987)

In the SCUMM model, the player character does not die. That means that the game is not over until the player hs completed all the puzzles; the player can make mistakes without ending the game before experiencing the whole story. Thus, the player is free to explore the world and experiment in it, in order to figure out how it works. In other adventure game models, such as Sierra's AGI or SCI models, the player character could die in certain parts of the game if the player made the wrong choice. For example, in Sierra's *Space Quest: The Sarien Encounter* (Sierra Online, 1986), if the player forgets to fasten the seatbelt before starting a space trip, the player character will die and bring the game to a premature end. Eliminating the death of the player character encourages players to complete the game, rather than abandoning it after dying in the same area several times in a row for no clear reason. The game manual of *Loom* (Lucasfilm Games, 1990a) explains the design philosophy of the SCUMM games:

"We believe that you buy our games to be entertained, not to be whacked over the head every time you make a mistake. [...] We think you'd prefer to solve the game's mysteries by exploring and discovering, not dying a thousand deaths." (Loom game manual, Lucasfilm Games, 1990a, p. 7)

The SCUMM model provides a specific type of story-driven game: point-and-click graphical adventure, with menu-driven commands, which encourages the player to explore and finish the game, rather than being punished whenever the player makes a mistake.

Since SCUMM is a proprietary engine and not available for non-commercial developers, the team chose Wintermute, an engine that incorporates many of the SCUMM features. Wintermute is freely available online (http://dead-code.org/), although it is not open-source.

Game engines are a double-edged sword. They speed up the process of implementation of a game, thanks to ready made code and samples. Engines also enforce the conventions of a specific genre which are already built into the system: e.g. having a player character, and a point-and-click interface to command the character what to do. This allows making more complex games, since the developers do not have to implement every single feature from scratch. Conversely, the ready-made blocks can also get in the way of innovation, since often they reflect a series of design decisions the developers have no control over. For example, Wintermute did not incorporate a verb menu by default, so the programmers of *Rosemary* had to perform a series of workarounds to implement the menu-driven User Interface.

Specifying the variation

The next step of the method is identifying a problem within the design space, which can be addressed within the possibilities of the chosen model. The problem will be addressed creatively by introducing a variation in that model, adding or modifying a set of rules that will alter specific aspects of the game. These new rules can be a new set of mechanics, i.e. rules that refer to the way the player interacts with the game (Sicart, 2008), or a new way to generate behaviours within the game (e.g. reactions of non-player characters that depend on whether the player has been kind to them in previous interactions).

The methods to specify the variation can be multiple—from a systematic survey of games, to an ethnographic study of players of a specific game or genre. Different research approaches will help identify the shortcomings of the model.

For *Rosemary*, the variation arose from an game idea the researcher had, in which memories resurfaced by revisiting a place one has not been to in a long time. Researching through a variety of adventure games indicated that although memory had been frequently used as a theme in adventure games (Thomas Disch's *Amnesia*, Cognetics Corporation, 1986; *Trace Memory*, CING 2005), there were no specific mechanics that modelled how memory works. This became the research issue of the project, creating a game where "remember" was the core mechanic of the game, and a means to obtain information from the fictional world of the game. "A core mechanic is the essential play activity players perform again and again in a game." (Salen & Zimmerman, p. 316). The adventure games that have dealt with memory as a theme do not have "remember" as one of the main activities in the game. Remembering is usually reduced to providing the player with information that she was not aware of through a description or a cut-scene, but there are no specific interactions that model how humans remember information.

The novel system had to simulate the player character's memory, not the player's. Remembering as a core mechanic had to consist of helping the character recall information, things that the character already knew, but she had not thought of in a long time. The researcher established a further restriction: amnesia could not be used as a device, either in the story or as part of the mechanics. Amnesia is a trite excuse to equate the knowledge of the player with the character's, and has been used too often in videogames.

By defining the game model and the problem the variation will address, researchers can scope of the game by identifying the design elements that will need the most work. The goal is to produce a finished playable prototype at the end of a specific period of time, in order to be able to test and later demonstrate the innovation. Choosing a game model provides a set of design decisions that the developers do not have to make. However, these ready-made design decisions can also be an obstacle, since part of the innovation will likely consist of reforming or even tearing down some of these conventions. For example, in *Rosemary* it would not have been enough to add an action "remember" to the menu, because that alone did not reproduce a system to help the player remember; "remember" as an action required more nuance.

Iterative Design: Bringing the player into the game

The success of the innovation introduced cannot be determined without evaluating player's experience. A game is not whole until the player experiences it; the player's interaction completes the game system. Thus, the figure of the player must be taken constantly into account during development. Iteration and playtesting are inextricable from the Genre Variation method (and from game development in general).

Iterative design is a methodology that allows developers to include the player in the game design process, and it is one of the most popular approaches to current game design (see Salen & Zimmerman, 2004; Fullerton, Swain & Hoffman, 2004; Braithwaite & Schreiber, 2009). Salen and Zimmerman describe this practice:

"Emphasizing playtesting and prototyping, iterative design is a method in which design decisions are made based on the experience of playing a game while it is in development. In an iterative methodology, a rough version of the game is rapidly prototyped as early in the design process as possible. This prototype has none of the aesthetic trappings of the final game, but begins to define its fundamental rules and core mechanics. [...] This prototype is played, evaluated, adjusted, and played again, allowing the designer or design team to base decisions on the successive iterations or versions of the game. Iterative design is a cyclic process that alternates between prototyping, playtesting, evaluation and refinement." (Salen and Zimmerman, 2004, p.11).

Iterative design invites a constant evaluation of the game, helping both developers and researchers to reflect on the design process. It encourages experimentation (change the game, evaluate in playtesting, change again), which makes it a particularly useful methodology to build games as research. Every iteration is a small experiment, whose results are incorporated into developing the game further.

Rosemary's iterations were tested with players who were not familiar with the game. There were three formal playtesting sessions, spread out through the 7 months of development. In the first session, most of our 11 players were experienced and familiar with the adventure game genre; the second set of playtesters were a group of 20 teenagers, who did not seem familiar with the genre. These two groups tested the implementation of the novel mechanics. The last group of 13 playtesters helped us ratify our design decisions before finalizing the game. All players were observed by the researcher and the development team while playing, and responded a written questionnaire about their experience after they finished. The evaluation of playtesting was qualitative (evaluating how players understood the game) instead of quantitative (e.g. asking players to qualify different aspects of their experience in a scale 1 to 5).

The problem of story-based games is that they can be difficult to prototype rapidly.[2] Since gameplay is dependent on the story, the story must be at least outlined before starting to play. Putting together a rough paper prototype, with a board and a few tokens, is a perfectly valid method for many other genres (see Fullerton, Swain and Hoffman's (2004) examples of how to prototype a first person shooter). The preparation time needed for a rough prototype in a story-based game can take much longer, since it needs building a fictional world, how it works, and how to interact with it. The "aesthetic trappings" that Salen and Zimmerman mention are necessary to construct that world, even if they are assets borrowed from other games or early versions of the actual asset. The first prototype of *Rosemary* was ready after six weeks of development, which can be a long time for an academic project. Thankfully, the prototype was relatively successful; if it had not, the team would have lost much of the work done until that point.

The team who made *Rosemary* managed to incorporate iterative design by generating builds that added, eliminated or revised features. Temporary art and incremental expansions in the game helped advancing the production and evaluating it periodically. The following sections explain the iterative process of the game, focusing on the novel aspects of it: the memory mechanics that modelled how the player character remembers people and events.

Rosemary: The Development Process

The first step of development was determining how memory worked in the game, which is part of defining the variation on the mechanics. As part of the preparation for development, the researcher presented the team with different models of how memory works, such as Pinker's comparison of the human mind with a computer (2005). The developers also went through several brainstorming sessions, in which they reviewed different events and actions related to human memory that may serve as the premise of the game. For example, the team discussed the Rashomon effect, in which the same events are remembered differently by a series of witnesses; they also considered how Alzheimer affects memory, or how humans remember in fragments rather than holistically.

Mnemotechnics, i.e. techniques and principles to organize memories and improve recall, were the key to introduce novelty in the game. The techniques are already a system, which makes them easier to formulate as game rules. Of the catalogue of mnemotechnics, Quintillian's concept of the Memory Palaces appeared to be the most useful as a set of potential mechanics, as well as the most evocative to make a game (Quintillian, 1920, Book XI, Chapter 2). Quintillian's method was meant to help an orator to commit his speeches to memory by turning each topic of his speech into a symbol, which would be then placed in an imagined house or other space he was familiar with. The orator would then traverse the space mentally; by recalling where each symbol was, he reproduced the speech that he had prepared.

Quintillian's Memory Palaces provide a productive model because it is already formulated as a set of mechanics, i.e. arranging memories and associating them with specific locations in order to recall the information. The association of memory with moving through a space also made it a particularly convenient model for videogames, because its implementation can take advantage of the spatial properties of digital environments, as described by Murray (2001), which allow the player to navigate a virtual space. The Memory Palaces could also benefit from the SCUMM model, which encourages players to explore the the game and try arranging memories in different ways without getting punished.

Story Premise

The next step was coming up with a story premise that would suit the concept of the Memory Palaces. After a couple of brainstorming sessions, the team found an intriguing premise that would set in motion the events of the game. The player character finds a photo that evidences that her imaginary childhood friend was a real person. She comes back to her home town, which she has not visited in many years. Nobody lives there any more, so the player explores the environment to trigger off her memories. The goal of the game would be to find out what happened to her friend by remembering people and events that may yield the right clues.

Modelling Memories

The game design evolved from the concept of the Memory Palace and the story premise, so that story and design advanced in conjunction. The mechanics of remembering were implemented as two different features: comparing between the character's memories and the present, and the Memory Palace itself.

Comparing Past and Present

The player can compare what the town looks like in the time the character is in with the way that she remembers it. A switch allows the player to go back and forth between past and present; comparing both versions allows the player to find differences that lead to new information. This feature was relatively easy to implement programatically, although it also doubled the amount of time needed to produce the visual assets. Every background and object needed two different versions, one for the memory and one for the present. The team was very confident they could produce the assets in the alloted time; and the mechanic was novel enough in adventure games that the feature was greenlit. Unfortunately, the estimates of the artists in the team were too optimistic; the assets were produced for four different locations, but the amount of time it took to produce the background of each location made it impossible to expand the number of locations in the game.

The memory/present comparison combined well with the Memory Palace. The player character would remember things by interacting with the environment. When a specific object or person triggered a memory, a symbol representing it would appear in the Memory Palace, which the player could manipulate there. Conversely, as the player solved puzzles in the Memory Palace, new objects and characters appeared in the memories of the town, allowing new interactions with the environment. For example, solving one of the puzzles in the Memory Palace made a lunchbox appear in the memories, which allowed the player to find the lunchbox in the present. It fit well with Quintillian's observation about memory and spaces (1920): "For when we return to a place after considerable absence, we not merely recognise the place itself, but remember things that we did there, and recall the persons whom we met and even the unuttered thoughts which passed through our minds when we were there before." Comparing memory and present aimed at reproducing how remembering events, people, or things may help us see the present in a new light and understand current events better.

During playtesting, this feature proved to be rather successful from the beginning. In every testing session, most players understood that they were comparing two versions of the same location, and that they were past and present. In the second evaluation, when all the final backgrounds were in place, only one player out of twenty thought that the difference was day and night (see Figure 2). Otherwise it the mechanic was easy to understand and play with.

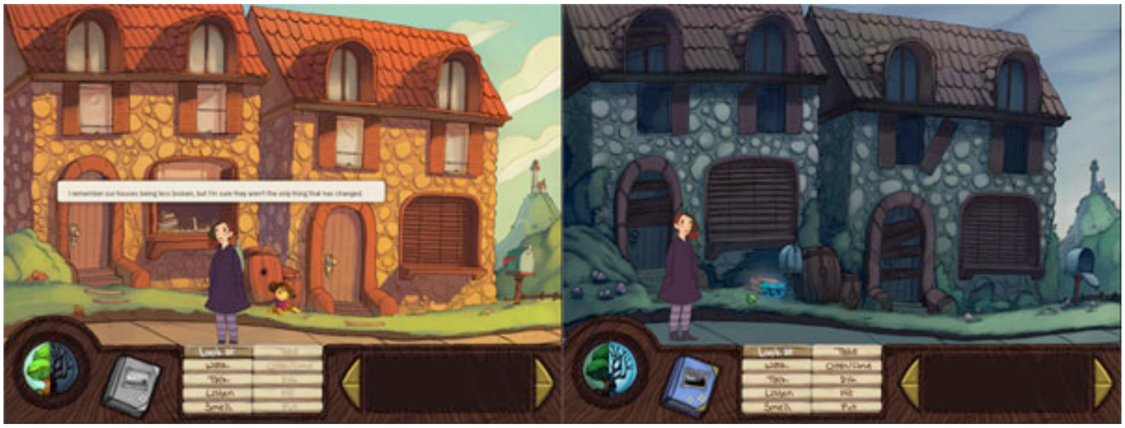

Figure 2: Comparison between memories and present in the final version of the game.

The Memory Palace

The Memory Palace represents the memories of the player character, where they are stored and arranged in order to allow the character to remember information. The mechanics of the Memory Palace primarily consist of arranging and connecting representations of memories.

The first version of the Memory Palace was presented as the interior of a tree house, where the character used to play with her friend (see Figure 3). This was a metaphor, not an actual location in the fictional world of the game. The tree house had a workbench at the front, where the memories would be placed in juxtaposition. If the memories were not connected, nothing happened; if they were, they would be cleared and a new memory would appear.

Figure 3: First version of the Memory Palace: the tree house.

This implementation was problematic, as the first playtesting session evidenced. Seven out of eleven players believed the Memory Palace was a real location in the game, not a metaphorical space—the outside of the treehouse was one of the locations of the game. The player could access the Memory Palace by clicking on one of the buttons in the menu at any time. The problem was that the button only appeared after visiting the outside of the tree house, in an attempt to introduce players to the game one feature at a time. Only four players understood the tree house as the representation of the memories of the character, the rest were not able to establish that relationship.

Another problem was how memories were connected. The player had to place the memories on the workbench; if they were related, they would disappear and make another memory appear in the tree house. In order to show the relationship between two objects, the player had to place them next to each other. Players were rather confused, because the puzzle that taught the the player the mechanics of the memory palace was connecting a trunk and a key. The point-and-click interface seemed to players to drag the key on the chest, trying to use them together, but that was not the right solution.

In short, playtesting evinced that the problems of the first version of the Memory Palace were its unclear metaphorical status with respect to the rest of the game, as well as a confusing interface, in the form of the workbench. Players figured out most puzzles through trial and error rather than understanding how the game worked, which was not the experience intended by the developers.

The re-desing of these mechanics kept the tree house metaphor (see Figure 4), but revised the mechanics of the Memory Palace. The player had to place the memories from the bottom of the screen on the right area of the house, such as a table or a shelf. When two related items were next to each other, they would stay in place, and make a new memory appear. The trunk and key pair was eliminated, since it did not make sense to put a key next to the chest to connect them. Arranging memories in space was closer to Quintillian's description, where the memory had to be in the right place in order to be able to remember. On the other hand, their implementation was somewhat problematic. While the mechanics were easy to implement, the visual assets were very specific. The place of every puzzle had to be defined beforehand; if any puzzle had to be changed or moved, all the visual assets had to be re-done. This would have hampered any further iterations and expansions on the puzzles.

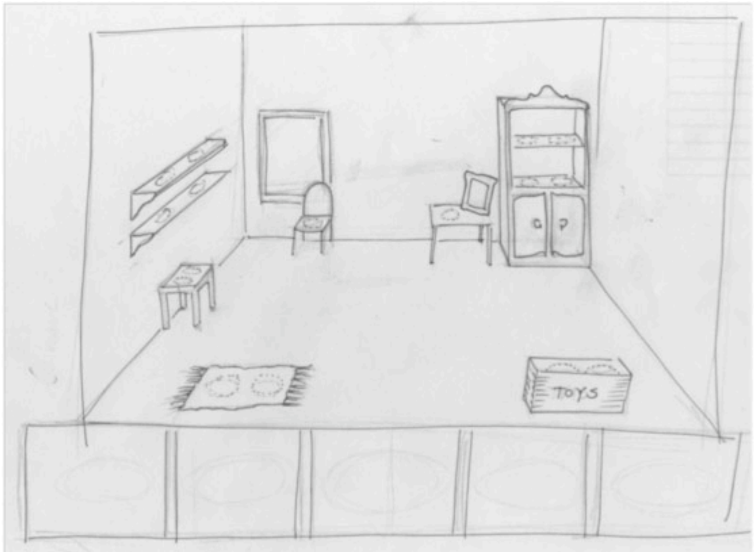

Figure 4: Sketch of the revised Memory Palace as a tree house.

The solution was keeping the mechanics (place the memory in the right area) and changing the metaphor. Rather than using an architectural space, the memory of the player character is represented by a photo album, where a photo stands for each memory (see Figure 5). Every page of the album has two empty slots to put the photos in. Each photography slot has a caption where four words were missing; each photo has two words associated with it, which would fill two of the empty slots. If two related photos are in the right slots, the puzzle is solved, the caption is be completed correctly, and a paragraph explains what the character remembers, providing more information to the player.

The photo album was a success during playtesting, since placing photos on their right slot was intuitive enough to most players; the Mad Libs-like type of mechanics provides further feedback to the player by indicating whether the photos are on the right slot. It was also a more appropriate metaphor—after all, photos are used as mementos of times past. In the final playtest, the photo album was interpreted in a variety of ways, which still helped players complete the game. Five out of thirteen players thought it was a journal where the character noted what happened to her; one interpreted it as "the puzzle of her life". Even if it did not use Quintillian's metaphor, it was also more true to the description of how it worked. After all the slots had been filled, the player can read a series of short stories that tell more of the past events in the town.

Figure 5: Final version of the Memory Palace as a photo album.

Evaluation of the Genre Variation Method

The Genre Variation method demonstrates that player experience is inextricable from the game design process, even when the initial focus of innovation is on the mechanics of the game. The game mechanics are inherent to generating player's experience, so that the degree of innovation and effective design cannot be assessed without playtesting.

Rosemary was a first experiment to evaluate whether it was possible to produce a brief adventure game in an academic environment. The innovation seems successful, since players quickly grasped the mechanics of memory by the second playtest. More significantly, younger players (15-17 years old) seemed to understand the novel mechanics better than the conventional mechanics of adventure games. These players thought that they could control the player character as if it were *The Sims* (Maxis Software, 2000), where the player clicks on a button and the character performs the action, rather than constructing a command by clicking on the menu and then the object on which to operate.

Genre Variation was a successful method to produce a story-driven game in a relatively short period of time (7 months during the academic term, 10 hours a week) with a small team (5 to 7 people at a time per semester). *Rosemary* can be completed in 15 to 20 minutes depending on the familiarity of the player with the adventure game genre. Providing a game that is polished and complete, albeit brief, also produces a much more welcoming attitude during playtesting, particularly in younger players.

The choice of game engine facilitated production, although it also created a series of bugs over which the development team had no control over. The most notable were some rare rendering problems, where the graphics would not load properly or display the wrong backgrounds. This affected the final polish of the game, although did not cripple playtesting.

The problem with this methodology is that it only evaluates one specific instance of the game, rather than comparing a set of different novel solutions to the same problem. This requires making several versions of the same game, or different games about the same problem, which is difficult with the limited resources of an academic laboratory. However, the experience of *Rosemary* has proved that early prototypes can also yield useful playtesting data. The new project based on Genre Variation the researcher is working on is based on building smaller prototypes, using different mechanics based on the same problem, which is modelling the logic of dreams. Each prototype takes the lessons learned on the previous one, and expands on the mechanics. The iteration happens in each game and from game to game, and they are all addressing the same problem.

The Genre Variation method aims at spurring creativity by helping define the problem that must be solved. Game design is thus similar to solving puzzles, a meta-game that developers can also play inventively.

Footnotes

[1] An exception to the rule is interactive fiction (IF) / text adventure games, where all the assets are textual.

[2] Again, Interactive Fiction may be an exception.

Clara Fernández-Vara

Clara Fernández-Vara is a Postdoctoral Researcher at the Singapore-MIT GAMBIT Game Lab. Her work concentrates on adventure games, as well as the integration of stories in simulated environments. She is particularly interested in cross-media artifacts from the standpoint of textual analysis and performance.

Reading the Tea Leaves: patterns of theorisation about design research

1. Introduction

Heterogeneity is regarded as an inherent and significant feature of the emergent and complex field of Design. This pluralism is recognised as an important factor underpinning design's increasingly significant role and position as an 'inter'discipline which is both integrative and an interface and has the potential to bridge traditional divisions such as the 'natural' orientation of sciences and the 'social' orientation of the humanities through a 'third culture' concerned with the 'artificial' (Jonas, 2000). It is also recognised as contributing to the increasing articulation and vibrancy of design discourse. However there is a critical need for greater relational understanding between different theoretical positions and research practices. This paper discusses ongoing research into the development of relational models based on an analysis and interpretation of different design research theories and reflections on how such hermeneutical models might inform the design of information resources about design research methodology.

There is a recognition in the approach taken to this analysis and modelling, that the pre-understandings of an author, of an analyst, reader or researcher, will affect the construction and the understanding of theories. A person using an information resource will approach it through his or her existing knowledge frameworks and historical understandings. This perspective, informed by information hermeneutics, recognises limitations in traditional computational approaches towards the construction of formal information structures as well as the need for greater relational understanding across the diverse concerns of the field.

2. Project context

The problem of design's theoretical complexity and lack of organisation has given rise to a number of different strategies, research groups and conferences that sought to solve, engage with or overlook the issue of heterogeneity. For example the Artificial Intelligence (AI) in Design group sought to develop formal design ontologies as ways of systematising and generalising design knowledge (Brown & Birminghan, 1997); Wolfgang Jonas's online event "Paradox endeavour to design a foundation for a groundless field"(Jonas, 2000) was based on the premise that design "is a groundless field, there cannot be eternal basics but rather arbitrary entry points."(unpaged) and sought to develop understanding through discourse; The 2008 "Undisciplined" Conference by the International Design Research Society, recognised dynamic shifts in the field but deferred the possibility of articulating them, claiming that "Designing seems to be moving into a new era, the disciplines that have framed our work are reshaping themselves, new kinds of designing are emerging and we are not yet able to define these new and hybrid professions." (http://digitalcommons.shu.ac.uk)

A number of limitations caused by, or associated with, the dynamic pluralism and theoretical heterogeneity of design research have been recognised. They include: the difficulty of representing this complex field to people outside the discipline (Buchanan, 2007), the resulting tendency to represent and practice design research through the ill-fitting frameworks of other disciplines (Jonas, 2007), a limitation of understanding and utilisation of the potential and range of available methodological approaches among design researchers (Cross, 2006), inhibition of the development of the discourse of design across different design research communities and approaches (Margolin, 2002), problems concerning the organisation of design knowledge in information systems (Poggenpohl, 2000) and a restriction of the development of new approaches that are needed to address complex contemporary problems that require multiple perspectives (Navarez & Feher, 2000). These problems have led to an acknowledged need for more dialogue and relationality between different theories and approaches. For example, Dorst (2007) has suggested this will require the identification of core assumptions that underpin existing ways of working, and from this, anomalies could be identified and “footholds for a further development” recognised (p.1). Complexity has been recognised as a distinctive attribute of design, arising from the dynamic interactivity of relationships. The need for greater relational understanding across the complex field of design research prompted this inquiry, with contextual and methodological issues that have underpinned this research being the focus of this paper.

3. Methodological Issues

Hermeneutics, as an interpretative activity, has been recognised as a way of approaching design’s diverse frameworks and multiple identities and challenge the fundamental dualisms that have been part of designs formative identity (Coyne and Snodgrass (1991, 1997). Within the methodological framework of this project, two different levels of hermeneutical processes can be recognised: one is concerned with the hermeneutical interpretation of texts, the other with information hermeneutics. These relate to phases of the project that are outlined in this paper; the first concerned with an analysis and comparison of design theory texts; the second with the identification of patterns across theories that might be used to form semantically based information structures. This approach, which builds from theories and perspectives from within the domain, must be distinguished from attempts to develop unified theories of design based on notions of a stable disciplinary core, fixed vocabularies and formal taxonomies. Such approaches have sought to create totalising, theories into which all aspects of design knowledge can be categorised. Buchanan has written:

> Many investigators are tempted with the prospect of a single monistic vision of design, but the diversity of potential monisms suggests that pluralism is an unavoidable reality. The pluralism of design research suggests that design is a field comprised of many fields, each shaped by its own problems and lines of investigation (2007, p.56).

The hermeneutical approach taken in this research recognises that the pre-understandings of an author, and those of a reader, will affect the production and the understanding of a text. In particular the history of design research, its various institutionalisations and the ideas that have informed its different methodological and conceptual developments, underpin our different understandings and interpretations. The significance of historical context is critical here, not only to the interpretation of older theories, but to an understanding of the present: “Any present is never just its present situation, but always also a particular version of the past that makes sense of the version of the future that the present is working on” (Tonkinwise, 2006, p.55). This recycling and dynamic of theories and methodologies of design research has been recognised by Jonas as a generational cycle: “We have ‘theory generations’ which are not ‘true’ or ‘false’ but ‘fashionable’ and ‘appropriate’ or ‘outdated’ and ‘inappropriate”(1999, unpaged). In this context the basis of the discipline of design is considered as a history of theories or discourses about design, rather than a history of objects, famous designers or styles. This perspective recognises the field of design research and its discourse as inherently unstable, but productive, because of this dynamic. Buchanan, (2007) has also identified this cyclical and historically inscribed process of design research theory building: “They have risen and declined in popularity but they have all persisted and been available when one or another embodiment of a strategy has temporarily run dry or has suggested further problems for which a different strategy was needed. Their interplay accounts for much of the vitality of the field” (2007, pp. 56, 57). However the history of design research is unevenly recorded and access to historical material to help better contextualise and understand design research theories, and enrich the broader discourse of design research theory is still limited.

This project has involved the identification, analysis and modelling of some twenty design research theories. These were selected from a review of over eighty texts produced between 1983 and 2008, which were drawn from across the spectrum of writing about design; from books, journals, conference papers, websites and theses. The selection of texts was made to represent a range of authorial perspectives and to include a variety of different theoretical understandings and approaches to design research, representing a broad historical and epistemological spectrum. A number of factors were taken into account when making the selection of texts for detailed analysis. For example, texts had to address the field or parts of the field of design research. They could not be based on specific design research projects, case studies, problems or applications, as such approaches tend towards description and generally provide a limited basis for research theory building. Texts focusing primarily on other areas of design as a discipline such as design practice, design history, design management, design education or design policy were also disregarded. While recognising that much can be drawn from these domains and productively related to the discourse of design research, such dimensions were beyond the scope of this initial inquiry. Other factors, which also influenced the selection of texts for more detailed analysis, included: the level of ontological or epistemological focus in a text – that is the author’s consideration of the nature or organisation of design and its knowledge, whether an author sought to give an overview of the field rather than detailing a personal observation or favoured methodological approach, the clarity and level of consistency across a theory was taken into account, the impact and significance of a theory - identified through citation, the standing of the publication and the profile of the author - was also taken into consideration. Research theories from other disciplines were excluded, unless such approaches had been significant in the development of design research, or had been adapted, reframed and used effectively in the field of design research.

Once an initial ten texts had been identified and analysed, some further criteria for selection were developed in relation to the overall range and focus across the group of selected texts. For example, further consideration was given to the relative depth and richness of some theories in comparison to the breadth and relative thinness of others. The selection of texts was not made systematically in that there was not an attempt to represent every major theoretical text or possible approach to design research, nor to create a definitive mapping of all the literature across the field. Rather, a representative selection was made of texts that, as a group, presented a diverse range of theories through which different approaches, understandings and relationships between different conceptualisations could be traced and explored. This involved the selection of a number of different texts that represented a range of theories and approaches so that the potential development of a relational overview, built from patterns identified across the dynamic and heterogeneous field of design research, could be explored .

This approach can be described as an a-posteriori approach, based on literary warrant. That is, information categories are developed from a study and analysis of literature from the field. Frohman (1983) has identified two different approaches to semantic analysis: Firstly, categories can be given a-priori as part of the meaning of a term for a concept. Such categories can be determined before examining the literature of a field and are usually based on established ontological beliefs or associated epistemological schema. The second approach locates categories within the specific discourse of which the associated term is part. Thus semantic relations are formed a-posteriori and can only be determined after an examination of the literature. Within the field of information science, such categorisation is regarded as more adequate, because it is contextually related, but less likely to be universal. The issue of “the degree to which the categories devised by human ontologists should be thought of a universally applicable or objective, as opposed to artifacts of particular contexts” has been recognised by Legg (2007, p. 425) as having “…bedeviled philosophical ontology from the beginning.” This issue continues to underpin debates about formal and applied ontologies in information science, and underpins debates about canonicalization and decentralisation, in relation to the development of new information technologies like the semantic web.

It also resonates with the fundamental ontological schism, based on overarching binary models, that informs much design research theory, described by Coyne and Snodgrass, (1991) as design’s dual knowledge thesis. In particular, the polarity between the rational, systematic approach of design science and that of intuitive, tacit, practice-based, approaches has underpinned much discourse about design research over the last forty years. Victor Margolin (2002) has suggested that such divisions are part of a history of institutionalisations and disciplines: “… between those practices that have traditionally been recognised as intuitive and aesthetic and hence located in schools of art, and those seen as technical and thus founded in colleges of engineering and computer science departments.”(p.29). He suggests that these divisions are cultural rather than epistemological, and that “the different ways of valuing aesthetics and technical knowledge are deeply embedded in the culture at large and have prevented greater communication among designers.” (p.31) The need to interrogate and re-negotiate these fundamental dualistic underpinnings and find new ways of articulating and researching design outside the confines of these historical divisions, has been recognised by a number of design theorists and has led to the development of some more nuanced interpretations. Certain models engaging with the nature of design research, the objects of its study, the ways design research is conducted or the form and nature of the knowledge it produces, have moved beyond this longstanding, dualistic framework. However research and literature which attempt to relate, critique or systematically analyse this body of design research theory are still limited.

The development of design research and its associated discourse has seen a significant growth in the quantity of published research findings. While the focus of much design research has been on processes of designing and the development of methods and tools to enhance the efficacy of design processes (Dorst, 2007), inquiry into other aspects of design is growing. However research and the development of the broader, reflexive discourse about the nature and scope of design research is still fragmented. This has made it difficult to organise, access and articulate the growing body of 'design knowledge' generated through design research, beyond specific professional or paradigmatic frameworks. A singular framework can't represent the diversity of design research approaches and understandings. This diversity places design research in a unique position, to engage and develop interdisciplinary understandings and methods to support cross disciplinary teams that are necessary for the development of new or improved technological and systemic approaches. To fully engage in any interdisciplinary process, design researchers need to be able to understand and draw from different disciplinary approaches as well as from emerging, designerly ways of thinking and researching. Nelson and Stolterman (2003) have noted:

> "Every chosen form of inquiry – intuitive, artistic, scientific, logic or a composite thereof – will lead to a specific body of knowledge. The chosen form of inquiry influences both what constitutes knowledge and how knowledge is gained. Each particular approach is based on some fundamental assumptions concerning what it means to create knowledge" (p.38).

However, the choice of approach to design research is often based on individual experience or institutional conventions, rather than through the review or identification of the most appropriate research process, or the questioning of fundamental assumptions behind a given methodological approach. While bodies of theory have developed in relation to specific forms of design inquiry there has been little focus on the development of relational understanding across these different areas and approaches. This project seeks to engage with design research theories and analyse them in order to try and understand, trace and relate the different conceptualisations, strategies and process that they articulate.

4. Mappings

The process of recording the analysis of a text, in terms of its key concepts and arguments, was made using concept mapping software, a process that enabled a level of structural and semantic representation. Jonassen, Beissner and Yacci (1993) suggest that structure is a way of identifying and representing the nature of patterns and relationships of entities. Structural knowledge has been described as a way of describing the knowledge of how concepts within a domain are interrelated. Concept maps are also known as semantic frameworks or networks. John Sowa (2000) defines semantic networks as "graphic notations for representing knowledge in patterns of interconnected nodes and arcs."

Concept maps, based on the work of Novak and Gowin (1984) into human learning and knowledge construction can be built using software called C Map tools. Concept maps were developed as a method for representing and communicating knowledge in Novak's early work on evaluating knowledge acquisition in science education. The structuring of concept maps is based on concepts, as primary elements of knowledge, and propositions, as relationships between concepts, to form a semantic unit. They can be used to produce an adjustable visual map representing the main concepts, concept relationships and thus ideas conveyed in a text. Two kinds of relations can be recognised using this approach to building a representational structure: between concept (c) – preposition (p) – concept (c), or between preposition (p) – concept (c) - preposition (p). These forms of mapping are not the same and offer quite different diagnostics. In developing robust C Maps both sets of relationships need to be considered. The c-p-c approach focuses on the relationship between subject and object, while the p-c-p approach tends to focus on the flow and location of concepts within the overall argument. In this flow an object in the first semantic unit can become the subject in the next. This mapping process attempted: to trace the ideas and flows of particular theoretical arguments made in texts, to identify certain similarities and distinctions across groups of theories and assist the identification of patterns and the development of composite models across groups of theories.

While attempting to 'map' particular theories as C Maps the actual terms and conceptualisations of authors were maintained as far as possible, so that the models were more proximate to concepts and arguments of a text. However, following the initial mapping of individual texts, some propositional terms were adjusted to facilitate comparison and relationality within and between different texts. These adjustments were made for purposes of clarification, rather than deliberately change meaning, however it is acknowledged that any such adjustments are interpretive and thus involve the researcher's own understanding in the development of the knowledge model.

5. Evaluating interpretations

Snodgrass and Coyne suggest that the main criterion for the hermeneutical assessment of a model is the degree of correspondence it has to what it models (1992, p.69). However, models are representations and so are necessarily incomplete. The models were considered in two respects: Firstly in relation to C Maps made about the particular design research theories of an author. It was recognised that any such modelling can only be an interpretation, and will involve assumptions about authorial intent and limitations of understanding on the part of the researcher. That is, such a modelling process cannot be completely objective. The intention was to approach the text openly, to try and find out more about the context it was produced in and to represent and reflect on key ideas and outline the argument of a text. This intention guided decisions made about the selection of key concepts and the form of the argument through the identification of propositions. This process saw the C Maps adapted over a number of readings with shifts in understanding of a particular theory occurring during this process. Secondly, through composite C Maps, which were developed to identify and represent common approaches and concepts across theories. This required the types of conceptualisation and reasons for associating particular concepts a cross different theories to be clarified and articulated. The process moved from an analysis of specific theories to a more associative interpretation of ways these theories could be correlated. The relevance of the C Map models was judged through an iterative process of correlation between the model with the original text or groups of texts. Most models required several re-readings, adjustments and stages of remodelling, until the level of correlation was considered to be satisfactory. That is, until it was felt that the main argument of the text could be traced in the C Map.

During a further process of evaluating the results of the analysis and identification of relational areas between different theories, consideration was also given to other writing about approaches and attitudes to research made by tertiary educational theorists who were involved in research about the nature and perceptions of academics towards research. Some strong correlations were identified, supporting the conclusions of the analysis of design theories. Angela Brewer (2001) and Gerlese Akerlind (2008) suggest that researchers, both within and across different disciplinary fields, have specific conceptions of the value and approaches they take to research. In particular Akerlind (p.22) identifies approaches that delineate academic's views of the nature of research which she summarises as: intentions, outcomes, questions and process. These were considered in relation to the shared conceptualisations that were identified through the analysis of design research theories in this project. This comparative approach indicated some fundamental perspectives on the nature of research and values ascribed to the activity of research, that were shared by groups of academics across different disciplines and institutions, and approaches taken to the theorisation of design research. These perspectives would seem to indicate that individual sensibilities or contexts might influence the way researchers understand research, and that this can be quite distinct from a disciplinary perspective. While these are informal categories they suggest some types of pre-understandings that can be correlated not only to the ways some design research theorists have framed or modelled particular theories about design research, but to different ways design researchers may tacitly understand or approach research. In this context it was proposed that these types or categories of models of design research could provide more personalised pathways - related to a researcher's implicit approach to research rather than their explicit understanding of theories about the domain of design research - through which information can be accessed and explored.

Capurro and Hjorland, (2004) have recognised the difference between the representation of information "in domains that have a high degree of consensus and explicit relevance criteria," - like science- and domains - like design - that "have different conflicting paradigms, each containing its own more or less implicit view of the informedness of different kinds of information sources" (p.395). They describe this domain analytic approach as hermeneutic because any understanding is determined by "the pre-understanding of the observer" (ibid). If these ways researchers, in general, tend to describe their approach to research can be correlated with an analysis of design research theories, these frameworks may provide a useful and usable way for design researchers to access information about design research: "With the statedness of a part of a community background in a system, the inquirer can match his/her questions and backgrounds of pre-understanding against it" (Capurro, 2000, p.4). Information hermeneutics has provided insight into ways that the problem of the limited forms of representation and accessibility to design research knowledge might be approached.

This inquiry was concerned with understanding design research theories and the ways relationships between theories might be modelled or represented as systems of theory, or theories about theory. The process of identifying relationships and common approaches between different theories and groups of theories was not aimed toward the development of a unified or meta-theory, but was guided by a recognised need to represent the pluralism of design research methodology, to inform the creation of a resource that could be accessed through multiple perspectives. These perspectives would be relevant to the prior understandings and knowledge of the researcher about research and the design discipline. A meta-theoretical approach implies a cohesive, overarching model that has not been, and may not be possible in a diverse and heterogeneous human science like design The C Map models – as models of theories by particular authors and as composite models of groups of types of theories - were developed to represent the ideas and forms of particular design research theories and the commonalities and divergences between different theories. This approach was developed to better represent the pluralistic understandings and approaches to design research. This hermeneutical approach to knowledge representation can be contrasted to logic based models which have tended to dominate approaches to design's ontological and epistemological framing. Coyne, Snodgrass and Martin have suggested that models are metaphors which cannot be assessed by logic but by the criteria which apply to matters of interpretation: "… the semantic and disclosive functions of models are not founded on their logical structures but on their metaphorical structures. Models are metaphors and metaphors convey their meanings by way of a hermeneutic understanding"(1992, p.56). They suggest that such hermeneutical metaphors should "replace the logic based models that have driven design research over the last fifty years" (1992, p.69.) Logic based models are built on assumptions of realism and fixed definition, while metaphors are interpretive - they do not claim to be the same as the actual thing they represent. As interpretations they are never closed or sealed. This metaphorical approach would seem to be more closely aligned with a conception of design which must always remain open to possibilities.

6. Conclusion

Through a process of relating, comparing, mapping, analysing and remapping theories, different strategic approaches and conceptualisations of design research were identified. While the emergence of these groupings across a number of different theories confirmed certain patterns of approach, there were some hesitations about the relevance and robustness of the identified categories. There was little work done in this field with which to compare these results. The value of this categorisation is being considered in terms of the way it might be used to inform the basis of a practical application in the form of an information structure and system to organise and relate information about design research theory . According to Gadamer, (1976) the validity of an interpretation can be gauged through the degree to which it gives rise to new insights and new disclosures of meaning, and the way it stands up to the test of its practical application. Snodgrass and Coyne, (1992, p 68) also recognise the importance of application: "The assessment of the validity of a metaphor or … model proceeds by an appeal to its potential deployability, arrived at by projective anticipations and not by objective logic or subjective intuition” (p 69). The strategy being taken to further test this analysis is through the development of a design for an information structure. Through this approach, different types of ‘informed-ness’ can be explored to support the organisation and access to information and to introduce more relational understandings.

The Complex Field of Research: for Design, through Design, and about Design

Lois Frankel, Concordia University, Carleton University, lois_frankel@carleton.ca

Martin Racine, Concordia University, mracine@alcor.concordia.ca

Abstract

The concept of design research is evolving through the literature, on-line discussions, and conferences. They revolve around defining what research is and where it belongs in design education and practice. This paper provides a framework for understanding the approaches to design research that builds upon existing overviews of the field provided by Bruce Archer, Richard Buchanan, Nigel Cross, Christopher Frayling, and Ken Friedman, among others. It begins with a brief history of design research to provide a foundation for understanding that research has been an integral part of the field of design since the early twentieth century. It then discusses the difference between clinical, applied, and basic research, providing an overview of the variety of approaches in each area. It is intended to serve as a guide to the discussion and provide a map of the literature. It is not intended as a detailed description or evaluation of the approaches or to serve as a vehicle for learning the methods, techniques, or theories of design research.

Keywords
design research; applied research through design; clinical research for design; basic research about design.

This paper, which is based on a literature review, presents a range of viewpoints about design research and provides a taxonomy with the objective of reducing some of the confusion and crosstalk. It gives a brief historical overview to indicate the context of the discussion and relationship of the various approaches. It is intended to serve as a guide to the discussion and provide a map of the literature. It is not intended as a detailed description or evaluation of the approaches or to serve as a vehicle for learning the methods, techniques, or theories of design research. It begins with a brief history of design research in the twentieth century.

A Short History of Design Research

In his book, *Designerly Ways of Knowing*, Nigel Cross provides a concise background of events in the twentieth century that contribute to the contemporary discourse about design research (2007a: 119-127). He conjectures that the systematic 1920's Modern Movement designers, such as Le Corbusier, established the groundwork for the1960's Design Methods Movement. It was believed that design methodology could prescribe an orderly, systematic procedure for arriving at a design solution through "diagnosis followed by prescription" (Downton,2003: 39; Gedenryd,1998). According to Henrik Gedenryd, the 1962 Conference on Design Methods established design methodology, the procedures or methods for designing, as a valid scientific research subject (1998: 19). This view was disseminated by other design thinkers including Christopher Alexander, John Chris Jones, Buckminster Fuller, and Herbert Simon (Alexander,1964; Downton,2003; Jones,1970; Simon,1969; Zung,2001). In 1966 the founding of the Design Research Society in England, and later initiation of the Design Studies Journal further supported this perspective. The approach remained influential throughout the 1970's and persists to today. More publications dedicated to this sort of design research emerged; *Design Issues* in 1984, *Research in Engineering Design* in 1989, the *Journal of Engineering in Design* in 1990, *Languages of Design* in 1993, and the *Design Journal* in 1997 (Cross,2007b: 47; Downton,2003: 41).

1981 Bruce Archer published *Systematic Methods for Designers* providing guidelines for generating objective knowledge for "design, composition, structure, purpose, value and meaning of human-made things and systems" (Bonsiepe,2007: 27). Archer describes the science of design research as:

- systematic because it is pursued according to some plan;
- an enquiry because it seeks to find answers to questions;
- goal-directed because the objects of the enquiry are posed by the task description;
- knowledge-directed because the findings of the enquiry must go beyond providing mere information; and
- communicable because the findings must be intelligible to, and located within some framework of understanding for, an appropriate audience (1995: 6).

In contrast, in the early 1970's some design researchers, including John Chris Jones and Christopher Alexander, began to reject the design science approach. Rittel and Webber posed the most severe challenge with their concept of wicked problems, which pointed out, among other things, how inadequate a sequential structured methodology was for understanding complex design problems (Cross,2007b: 42; Gedenryd,1998: 57). There are ten characteristics of "wicked problems" that make them ill defined, including the impossibility of formulating an exact problem due to the complexity of evolving variables that make it difficult to arrive at one definite solution (Buchanan,1992; Downton,2003: 43; Rittel,1973: 161-167). Wicked problem theory presented an alternative to the scientific approach that had been attributed to design research.

According to Cross, "method may be vital to the practice of science (where it validates the results) but not to the practice of design (where results do not have to be repeatable, and in most cases, must not be repeated, or copied)" (2007b: 43). Cross also notes that, in 1983, the late MIT professor, Donald Schön "explicitly challenged the structured doctrine underlying much of the 'design science' movement, and offered instead a constructivist paradigm[1]" (Cross,2007a: 123). Schön says:

> I begin with the assumption that competent practitioners usually know more than they can say. They exhibit a kind of knowing-in-practice, most of which is tacit…Indeed, practitioners themselves often reveal a capacity for reflection on their intuitive knowing in the midst of action and sometimes use this capacity to cope with the unique, uncertain, and conflicted situations of practice (1983: viii).

Schön was developing his theory much like a social scientist does, based on an analysis of actual design processes, rather than forcing them to fit into prescribed and structured methodologies. Simultaneously, social science researchers were beginning to apply ethnographic field research into the work activities and local knowledge of technologically connected work communities to help designers better understand the needs of their users (Frankel,2009a; Wasson,2000:380). These approaches continue to influence industrial designers today.

[1] A constructivist or interpretive paradigm, defined by Denzin and Lincoln is " a relativist ontology (there are multiple realities)… and a naturalistic (in the natural world) set of methodological procedures" (2005: 24). The main goal is to come to understand the relations between people, their activities and their physical environment. In the words of Frederick Erickson, a constructivist approach is to see the familiar through different eyes by continually asking "Why is this_______(act, person, status, concept) the way it is and not different" (Erickson,1984; Frankel,2009b).

Buchanan says, “What I believe has changed in our understanding of the problem of design knowledge is greater recognition of the extent to which products are situated in the lives of individuals and in society and culture” (2001:14). Now, according to Buchanan, a significant challenge is “to understand how designers may move into other fields [such as the social sciences] for productive work and then return with results that bear on the problems of design practice” (2001: 17). This idea seems radical in comparison to preceding approaches to design research, but represents the crux of complexity in current design research considerations.

As noted earlier, today’s prevalent interpretation of design research focuses more on processes for prescribing designed products and fails to provide an explanatory framework for the subjects of design content, the designer, and the design context (Dorst,2008: 5). According to Forlizzi, Stolterman, and Zimmerman the design community is taking note and design research and design practice are evolving “new design theories and new theories of design” (2009: 1). This paper aims to chart the prevailing design research theories discussed in the literature, but first it is important to establish a common ground by discussing design and design research.

Design and Design Research

There is no single common definition of design and some definitions even seem to contradict each other. Many design theorists talk about the activity of design as separate from the artifact and the designer, albeit undertaken by designers. Guy Julier places a material culture emphasis on “Design”– as the designed *artifact* which has been raised to elite cultural status in the media and business interests (2008: 103). On the other hand, Sanders, sees design as a distributed collaborative *activity* for researching conceptualizing, and developing improved or innovative products in which the designer no longer plays an expert role (2008: 13). Indeed, the word “design” is both a verb and a noun (Friedman,2000: 8; Gedenryd,1998: 43; Glanville,1999: 81; Julier,2008: 4; Lawson,2003: 3). The verb comes from the Latin root *designare* meaning to specify and the noun comes from the root *signum* meaning sign or specification (Gedenryd: 42). Therefore in this paper, design is an activity for planning and implementing new products, which includes the byproducts of the processes involved such as drawings, models, plans, or manufactured objects.

The research activity related to design is exploratory, and is both a way of inquiring and a way of producing new knowledge (Cross,2007a: 52; Downton,2003: 1). According to Buchanan the approaches to new design knowledge can be broken into the three categories recognized by universities, corporate and governmental funding agencies (Buchanan,2001: 17; Friedman,2000:18). These form the basis of the taxonomy presented here and are discussed in greater detail below:

Clinical Research

Clinical research focuses on design problems that are specific and individual cases requiring information for that unique situation. For example, the design of a particular walking aid for one company would require research specific to that project, that would involve gathering wide-ranging information about users, environments, materials, and competitive products. This sort of research may be documented in a case study or journal article. The common trait of case studies is that they assemble information or data that may give insight into problems that reach beyond the individual case (Buchanan,2001: 18; Friedman,2000).

Applied Research

Applied research focuses on investigating general classes of design problems or products. The common trait of applied research is the [systematic] attempt to gather from many individual cases a hypothesis or several hypotheses that may explain how a class of products takes place, the kind of reasoning that is effective in design for that class (Buchanan,2001: 18). An example of applied research occurs in the area of inclusive design, which focuses on classes of design problems that may exclude users of different abilities (Keates & Clarkson,2003). This sort of research, developed through long-term academic investigation, often generates the kind of knowledge that designers can apply in their clinical research (Downton,2003). Buchanan thinks that applied research is critical to advancing the understanding of design because it can establish connections among many individual cases (2001: 19). Buchanan and Friedman both stress the importance of systematic inquiry (Buchanan, 2001: 18; Friedman 2000: 19).

Basic Research

Basic research focuses on empirical examination of fundamental principles that lead to developing theories about design that has far-reaching implications for the discipline (Buchanan,2001). Bruce Archer developed a series of design topics worthy of basic –and, in some cases, applied– research investigations: *Design taxonomy*, for example was to focus on the classification of phenomena (observable activities) in the design area; *design praxiology* referred to the nature of design activity, its organization and its apparatus; while *design epistemology* was to be concerned with identifying special designerly ways of knowing, believing, and feeling (in Margolin,2002: 247). Nigel Cross adds another category to Archer's list: *design phenomenology* which is "the study of the form and configuration of artefacts" (2007b: 48).

Bruce Archer had a strong influence on several design researchers; especially on Nigel Cross who uses Archer's lecture notes to provide a current description of what good research is:

Purposive:	based on identification of an issue or problem worthy and capable of investigation
Inquisitive:	seeking to acquire new knowledge
Informed:	conducted from an awareness of previous, related research
Methodical:	planned and carried out in a disciplined manner
Communicable:	generating and reporting results which are testable and accessible by others (2007a: 126)[2].

Since Cross points out that these features are not unique to design research, the next section looks at those that are much more closely aligned to design.

Design Research Strategies

This section attempts to align the approaches discussed in the literature, building on the previous discussion about clinical, applied, and basic research areas. The literature refers to three categories of design research, attributed to Sir Christopher Frayling who apparently derived them from Herbert Read (Archer,1995 as transcribed by Rust in 2009; Frayling, 1993:2; Friedman, 2008; Newbury, 1996:2). They are: research for design; research through design; and research about design (Archer,1995; Cross,2007a; Downton,2003; Findeli,1999; Frayling,1993; Friedman,2003; Jonas,2007). These map closely with the three categories of clinical, applied, and basic research.

[2] Cross does not mention "replicable" which involves coming to the same conclusions when repeated. This is a concept that is not well received in the field of design, as mentioned earlier.

Clinical: Research for Design

Downton, whose book, *Design Research,* is organized according to Frayling's three categories, calls this area "research to enable design". This research area provides the information, implications, and data that designers can apply to achieve an end-result in their design projects (Downton,2003; Forlizzi et al.,2009). Downton describes this category as primarily prescriptive research methods for specific and feasible design solutions. He gives an example of a Cadillac design team that purchased and dissected a BMW to examine its inner workings (2003: 20). He also identifies some kinds of data that apply to clinical design research: "establishing pertinent regulations & standards, finding the appropriate formulae, finding meterological data, finding performance specs of materials or equipment, obtaining data on human physical characteristics & understanding human behaviour" (2003: 22-28).

According to Archer, "There are circumstances where the best or only way to shed light on a proposition, a principle, a material, a process or a function is to attempt to construct something, or to enact something, calculated to explore, embody or test it" (1995: 11). He calls this approach "Action Research" (also called practice-led research by Rust, 2007, activity-based research by Kumar and Whitney, 2003, design-oriented research by Fallman, 2005, and action research-by-project by Archer, 1995), after Frayling, or "systemic enquiry conducted through the medium of practical action; calculated to devise or test new, or newly imported, information, ideas, forms or procedures and generate communicable knowledge" (1995: 11). The practical action approach includes usability testing or user testing, in which methods are used to "measure a [specific] product's ability to satisfy the needs of the end user (accessibility, functionality, ease of use) while also meeting project requirements (budget, size, technical requirements)" (Visocky O'Grady,2006: 52).

Notably, research for design is the category of research that most practitioners and many academics associate with the term "Design Research," perhaps because it has the most potential to contribute to successful design outcomes (Dorst,2008; Friedman,2003; Roth,1999). This singular focus warrants some explanation. According to Friedman, " in today's complex environment", a designer is charged with rapidly progressing from identifying problems to realizing solutions, usually in multi-disciplinary teams. He argues that, in addition to traditional visual and material skills, designers require the capability to analyze, synthesize, organize, and evaluate within specific and uniquely different clinical situations. Design practice is therefore closely linked to research training even though "no single individual can master this comprehensive background stock of knowledge" (2003: 511). As noted earlier, since design research is a more recent phenomena in academia few practitioners have been trained in research methods (Friedman,2000: 15; Roth,1999: 18). In this category, both quantitative and qualitative research methods may be appropriate (Roth,1999: 22- 25).

Quantitative research involves objective and systematic data collection and analysis in the form of quantitative measures that are statistically valid, and fits well within a design science paradigm. Quantitative research is associated with unbiased logic, measurement, and separation between the researcher and the subjects (Sanghera,2007). In this case the size of the sample population has to be large enough to be able to accurately predict and generalize the results to the population at large (Ladner,2007). Roth provides some examples of quantitative research: written surveys; demographics; statistical analyses; anthropometrics; structural testing; and standardized tests (Roth,1999: 23).

According to Denzin and Lincoln, editors of the *Sage Handbook of Qualitative Research,* "qualitative researchers study things [and people] in their natural settings, attempting to make sense of, or interpret, phenomena in terms of the meanings people bring to them" (Denzin & Lincoln,2005: 3). Qualitative research can include: observation/notation; personal interviews; diaries and self-reporting; video ethnography; focus groups; contextual inquiry; and activity analysis (Denzin & Lincoln,2005: 3; Roth,1999: 22). Qualitative research is subjective since it focuses on describing and interpreting people's meaningful experiences though the eyes of the people involved and it does not matter how many people are included in the sample (Ladner,2007). Qualitative research is associated with discovery, description, understanding and shared interpretation in which the researcher-personal biases and values- is part of the process (Sanghera,2007).

Design consultants Jenn and Ken Viscocky O'Grady note that researchers may use primary research methods (original research that they generate) or secondary research (research findings that have been previously published by an outside party) (2006: 19). They also explain the concepts of formative (aids in problem identification and problem solving) and summative (aids in framing and deciphering the outcome of an investigative process) research (2006: 20).

Many of the methods briefly mentioned in this section could generate findings that are relevant beyond the scope of one clinical situation, but often they are inadequately developed in practice. How does this practical research become knowledge in the field of design, especially when the particular processes employed in contractual research for design are often protected by non-disclosure agreements? The discussion about research through design begins to address this issue.

Applied: Research through Design

The literature is divided about the meaning of Frayling's ambiguous phrase "research through design" (Jonas,2007: 190). Findeli differentiates it from research for design by associating "through design" with theory and "for design" with practice (1995: 2). Jonas considers research through design the only genuine research paradigm because it is here that new knowledge is created through an action-reflection approach (2007: 189-192). In this approach, the emphasis is on the research objective of creating design knowledge, not the project solution. This may also be called project-grounded research and/or research-oriented design (Fallman,2003; Findeli,1995: 2; Jonas,2007: 192). According to Schneider, research through design may combine the practice-based research approach of practitioners with reflection and a research question that "is not restricted to the product on which research is being conducted" (Schneider,2007). His view is similar to that stated by Friedman:

> Design is both a making discipline and an integrated frame of reflection and inquiry. This means, that design inquiry seeks explanations as well as immediate results"(2000: 20).

The most important aspect of research through design is that it seeks to provide an explanation or theory within a broader context. Buchanan calls this a "Dialectic Strategy" (2007: 57). To Downton, the value of this kind of investigative theory is that it explains and also becomes " a vehicle for acquiring and shaping knowing" that assists in future design activities (2003: 77). Buchanan calls it "Productive Science" and includes the study of form and function in relation to human activity, as well as the study of materials (2007: 63).

This category is unique for several reasons: it is derived from and valuable for practice; it is growing rapidly; both practitioners and researchers are contributing significantly to the literature and on-line discussions; the discussion is extensive, addressing hundreds of approaches; and much of the subject matter has been derived from the social sciences, business, and marketing. Systematic design methodologies form much of the literature in the research through design category (Buchanan,2007; Cross,2007b; Dubberly,2005).

In recent years, human-oriented design methods feature prominently as a separate area of research in the current design discourse (Hanington,2003; Roth,1999; Rothstein,2000; Sanders,2006, 2002; Squires & Byrne,2002; Woo,2007). In her evolving map of design research methods, Sanders represents the range of attitudes towards human-oriented design, from the expert mindset and the participatory mindset, in both research-led and design-led inquiries. In the more traditional expert approach, such as in human factors (also called ergonomics), she says design researchers see themselves as experts and they see the people they are researching (and designing for) as "subjects," "users," "consumers," etc. Whereas the Scandinavian inspired participatory approach sees design researchers collaborating with the people, who are being served by design, as co-creators in the process (2008:13-15). Other human-centered research areas that fit into her model include "design and emotion" that investigates people's emotional interactions with products (Design & Emotion,2009; Green & Jordan,2002) and "experience design" that focuses on the relationship between people and their experiences with products, services, events, and environments (User Experience,2009; Woo,2007: 3-4). Brenda Laurel's book, *Design Research: Methods and Perspectives* is one of many that present human-oriented methods adapted "from the applied social and behavioral sciences and/or from engineering: human factors and ergonomics, applied ethnography, and usability testing" (Holzblatt & Beyer,1998; Laurel,2003; Sanders,2008: 14).

At The Institute of Design at Illinois Institute of Technology, graduate students working with Professor Vijay Kumar and Vincent LaConte have assembled a poster documenting ninety-three methods, indicating where they belong in the following five iterative design modes: definition (sense context); research (know context and know users); analysis (frame insights); synthesis (explore concepts and frame solutions); and realization (make plans) (Kumar, LaConte, & Students,2007). The Design Consultancy IDEO has published the *IDEO Methods Cards* documenting fifty-one techniques for researching human-centered issues (Moggridge,2007). While these methodologies are applied in clinical research, they belong in the design through research section because they are part of the general theoretical knowledge base about how to do design research. In addition research can also investigate and generate knowledge about fundamental design epistemologies, as discussed in the next section.

Basic: Research about Design

Findeli describes much of the research about or into design as the work that is "carried out under the heading of other disciplines (sociology, psychology, semiotics, economics, history, etc.... of design" (1995: 2). He appears to believe that this represents the most prevalent kind of design research available. According to Schneider, the research areas include history of design, aesthetics and design theory, as well as the analysis of design activity (2007).

Buchanan calls this area of research "design inquiry" and he sees it as searching for "an explanation in the experience of designers and those who use products" (2007: 58). He breaks this into two categories: "the discipline of designing" and "creativity of the designer". Cross also believes this area addresses "the nature of design activity, design behaviour, and design cognition" (Cross,2007a). He focuses much of his research on "designerly ways of knowing," which is discussed in considerable depth in the design research literature (Bonsiepe,2007; Dorst & Cross,2001). Findeli and Cross acknowledge the importance of understanding the unique forms of knowledge that contribute to designers' creative skills and awareness (Cross,2007b: 46; Findeli,1995: 3). Dorst and Cross break down designerly activities into a long list of meta-activities (such as creating ways to keep on learning from their design activities, creating a view about design quality, and constructing a design argument, among others). They also identify characteristically different approaches to design problems for designers with different ranges of experience and discuss how they work together (Cross,2007a: 12, 46, 51; Dorst,2008: 9 & 10).

Another fascinating area in which substantial research has been done is in defining the design problem[3], which falls into the category of designerly ways of knowing. In his PhD thesis, Henrik Gedenryd points out that while a designer is expected to solve a problem, in fact "producing the problem is the [significant] work that the designer must do" (1998: 69-70). Lawson, in reference to Rittel and Webber's "wicked problem" theory, says that, "it seems more likely that design is a process in which problem and solution emerge together" (2003: 47). Buchanan refers to the process of discovering the problem as "rhetorical inquiry", which is partly verbal and partly in "the sketches,

[3] It is fascinating because this is the fundamental understanding a designer needs to have to be able to do his or her work and this is often not explicitly acknowledged in our traditional industrial design curriculum.

models, and prototypes that are characteristic of design work" (2007: 64). Schön calls this activity "problem setting" in which, "we select what we will treat as the "things" of the situation, we set the boundaries of our attention to it, and we impose upon it a coherence which allows us to say what is wrong and in what directions the situation needs to be changed" (Schön,1983: 40). Dorst and Cross refer to this as "defining and framing the problem" (2001: 431-432). Cross, Dorst, Downton, and Gedenryd adopt Schön's view that the sketches, models, and other primarily visual representations designers develop while evolving their concepts are "reflective conversations with the situation" (Dorst & Cross,2001; Downton,2003; Gedenryd,1998).

In addition to these traditional explorations, designers may also raise questions that are not characteristic of other disciplines because often the answers are translated into form, colour, and the objects that surround us. This affords practitioners, students, and educators with the challenge to produce discipline specific knowledge that may be communicated by drawings, sketches, models, and other visual representations embodying non-verbal codes or messages as well (Cross,2007a; Dörner,1999; Downton,2003; Lawson,2003; Stappers,2007).

There are additional areas of investigation that have not been covered in this brief overview that are also part of the body of knowledge that is design research. The following section brings together the many approaches discussed in this paper.

The Relation between Design Research Categories

In his paper, *Creating design knowledge: from research into practice,* Ken Friedman asks, "How does new knowledge move from research into practice"(: 1). He goes on to answer:

> Concrete research results become visible to practitioners in a myriad of ways. Journal results, conferences, corridor talk among colleagues, knowledge transfer in shared projects, Internet discussion groups. The important issue is that a field must grow large enough and rich enough to shape results and circulate them. As this happens, the disciplinary basis of the larger field also grows richer. This leads to a virtuous cycle of basic results that flow up toward applied research and to clinical applications. At every stage, knowledge, experience and questions move in both directions…Practice tends to embody knowledge. Research tends to articulate knowledge (2000: 23).

Building on Friedman's thinking, the following map represents the relative positions of the categories and subcategories discussed so far in this paper. It illustrates the flow between research for design, research through design, and research about design as a circular process, each informing the other.

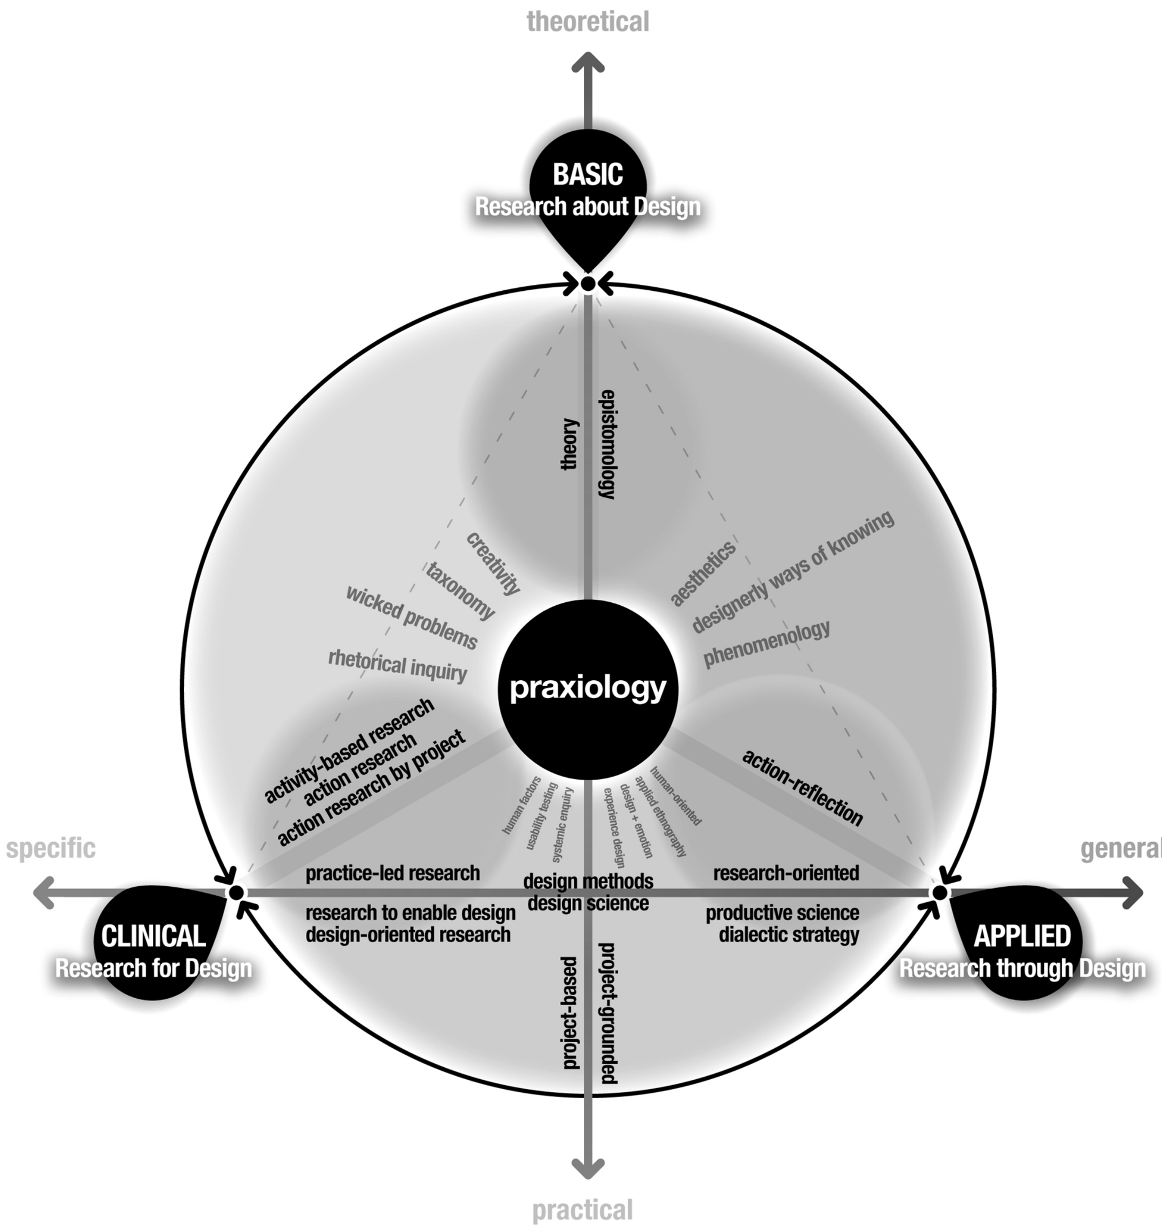

Fig 1. Map of Design Research Categories

While these categories of design research are interrelated, they also represent different levels of design knowledge. Downton writes about three kinds of knowledge: “how-to-knowledge” (a person demonstrating she knows how to draw) “knowing-that” knowledge (a person learning about how someone else draws), and “knowledge-of” (a person has peripheral knowledge that people can draw) (2000: 62). He goes on to say that, “Design theories are concerned with what design is, what it should be and what it could be” (2003: 79). From this perspective, one could expect to engage in design research at any of these levels and in a variety of combinations, depending on the initial question or hypothesis. With such a multifaceted range of options, is it any wonder that the discourse is as extensive as it is?

A visit to the PhD-DESIGN List serve[4] brings up many threads of discussion that run through this paper. It has become the central clearing house for current issues related to the academic relationship with design research–many of the key design researchers mentioned here share their explanations, perspectives, and evolving thinking. While that may validate the content of this literature search the list doesn't make sense in and of itself. The discussion threads often provide uncontextualized snippets of information. In response, this map illustrates the increasingly complex approaches to design research.

Conclusion

The multiple perspectives for describing design research in the literature are signs of healthy growth and of a field that is advancing to face the challenges of our times, rather than becoming overwhelmed by them. This paper develops a frame of reference that endeavors to organize the information found in the literature, primarily to develop insight into the complex field of research: for design, through design, and about design. It draws from the wide range of activity in the area of design research that is fueling the discourse and spreading design research knowledge. The initial historical overview provides a context for understanding the foundations of design research, which have been an ongoing part of the process since design emerged as a field on its own in the early twentieth century. In spite of the relatively short history of research and design, the foundation for thinking about contemporary design issues has been firmly established and promoted by many dedicated academics and practitioners, not all of whom share the same taxonomies. The complexity is not merely a matter of taxonomy; it is also a matter of breadth. The wide range of research approaches discussed in this paper are used to varying degrees in the pursuit of knowledge that is either specific to a design project, relevant to a class of design problems, or fundamental to the very nature of design.

The model presented here aims to provide a framework that will evolve along with the field of design research. By relating Frayling's terms –design for, about, and through research– to those of contemporary funding bodies–clinical, applied, and basic– and of current practice this paper attempts to provide continuity, while sorting out the different points of view.

Author Biographies

Lois Frankel

Lois is an Associate Professor and past Director at the School of Industrial Design at Carleton University. She is also a PhD student at Concordia University, with the generous support of a Doctoral Fellowship from SSHRC (the Social Sciences and Humanities Research Council). The focus of her work is simplifying the relationship between people and computer-enabled products.

Martin Racine

Martin is the Director and Associate Professor in the Design program at Concordia University, where his research is oriented towards ecodesign and new technologies (rapid prototyping, 3D scanning). As a founder of the Institute for Research and Creation in Media Arts - Hexagram, Martin Racine has initiated, with Professor Philippe Lalande (University of Montreal), a Research Laboratory related to new technologies in design.

Caractérisation des activités collectives réunissant designers et chercheurs

Clément Gault, Orange Labs, clement.gault@gmail.com

Anne-France Kogan, Ecole des Mines de Nantes, France

Abstract

En février 2008 s'est tenue au MoMA de New York l'exposition Design and the Elastic Mind. Par la présentation d'un peu plus de 200 projets, l'événement culturel voulait mettre en avant "un des rôles les plus fondamentaux du design : la traduction des révolutions scientifiques et technologiques au travers d'objets accessibles changeant la vie des gens".

Bien que les activités respectives du designer et du scientifique (chercheur et ingénieur) soient différentes, l'exposition montrait la plus grande proximité qu'entretiennent désormais les milieux du design et de la science. Que ce soit par la portée des propositions, des connaissances mobilisées ou des connaissances nouvelles que les projets en question ont apportées, le design investi par les dernières avancées scientifiques semble apporter des perspectives nouvelles aux deux disciplines concernées. Mais quand est-il des pratiques respectives, celles du designer et du chercheur ? Dans cet article, nous proposons d'explorer cette question par l'analyse d'une série d'entretiens semi directifs. Ces rencontres se sont étalées entre juillet et septembre 2009 et ont concerné 7 designers et 7 chercheurs ayant travaillé ensembles.

En février 2008 s'est tenue au MoMA de New York l'exposition Design and the Elastic Mind. Par la présentation de plus de 200 projets, l'événement voulait mettre en avant "un des rôles les plus fondamentaux du design : la traduction des révolutions scientifiques et technologiques au travers d'objets accessibles changeant la vie des gens"[1]. En cela, les projets se situaient dans une perspective proche du "design scientifique" de Nigel Cross [1] où l'objectif est de concevoir des objets basés sur les dernières avancées scientifiques. Comme l'affirme Raymond Willem, ici le design "rend la science visible" [2].

Bien que les activités respectives du designer et du scientifique soient différentes, l'exposition montrait la grande proximité qu'entretiennent désormais ces deux milieux. Que ce soit par la portée des propositions, des connaissances mobilisées ou des connaissances générées, le design investi par les dernières avancées scientifiques semble apporter des perspectives nouvelles aux deux disciplines. Mais qu'en est-il des pratiques respectives ? Dans cet article, nous proposons d'explorer cette question par l'analyse d'une série d'entretiens semi directifs. Ces rencontres se sont étalées entre juillet et septembre 2009 et ont concerné 7 designers et 7 chercheurs ayant travaillé ensembles.

Bien que partageant des valeurs identiques que sont l'innovation, la création de nouveauté et de connaissance, le design et la recherche supportent des pratiques différentes. Comme le rappelle Armand Hatchuel, professeur à l'Ecole de Mines de Paris, le designer se doit de "produire un objet inconnu qui séduisent et surprennent, tout en étant immédiatement reconnu". Tandis que le chercheur, de par les connaissances liées aux dernières avancées scientifiques qu'il mobilise, peut se permettre de surprendre par des objets inconnus qu'il aura loisir d'expliquer et de démontrer par la suite [3]. Il convient de rappeler que le fossé est d'autant plus important en France où la recherche en design n'est pas institutionnalisée : il n'y a pas de doctorat en design. En référence à la classification de Christopher Frayling, cette absence d'étude doctorale amène à constater que le profil du chercheur sur le design prévaut à celui du chercheur en design [4]. Aussi, la rencontre en

[1]. Glenn Lowry dans l'introduction du catalogue de l'exposition Design and the Elastic Mind.

France entre designer et chercheur est avant tout une rencontre de deux pratiques avant d'être celle de deux praticiens.

Des lectures aux entretiens

Les lectures qui ont précédés nos entretiens nous ont amené à nous intéresser à l'apport particulier que pourraient offrir les ressources de médiation. Que cela passe par les dessins, les croquis, les maquettes ou les représentations 3D, de nombreuses recherches ont déjà été menées pour qualifier leurs implications durant les activités de conception collaborative. Durant un travail d'analyse ethnographique de la conception d'un produit technique simple, Eric Blanco, chercheur en génie mécanique, a étudié le rôle particulier du croquis griffonné [5]. Le chercheur en est arrivé à argumenter que ces derniers ont la capacité de décrire à la fois le processus et sa temporalité. Ils sont à la fois traducteurs et médiateurs de l'activité. Le chercheur insiste aussi sur une des limites des brouillons : leurs faibles niveaux de codification les dédient à la conception et ils ne peuvent transmettre la mémoire du sens donnée au projet. Ils sont aussi à distinguer des objets dits "fermés", fortement codifiés et qui fonctionnent selon un régime descriptif. Ils sont pour cela dédiés à la fabrication. Dans un contexte proche, le sociologue Dominique Vinck a étudié le rôle des représentations graphiques dans la coopération entre métiers [6]. Renforçant l'analyse d'Eric Blanco il complète en avançant que les rapports de prescription entre acteurs sont entretenus par les modalités de production et de mise en circulation des représentations graphiques. En tout état de cause, il nous a été peu évident d'étudier les nombreux éléments identifiés dans la revue de la littérature, notamment ce qui concerne les traces de l'activité supportées par les ressources de médiation. La plupart des écrits retranscrivent des études de terrain s'avérant riches en informations propres à une analyse ethnographique. Aussi, elles sont difficilement identifiables dans le contexte de l'entretien semi directif. Pourtant, nous avons su déceler que les activités collectives réunissant chercheurs et designers s'inscrivaient dans un cas particulier au niveau des rôles réciproques joués par les ressources de médiation entre les acteurs.

Pour commencer, un designer industriel ayant une forte expérience de travail avec les chercheurs, nous a expliqué le rapport particulier qu'il entretient habituellement avec un chercheur : "le chercheur n'est pas un client […] il n'est pas à séduire. Donc lui montrer un produit fini n'aurait aucun sens." Le designer opère ainsi d'une autre manière vis-à-vis des chercheurs en "leur "montr[ant] des réalisations antérieures. Pour qu'ils puissent voir où tout ça peut emmener, dans quel degré de finalisation, de sophistication [le projet] peut aller." Poursuivant sur le rôle particulier des croquis et des brouillons, les recherches du designer, il explicite alors sa stratégie. Pour lui, il s'agit de "montrer que le projet est encore extrêmement fragile et ouvert. […] comme indéterminé, en transformation pour que la personne qui est en face de [lui] trouve sa place et puisse s'approprier le croquis ou la pré-maquette". Ainsi, le designer a compris que le fait de présenter au chercheur un "objet fermé" ne peut engager la coopération car cela implique tacitement un rapport de prescription du designer sur le chercheur [5]. Au contraire, présenter un objet "fragile et ouvert" offre ce que Dominique Vinck appelle des "prises" [6]. Comme en alpinisme, une prise relève à la fois des particularités de l'objet et de l'action qui est engagée avec lui. En cela, comme le designer le rappelle, il ne se présente pas selon le régime habituel de la séduction. Il n'est donc pas dans la monstration mais davantage dans la démonstration. Ainsi face à un chercheur, le designer présente ses recherches formelles et d'usage selon une posture qui le rapproche davantage du chercheur où le fait de convaincre prime sur la séduction.

Les entretiens nous ont aussi amené à observer le mouvement inverse : le chercheur prend conscience que le rôle des ressources de médiation est partagé. Un chercheur sur les agromatériaux rapportait lors d'un projet de collaboration qu'il avait été amené à manipuler, dans le sens expérimental du terme, ses agromatériaux avec les designers. L'objectif était didactique : le designer avait la volonté de comprendre le processus de conception de ces nouveaux matériaux. Par la suite, il a fait un rapprochement intéressant. Selon lui le travail de croquis du designer apparaissait comme le pendant des "manipulations" du chercheur. Il pointa alors l'aspect fortement itératif qui vise à aboutir à un résultat présentable, non pas pour séduire mais pour prouver et démontrer. Ce chercheur a insisté sur le fait que le designer, dans le cadre des activités collectives auxquelles il a participé, doit lui aussi vérifier la faisabilité de ses idées. En insistant sur le travail de réflexion, "le designer va mettre [son idée] sur papier, nous [les chercheurs] on va la mettre dans nos éprouvettes ou dans nos extrudeurs et faire un test".

Ces rapprochements dans les fonctions induits par les ressources de médiations ne vont pas uniquement dans le sens du designer vers le chercheur. Un autre chercheur, docteur en science de l'informatique, nous rapportait son expérience avec les designers. Durant une période de recherche dans un laboratoire transversal où se côtoyaient des chercheurs en informatique des architectes et des designers, il prit conscience que sa production de chercheur devait "inspirer, informer, soutenir la démarche du designer et pas du tout s'y suppléer et se substituer à son travail." De là, il s'est "rendu compte qu'il fallait mieux utiliser les mêmes outils que les designers pour pouvoir bien communiquer avec eux." Finalement, l'objectif pour lui était de réutiliser les ressources de médiation des designers afin d'apporter un maximum de "prises" au sens de Vinck, avec des modalités pertinentes et accessibles pour les designers. Enfin, il a souligné un paradoxe dans l'utilisation des ressources de médiation propres aux designers : "plus le rapport évolue, plus [il a] l'impression de rentrer et d'être considéré par certaines personnes comme un designer." Le fait d'utiliser certains outils, certaines manières de fonctionner qui sont proches du design amènent des personnes à penser qu'il est designer.

Un rapprochement par les ressources de médiation

Aussi, si un rapprochement peut se faire selon les pratiques de manière générale, il s'observe surtout dans notre étude par les ressources de médiation. Leurs rôles réciproques semblent de ce fait se confondre entre designers et chercheurs : chacun semblant adopter les modes de communication de l'autre. L'aspect séduisant des ressources de médiation du designer semble laisser le pas à une forme davantage démonstrative. De son côté, les ressources de médiation des chercheurs sont adaptées aux designers en empruntant leurs manières de faire. En cela, le dernier chercheur évoqué précisait qu'il utilisait entre autres le scénario pour travailler avec les designers. Dans son contexte de chercheur, il nommait ces ressources de médiation par le terme de "représentation intermédiaire". Un terme que l'on retrouve dans nos lectures. En effet, Eric Blanco parle "d'objet intermédiaire" pour qualifier les objets qui médiatisent les interactions entre acteurs en représentant "à la fois les intentions et compétences de leurs auteurs et le produit à venir" [5].

Au-delà du rapprochement, l'apport

Le fait que les pratiques des designers et des chercheurs soient d'une manière générale relativement proches n'est pas une nouveauté en soi. C'est en partie pour cette raison que nous avons choisi jusqu'à présent de nous intéresser aux ressources de médiation et non aux pratiques. Annie Gentès, chercheuse à Telecom PartisTech, explique que les processus de conception des designers et des ingénieurs/chercheurs sont en réalité proches du fait que les deux utilisent un processus de "médiation créative" [7]. Concrètement, ce processus correspond à la production d'un objet pour rendre compte médiatiquement d'une invention technique dans un contexte social, voir économique. Basant son analyse dans le cadre des technologies de l'information, Annie Gentès avance que les designers cadrent la technologie dans une narration précise en la plaçant dans un contexte et un environnement particulier selon un apport sémiotique. De leur côté, les ingénieurs/chercheurs ont recours au récit descriptif des fonctions de la technologie en détachant l'objet des facteurs externes. Les deux modes de représentation bien que partiellement similaires, se complètent : les designers tentent de placer les technologies de manière pertinente dans un contexte choisi quand les ingénieurs/chercheurs illustrent leurs limites. Dans le cas de notre travail de recherche, la complémentarité entre chercheurs et designers dans les modes de représentation va de pair avec les apports réciproques aux pratiques de chacun. Les apports ont en effet été plus facilement identifiables lors des entretiens.

Dans cette optique, un designer nous expliquait qu'il ne souhaitait pas apporter des réponses "fantaisistes ou juste prospectives ou vaguement manifestes" dans son travail. De ce fait, il avouait sans peine qu'il était "très vite en limite de compétence", ce qui le motivait à faire appel à un scientifique. Il identifiait là les limites dans sa pratique : "Je n'ai ni envie, ni intérêt à continuer tout seul. Parce que sinon ça veut dire que je deviens moi-même une sorte de scientifique […] ou à singer une attitude de scientifique. Je suis beaucoup plus intéressé par créer des collaborations [...] plutôt que de m'imaginer omnipotent, apte à être le designer, le scientifique et le chercheur à la fois." Ce constat est également partagé par de nombreux chercheurs qui identifient clairement leur apport de cette manière. A titre d'exemple, le chercheur sur les agromatériaux dont nous avons déjà parlé identifiait son apport comme une "caution scientifique".

Le chercheur n'est pas en reste. Là aussi l'apport attendu par l'aide du designer favorise les conclusions d'Annie Gentès. De ce fait, la mise en contexte du designer devient un moyen de tester les limites d'une technologie issue d'un laboratoire. Un chercheur en traitement du signal nous rapportait le cas d'un *workshop* entre son laboratoire et une école de design. L'intérêt pour lui était de "voir en fait quels sont les vrais problèmes, […] les vrais obstacles pour l'utilisation de [ses] outils." En ce sens, le chercheur cherchait à contextualiser ses travaux : "parce que nous [les chercheurs] on développe des outils informatiques mais on ne sait pas finalement comment ça va être utilisé. C'est naturel qu'à travers ce genre d'interaction on ait un *feedback* pour améliorer nos outils."

Si les apports respectifs semblent obéir à des connaissances rencontrées dans nos lectures, nos entretiens ont néanmoins décelé que le rapport pouvait parfois s'inverser. Nous l'avons davantage constaté du côté du chercheur qui à son tour se révèle être en "limite de compétence". Dans ces cas précis, le designer ne va pas aider à repousser les limiter d'une technologie mais une mise en contexte particulière va offrir au chercheur des problématiques jusqu'à alors inédites. Un designer témoignait son expérience lors d'un projet pour créer des bottes de protection contre les mines antipersonnel. Son hypothèse initiale était de ne pas chercher à résister à l'explosion mais de concevoir une forme qui en dévierait le souffle. Aussi, il a fait appel à des chercheurs d'un laboratoire en balistique "pour qu'ils nous fassent part de leurs connaissances", pour qu'il puisse "valider [ses] hypothèses". Nous sommes dans un rapport classique entre designer et chercheur. Mais il s'est avéré "qu'il y avait très peu de connaissances dans ce domaine, c'est-à-dire on ne caractérisait pas finalement ce que produisait l'explosion d'une mine." La question amenée par le designer a finalement intéressé le laboratoire qui "a fini par financer une partie des essais", ce qui a produit des connaissances scientifiques publiées par la suite.

Conclusion

Pour conclure, notre étude a permis de caractériser deux cas typiques dans les activités collectives réunissant designers et chercheurs. Il y a en premier lieu celles où les apports réciproques sont ceux identifiés par Annie Gentès : le chercheur apporte des connaissances et des nouvelles technologies quand le designer teste leur validité par contextualisation. Ces activités collectives sont ponctuelles, de courte durée et organisées par la rencontre des institutions correspondantes : laboratoire de recherche, université, école de design, cabinet de design, centre d'art, etc. En second lieu, nous avons les activités collectives où une influence des pratiques est à l'œuvre : l'apport du designer vient nourrir le travail du chercheur, et ce dernier envisage différemment ces recherches par l'apport du designer. Ces seconds cas sont la plupart du temps initialement issus d'une activité collective traditionnelle. En revanche ces activités collectives particulières s'actualisent par la suite et deviennent pérennes sous de nouvelles formes d'organisations. Différents projets comme Variable Environment[2] réunissant l'Ecole Polytechnique Fédérale de Lausanne (EPFL) et l'Ecole Cantonale d'Art de Lausanne (ECAL) ont été les initiatives à l'origine du laboratoire commun EPFL+ECAL Lab[3], "nouvelle unité de l'EPFL en collaboration avec l'ECAL" marquée par "une stratégie pour stimuler des travaux à l'interface entre des disciplines essentielles de l'innovation." Cela démontre que les organisations pour favoriser les activités collectives sont véritablement à créer. Si les designers semblent avoir moins de contrainte dans leur activités professionnelles, cela ne semble pas le cas pour les chercheurs. Un jeune chercheur qui a eu l'occasion de travailler plusieurs fois avec des designers nous expliquait qu'il ne pourrait pas poursuivre ce genre d'expérience dans le monde de la recherche et qu'il allait "devoir arrêter d'être un chercheur."

Abstract

Investigating and extracting users' desires and aspirations often conduct design researchers to a great deep challenge. Therefore, the designers usually examine several ways to get closer to these unrevealed feelings. These ways include applying various qualitative and quantitative techniques. Amalgamation of these techniques might be the most desired technique among designers in revealing deep inside feelings. But once a qualitative technique is applied, the design researchers deal with the difficulties of making the outcome data, including verbal and visual expressions, comprehensible enough in order to be used in the subsequent steps of design or to be conveyed to product developers. So, their usage of such qualitative techniques would be subject to misconception and misunderstanding, and here, the expertise of designer will have a crucial effect. Consequently, designers often find qualitative data formats as imperfect reports as they might not be applied convincingly throughout the design process.

This paper presents some encountered complexities of a pilot survey titled "Designing and Implementing an Artificial Design Tool Based on Improved Kansei Engineering" which, due to its concept, involves applying intermingled quantitative and qualitative methods. In addition, this paper is an effort to describe the borderline between quantitative and qualitative methods and their transformation point, and also to describe some practical solutions suggested by the authors.

Within any mixture of quantitative and qualitative techniques, there are two participants: human in one side (both as designer and also the focused and target group) and machine (computer) on the other side. In other words, within any combination of these two techniques, we encounter the qualitative data expressed by the target group and self perception of designers on one hand, and the quantitative data produced or required by the machine on the other hand. And then, the problem will be how to take advantage of these two sources for the analysis and concept generation phases. Surely the future methods of design together with the future design-assistant machines will raise this fundamental question: how can we overcome the rigid borderline between qualitative and quantitative methods and make a seamless concept of co-qual-quant model which will bolster the real human-machine connection. It is one of the design complexities of the time and one of the requisites of the future. We have come up with a solution through a conducted case study, in which we have made a bridge between the human and computer. So, we have used some qualitative methods on the human side (for example PPP and Mood Board) and some quantitative techniques (such as AHP) on the other side and we have tried to infer some co-qual-quant model-based parameters to inject to the design machine as a pure quantitative instrument.

Keywords

User-centric design, qualitative techniques in design, design problem solving, Kansei engineering, AHP in Kansei Engineering, co-qual-quant model in KE

Emotional bonds between users and products are an essential element that can determine the commercial success of a product. Eliciting user desires and emotions often presents a challenge to design researchers. Users can offer a valuable design resource to support the designing process. However, such involvement can be perceived as problematic. This is partly because users find it difficult to conceptualize and express their ideals and wishes, and therefore, they need to be supported. Product functionality as such is closely interwoven with social and cultural values. Users are not always conscious of their needs or may not regard particular pieces of information as useful. Likewise, users are not always able to verbalize their emotions and reflections. Coates distinguishes between the idea of the stereotype (what a typical product is currently like) and the ideal (the imagination of how an object should be like). New designs aim to come reasonably close to the ideal, whilst not leaving the perception of the stereotype (standard) too far behind. Coates criticizes the use of focus groups in market research based on its preoccupation with stereotypes instead of ideals, because the stereotype is what participants know best about and agree most upon. Ideals are "fuzzy" as they vary across people and are not necessarily conscious. *Blue-sky* and *what-if* possibilities are therefore more difficult to reflect upon and verbalize.

So, it is important to give users many different channels through which they can express their requirements and ideals. Several qualitative techniques like Mood Board and Product Personality Profiling have been proposed and employed recently to retrieve peoples' ideals rather than their stereotypes to overcome these shortcomings. A methodological "trick" to trigger novel ideas was employed by encouraging people to consider the "future". By assisting users in *suspending reality*, new ideas and wishes may emerge. People begin to think more creatively and disclose their wishes and ideals more freely.

These techniques broadly use Images and enable communication of intangible emotions such as happiness, sadness and calm, beyond linguistic restrictions. Images are a powerful resource to convey meanings, particularly emotional values and experiences. Especially, abstract imagery which is applied in Mood Boards is often more successful in this than figurative images which can have strong literal interpretations. As they tend to be purely visual, they transcend linguistic restrictions. Their application can serve as an important tool to communicate values that cannot be expressed easily through words.

As the subject of design becomes more novel and complex, it would be more difficult for the users to think and imagine the hidden aspects of the subject, and also their unrevealed desires. Here, Qualitative techniques play an important role. They are more powerful tools in helping people visualize the current and future context of design and their imaginary and ideal products. Therefore, applying them seems crucial, but also interpreting their result might be a bit of minefield. So, in some occasions converting these qualitative data to quantitative data will bring about confusion and should be solved using combination of appropriate techniques. This is the main approach which will be discussed in this paper.

Framework of the paper:

As a descriptor for the applied technique, we propose a framework which governs all parts of the model. Here, the framework and its basis will be described.

The technique mainly combines AHP, Mood Board and PPP to provide the optimization algorithm with the necessary input parameters (attributes) and also importance weights (final weights resulted from AHP) of those parameters. The novelty of the design subject also made usage of Mood Board inevitable, because we had to reduce the representative objects in the questionnaires (sample products) into more sensible ones for the users. We used Mood Board for simplifying and reducing the representative objects from a complex, concrete and real world object (for example image of some green cars) to some simple and abstract images. Also it helps us to communicate with the unawareness of the users. In addition, we have further used our findings from both Mood Board and PPP in defining AHP criteria. Then, the final extracted weights of importance from AHP were inputted as the coefficients of the fitness function in Genetic Algorithm optimization, the project's synthesis phase.

We will split the whole framework into some modules and will describe them separately. These segments include "attribute gathering", "attribute reduction" (includes two sub-segments), "verification", "importance weight extraction and final quantification", and "result convergence".

Case study:

This section is assigned to parts of a conducted project titled "Designing and Implementing an Artificial Design Tool Based on Improved Kansei Engineering" in which we examined application of Mood Boards and Product Personality Profiling as two qualitative techniques in some phases of Kansei engineering parallel to routine exploited quantitative tools. Further, we assessed the results by repeating the procedure with the conventional quantitative approach. The detailed procedure of case study in the first approach is illustrated in the following flowchart. Each block will be discussed separately in the following statements.

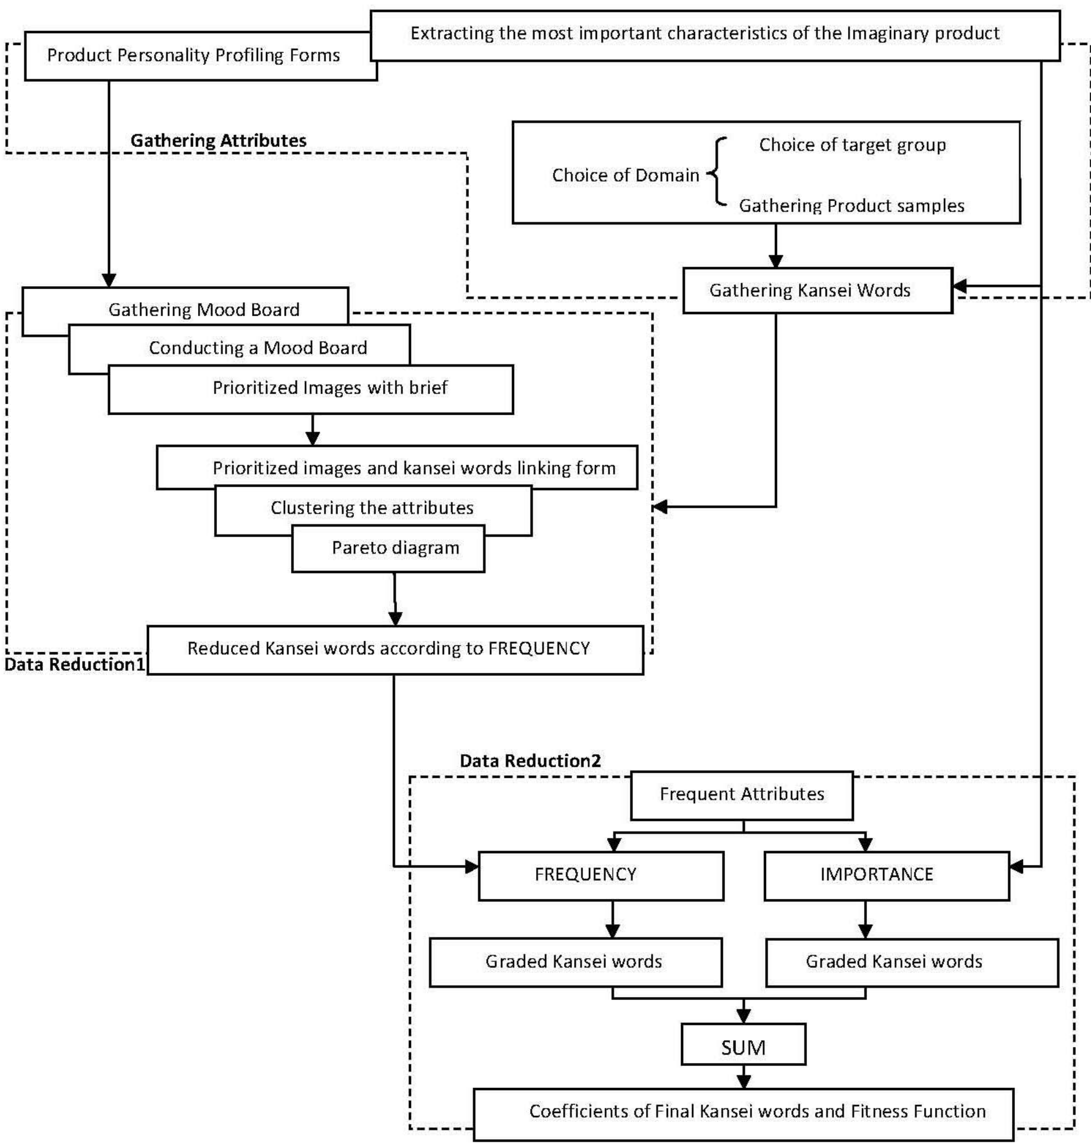

Figure 1. An overview of the whole process

Gathering attributes (Kansei words)

Commonly, the procedure of KE initiates with choice of domain in which the target group and sample products are chosen. The target group included 20-40 Iranian women and sample products ranged from electric and hybrid urban vehicles of renowned manufacturers to some new concepts. In the phase of gathering the Kansei words which is portrayed in the first dashed box in figure1, first all of the related sources such as internet, magazines, pertinent literature, experts, experienced users, relating Kansei studies, ideas, and visions were investigated, also a discussion group was held consist of 20 industrial design girl students in which they were asked to talk about the product samples and choose 3 most preferred ones in accordance with the project. All chosen samples were graded respecting their frequency and 3 of them were applied in the later PPP analysis. Then, we conducted a PPP session which included 20 participants who were shown PPP forms. This form included 3 columns for 3 selected products and also one more column for describing the imaginary product. One sample of this form is presented in figure 2.

Imaginary product	Product C	Product B	Product A	participant	
					sex
					age
					occupation
					lifestyle
					car
					personality
					Family environment
					clothes
					newspaper
					pet
					Favorite TV program
					Music
					Food
					Name
					Role in the family
					Favorite Cartoon Character
					Perfume
					Do you like to buy this product?
					Color

Figure 2. A sample of PPP form

Through PPP analysis we extracted a series of the most important attributes for imaginary products which were useful to be included with other gathered Kansei words. This analysis was also helpful for “data reduction phase”, the next step in KE.

Reduction of attributes, Phase 1:

The outline of this phase is shown in the second dashed box in figure1. Instead of regular application of marketing tools in this phase, Mood Boards was applied. At this point, previous PPP analysis was supportive in helping the design team to have much better visualization while gathering abstract images for Mood Boards. Afterward, one Mood board session consist of the same former 20 participants was held. A variety of images numbered as 778 from various categories were chosen. These images reduced to 271 images in the second classification. Then, all the participants were asked to set a layout of their 7 preferred images and also to prioritize them in accordance to their importance and relevancy to the Mood board question. They were also asked to express a short brief for each of their choices. Some of the advantages of using Mood Board were noticed as high enthusiasm among participants in fulfilling the task, and quicker understanding of the subject. One of these layouts is shown in figure 3.

Figure 3. A sample of a mood board layout used in the case study

The next task was to convert these qualitative responses to some fathomable values for the synthesis phase while reducing the number of Kansei words to the most important ones. Therefore, firstly all the gathered attributes were clustered and then linking forms were planned. This form included a list of all the new attributes and was presented to the participants to be marked for each of their 7 selected images. The list of attributes printed in the form is shown in the table 1.

Lightness	Particularity	Power	Slowness	Fun	Excitation	Complexity	Sensible
Heaviness	Ordinary	Softness	Rapidity	Seriousness	Calmness	Simplicity	Ornamental
Delicate	Sturdy	Sport	Spacious	Kind	Stylish	Compact	Happy
Sad	Mature	Childish	Feminine	Masculine	Smartness	Silliness	Unfriendly

Table 1. List of attributes

In the next step, these data were processed and the most frequent attributes were determined using Pareto diagram. The most frequent attributes in the first three priorities is illustrated in figure 4. These frequency values built the **Frequency** criterion for the second data reduction step.

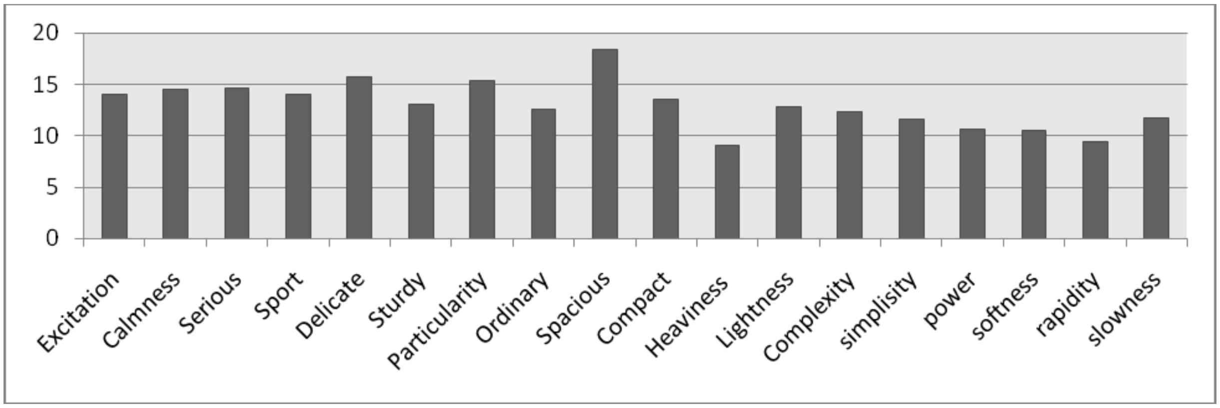

Figure 4. Comparative chart for frequency of attributes

Reduction of attribute, Phase 2:

In order to assign inclusive values to the attributes based on ideas of both participants and design team (the human side of design procedure), another reduction was conducted applying AHP. This phase is shown in the third dashed box of the figure1.As it was discussed in previous section, the output of the first reduction phase was used in defining the frequency criterion in the second step. Also, most of these attributes were in contrast with one another in the meaning; therefore, the attributes were rearranged to polar Kansei words like Spacious-Compact, Excitation-Calmness before being processed.

On the other hand, the **Importance** criterion was defined in accordance to the results gained from PPP analysis based on the designer's viewpoint and interpretation. Within this free point of manipulation, designers will be able to incline the results with respect to the main objectives of the project. For example if designers wish to orient towards a highly delicate final concept, they can assign a greater importance degree to the delicate attribute while processing it in AHP.

Furthermore, the partial scores for each attribute in both criteria were added together and the final scores were determined. Table 2 presents the first 5 attributes with higher final scores. These values were further used as coefficients of fitness function in the synthesis phase based on Genetic algorithm optimization.

FINAL SCORE	ATTRIBUTE
0.17	Spacious-Compact
0.114777	Sturdy-Delicate
0.088467	Particularity-Ordinary
0.083879	Serious-Sport
0.082718	Excitation-Calmness

Table 2. Final score of attributes based on co-qual-quant model

Verification:

In order to evaluate the quantification procedure of qualitative input data, a parallel process was conducted. Within this process all the attributes were graded using seven grade scales, and then the ten highest scored attributes were used in the first step of fuzzy survey. Figure5 shows a frame of the interface of this survey in which all the samples were scored with respect to attributes.

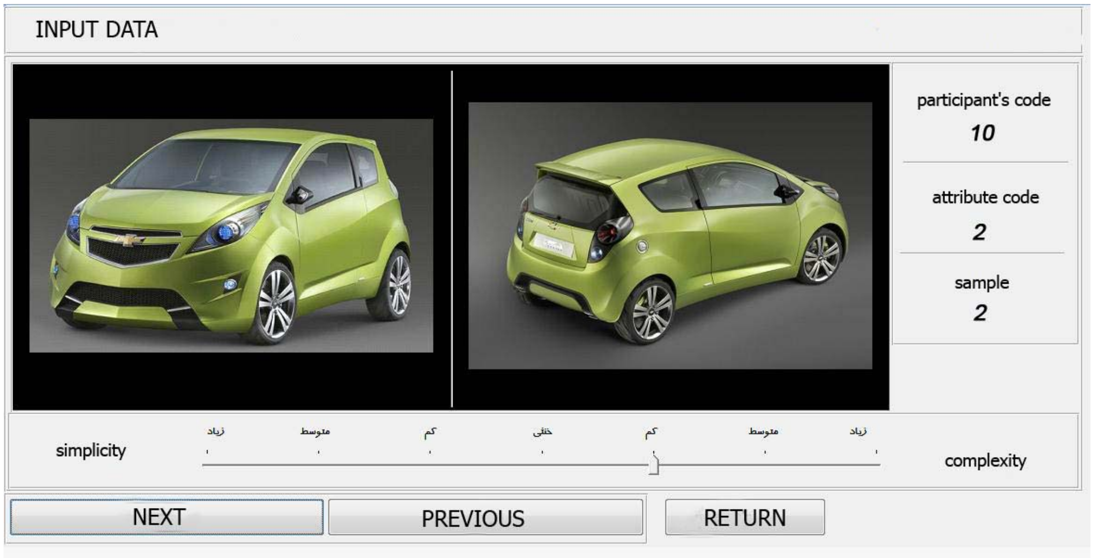

Figure 5. Fuzzy survey interface sample (Phase 1)

The output matrix of the first fuzzy step was categorized and reduced using Factor Analysis. By applying factor analysis the dependant variables or attributes were recognized and merged into one unique group, and then new name was given to this group of attributes. Interestingly, it was possible to categorize and name the main extracted attributes within similar five attributes obtained in the previous procedure like Spacious-Compact, Sturdy-Delicate, Particularity-Ordinary, Serious-Sport, and Excitation-Calmness.

In the second step of fuzzy survey, the data base obtained from the first step was used in order to give the participants a chance for comparing (and making a convergence between the mental concepts of Kansei terms), and also enhancing the accuracy of their choices. A frame of the survey interface is shown in figure 6. All participants were asked to firstly score the vehicle in the left side of the screen and then click the Enter button to see the car with the closer score to her choice. She was then free to change in her assigned scores according to her preference and was able to see the changes in data base accordingly. She was able to continue the procedure as long as she would feel pleased by her scores.

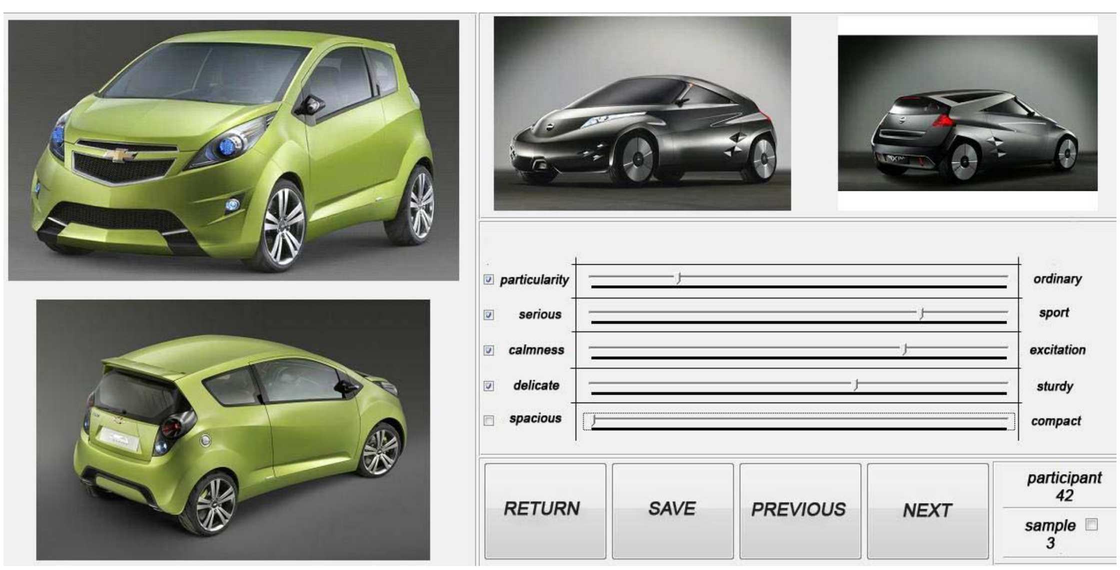

Figure 6. Fuzzy survey interface sample (Phase 2)

Importance weight extraction and final quantification

Due to the overall positive meaning of all of these attributes, in the next task they were all graded based on variance, which means that attributes with lower range of variance are of the most importance and have balanced mixture of both polar attributes, and vice versa. So, the attributes were again prioritized and scored applying AHP based on variance. Table 3 presents the new degrees of these attributes after AHP.

FINAL SCORE	ATTRIBUTE
0.177954	Spacious-Compact
0.088992	Sturdy-Delicate
0.077788	Particularity-Ordinary
0.09352	Serious-Sport
0.06641	Excitation-Calmness

Table 3. Final score of attributes based on pure quantitative procedure

Results Convergence:

After comparing the result of both methods (the pure quantitative method and the new co-qual-quan-titative method), it seemed that there was a meaningful correlation between the two sets of results. It was also expected that there would be such correlation and similarity between the results, because we have had selected a concrete and previously well defined object as the object of the design: a car. But it should be clearly mentioned that for different design objects or methods (for example for pure conceptual or state-of-the-art objects of design or for methodologies which use pure conceptual medium objects) there will be no guarantee for the convergence of the two results, indeed there will be a degree of divergence from a little difference between outputs of two methods up to total different sets of results.

Conclusion:

The new methods of design require the designer to use the numeric and quantitative tools. On one hand the daily developing use of CAD tools and computers and on other hand the need for satisfying the public interest, both force the designer to use computational and quantitative methods. This surely will save a lot of time and expenses in the manufacturing and designing industries, and accordingly will guarantee predicted success for the product.

But on the other hand, this may rise up some new problems in the design area: the designer role will be diminished and the users may show a faulty or unaware response to the quantitative design tool. This requires the methodology designers to revise the methods for overcoming this method.

On of the solutions is to inject some sort of “unconscious” awareness to the tool, and on the other hand there should be always enough role be left for the radical or intended presence of the designer.

As the result of such intention, we have re-designed some parts of a classic “Kansei Engineering” methodology to fulfill these needs. We have added some qualitative methods (as mentioned above, including PPP, MoodBoard and AHP) to the methodology and tried to expose the participants to some fully conceptual aspects and meanings of the object of design. Also we have tested the results in a real-world implementation, a project entitled “Designing and Implementing an Artificial Design Tool Based on Improved Kansei Engineering”.

As the final verification method, and as long as the subject of our project permitted us, we have rechecked the whole results with a pure quantitative and tested method and the result was to a compelling degree consistent. Despite what was mentioned above, in different design solutions or objects, the results might not be convergent like the mentioned project. However, as it seems that the philosophy of the modified methodology is enough reasonable and obvious, we suggest the usage of co-qual-quant techniques in such kind of complexities; for instance, a conceptual and ambiguous object or a culturally unfamiliar one. Not to mention the fact that surely there would be other combinations of such approaches, mixture of qualitative and quantitative approaches, which would yield the appropriate results.

Authors Biography:

Neda Ghadir

An Iranian designer and researcher basically interested in emotional design and design methodologies. She graduated in electrical engineering as her bachelor education, and then finished industrial design as her master degree. She has worked on design and problem solving methodologies like TRIZ, QFD, and Kansei Engineering with mainly concentration on KE and has accomplished two projects in this field. One of her recent papers titled "AN IMPROVED CONSTRUCTIVIST KANSEI ENGINEERING METHODOLOGY" is accepted in International Conference on Kansei Engineering and Emotion Research, Paris, 2010. Email: nedaghr@gmail.com

Dawood M. Garavand

An Iranian researcher basically interested in computational and optimization methods implementation in innovative applications and usages, such as biology, drug design, industrial design and human-interactive systems. Also at the current time he is working in a film production and research company as R&D manager and working on optimized render frame dispatching systems (as one of his projects). One of his recent papers titled "AN IMPROVED CONSTRUCTIVIST KANSEI ENGINEERING METHODOLOGY" is accepted in

International Conference on Kansei Engineering and Emotion Research, Paris, 2010. Email: morady@gmail.com

Ali Faraji

B.Sc, M.Sc and Ph.D. (Mechanical Solid Design), is Assistant Professor in the Department of Industrial Design at the University of Tehran since 2004. He is an active researcher in the applied design and technology fields and his main interests are in design methodology and analysis in industrial as well as mechanical domain. His book is under the title: *Elastic and Elastoplastic Contact Analysis: using Boundary Elements and Mathematical Programming, 2005* Series: Topics in Engineering Vol. 45, ISBN: 1-85312-733-7, WIT Press, Southampton, UK.

Synergizing Positivistic and Aesthetic Approaches to Improve the Development of Interactive, Visual Systems Design

Michael R. Gibson, Department of Design, The University of North Texas, Denton, Texas, USA

Daniel Peak, Associate Professor, Information Technology and Decision Sciences, The University of North Texas

Victor Prybutok, Professor, Information Technology and Decision Sciences, The University of North Texas

Abstract

An extensive literature review undertaken at the outset of this endeavor revealed that the current status of interactive visual systems development, implementation and sustenance has evolved from theory and research that is neither especially pluralistic nor synergistic.

There exist two distinct systems design approaches: 1. the largely positivistic and functionally guided approaches derived from the realm of information technology (IT), and 2. the incorporation of the more qualitatively based, aesthetically and experientially guided approaches derived from the realm of dynamic interaction design.

The authors hypothesized that this paradigmatic schism required a new approach that could bridge fundamental gaps in knowledge and understanding between visual interaction designers and IT professionals. They further hypothesized that achieving this goal would enhance the usability and usefulness of many types of interactive visual systems.

The authors created a theoretical, pluralistic process model comprised of aesthetic and positivist design characteristics of interactive visual systems.The model consisted of a process framework and a typology of design characteristics that depicted how aesthetic and positivist design characteristics affect each other. They then tested the hypothesis that diverse individuals perceive design characteristics in interface construction across paradigms by conducting a small-scale visual experiment on 105 participants. This hypothesis was formed by combining an aesthetic visual design approach with a functional, systems-based approach.

This experiment strongly confirmed the hypothesis; it affirmed the efficacy of using this type of pluralistic research typology and framework to better inform designers and IT researchers and practitioners who are challenged to design dynamic, interactive visual systems.

Keywords

aesthetics, IT systems development, interactive visual systems design, pluralistic research framework, positivism, user experience

Both the completed and ongoing research upon which this paper is based have been and are predicated on the same premise. It contends that the decision-making processes that inform the development of interactive visual systems would yield more efficacious results if they were guided by an inclusive, pluralistic research paradigm that could account for both functionalistic and aesthetic concerns. The primary objective of the authors' endeavors is to demonstrate how thinking derived from the discipline of visual communication design might be better integrated with thinking derived from the discipline of functional information systems design. To this end, the authors propose the application of a pluralistic framework to positively catalyze the operation of interactive visual systems that synergizes the systems-based, utilitarian approaches distilled from the information technology disciplines with the aesthetically based, user experience-driven appoaches distilled from the realms of design. (Again, information technology is broadly classified here to include information systems, human computer interaction and computer science.)

Justifications for altering existent research methods that affect the development and operation of interactive visual systems and that have become more inclusive and less reliant on narrowly structured archetypes have recently been authored by researchers working in the disciplines of IS, IT and interaction design. Goles and Hirscheim (2000) advocate a pluralistic approach to IS research as a means to overcome the limitations imposed by a single research perspective. They conclude that myopically informed research in this area limits, distorts, or even obscures relationships between information systems, people, organizations and society: "…paradigmatic pluralism should not simply be tolerated, but [is] a goal the IS community should strive for. Paradigmatic pluralism's strength is its recognition of the intrinsic diversity of problem formulations faced by the community of IS researchers (p.263)." Fallman (2008) calls for interaction design research to accommodate the interpretative attitude of many of the humanities disciplines, but he also calls for it to synthesize many positivistically framed scientific ideals without suppressing the role of aesthetics in favor of functionalism. Fallman asserts that "…when it comes to interaction design research, issues of aesthetics concern not only how something looks and feels, but also the aesthetics of the whole interaction, including how something works, how elegantly something is done, how interaction flows, and how well the content fits in (p.8)." Appeals for more inclusive approaches regarding the application of research methodologies applied to interactive visual systems design have also come from researchers working in the realm of human computer interaction. Bertelson and Pold (2004) have called for the re-orientation of HCI as a discipline that must address aesthetics as a crucial factor that informs interaction design research, arguing that "…predominantly positivist approaches are narrow, inflexible and cannot properly assess how aesthetic considerations affect user perceptions or actions (p.26)."

The objectives of this paper, and of the research that has been undertaken to inform its premise, are threefold. The first is to improve the iterative development processes that guide the creation and implementation of interactive visual systems. The second is to broaden the disciplines of communication design and information technology by facilitating a cross-pollination of theory and practice. To achieve these first two objectives, the authors created a model that is a pluralistic research typology and a framework of interactive visual systems design constructs, dimensions, and variables that bridge the paradigmatic planes occupied by these disciplines. As of this writing, this model is presented as an initial prototype that has been and still is in the process of being tested and evaluated—the authors' research will yield data and new knowledge that will cause it to undergo more iterative development over the course of the next two to three years. The authors believe that utilizing this type of model judiciously and effectively will help them at least begin to achieve their third, more "user-focused" objective. This involves improving the efficacy of the development and implementation processes that affect both the systemic functionality and the aesthetically affected perception and interpretation of interactive visual systems.

These objectives are articulated in the form of the following research questions.

How might the paradigmatically synergic framework that we have proposed to bridge gaps between positivistically informed approaches and aesthetically and experientially informed approaches to creating interactive visual systems efficaciously affect the decision-making processes that will guide their future development?

How should this unique approach to visual systems development, implementation and sustenance begin to fill current voids in the research and development infrastructures in the realms of information technology and dynamic, interactive design?

How will the pluralistic research typology we propose benefit user-centered IT applications in a manner that better accommodates the diverse perceptions regarding operability, adaptability and essential functionality among diverse groups of users?

A Rationale for Constructing This Type of Approach

The authors believe that practioners and researchers from IT and visual systems design can improve the effectiveness of interactive information systems by integrating theory, processes and methods from both paradigms. Representing these two paradigms, the research team was comprised of individuals from communication design (aesthetic paradigm), and from IT systems design and management science engineering (positivist paradigm). Each contributor had to accept the possibility that knowledge that originated outside his discipline might have to be included or acknowledged as an integral part of their collective endeavors. For the communication designer, it meant accepting that at least some of the theory that guides research regarding the design of interactive systems is viably grounded in the positivistic tradition that originated in the hard sciences. For the IT systems designer and management science engineer, it meant addressing how the aesthetic configuration of components that exist in space and that are operated in real time affect the perceptions of users and their behaviors, and that ultimately shape how these people construe meaning.

This work is motivated by what is possible rather than what has already been established, and by what the team members have deemed “the ‘what if?’ factor,” which may involve permeating and dissolving the existent paradigmatic boundaries of their respective disciplines. Viewed from the limited technical and vocational perspective of communication design, the outcomes of their endeavors offer a means “…to begin initiating, facilitating and managing new concepts as intelligent authors, researchers and developers of content (Storkerson, 2008, p. 4).” Viewed from the positivistic, functionally dominated research perspectives of information technology, the approach advocated by the research team expands the literature in these disciplines that addresses aesthetics as a vital factor affecting the operation of interactive visual systems. This work challenges the mindsets of IT and Information Systems (IS) that are “…at best, suspicious about beauty. ‘If it is pretty, it won’t work,’ summarizes one of the common prejudices among HCI and IT researchers and practitioners, and sometimes a pretty product is accused of hiding ‘harm behind its beauty’ (Russo and De Moraes, 2003, p.143).”

In order for an interactive visual system like a website to be “useful, useable and desirable (Cagan and Vogel, 2002)” to its users, its operation must be facilitated by the practical application of knowledge derived from both IT and communication design. In the absence of aesthetic knowledge, developers of functional systems rely on their users’ experiential sensibilities to make the systems usable. In the absence of functional IT systems knowledge, developers of aesthetic systems rely on their users’ aesthetic sensibilities to make the systems usable. Despite these interdependencies, the domains occupied by these two sets of researchers and practitioners tend to remain conceptually separated. Visual aesthetic design rests on an artistic framework of aesthetic, right-brain-oriented, subjective, qualitative criteria. Alternatively, IT website development rests on a functional framework of positivistic, left-brain-oriented, objective, quantitative criteria. Not surprisingly, no published research typology listing the characteristics of these now interdependent disciplines exists in either the scholarly literature of IT or communication design. Hassenzahl (2004) called for a pluralistic research typology when he wrote, “Future research must aim at unifying approaches to user experience. Its major objectives will be the selection of key constructs and a better understanding of their interplay (p. 345).” Tractinsky (2006) echoed, “To improve our understanding of the role of aesthetics in IT, we should identify relevant constructs and dimensions (p. 342).”

The authors agree with this call to action, and believe that a pluralistic typology is necessary to establish a research framework for interface development, website design, and all other endeavors that require interactive visual systems design. They propose that interactive visual systems design requires the integration of a fundamental understanding of visual communication design and IT. Those working in IT would benefit from a much deeper understanding of how meaning emanates from the aesthetic forms and configurations that allow users to operate their systems. Those working in visual communication design would benefit from understanding how and why the functions their design work actuates are planned, organized and sustained.

Constructing the Pluralistic Typological Framework for Interactive Visual Systems Design That Informed This Study

The authors utilized the aforementioned concepts to construct a typological framework that integrates aesthetics and positivism into a model of interactive visual systems design. They hypothesized that this framework could contribute to an increase in cross-disciplinary understanding between interactive systems designers informed by knowledge of visual communications and interactive systems designers informed by knowledge from IT. The framework was constructed in three steps. They began by categorically grouping characteristics that affect decision-making that are rooted in aesthetic concerns into the first of two “paradigmatic planes (Figure 1).” They then categorically grouped characteristics that affect decision-making that are rooted in positivistic, primarily functional concerns into a second paradigmatic plane (Figure 2). The third step involved configuring these two paradigmatic planes so that they intersected each other in a (virtually) three-dimensional problem space (Figure 3). The intersection of these two planes, represented by the darker area bisected by the dashed, vertical line, depicts an area of concern that is shared by interactive visual systems designers who hail both from visual communications and IT.

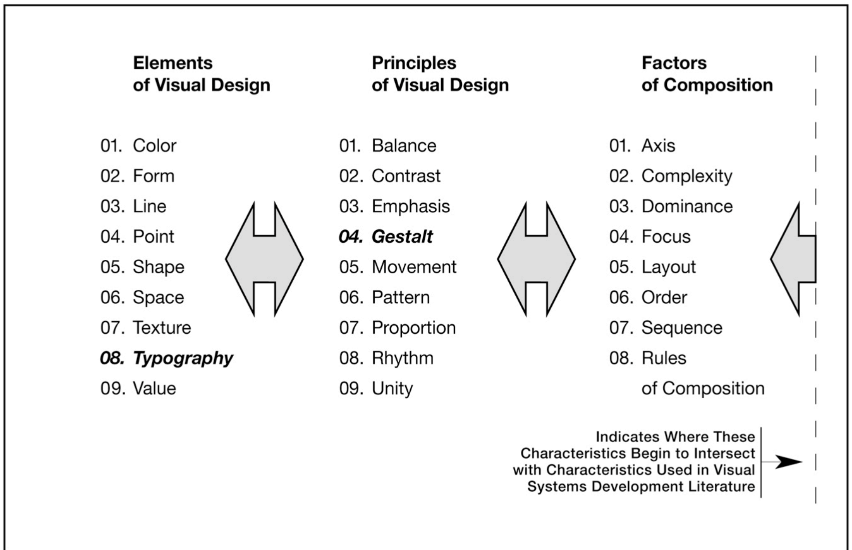

Figure 1. Aesthetic Characteristics Derived from Traditional Visual Design

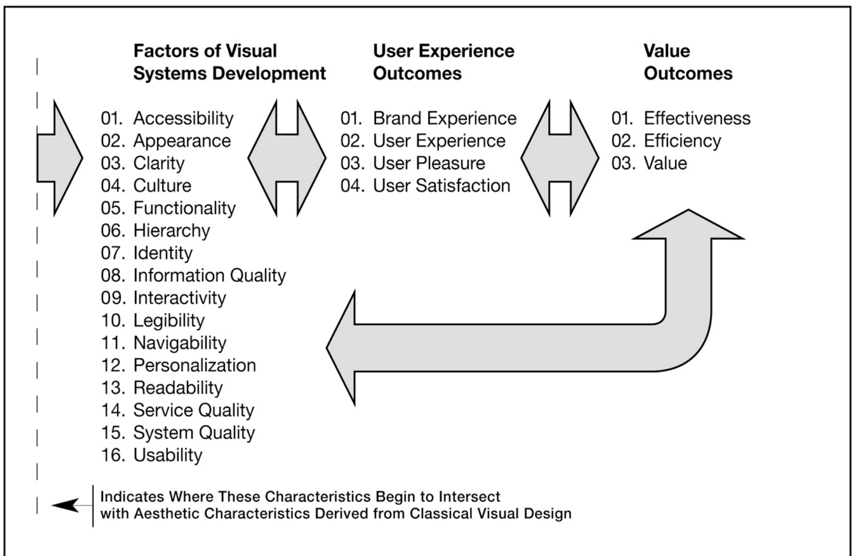

Figure 2. Functional Characteristics Derived From Visual Systems Development Literature

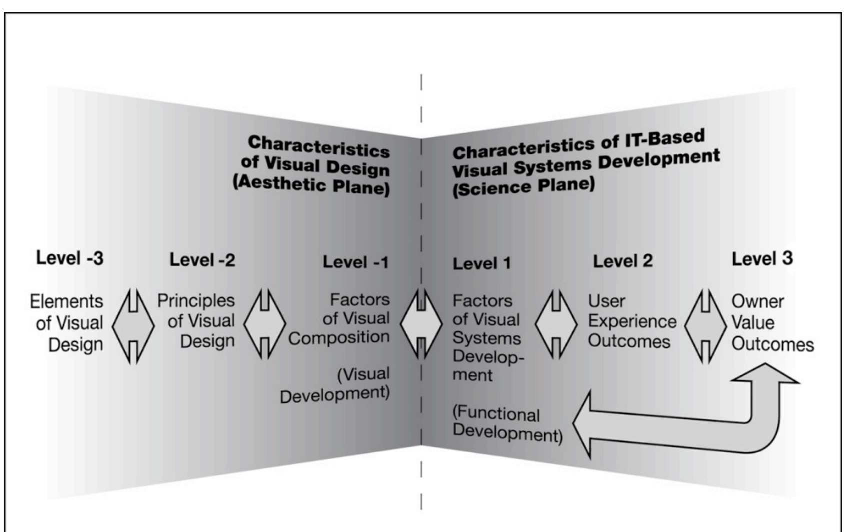

Figure 3. Framework for Visual Systems Design

The terms listed under the headings Elements of Visual Design, Principles of Visual Design, and Factors of Composition in Figure 1 and in other parts of this paper are derived from visual arts and visual communication design (these are articulated in detail in Tables 2, 3 and 4); similarly, the terms that are listed under the headings Factors of Visual Systems Development, User Experience Outcomes and Value Outcomes in Figure 2 and in other parts of this paper are derived from researchers and practitioners who develop their theories and test their hypotheses according to the scientific method (these are articulated in detail in Table 5, 6 and 7). While the authors acknowledge that these two sets of terms evolved separately and for different reasons, they believe that they can be carefully joined. This led them to the realization that all of the terms under the aforementioned headings in Figures 1 and 2 could function in this study as “variables,” and that these groupings of headings and their respective variables could be called “dimensions,” which are descibed in more detail in the next two paragraphs. These dimensions can then be formed into the “constructs” that are depicted as the two intersecting paradigmatic planes in Figure 3. The designations constructs, dimensions, and variables are positivistic research terminology.

Table 2. The Elements of Visual Design; Dimension Level -3 in the Typological Framework for Visual Systems Design

Element/Variable	Definition
Color	The perception of particular wavelengths of light as specific hues by the color receptors of the human eye
Form	3-dimensional, the visual appearance of an object in space
Line	1-dimensional, a continuous series of points; defines the edge of a shape or the boundary along which two shapes meet
Point	0-dimensional, a dot on a surfacee-Service Journal
Shape	2-dimensional, the boundary of an object; a self-contained area of either geometric or organic form
Space	The portion of an area that appears to be empty, the portion of a surface that is unfilled; the portion of a page left unmarked, existing between graphics, margins, gutters, columns, and text elements
Texture	The visual sensation of touch; the surface quality of a shape or form
Typography	Describes how the visual design of elements such as letterforms and the configuration of systems of these elements are organized on a printed or pixel-rendered page to facilitate the visual communication of language
Value	The lightness or darkness of a color

Table 3. The Principles of Visual Design; Dimension Level -2 in the Typological Framework for Visual Systems Design (These Involve Combining One or More Elements of Design)

Principle/Variable	Definition
Balance	The symmetrical or asymmetrical arrangement of objects or spaces within a composition so that they are perceived as having specific visual weight within it
Contrast	Visual dissimilarity between adjacent or juxtaposed objects, textures spatial arrangments or configurations of these within a given visual structure
Emphasis	Relates to the creation of the perception of varying degrees of dominance between the elements that comprise a given composition
Gestalt	A psychological theory suggesting that the mind's perceptions are holistic, continuously attempting to organize unassociated items into a coherent whole; In visual design, the combination of two or more compositional elements with distinct meanings as a means to create a unique, singular perception of new meaning
Movement	Occurs when the arrangement of elements and the spaces between them create the perception of motion (overlaps with rhythm) 2-dimensional, the boundary of an object; a self-contained area of either geometric or organic form
Pattern	An underlying model or structure that organizes surfaces or structures in a consistent, regular manner
Proportion	Scale-based relationships between one element and another, or between an entire entity and its component parts
Rhythm	Visually-timed or organized movement through space achieved by repeating or alternating elements and the intervals between them
Unity	Describes the relationships between the individual parts of a composition and the whole entity necessary to create the perception of wholeness

Table 4. Factors That Affect Compositional Structure in Visual Design; Dimension Level -1 in the Typological Framework for Visual Systems Design; Intersects with the "Science" Plane

Principle/Variable	Definition
Axis	Establishing a straight or curved line along which particular elements may be aligned to achieve balance and order within a composition
Complexity	The relative number of related parts in a composition; the degree of organization resulting from manipulating elements and principles of visual design
Dominance	The most prominent object(s) or characteristic(s) of a composition; establishing a perceptible hierarchy of emphasis, from most-important element(s) to least, in a given composition
Focus	A single, particular area of emphasis in a composition
Layout	The planned arrangement of objects and the spaces between them on a surface or page
Order	An organizational hierarchy of object characteristics arranged by importance; establishing varying degrees of emphasis in a composition through the successful manipulation of the elements and principles of visual design
Sequence	An underlying model or structure that organizes surfaces, spaces, or structures in a predictable, regular manner
Rules of Composition	Rule of thirds, rule of odds, rule of space, rule of the golden mean, etc.

Table 5. Factors That Affect the Development of IT Systems; Dimension Level 1 in the Typological Framework for Visual Systems Design; Intersects with the "Aesthetic" Plane

The factors presented in this list appear in alphabetical order in Figure 2.

Factor/Variable	Definition
Operational Factor *(Accessibility)*	The capacity to serve all users: "How well does the system comply with best practices and laws that address the needs of specially abled users?"
Operational Factor *(Functionality)*	How effectively does a given interactive visual system meet and fulfill the essential purpose(s) for which it was constructed?
Operational Factor *(Interactivity)*	How easy is it for specific users to cognize the manner in which the components that comprise a given interactive visual system are supposed to be operated to facilitate that system's functionality? Having done this, how easy it for them to actually operate them?
Operational Factor (Personalization)	How effectively can a given interactive visual system be adapted by a specific user to suit his or her personal preferences?
Operational Factor (Usability)	How effective, efficient, and satisfying is the experience of using a given interactive visual system to a specific user as he or she accomplishes necessary or desired tasks?
Actualization Factor *(Hierarchy)*	The cumulative ranking, order, complexity, and depth of the parts that consitute a given interactive visual system; also a factor crucial to visual design (as expressed in *Factors of Composition* such as *Dominance, Focus, Order* and *Sequence*)
Actualization Factor *(Navigability)*	How effectively can a user perceive and traverse a given system's hierachy of information? (Also a factor crucial to visual design, as expressed in *Factors of Composition* such as *Dominance, Focus, Order* and *Sequence*)
Visual Perception Factor (*Appearance*)	Accounts for "look and feel:" How does the initial impression of the system affect the visual perceptions of given groups of users?
Visual Comprehension Factor (*Clarity*)	How effectively are essential messages perceived, interpreted and acted upon by specific users?
Visual Comprehension Factor *(Legibility)*	How easy is it for someone who is not visually impaired to discern the inherent empirical differences in the typographic elements that appear throughout a given interactive visual system well enough to be able to read them?
Visual Comprehension Factor *(Readability)*	How psychologically "unintimidating" and "easy-to-read" do the typographic elements that appear within a given interactive visual system appear to a specific user?
Empathetic Factor *(Culture)*	How effectively has the inherent functionality of the system been tailored to accommodate the shared beliefs, customs, attitudes, and preferences of particular groups of users?
Empathetic Factor *(Identity)*	How effectively does the system accommodate and reflect a given user's/user groups' unique sense of social, cultural, economic or political belonging? (This factor is often referenced in relation "persona-based marketing" and "tribal marketing.")
Qualitative Factor *(Information Quality)*	How effectively does the information presented within a given interactive visual system meet the real and perceived needs of a given user?
Qualitative Factor *(Service Quality)*	How effectively do the transactional, logistical, and information delivery services providided by a given interactive visual system meet a specific user's real and perceived needs?
Qualitative Factor *(System Quality)*	How effectively does the overall functionality facilitated by a given interactive visual system meet a specific user's needs?

Table 6. User Experience Outcomes; Dimension Level 2 in the Typological Framework for Visual Systems Design; Intersects with the "Aesthetic" Plane

Outcome/Variable	Definition
Brand Experience	The quality, extent, and intensity of a specific user's understanding of and experience with a given brand's essential promises, touch points, marketing axioms, etc. as facilitated by the manner in which these are communicated throughout a given interactive visual system; it is this outcome that informs how a given product or service is perceived differently from others that are very similar to it
User Experience	Describes the overall quality of a specific user's experience with a given interactive visual system; this outcome is affected by how the system is perceived, learned and actually used
User Pleasure	Describes the level of enjoyment or delight that a specific user experienced as a result of his or her interactions with a given interactive visual system
User Satisfaction	The level of contentment or approval a specific user experiences as a result of his or her interactions with a given interactive visual system; the degree to which the user actually "likes" interacting with the system

Table 7. Owner Value Outcomes; Dimension Level 3 in the Typological Framework for Visual Systems Design; (these measure the overall success of the system on behalf of its owner)

Factor/Variable	Definition
Effectiveness	The extent to which a given interactive visual system accomplishes the purpose or purposes for which it was developed
Efficiency	The extent to which the benefits generated by a given interactive visual system outweigh what it costs to operate it
Owner Value	Subjectively, the extent to which a given interactive visual system contributes to the satisfaction of some predetermined criteria, including customer satisfaction, compliance, loyalty, revenue generated, etc.

The "Aesthetic Plane" (fully articulated in Figure 1) in this framework is comprised of a hierarchical arrangement of characteristics that have been appropriated from several sources of current, empirically based visual theory (Leborg, 2006; Arnheim, 2004; White, 2002; Wong, 1993; Dondis, 1974; Wong, 1972) and from the author with a background in communication design education and research. These characteristics are organized into The Elements of Visual Design, The Principles of Visual Design and The Factors of Composition, and are depicted in Figure 1. They are also depicted as hierarchical dimensions numbered -3, -2 and -1 respectively in the "intersectional diagram" illustrated in Figure 3. Tables 2, 3 and 4 articulate the meanings of the terms that constitute each of these hierarchical dimensions. Variables from Tables 2, 3 and 4 (contrast, emphasis, balance, focus, readability and appearance) that are used in this study were presented to 105 participants in the study, described later in this paper. This occurred prior to their engagement in any of exercises that involved their operations and assessments of the samples of interactive visual systems during the study.

The "Science Plane" (articulated in Figure 2) in this framework is comprised of a hierarchical arrangement of characteristics aggregated from a review of scholarly literature that informs IT web development, HCI, IS, CS and e-commerce ventures (Table 1), and from the two authors who have extensive experience in IT and HCI research and teaching. These characteristics are organized into Factors of Visual Systems Development, User Experience Outcomes and Value Outcomes and are depicted in Figure 2. They are also depicted as hierarchical dimensions numbered 1, 2 and 3 respectively in the "intersectional diagram" that forms Figure 3. Tables 5, 6 and 7 articulate the meanings of the terms that constitute each of these hierarchical dimensions.

It is important to note that the authors have configured the intersecting Aesthetic and Science Planes in Figure 3 so that the three dimensions (described as Levels) that comprise them can exist such that a bi-directional "flow of influence" affects the variables under each dimensional heading. In this way, an Element of Visual Design/Level -3, such as value can affect a Factor of Visual Systems Development/Level 1, such as readability or system quality. Knowledgeable visual communication designers learn this during the earliest stages of study as an undergraduate, but often have great difficulty articulating how the variables under the Aesthetic Plane affect those that exist under the dimensions that form the Science Plane, especially to those unfamiliar with design programs (Frascara, 2007). IT theory and practice inadequately addresses aesthetics and the variables in the Aesthetic Plane. Instead, IT theory and practice confines itself almost exclusively to the Scientific plane. Conversely, the opposite is also true for Communication Design theory and practice. It inadequately addresses how the variables in the Scientific Plane affect the variables in the Aesthetic Plane, and confines itself almost exclusively to the aesthetic plane.

The authors contend that the dissimilar treatment of the aesthetic and positivistic approaches to systems design has resulted in dysfunctional processes in the aesthetic realm and unaesthestic systems in the positivistic realm. The authors' research has led them to the realization that the common knowledge of the IT world is not the common knowledge of visual interaction designers and vice-versa. This paradoxical problem "…works both as a trigger to creative imagination and as a context for the evaluation of the design. For a solution to be a solution, it needs to be recognized as such by all of the relevant discourses. In practice, it should be acceptable to all of the relevant stakeholders (Doorst, 2006, p.15)". The research in this paper is a first step in a process of "bridging a gap in understanding" between researchers whose work is fundamentally informed by two different paradoxical perspectives, and it represents an initial movement toward achieving greater appreciation and comprehension between the two.

Assessing the Affects of Specific Dimensional Variables from the "Science Plane" on Those from the "Aesthetic Plane"

A Contextualization of the Authors' Approach

Research that affects the design and development of interactive visual systems has to account for issues that are framed by epistemological, praxiological and phenomenological concerns (Cross, 1999). It is in response to this diversity of fundamental concerns that the essential contentions of this paper are made. Just as there once was a time in IT systems design when functional websites were developed without database design (and now they are), current IT systems websites are developed without enough knowledge of the affects of visual design (and they still are not). Similarly, there was once a time when interaction designers failed to approach the design of visual interfaces differently than for print (and now they do), current interaction designers develop websites without enough knowledge of the effects of IT (and they still do not).

Interactive visual systems must effectively facilitate web applications, social networking and the semantic interpretation of data. The way they are used, and the way those who use them interpret meaning and act on those interpretations is based on how both the aesthetic configuration and the functionality of all of the elements of a given interactive visual system are perceived by particular people. The perceptions and subsequent actions taken by any group of users within such a system are directly and indirectly affected by several factors. Among them are:

- the user's ability to synthesize data derived from sensory cues (cognition);
- their socio-cultural perceptions of visual gestalts (semiotics);
- their emotional responses to specific representations of information presented visually (psychology);
- their abilities to conform their activities to the system based on how the design of that system has been configured to facilitate its functionality (information design).

The first and third items from this list form rubrics for the factors that were of greatest concern to the authors during the study, but this does not imply that the authors believe they are most important among this group. Rather, in the context of the test instrument utilized in this early phase of their research, they were the most straightforward in examining constraints imposed by time, the ability to secure viable responses from a large enough group of participants, and the accessibility of necessary physical facilities.

A Description of the Study and of the Methodology That Guided It

The demonstration study described in this section was designed to test a given group of users' abilities to perceive the way that the manipulation of particular sensory cues influenced their visual perception of a specific interactive visual system. This system was a simple, commercial website interface for a small interior design firm. This interface was selected due to its uncomplicated visual organization and low level of functional complexity, and these characteristics were held constant throughout the study.

The authors' primary objective was to test their hypothesis that a dependent variable located in the positivistically informed, paradigmatic "Science Plane" (see Figures 2 and 3) could be directly influenced by the manipulation of one or more variables from the leftmost edge of the paradigmatic "Aesthetic Plane" (see Figures 1 and 3). They chose the factors appearance and readability from dimension Level 1 as representative variables from the Science Plane, which exist under the dimension Level 1 heading Factors of Visual Systems Development and are described in Table 5 as sub-dimensions of Visual Perception and Visual Comprehension. From the Aesthetic Plane, the factors color and value were chosen from under the dimension Level -3 heading Elements of Visual Design. The variables contrast, emphasis and balance were chosen from under the dimension Level -2 heading Principles of Visual Design, and the variable focus was chosen from under the dimension Level -1 heading Factors of Visual Composition. The authors chose not to examine how variables under the dimensions of the Science Plane influenced the variables in the Aesthetic Plane because a). that research is ongoing and not yet complete, and b). even if it had been completed in time to include in this paper, it would constitute the content of either a separate paper or a lengthy addition to this one.

The authors used the original version of the website interface as the control element of their test instrument (Figure 4). They created altered versions of it wherein the factors color and value from the dimension Level -3 heading Elements of Visual Design were manipulated so that the visual perception of these altered versions would be perceived as significantly different from the original version. The authors then performed three stages of instrument development: alpha, beta, and pilot testing. The alpha testing stage involved soliciting contributions from a panel of five communication design, information technology, and survey design experts from within the sphere of the authors' University, who developed, tested, and obtained approval for the initial instrument from their University's institutional review board. The beta testing stage involved the review and testing of the instrument by a panel of 10 doctoral students from all of the University's College of Business' (CoB's) five departments. The beta testing stage revealed that several more minor revisions needed to be made to the test instrument (depicted in Figure 5) before it could be utilized with undergraduate participants from both CoB and the University's College of Visual Arts and Design's (CVAD's) Department of Design. Once the authors completed these revisions, the test instrument was made available for online operation to 38 fourth-year, undergraduate, communication design majors (although only 18 responded) and 67 third-year, undergraduate information technology and decision sciences and marketing and logistics majors.

Facilitating the Study with the Test Instrument

The test instrument contained six groups of six identical questions and required an average of less than ten minutes to complete. The authors assured students that their anonymity would be preserved, and that their participation was entirely voluntary. Students had a choice between completing the questionnaire for extra credit, completing an equivalent extra credit activity, or not participating in the study at all, which resulted in receiving no credit.

The participants in the study from communication design were all enrolled in a fundamental, web-based, interactive systems design course and had just completed week six in their course schedule when they participated in the study. The students enrolled in CoB majors participated in the study at various times during the 15-week semester during which the test instrument was made available to them online. To account for the disparity between the two groups regarding the understanding of how aesthetic considerations affect and effect interactive visual systems, the authors crafted the study so that it only challenged participants to identify to what degree they perceived change between between the control website interface and a series of six variations to this interface (see Figure 5).The authors did not call for participants to render any type of judgment about whether or not the changes in any of the six variations improved or worsened the interface design in any of the Levels on either of the two paradigmatic planes depicted in Figure 3. This would have required the entire group of participants to possess relatively well-developed aesthetic skills and sensibilities, which was not the case, since students in the CoB typically do not receive instruction in visual design. The authors determined that student participants were appropriate for this study because all of them were regular computer users and had a great deal of familiarity with operating interactive visual systems, especially the types necessary to use websites and navigate the Internet.

The test instrument manipulates, in sequence, two independent variables in the design of the control interface: value and color (Elements of Design, Level -3 in the Aesthetic Plane, Figure 1). The authors manipulated these to change the way that the components of the control interface (Figure 4) might be perceived by the student participants of the six different color/value variations. An example of a how the student participants were presented with a configuration of the control interface and a variation of it appear together in Figure 5. Each of the six variations was accompanied by an image of the control interface for comparison purposes. The study participants only needed to acquire a basic understanding of contrast, emphasis, and balance (Principles of Visual Design, Level -2, see Figure 1), focus and readability (Factors of Composition, Level -1, see Figure 1), and appearance (Factor of Visual Systems Development, Level 1, see Figure 2), since these were the characteristics about which they would be queried throughout the test instrument. The communication design students in the study were already familiar with these terms, as their coursework requires them to develop a working knowledge of them. The authors provided definitions for each of the terms prior to the commencement of the study. The participants received access to explanations and definitions of the terminology in three ways: 1. verbally, 2. in the explanation section of the online instrument and, 3. by mousing over them whenever they appeared in the online test instrument. The compositional configuration of the interface was held constant throughout the study; the Factors of Visual Composition, Level -1 (Figure 1)—order, complexity, layout, rules of composition—were not manipulated in any of the six variations to the control interface during the study. The authors believed that introducing more variables would be beyond the scope of this study.

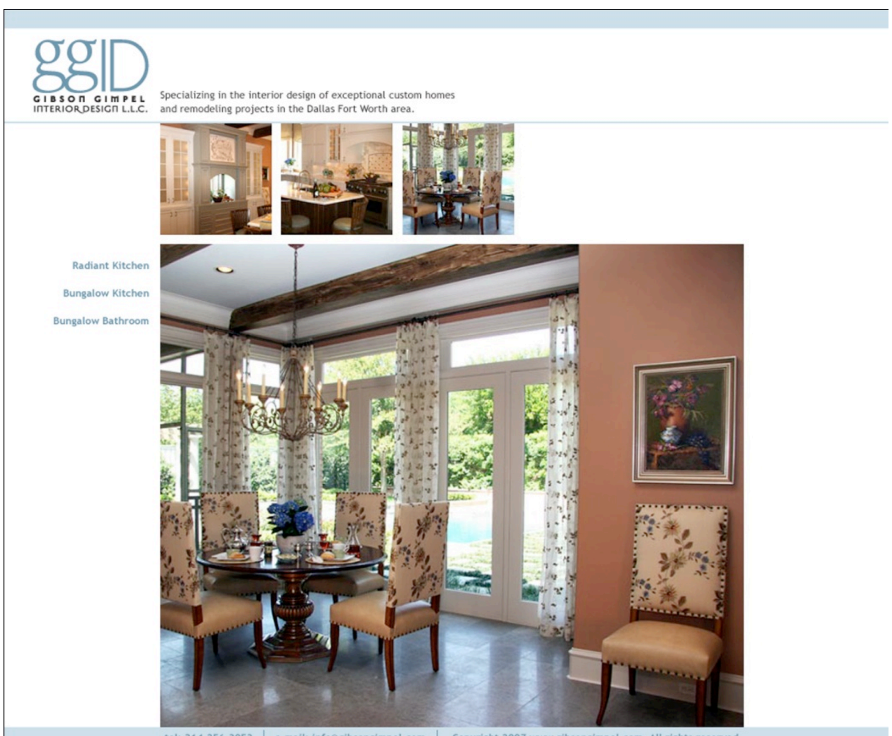

Figure 4. The original ("control") web interface used in the Study

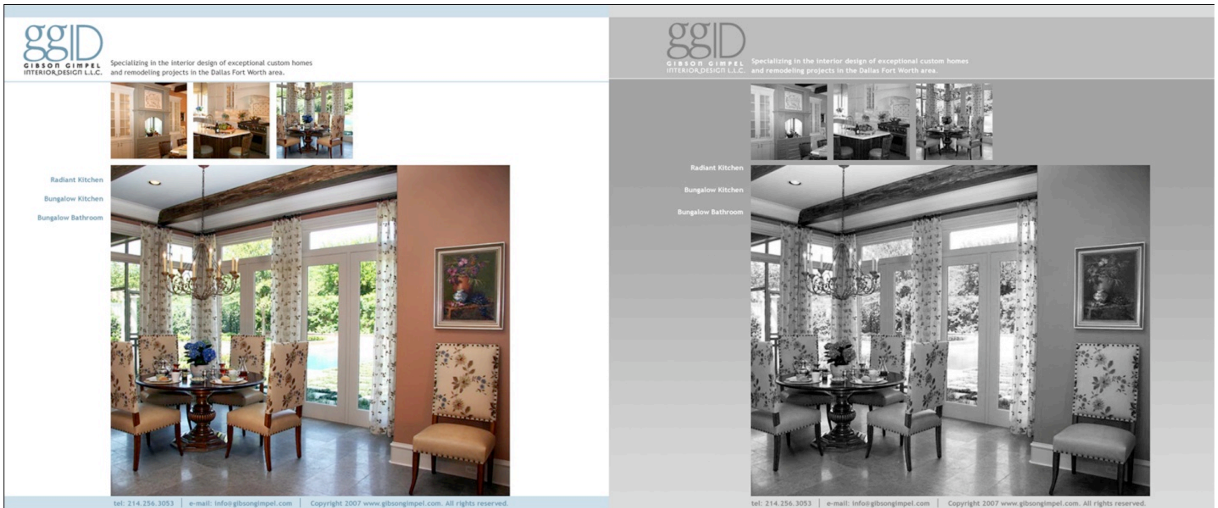
Change in each of the six variations to the control was achieved by manipulating either the colors or the values of the components that appeared within it. The authors presented six questions directly beneath this configuration; each question solicited responses by using a seven-step Likert scale from “Strongly Disagree” to “Strongly Agree” (Figure 5).



1. You perceive a change in the ***contrast*** between the original interface design and the variable. — 1 2 3 4 5 6 7
2. You perceive a change in the ***emphasis*** between the original interface design and the variable. — 1 2 3 4 5 6 7
3. You perceive a change in the ***focus*** between the original interface design and the variable. — 1 2 3 4 5 6 7
4. You perceive a difference between the ***readability of the type*** in the original interface design and the variable. — 1 2 3 4 5 6 7
5. You perceive a change in the ***visual balance*** between the original interface design and the variable. — 1 2 3 4 5 6 7
6. You perceive a difference between the ***overall visual appearance*** in the original interface design and the variable. — 1 2 3 4 5 6 7

On this scale:
1 = strongly disagree;
4 = neutral;
7 = strongly agree

Please indicate your strength of agreement by choosing only one of the seven roundels per line in the scale at left.

Figure 5. A sample page from the Pilot Survey, depicting the control interface and a manipulated interface as the participants in the Study encountered them. Each time a participant encountered one of these comparisons (six were used), he/she was asked to respond to the six statements that appeared immediately below the two interfaces by checking one of the radial buttons in the seven-step Likert-scale response table. Each participant could view a brief definition of the italicized terms by mousing over them at any point during the Pilot Survey.

The Results of the Study

A total of 105 responses were collected from the combination of communication design and CoB students. The communication design group of participants was used as an expert calibration group. These participants had all completed at least three years of undergraduate study in the communication design curriculum at the authors’ university. Approximately 83 percent of their responses were above neutral Likert item 4 (see Figure 6). This established a baseline for 83 percent of the items they perceived, indicating that visual change had occurred. For 72 percent of the items above Likert item 5, they either agreed or strongly agreed that change had occurred.

The three business groups, having 87 total respondents, reflect the same perception patterns, with frequencies of 77, 78, and 75 percent above neutral, and a 66, 60, and 61 percent in agreement or strong agreement that change had occurred. The authors suggest that these results indicate that the communication design students had a deeper understanding of the extent to which color and value affected change in each variation.

Figure 7 depicts the arithmetic means for the independent variables in all groups. In the expert communication design group, the variables that exhibit the strongest agreement are the visual variables of appearance, contrast, and readability. The three business groups also exhibit the strongest agreement for these three variables. Similarly, these three variables account for 57 percent of the measured change for the expert group, and 54, 52, and 54 percent for the business groups. The variables balance and emphasis received the lowest scores in all groups. Although the business respondents' results do not demonstrate the crispness and clarity of perception possessed by the communication design group, the results support the contention that the business groups perceive almost the same intensity of change and the same direction of change as the more expert group. The scores and means of the respondents for all groups confirmed that all of them perceived that a visual change had occurred, and all groups agree that changes occurred, and all groups agree regarding the intensity of that change. Generalizing this finding, we confirm the substantial research across a multitude of disciplines asserts that the effects of aesthetic design can be perceived by most normally-sighted individuals.

The authors also believe that these results support the idea that aesthetic training enhances the visual perceptions of individuals who use or develop visual interfaces. Although this may seem obvious to designers who regularly operate in the Aesthetic Plane, the authors believe it is not known or understood to IT systems developers who regularly operate in the Science Plane. This pluralistic testing of aesthetic phenomena in interactive visual systems design is based on a positivistic inquiry, using the scientific method. Thus, the authors believe that this supports their premise that the two paradigmatic planes are compatible for interactive visual systems design.

Conclusions

The authors' implemented their proposition that the intersection of the Aesthetic Plane and the Science Plane can be compatible. The instrument used to test this assertion manipulated a limited array of visual design variables: color and value (which were independent), contrast, balance, emphasis, focus, readability and appearance (which were dependent), and order, complexity and layout (which were held constant). All of the participants in the study, regardless of their educational backgrounds or training, perceived aesthetic changes similarly when measured by a scientific instrument.

The results suggest that interactive visual systems researchers and developers from both paradigms can perceive visual changes to the systems similarly, even if their perceptions are informed by different philosophical approaches. It also suggests the value inherent in challenging researchers and practitioners working in communication design and IT to significantly expand their inquiries into each others' spheres of understanding. It is not enough for those working in IT to have "read a bit of Moggridge, Winograd, Mullet and Sano" to improve their knowledge of the effects of aesthetics on various user groups' abilities to operate interactive visual systems, just as it is conversely not enough for communication designers to have "read a bit of De Angeli, Sutcliffe, Hartmann and Kristof" to improve their knowledge of the design and implementation of functionally focused interactive visual systems.

That being said, the authors also concluded that the variables that form the two intersecting paradigmatic planes utilized here reveal a set of limitations that further study must overcome. The necessity of further empirical study and more broadly informed reasoning from both communication design and IT must be brought to bear if the relationships between the sets of variables that occupy the Levels and the Planes are to reveal more useful, useable knowledge.

Further examination of the "cross-Level" effects of the variables of each of the Planes presented a vast and complex network of interdependent, cause-and-effect relationships between elements, factors, variables, sub-variables, dimensions and constructs. Accounting for how the complex web of relationships throughout the entire amalgam of the variables from beyond Levels 1 and -1 affected each other was a complex task, and this complexity limited the authors ability to some degree throughout the study. This complexity also inhibited their attention on the area of the two intersecting planes that form the main bridge between visual design and IT, in which they had originally anticipated a broader accounting of variables from all the Levels.

Next Steps

This experimental study leads the authors to conclude that their hypothesis is confirmed. It affirmed the efficacy of using this type of pluralistic research typology and framework to better inform designers and IT researchers and practitioners. In addition, these results justify integrating the knowledge that exists in the realms of visual design and functionally motivated information systems, and information technology design.

The authors' research findings reveal that the greater contribution to both the IT and the interactive visual systems design communities will be made by concentrating their efforts on integrating the tenets of traditional (functional) systems design and visual design. This concentration will steer them away from attempting to study aesthetics with a positivist approach, which is a less viable approach for achieving their research objectives. The ultimate goals are still to 1. address deficiencies in IT researchers' and professionals' understandings about how aesthetic decisions affect users' perceptions of and actions within functional systems, and 2. to address deficiencies regarding visual systems designers' understandings of how functional IT systems are planned, implemented and effectively sustained.

For the next step in this research, the authors will focus on how selected factors of visual development should be integrated with the factors of functional information systems design. This research will proceed in stages, incorporating the knowledge that the authors have gained from the model presented in this paper, but will be limited by examining the effects of only a few of the variables at a time from the current model's Level -1 and 1, which a few others have recently demonstrated to be more easily supported by empirical findings (Hassenzahl, 2003). The next study that the authors plan will focus on groups of communication design students and CoB students and practicing business professionals in the near future.

Authors' Biographies

Michael R. Gibson

Michael R. Gibson teaches communication design studio courses, as well as design research, criticism, history, theory and interactive media at The University of North Texas (UNT) College of Visual Arts and Design (CVAD). He is also the Program Coordinator for UNT CVAD's graduate programs in Design with concentrations in Innovation Studies. These programs immerse graduate students from a diverse array of backgrounds in learning situations wherein design research operates as a means to utilize design methods to reveal or generate new knowledge that emerges during their engagement in select design processes. Associate Professor Gibson has managed a strategic design consultancy since 1987, which has afforded him numerous opportunities to attempt to bridge the divide between the practical demands of professional practice and the need to account for how the results of design processes affect and are affected by a broad spectrum of social, technological, economic, environmental and political issues. His original and applied research projects have addressed issues in freshwater conservation and management, the marriage of positivistic and aesthetic research paradigms in interactive visual systems design, children's and women's health, media ethics, and the introduction of design pedagogy in select middle school settings.

Daniel Peak

Daniel Peak is an Associate Professor in the Information Technology and Decision Sciences Department in the College of Business at the University of North Texas. He has extensive information technology (IT) consulting experience in the corporate arena, and has serviced clients as diverse as Chase Manhattan Bank, The Atlantic Richfield Company (ARCO), Prodigy, IBM, Pacific Bell, Ernst and Young and The Union Pacific Railroad Company, among others. He has also published extensively to document his research in the areas of IT alignment planning, information science system service quality, IT education, and the evolution of media technology in select academic disciplines.

Victor Prybutok

Victor R. Prybutok is a Regents Professor of Decision Sciences in the Information Technology and Decision Sciences Department and Coordinator of the ITDS Department Doctoral Program in the College of Business at the University of North Texas. He served as the Director of the Center for Quality and Productivity in the College of Business at the University of North Texas (UNT) from 1991 to the summer of 2008. Dr. Prybutok has made numerous presentations on quality control, including the Keynote Address and CEO session at the College of Osteopathic Health Care Executives Annual Conference and the American Osteo-pathic Hospital Association Trustee Forum (March 29–April 1, 1992). He has authored over 90 journal articles, more than 70 conference presentations / proceedings, and several book chapters in applied and theoretical areas of information systems measurement, quality control, risk assessment, applied statistics, and the instruction of statistics. Journals where his published articles have appeared include *The American Statistician, Communications of the ACM, Communications in Statistics, Data Base, Decision Sciences, European Journal of Operational Research, IEEE Transactions on Engineering Management, MIS Quarterly, OMEGA: The International Journal of Management Science,* and *Operations Research.*

Design Fiction: A Method Toolbox for Design Research in a Complex World

Simon Grand, University of Applied Sciences Northwestern Switzerland,

simon.grand@fhnw.ch

Martin Wiedmer, University of Applied Sciences Northwestern Switzerland,

martin.wiedmer@fhnw.ch

Abstract

Current debates on design research, and its relation to other research fields and scientific disciplines, refer back to a fundamental distinction introduced by Herb Simon (Simon, 1996 (1981)): Design and design research do not primarily focus on explaining the world as it is; they share with engineering a fundamental interest in focusing on the world as it could be. In parallel, we observe a growing interest in the science studies to interpret scientific research as a constructive and creative practice (Knorr Cetina, 1999; 2002), organized as experimental systems (Rheinberger, 2001). Design fiction is a new approach, which integrates these two perspectives, in order to develop a method toolbox for design research for a complex world (Bleecker, 2009; Wiedmer & Caviezel, 2009; Grand 2010).

epistemology; science studies; design fiction; experiment

Introduction

Research Context & Basic Hypothesis

Design research looks back to several decades of debates concerning the practice, theory, methodology and epistemology of design research (Cross, 2007; Bayazit, 2004). Thereby, we can identify different approaches to defining and structuring the field: some scholars focus on mapping and structuring the multiple existing, *self-declared research projects, identifying dominant clusters* and research fields (Sanders, 2006; Laurel, 2003; Gray 2004), assuming that what identifies as design research actually qualifies as design research; some scholars argue for *particular epistemologies and theories* as a promising starting point to define possible approaches in design research (Cross, 2007; Fallman, 2003; Findeli & Bousbaci, 2005), suggesting that design implies particular ways of knowing and thus also particular epistemologies; some scholars characterize design research in relation to other scientific disciplines or a general pre-understanding of science, arguing for *particular qualities of design as a scientific research discipline* (Cross, 2006) or *emphasizing the oxymoron* inherent in any attempt to link design to scientific research (Frayling, 1993; Krippendorff, 2006).

One interesting observation thereby is, that implicitly or explicitly, these various attempts continue to refer to a fundamental perspective introduced decades ago as a root distinction in design research (Simon, 1996 (1981)): Design and design research do not primarily focus on the world as it is, like most scientific disciplines, trying to develop descriptions, interpretations, and explanations of existing objects, processes, and activities; design and design research share with engineering a fundamental interest in *focusing on the world as it could be, on the imagination and realization of possible futures*, as well as on the disclosure of new worlds. This implies a reflection of the contingencies of our world today, and of the practices for creating, imagining, and materializing new worlds. Another interesting observation is, that the controversies in the science studies concerning scientific research in general increasingly emphasize the *inherently constructivist and imaginative nature of scientific practice* (Galison, 1997; Knorr Cetina, 1999; 2002), the importance of improvisation (Knorr Cetina, 2002) and experimentation (Rheinberger, 2001) for the research process in general, or the primary role of artifacts (Knorr Cetina, 1999), images (Jones & Galison, 1998), or materiality (Galison, 1997) and their design in research practice.

Instead of arguing for design research as a particular approach to scientific research, or for design research as being systematically different from scientific research, it is much more appropriate to understand in more detail the close relation between design as the imagination and creation of possible future realities (Jonas, 2007; Bonsiepe, 2007) on the one hand, and the construction of reality and objectivity in scientific research (Daston & Galison, 2007) on the other hand. In this perspective, we argue for an approach, which understands *research as design* (Grand, 2010), and thus as a systematic extension of the current discussions in design research. Such an approach has two fundamental implications: First, it implies that the conceptualization of design and design research as a practice and research field, which particularly focuses on the world as it could be, should be taken as the actual core for defining and practicing design research: This is what we call *design fiction* (Wiedmer & Caviezel, 2009; Bleecker, 2009). Second, it implies that design is a productive approach to conceptualize scientific research itself as a design practices: This is what we call *research as design* (Grand, 2010; Jonas, 2010).

Current Relevance & Open Issues

This characterization of design and design research, as well as of scientific research in the perspective of design, is particularly important and relevant today: As we learn from the recent science and technology studies (among others: Nowotny, 2008; Nowotny, Scott & Gibbons, 2001; Rheinberger, 2001; Bijker & Law, 2000; Biagioli, 1999; Latour, 1999; Felt, Nowotny & Taschwer, 1995; Bjiker, Hughes & Pinch, 1989), our societies are involved and engaged in fundamental debates and reflections concerning not only the world as it is, but concerning possible futures, in many areas. Thereby, those debates and reflections are characterized by a high complexity, due to the multiple perspectives, interests, concerns, issues, and approaches, which are represented by the multiple parties involved. From the perspective of the development of our contemporary societies, we can argue that these societies become increasingly knowledge intensive (Stehr, 1994), reflexive (Beck, Giddens & Lash, 1994), and experimental (Latour, 2004), implying that knowledge creation, scientific research and technological innovation are central to our societies. From the perspective of scientific research, we can argue that the sciences are social (Nowotny, Scott & Gibbons, 2001), technological (Bijker & Law, 2000), and commercial (Stehr, 1994).

Our world is increasingly involved and engaged in complex, collective political and economic debates and experiments (the current financial crisis is just one of the most recent examples), in which different actors including governments, companies, NGOs, social movements, virtual communities, … are engaged, and in which the differentiation between scientific research, institutions and laboratories on the one hand, and societal and political processes on the other hand, are blurring (Novotny, 2008). As the same time, this opens new opportunities for research as design, if design is understood as the creation, realization and materialization of possible future realities. In most cases today, the reactions and actions in those collective debates and experiments are not particularly imaginative and creative. We thus suggest that design and design research are pre-disposed to play a very active and important role in those controversies and collective experiments, and that design and design research should make its particular practices, tools and methods relevant to those debates, while at the same time developing new tools and methods, which are important for collectively dealing with possible futures in a complex world.

Research Question & Argumentative Structure

In our paper, we develop a strategy for design and design research to contribute to those controversies and activities, which we call “Design Fiction”, asking the research question:

How can design research contribute to the collective controversies and experiments, in which our societies deal with fundamental current and future challenges and transformations of our complex world?

In order to answer this research question, we proceed in three steps: in Part 1, we discuss recent contributions on the epistemology of design research, which indicate productive building blocks and relevant insights into a re-conceptualization of design and design research as design fiction (Bleecker, 2009; Brown, 2008; Bonsiepe, 2007; Krippendorff,, 2007); in Part 2, we discuss some recent contributions in the science studies, which explore, describe and analyze the inherently constructive, creative, controversial, critical, material and imaginative nature of scientific research in general, thus allowing to re-conceptualize the research process as a design process (Latour, 1986; 2005; Galison, 1997; Knorr Cetina, 1999; 2002; Rheinberger, 2001; Nowotny, 2008); in Part 3, we identify current approaches in design and design research (as well as scientific research), which provide particular methods and tools to conduct research in this design perspective (Dunne, 2005; Dunne & Raby, 2001).

Part 1: From Design Research to Design Fiction

The ongoing discussion regarding methodology in design research is characterized by a strong dualism between the assertion of what scientific research means and of what designers do (Chow & Jonas, 2009). In order to explore the current state of the art in this debate, as well as to introduce “design fiction” as a new possible perspective, we discuss some promising epistemological approaches in design research today.

In general, the debate is strongly connected to stereotypes of what artists, designers and scientists do. According to Frayling (1993), the stereotypes of an artist or a designer are typically anti-rational and inward looking; the designer practices hands-on experimentation, not based on systematic hypotheses or orderly procedures. The scientist, to the contrary, has “… conjectures on hypotheses and sets about proving or disproving them according to a set of orderly procedures. His subject exists outside himself […]” (Frayling, 1993, p. 3). Frayling dissolves these stereotypes through investigating the blurred zone between art, design and science.

The identification of the intersection between research and design is thereby a significant thread in many relevant perspectives. Frayling stresses the process of discovering as an important intersection between experimental scientific research and artistic creation. He is going even one step further and references the recent research into the philosophy and sociology of science: “Doing science is much more like doing design” (Frayling, 1993, p. 4) .

He is joined by other approaches, which emphasize for example the intersection of analytic and synthetic processes (Owen, 2007), of design-led and research-led practices (Sanders, 2006), of research-oriented design (focusing on the real) and design-oriented research (focusing on the true) (Fallmann, 2007), as essential for both, design practice and research practice.

Implied in this focus on discovery processes is an explicit focus on processes. “Tinkering” is one of the key factors for innovation in design and sciences according to Bonsiepe (2004). Science as a cognitive and design as a non-cognitive process shows a structural similarity and are both intentional (Joas, 1991). As consequence, Bonsiepe argues in favor of a particular school of reflexivity and thinking (“Schule des Denkens”) in the area of design and design research, nourished and inspired by the particularities of design experience. As a consequence, design research must involve designers, if we understand designers not as a disciplinary category, but as those people able to create and realize possible futures through their thinking and acting, generating new knowledge for design practice.

„Engineering, medicine, business, architecture and painting are concerned not with the necessary but with the contingent - not with how things are but with how they might be - in short, with design“ (Simon, 1969, p. xii). Design research and design can thus be seen as a discipline (amongst others) which deals with practices and processes in order to create preferable, future situations. Designers are aimed at discovering situations which are changeable and designed (Bonsiepe, 2004). They are motivated by challenges, opportunities and possibilities, not seen by others, to change something (Krippendorff, 2007).

When designers envision possible futures, they can rely on multiple ways, methods and strategies how to communicate and materialize possible futures. These „diegetic prototypes“ (Bleecker, 2009, p.7) or sketches in the figurative sense, are more than fully functional engineered prototypes or already finished designs. Design artifacts are an entrance point for critical thinking about the self evident, not only as the world could be, but rather to find a new, distant perspective on reality as it is. In critical design, artifacts thus „… should draw attention to how product limit our experiences and expose to criticism and discussion their hidden social and psychological mechanisms …“ (Dunne, 2005, p. 24).

In line with these prominent approaches in design practice and design research, “design fiction” can be interpreted as a new strategy for design research, trying to benefit from the qualities of a “designerly way of knowing” (Cross, 2007) and the current discussion of design research frameworks, by systematically questioning and deconstructing the self-evident, transcending it towards new, possible futures; concretely materializing, visualizing and embodying relevant controversies and perspectives in the form of artifacts, interfaces, installations and performances; asking “how the world could be” instead of discussing how the world is; thus taking the inherent contingency of the world seriously and thereby exploring insights from different disciplines. Thereby, it is important for any initiative and intervention in design research to find the right focus “in between” the simply utopian, which is too far away from our current concerns and issues to have an impact on the current controversies and approaches, and the too realistic, which is so close to what we already know and experience that no real provocation, relevant challenge, new perspective can emerge.

Part 2: From Scientific Research to Research as Design

Controversies concerning Images of Knowledge

In the science studies, we observe a growing interest to interpret scientific research as a constructive and creative practice (Knorr Cetina, 1999; 2002). It is argued that scientific research itself is a particular way of enacting and shaping reality. If we take this seriously, we can identify two major implications: on the one hand, it must be concluded that what we accept as scientific knowledge at a particular point in time is, emerging from ongoing controversies among multiple parties (Latour, 1999); what we discussed as “designerly” ways of knowing are not inherently scientific or non-scientific, but they must be seen as particular perspectives on scientific research, which over time either become part of a collectively shared understanding of scientific research (Foucault, 1971), or they remain dissident (Krippendorff, 2007).

On the other hand, we learn from the science studies that scientific knowledge itself must be differentiated into three dimensions (Elkana, 1986): the corpus of knowledge is identifying the content of scientific knowledge; the images of knowledge are focusing on the types of knowledge which qualify as scientific (this is the dimension, which is most important in our context); and social values, indicating the inherently political and ideological dimension of scientific practice in general. Our attempt to argue in favor of “design fiction” as a way of approaching design research as scientifically relevant is thus an attempt to enter a controversy and establishing this forward-looking, creative way of knowing as relevant to scientific research in general. Thereby, the science studies themselves increasingly emphasize the inherently constructivist and imaginative nature of scientific practice (Galison, 1997; Knorr Cetina, 1999; 2002), the importance of improvisation (Knorr Cetina, 2002) and experimentation (Rheinberger, 2001) for the research process in general, or the primary role of artifacts (Knorr Cetina, 1999), images (Jones & Galison, 1998), or materiality (Galison, 1997) and their design in research practice.

Scientific Research and Experimental Systems

More specifically, we observe a preoccupation with research on the important role of experimentation in the recent science studies (Knorr Cetina, 1999). It is argued that experimentation has increasingly become the predominant way of scientific research to enact and shape reality in ways, which allow for the exploration of particular research questions and the realization of specific research agendas. Thereby, experimentation is embedded in the creation and construction of specific systems, as specific assemblages of technologies, artifacts, representation tools, methods, research questions, disciplinary perspectives …, which together form an experimental system (Rheinberger, 2001). This implies that contrary to multiple perspectives, which see experimentation in design and design research as a clear indication of the inherently scientific nature of design practice, we argue that it is only through the creation and construction of an experimental system, which allows to explore important open research questions and to investigate a particular research agenda, that design practice and design research have the potential to develop knowledge which potentially qualifies as scientific (Grand, 2010).

Furthermore, we learn from the detailed study of experimental systems, that they are equipped with a series of tools and artifacts, methods and practices, which are closely related to design: first of all, experimental systems are ways of exploring unanswered questions, a feature which we find in various design practices (see below); second, experimental systems require tools and machines, which allow to document and represent the various experiments as they take place, this implying the development and usage of particular representation tools and documentation strategies; third, it is systematically emphasized how important the materialization of an experimental system is, including the selection of particular materials for building experimental assemblages (Galison, 1997), the development of multiple interfaces to conduct those experiments (Knorr Cetina, 2002), the physical, chemical and biological processes, which typically take place in these experiments.

Blurred Boundaries and Collective Experiments

As we learn from some unconventional perspectives in the science studies, the traditional view on experimental systems as taking place in well-defined laboratories with clear boundaries, it is argued more recently that actually those experimental systems have blurred boundaries and involve multiple parties (Nowotny, 2008; Nowotny, Scott & Gibbons, 2001; Rheinberger, 2001; Latour, 1999; Felt, Nowotny & Taschwer, 1995; Bjiker, Hughes & Pinch, 1989): today, most important societal issues and unanswered questions are somewhat related to what could be called collective experiments (Latour, 1999). Our societies can be characterized by fundamental debates and reflections concerning their possible futures, implying a high complexity, due to the multiple perspectives, interests, concerns, issues, and approaches, which are represented by the multiple parties involved. As we discussed above, these societies become increasingly knowledge intensive (Stehr, 1994), reflexive (Beck, Giddens & Lash, 1994), and experimental (Latour, 2004), which implies that (scientific) knowledge creation shifts to the center of society itself; the sciences are thus social (Nowotny, Scott & Gibbons, 2001), technological (Bijker & Law, 2000), and commercial (Stehr, 1994).

Our world is thus itself engaged in multiple complex, collective political and economic debates and experiments, our discussion of experimental system thus grows beyond the traditional scientific laboratories and become increasingly relevant for our understanding of the (knowledge) society in general (Stehr, 1994; Latour, 1999). The opportunities of re-thinking the role of design in scientific research, as well as of re-defining scientific research in the perspective of design, are thus not only appropriate within the boundaries of traditional laboratory settings, but might actually become a way of understanding, describing, structuring and creating the experimental systems, which our societies need to deal with their most controversial, essential and complex questions and challenges. This is what we call research as design, arguing that a designerly way of knowing is fundamental for any attempt to build experimental systems, playing a very active role in those controversies and collective experiments. In this perspective, design and design research should make their particular practices, tools and methods of imagination, materialization, visualization, representation and interaction relevant to those debates, while at the same time developing new tools and methods, which are important for collectively dealing with possible futures in a complex world.

Part 3: Toward a Method Toolbox for Design Research

We argue that our way of conceptualizing design fiction (Part 1) is a particularly promising way of conceptualizing design research and design practice in the perspective of re-interpreting scientific research itself as design (Part 2). In the remaining sections of this paper, we identify some major dimensions for a method toolbox for such design research practices, as well as identify a series of design methods relevant for such a toolbox (Part 3).

Basic Criteria

Based on our discussion of design research and design fiction, as well as of research as design, we see the following dimensions as particularly important for evaluating the scientific relevance of design practices, design methods and design tools for design research: (1)

design fiction requires methods, practices and tools which allow for the *creation and construction of possible future worlds*, in relation to the actual world; (2) furthermore, these methods, practices and tools must allow for *materializing those possible future worlds*, in terms of images, artifacts and interactions realized in diverse media; (3) in addition, it is important to develop a method toolbox which is characterized by a plurality of different perspectives and approaches, which get beyond ideological premises and allow to map and assemble the *pluralities and the multitude of potentially relevant perspectives*; (4) furthermore, these methods and tools must be able to represent, visualize and document the *experimentation processes*; (5) then, we emphasized the importance of understanding experimentation as being generated through an *experimental system*, which implies a focus on asking a series of questions, allowing for a series of experiments, or the exploration of a series of related hypotheses. Finally, (6) it is important to understand that these multiple methods and tools, visualizations and representations, experiments and questions, will *change the design research practices* themselves over time.

Looking at those six criteria, we see that our approach is somewhat parallel to the four fundamental processes, which characterize translation in Actor-Network Theory (Latour, 1999): The creation and construction of possible future worlds inherently implies what Actor-Network Theory identifies as *problematization*: Any suggestion of a future possibility is at the same time a way of questioning the world as it is, it is emphasizing the contingency of our taken-for-granted reality and identifying alternative possibilities as a general option. Furthermore, our emphasis on materializing through the involvement of multiple artifacts, images, media, and on the engagement of multiple perspectives goes in parallel with *mobilization* in Actor-Network Theory. In addition, we emphasize the importance of collectivizing the experimentation processes, engaging multiple actions, artifacts, actors, activities into the process, thus referring to what Actor-Network Theory identifies as *interessement* and *enrolement*. At the same time, our approach is distinct from Actor-Network Theory in two respects: through its emphasis of creating and constructing new possible futures, which can be identified as the distinct contribution of a design perspective on experimentation; and through its emphasis on the systemic nature of experimentation, which is not at the core of the conceptualization of translation in Actor-Network Theory, but important more general.

Possible Research Strategies in the Method Toolbox

In order to systematize our design research method toolbox, we allocate individual research strategies to particular dimensions of the method toolbox. At the same time, it is important to note that each research strategy obviously fulfills multiple criteria and could thus be related to multiple dimensions of the "Design Fiction" method toolbox.

1. Creation and construction of possible future worlds: As discussed, creating possible future worlds at the same time implies to refer to the world as it is: In this perspective, *critical design* (Dunne & Raby, 2001; Dunne, 2005) for example is a promising approach, which is building artifacts, which materialize and visualize the often invisible dimensions of new technologies (including for example electromagnetic fields, …), thereby at the same time criticizing these existing technologies and their ways of hiding important features, while exploring alternatives. Furthermore, multiple design practices are characterized by their focus on exploring research questions: a particularly promising approach in our context is to *ask unanswerable questions*, as it is done by MVRDV in their five minutes city project (as well as in many other research projects), where an unanswerable question triggers the development of unconventional and creative approaches for dealing with urbanistic themes (Maas, 2003). *Reinterpreting the past* is another way of opening new future possibilities, by transforming and translating what is into what could be. Fashion design for example is characterized by the continuous re-interpretation of existing collections for the creation of new collections.

2. Materializing those possible future worlds: Throughout our paper, we have been emphasizing that "design fiction" is an approach, which combines the invention, creation and construction of possible futures, which are explored, tested, evaluated and improved through a constant attempt to materialize their central features. *Sketching* is the central approach in design, which advances at the interfaces between the future and the present, the possible and the actual, the imaginative and the realist (Gänshirt, 2007). Thereby, we learn from an interdisciplinary view on the multiple design practices, that sketching takes multiple forms: *drawing* on paper is the prototypical approach, but *building simple models* in architectural design and industrial design in going in a very similar direction, or *the development of a mood board* in fashion design, or *simulating interactions* in the new media. Furthermore, we can argue that the *ethnographic observation of design in use* is another way of exploring potentially inspiring new ways of materializing, visualizing and embodying the future (Kelley, 2001); in this perspective, the future is actually seen as always already taking place in the everyday activities of people *using and mis-using design* for their purposes and embedded in their mundane practices.

3. Plurality of different perspectives and approaches: This interpretation of design practice and design research as combining the invention of possible futures, combined with sketching and materializing those possible futures, is at the core of design practice in general, as well as of multiple modernist design ideologies. As a consequence, it is essential to complement this perspective with an emphasis on the plurality of possible futures, as well as on the multitude of possible approaches and strategies in inventing, sketching, materializing and

visualizing those possible futures. In this respect, we share the basic intuition of Actor-Network Theory (Latour, 1999), which emphasizes the importance of continuously challenging the taken-for-granted, un-questioned, self-evident “nature” of the world as it is, while at the same time emphasizing and mapping the multitude of possible alternative worldviews. Interestingly, it is in this context that convincing design research strategies are missing, or that the development of tools and methods for mapping those multiple perspectives and related controversies is gaining its relevance (Latour & Weibel, 2005). The recent interest in artistic and design practice and research for mapping technologies is indicating a growing awareness of the importance to advance our competencies and methods in this respect.

4. Representing, visualizing, documenting the experimentation processes: Interestingly, this is at the same time a pre-condition for advancing with respect to another fundamental issues for design research: in order to advance in our understanding, description and explanation of how design practices are inventing and materializing, imagining and visualizing, creating and embodying new possible futures, we need tools and methods, which are able to document and represent, map and visualize those design processes themselves. It is interesting to observe that in many design fields, this emphasis on the design and research process is coming to the forefront of discussion: in urbanistic and architectural contexts, *publicly arguing based on models and computer simulations*; in fashion design, exhibiting the *materiality, processuality, multiplicity of design as a practice*, instead of overemphasizing the resulting outcomes and artifacts (Maison Martin Margiela, 2008); in iconic research, emphasizing the importance of integrating the *sketches, drawings, models, simulations* as important for our understanding of the resulting picture or installation (Boehm, 2007). Furthermore, the growing interest in exploring the potential of *programming design processes*, as an important way of better understating the processuality of design, is interesting to observe (Maeda, 2000).

5. Experimentation as being generated through an experimental system: With this new focus on programming, the inherently systemic nature of creation and experimentation is also more explicitly considered. As discussed above, design research can only benefit from the recent insights in the science studies, if the *processual and systemic nature of experimentation* and the importance of creating and establishing experimental systems is really understood (Knorr Cetina, 2002; Rheinberger, 2001). In parallel, it becomes obvious that those design practices are particularly important for advancing and conceptualizing design research, which already considering experimental systems as their way of organizing practice and research: the current interest in *programming design processes* is obviously one way of advancing this research field (Maeda, 2000); in parallel, *artistic processes exploring seriality* are very important, as they allow to better understand the close interplay between shifting research

questions, and their relation to shifting experimental arrangements (Calle, 2003). Furthermore, we see a growing interest in understanding archives as laboratories, as already realized and materializes series of artistic and designerly practice (Bismark et. al., 2002). Overall, we observe a growing interest in exploring design practice and design research as taking place in *laboratories*, which are characterized by a specific materialization, allowing for processuality and ensuring the systematic representation of what is going on (Obrist & Vanderlinden, 1999).

Changing the design research practices themselves: As discussed above, design research is closely related to design practice (6.), so in the long run it will be interesting to observe how the method toolbox for design research, as it is sketched in this paper, will impact on design as a field of practices.

Conclusion

In this paper, we argue that the distinct contribution of design as a field of practice and research lies in focusing on the world as it is; design shares with engineering the fundamental interest in focusing on the world as it could be. However, while this perspective is important in many classical approaches to design research, as well as in multiple approaches to design practice, it has not been systematically explored as the actual starting point for conducting design research. We argue that “design fiction” as a way of approaching design research allows to advancing in this direction, by explicitly identifying and discussing a method toolbox for design research in this perspective.

In parallel, we argue that “design fiction” can benefit from the science studies. In this perspective, design research and scientific research in general can be interpreted as a constructive and creative practice (Knorr Cetina, 1999; 2002), organized as experimental systems (Rheinberger, 2001). By emphasizing the processual and systemic nature of experimentation, as well as the importance of developing tools, methods, techniques and media for mapping, representing, visualizing those experimental processes, “design fiction” allows to open a new research field of design research, which at the same time leverages the unique qualities of design as a practice, and incorporates the quality criteria for productive and creative experimentation in scientific research.

Author Biography

Simon Grand

Dr. Simon Grand, economist (founder and academic director, RISE Management Research, University of St. Gallen), entrepreneur (founding partner, TATIN Scoping Complexity), design researcher (Institute for Research in Art and Design IDK, University of Applied Sciences Northwestern Switzerland).

Martin Wiedmer

Martin Wiedmer, Head of the Institute for Research in Art and Design IDK. Architect (HTL). Lecturer for Master of Arts in Design – Master Studio at the University of Applied Sciences Northwestern Switzerland. Project manager of various design research projects in the field of mixed reality.

Visual Means for Collaboration Across Disciplines

Abstract

The complexity of today's design problems—the global economy, rate of change in new technologies, the challenges of sustainability development—requires diverse design teams, comprised of multiple disciplines as well as multiple cultures, to look at broader and different perspectives and larger scopes of investigation. Due to the multilayered and multifaceted interactions between team members, effective communication and collaboration among people in multidisciplinary design teams becomes critical to ensure a project's success, in particular, and for innovation, in general. Research shows that one of the most important aspects of collaboration is effective information sharing—shared knowledge and shared understanding among all team members (Citera, et. al., 1995). Design teams traditionally share information verbally as well as visually through representations such as drawings and sketches, three-dimensional models, project walls, or conceptual maps. Consequently, an important aspect of communication is the role that visual thinking and visual communication practices play in the success of the design team. The exploration and finding of a current frame of reference for creating and utilizing visual tools for communication, capable of serving as a common means of expression for multidisciplinary teams, is the purpose of this research paper. To that end, individual field focused interviews were performed with distinct groups of stakeholders from the business, design and engineering professions. The interview included visual participatory research methods that prompted visual responses and reflected the interviewee's own use of visual methods for communication. In every case, visual means proved to be valuable thinking and communication assets. Two specific dimensions of communication that allowed team members to define, generate, and communicate innovation opportunities—storytelling and representation—were identified. The research findings and interpretations also generated conclusions and future opportunities for the design manager, for the instructors of design, and for the design, engineering and business professionals.

Keywords

Collective innovation; multidisciplinary collaboration; visual thinking;
design management; design thinking

Design problems are unstructured and ill-defined by nature, and, in today's dynamic and changing world, most of them are also "wicked problems." Reed (2002) defined an ill-defined problem as one that addresses complex issues and thus cannot easily be described in a concise, complete manner. Wicked problems in design include issues such as sustainability challenges in products with differing regulations as they are assembled and manufactured in different countries, optimizing the features of an existing car to a new model, a new banking business model, or the visual labeling of universal health-related drugs. The task of designing the outcome at the same time as the context is embedded in wicked design problems. “We have also come to realize that no problem ever exists in complete isolation. Every problem interacts with other problems and is therefore part of a set of interrelated problems…” explained Ackoff (1974, p. 21). Because of this interconnectedness of problems, the design problem-solving process has to be a multidisciplinary endeavor—functional disciplines working in close collaboration across functions, instead of looking in narrow silos like ergonomics, finance, human factors, product design, or marketing, to name a few. (Martin, 2006; Olson et. al., 2001). However, discipline and cultural differences between design team members can create high levels of skepticism that may even extend to the desirability or utility of pursuing collaboration among them (Horn and Weber, 2007). Design problems are hard to solve because, basically, they are inherently complex and this complexity increases the difficulty in understanding them and finding reasonable ways to resolve them. Research shows that for team members to reach a shared understanding of problems and a successful agreement to potential solutions, critical thinking is needed along with innovative problem-solving methods across disciplines (e.g. Citera, et.al. 1995; Diestler, 2004; Feldman, 2002; Sternberg, 1998). In the words of Horn and Weber (2007), to get to the root of ill-defined problems, collaborative reasoning and resolution are needed.

For multidisciplinary teams to collaborate and to obtain insight collectively and successfully, they need to process and develop a shared understanding of all the relevant information involved in the design project (user, concept, context, constraints, team member perspectives, etc..). “All [this] information must be processed by the team so that all team members have a shared understanding… Whether it is a case of dealing with inter- or intra-team communication, visualizing early and often is essential to develop that shared understanding,” described Cagan and Vogel (2002, p.207). Visualizing ideas and displaying them in a clear way that everybody can see, or visualizing concepts in two and three dimensions, are some ways to develop that shared understanding. Typically, design team members communicate face-to-face through verbal explanations but also through the use of visual and physical representations or, in recent studies, a full integration of words, images, and shapes into a single, unified communication unit, which Robert Horn defined as *Visual Language* (Horn, 1999). This is especially important during the initial stages of the design process. Currently, the starting point of the design process for many design disciplines in the professional practice is the making of the design brief. The design brief is, basically, an early definition of the design problem and the possible descriptions of the strategy to solve it. The design brief corresponds to what some authors have defined as the “fuzzy front end” (e.g. Koen et. al., 2002; Sanders and Stappers, 2008) and others as the formulation phase (e.g. Buijs, 2003; Gill and Lilly, 2008). According to Koen et. al. (2002), the innovation process may be divided into three areas: the fuzzy front end (FFE), the new product development (NPD) process, and commercialization. Koen et. al. described the FFE as “experimental, ambiguous, and often chaotic, with a great deal of uncertainty. In contrast, an efficient NPD part of the innovation process is disciplined and goal-oriented, following a clearly defined process” (2002, p.13). They indicated that is at the FFE of the process where the greatest opportunities for innovation may emerge.

In sum, the need to develop tools and methods that enable clear, effective communication among team members has become essential for the understanding and resolution of complex design problems. The exploration and finding of a current frame of reference for creating and utilizing visual means for communication and collaboration, capable of serving as a common means of expression for multidisciplinary teams, is the purpose of this research paper. This study will mainly use visual means as a general term to describe the visual products of all the possible interactions between design team members working together in a design project.

Methods and Analysis

Overview

This paper is a qualitative research study looking at the communication flow and the visual means of communication and idea generation utilized during eighteen different design situations or scenarios by multidisciplinary design teams. This study defined communication flow as the different communication activities and interactions that design team members go through during the process from design problem setting to initial problem-solving proposal.

The intention in this work is to research how multidisciplinary design teams comprised of design, engineering and/or business professionals use visual means for communication and collaboration, identify which ones are used, and when they are used in the process. A pilot-questionnaire was created to identify the scope of the problem, and, from its results, focused one-on-one interviews were developed with open-ended questions and participatory design research methods. The focused interview techniques were chosen because they are helpful in finding out in-depth information about a specific situation—important considerations, consequences and feelings (Zeisel, 2006; Merton, et. al., 1956). The participatory design methods were chosen because their intuitive use of images has the potential to trigger emotions and to understand a specific situation that can aid verbal descriptions (Sanders, 2005). The focused interviews were conducted on 18 design project scenarios from different design, engineering and business professional practices that were representatives of the consumer and service industry, and governmental agencies. The location of the interviewees was in the Columbus and Dayton, Ohio areas.

The data collected were analyzed through abstracted diagrams (visual perspectives) in order to look for patterns and relationships. Three general communication activities among stakeholders emerged to be common to all 18 design project scenarios. Visual means for communication and collaboration utilized by discipline and communication activity were also identified, which resulted in two dimensions of communication as focus areas for this study: storytelling and representation.

Finally, the research findings and interpretations were used to build a current frame of reference for using and generating visual means for effective sharing of information within multidisciplinary teams. The research findings and interpretations also generated conclusions and future opportunities for the design manager, for the instructors of design, and for the design, engineering and business professionals.

Interviews: responses and analysis

The interviewees were eighteen professionals: general managers, marketing managers and creative directors with backgrounds in industrial design, interior design, graphic design, marketing strategy, public relations and communications, mechanical engineering and industrial engineering. The 18 interviewees were asked to describe the different communication activities and interactions that design team members went through during the initial stages of a relevant design project of their choice that included design, engineering and/or business professionals. The interview combined brief questions concerning the interviewee's discipline, area of specialization, and number of team members by discipline together with open-ended questions, such as reflections on working with other disciplines or how they personally learn about a problem. Primarily, interviewees were asked to explain the communication process from the very first moment they were assigned to work on a design problem until the moment when the design team was ready to provide the initial solutions or recommendations to the client.

The methodology used for the interviews was to voice record their descriptions and to give them the option of generating a visual narrative of their experience (see Figure 1). At the end of their narratives, interviewees were given a list to check of the possible visual means of communication that they might have used during the communication process (see Figure 2). While checking from the list, interviewees were asked to identify in which part of the communication process the visual means selected were used.

Figure 2
List of possible visual means used in the communication process given to the interviewees at the end of the interview. The interviewees identified which visual means they used and in which stage of the process.

At the completion of all the interviews, the data collected included the audio recordings of the eighteen design project scenarios plus answers to the open-ended questions of the interview, the visual narratives supporting the interviewee's verbal descriptions, the completed lists of visual means of communication used in the design experiences described, and a lot of notes from the interviewer. To start analyzing the results, a tally was done of the visual means utilized by the interviewees. That gave some initial insight into the way the different disciplines were using visual means for communication and collaboration. Then, the audio recordings were reviewed with special attention paid to each individual communication process depicted. Afterwards, the communication processes of all the eighteen design experiences were analyzed through abstracted diagrams to provide a visual perspective that allowed for the emergence of relationships. As Albarn and Smith (1977) put it, “The diagram can present at a glance what a verbal description can only present in a sequence of statements. It is the ideal mode for describing relations between things.” (1977 p.69). The communication process between design team members is a highly interactive process that arises from the relationships and interactions across the parts, not from individual parts in isolation. How the parts of a system and levels of analysis are defined is a matter of perspective and purpose (Beinhocker, 2007). The interviews only offered the individual perspective of each interviewee, but her/his description of the communication process included the interactions between members as well as the purpose of those interactions to the process.

Tally of visual means utilized in the communication process

A first tally of all the different visual means employed during the scenarios described by the interviewees revealed that professionals from different backgrounds utilized visual means in very different ways, as shown in Figure 3.

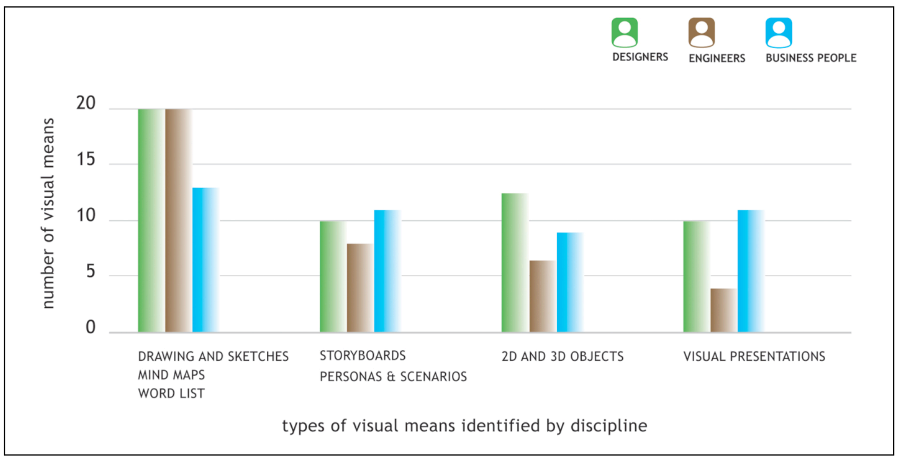

Figure 3
Number and types of visual means identified and utilized by discipline.

While all interviewees were involved in utilizing and generating visual tools, there were differences in how many visual means were used for communication between members and at what point during the process they were used. The pattern that emerged at looking at the results of the tally of visual means utilized is that designers and engineers were heavily involved in producing visual means as aids for analysis and idea generation (individually and collectively), while business people preferred to utilize the representations generated by the team for dialogue and feedback.

For instance, in the scenario described by a mechanical engineer, a team of four engineers and one industrial designer situated in two different locations discussed a design project using sketches and CAD drawings. One of the engineers made a paper model of the new design that was used by a business manager for presentation to the client. The business manager had to meet with the client several times because the changes requested by the client were not feasible, and he wasn't able to discuss the changes without going back to the office and consulting with the engineers. A last meeting with the client and business manager had to include one of the engineers to analyze the viability of the changes. Another example is the scenario described by a marketing director using the designer's boards to test and sell a new idea. Usually, designers mount sketches and layouts of possible ideas on cardboards or simply boards for ease of viewing and sharing. The marketing director identified a new business opportunity and used several boards crafted by a visual communication designer to explain the purpose and content of the prospective idea to her different company's departments. The marketing director used the boards to generate dialogue outside the design team, and didn't participate in the making of the boards other than by giving verbal feedback to the designer's sketches. In both scenarios, the way that the three disciplines, design, marketing, and engineering used visual means was an indication of the lack of integration within the team. This demonstrates the traditional approach where disciplines work independently from each other: "Marketing traditionally has defined the product, while engineering and design have iterated between themselves based on their respective, and usually differing, interpretation of the marketing criteria," explained Cagan and Vogel (2002, p.139).

In order to identify patterns and relationships in the types and uses of visual means through the communication interactions between team members, each scenario was analyzed through abstracted diagrams. Again, the diagrams were produced based on the interviewees' own visual narratives developed during the interviews, the audio recordings, the list of visual means, and the interviewer's notes. The methodology employed to create the diagrams was to first identify the participants and their interactions throughout the communication process and then match which visual means they used during those communication interactions. The measure of success of the communication flow was mainly determined by what the interviewee expressed. For example, a marketing director expressed the success of the design project described by saying "we were able to present new innovative concepts to management in just three days"; while a very unsuccessful design project scenario was expressed by a creative director saying, "it was a nightmare of process and outcome". It resulted ten successful and eight unsuccessful communication flows. Figure 4 shows an example of an abstracted diagram of communication flow and visual means utilized in the design project scenario described by an industrial designer.

Communication activities identified

A general communication process emerged after a first draft of the abstracted diagrams of the eighteen design project scenarios. In all of the scenarios described, the communication process started with an expressed need from a client (individual or team) who searched for recommendations and/or solutions to a design problem. The client was usually from outside the design company, but sometimes it was management from other departments of the same company. During this study the design company is referred to as the team of professional designers, business and/or engineers that participated in the design project that the interviewee described, regardless of the "real" type of association. The initial flow of information occurred between the client and the representative(s) of the design company, usually the design manager or project manager. During preliminary meetings the client and the design manager defined the perceived needs or design problem. Then, the design company initiated its own process of generating ideas and/or

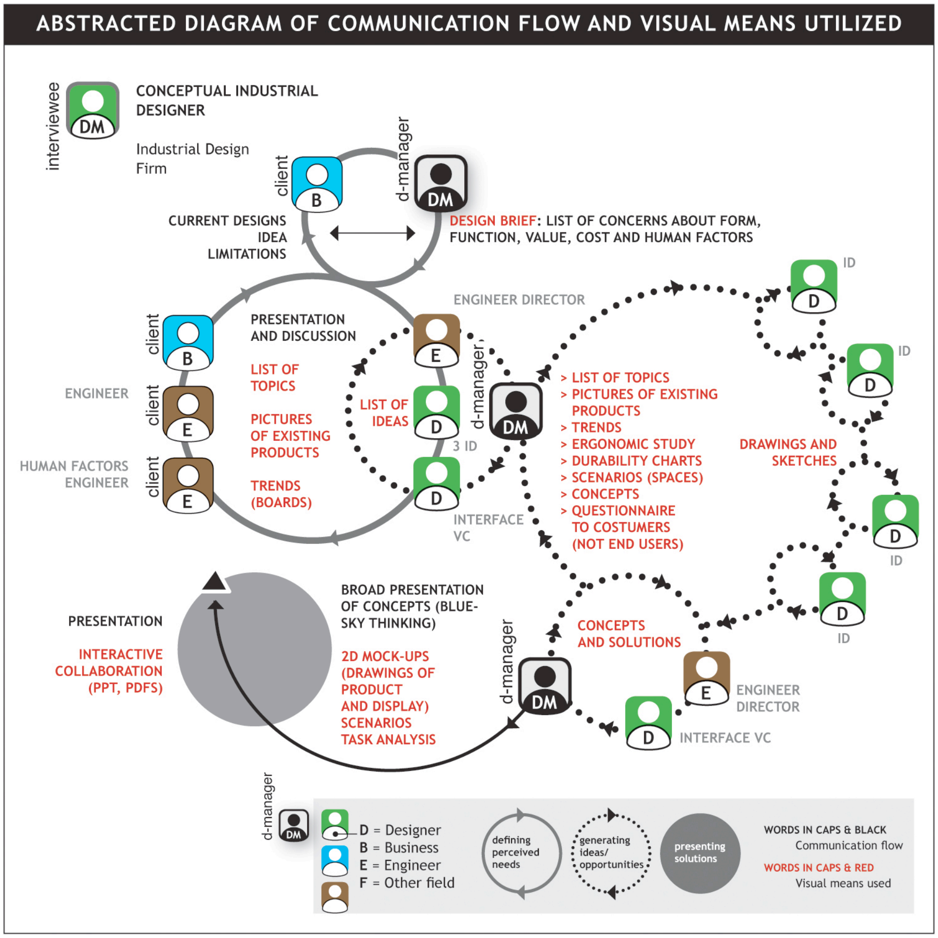

Figure 4
Example of an abstracted diagram of communication flow and visual means utilized in the design project scenario described by an industrial designer.

design opportunities in a more or less collaborative and inclusive way in order to present recommendations or possible solutions to the client. So, in general, the communication process in all design scenarios could be broken down into the following three communication activities (see Figure 5):

1. The communication interactions between the client and the design company for the purpose of *defining the problem or perceived needs*.
2. The communication interactions between the team members of the design company for the purpose of *generating ideas and opportunities*.
3. The communication interactions between the design company and the client for the purpose of *presenting solutions and/or recommendations*

During those three communication activities, team members reviewed existing data, researched new data, developed design briefs, defined constraints, brainstormed new ideas and opportunities, discussed with each other, drew and sketched, shared information, made quick prototypes, and presented new ideas.

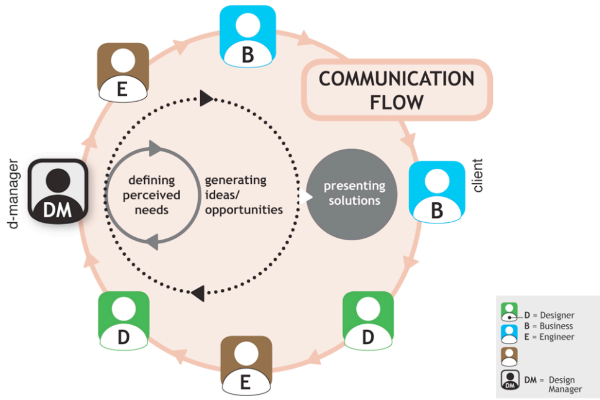

Figure 5
The three general communication activities identified in the communication process of the eighteen design scenarios described by the interviewees.

Synthesis and Interpretation

Visual means by discipline and communication activity

To understand how the different disciplines utilized visual means and for what purpose, new sets of diagrams were generated with a summary of visual means by discipline and communication activity to identify patterns and insights. The diagrams show the most representative visual means compared by discipline (averaged) and identified by more than three interviewees during each of the communication activities: defining perceived needs, generating ideas/opportunities and presenting solutions.

Visual means utilized during defining perceived needs

Overall, interviewees defined the perceived needs of the design project through word lists, drawings and sketches, background research and associative thinking.
(See Figure 6).

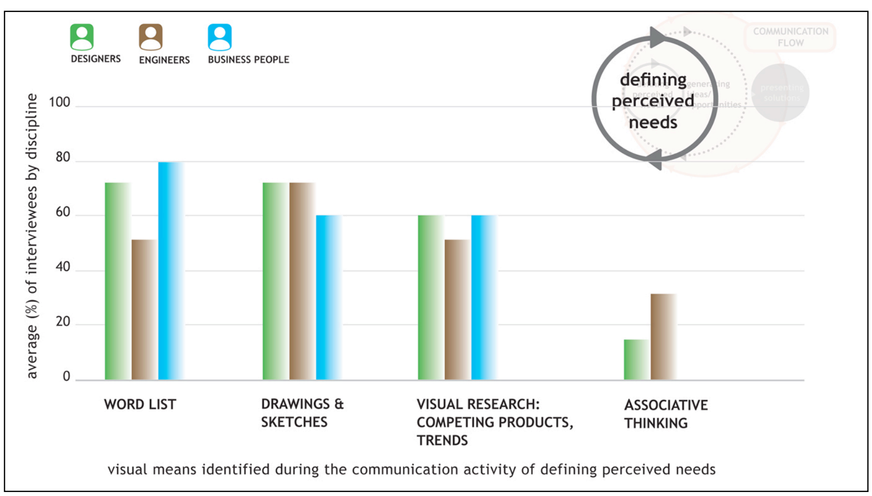

Figure 6
Visual means comparison by discipline during the communication activity of defining perceived needs.

It is interesting to note the extensive use of word lists (list of needs, list of specifications, list of topics, list of concerns, list of goals, etc…). Twelve out of the eighteen interviewees expressed the use of word lists to define the needs of the design project. The down side of using word list to define a design problem is the difficulty to find relationships. Especially at the beginning stages of the design process, it is essential to look at the connections between the functional disciplines, and consider a broader set of interrelated perspectives (that a word list cannot provide) to define the perceived needs of the design problem. Mind maps, for example, are an alternative to linear thinking, because of the radial, graphic, and non-linear presentation of concepts. Mind maps can help look at the whole dimension of the problem by depicting thoughts and associations that are not obvious when the information is organized by lists of categories or priorities (Buzan and Buzan, 1993). Business professionals and design managers could benefit from using mind maps or a similar visual tool to become more effective team leaders.

> … successful leaders consistently reject an approach that leaves things off the table, or distorts the view by parsing pieces of the problem out to various other people. Successful leaders take the whole piece and work on it as a whole; so they keep a holistic view of all the things that they think are salient. Like a painter they put some things in the background and some in the foreground, but everything is always in view. (Stuart quoting Roger Martin, 1999, p.6)

Drawings and sketches were the most utilized visual means during the communication activity of "defining perceived needs" (thirteen out of eighteen design project scenarios), followed by word lists and visual research (the visual part of competition analysis and trends). Visual associations could be also considered visual research during this communication activity. Looking at the visual means exclusive to a single discipline, two designers mentioned taking pictures, two engineers mentioned the use of functional demonstrations, and one businessperson mentioned the use of whiteboards to aid the collective definition of the design problem.

Visual means utilized during generating ideas and opportunities

Overall, interviewees collectively generated ideas and opportunities through drawings and sketches, scenarios, 3D objects, task analysis, 3D models, flow charts and storyboards. (See Figure 7).

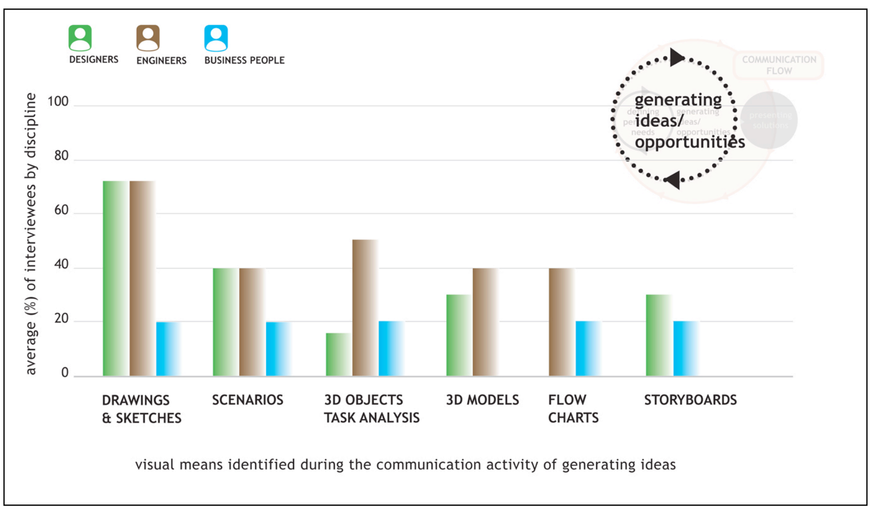

Figure 7
Visual means comparison by discipline during the communication activity of generating ideas and opportunities.

Designers and engineers were more heavily involved in using visual means for idea generation than business professionals, especially drawings, sketches, and scenarios. Scenarios could be descriptions of a-day-in-the-life activities of the user, or descriptions of the context of use for a product or service. A creative director referred to “scenarios” as the different web-page simulations that her team performed. Another pattern of the diagram illustrated in figure 6 is the favouring use of 3D objects and task analysis by engineers. This is not surprising due to their functional decomposition techniques for idea generation: engineers decompose artifacts by pieces associated with functions. Looking at the visual means exclusive to a single discipline, two designers mentioned user testing, one designer visual associations, another blue-sky thinking and another designer and ergonomic study; while one business person mentioned the use of a project wall and another the generation of image banks.

Visual means utilized during presenting solutions

In sum, interviewees presented solutions mainly through power point presentations (PPT) or PDF files, 2D and 3D mock-ups, interactive collaboration and storyboards. (See Figure 8).

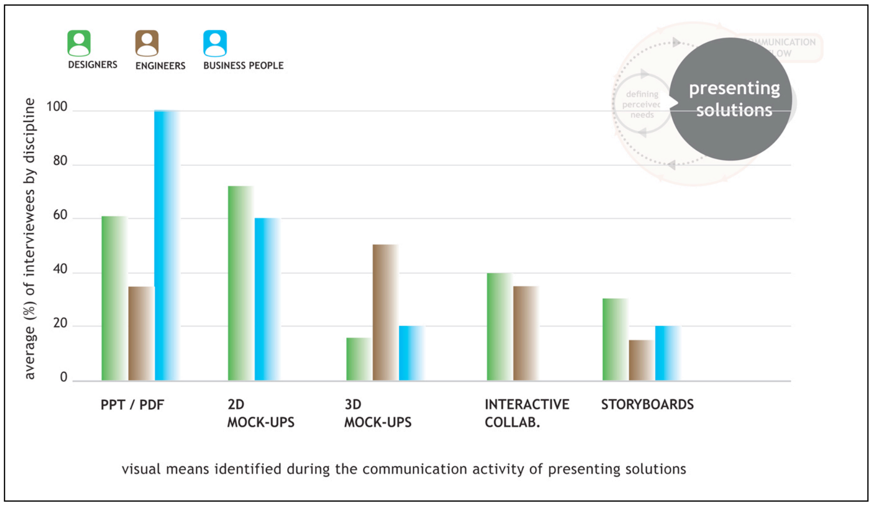

Figure 8
Visual means comparison by discipline during the communication activity of presenting solutions.

Deciding which elements of the design proposal are going to be presented, how to organize them, and in which medium and format, are all crucial decisions in developing effective visual presentations. By interactive collaboration interviewees did refer to the interactive communication made possible through computer screens (e.g. presenting a rendering in a PDF format and receiving feedback through a modified PDF file with virtual sticky notes on it). Currently, the use of PDF files to show drafts or proposals for feedback is common practice, especially in visual communication and interface design. However, the various ways that a design team can present a proposal through interactive collaboration—including face-to-face, in a group, in a conference setting, synchronized in a network, or asynchronized (send it or leave it without explanations)—calls for a further research into the technologies that can support each one. Especially if the design team presenting solutions is not co-located, i.e. in virtual settings.

Summary: *making* visual means and *telling* through visual means

A summary of all the visual means identified by discipline and communication activity was put together in a chart (see Figure 9). The chart illustrates the number of interviewees by discipline that expressed utilizing the visual means listed on the left column during one of the three communication activities showed at the top of the chart.

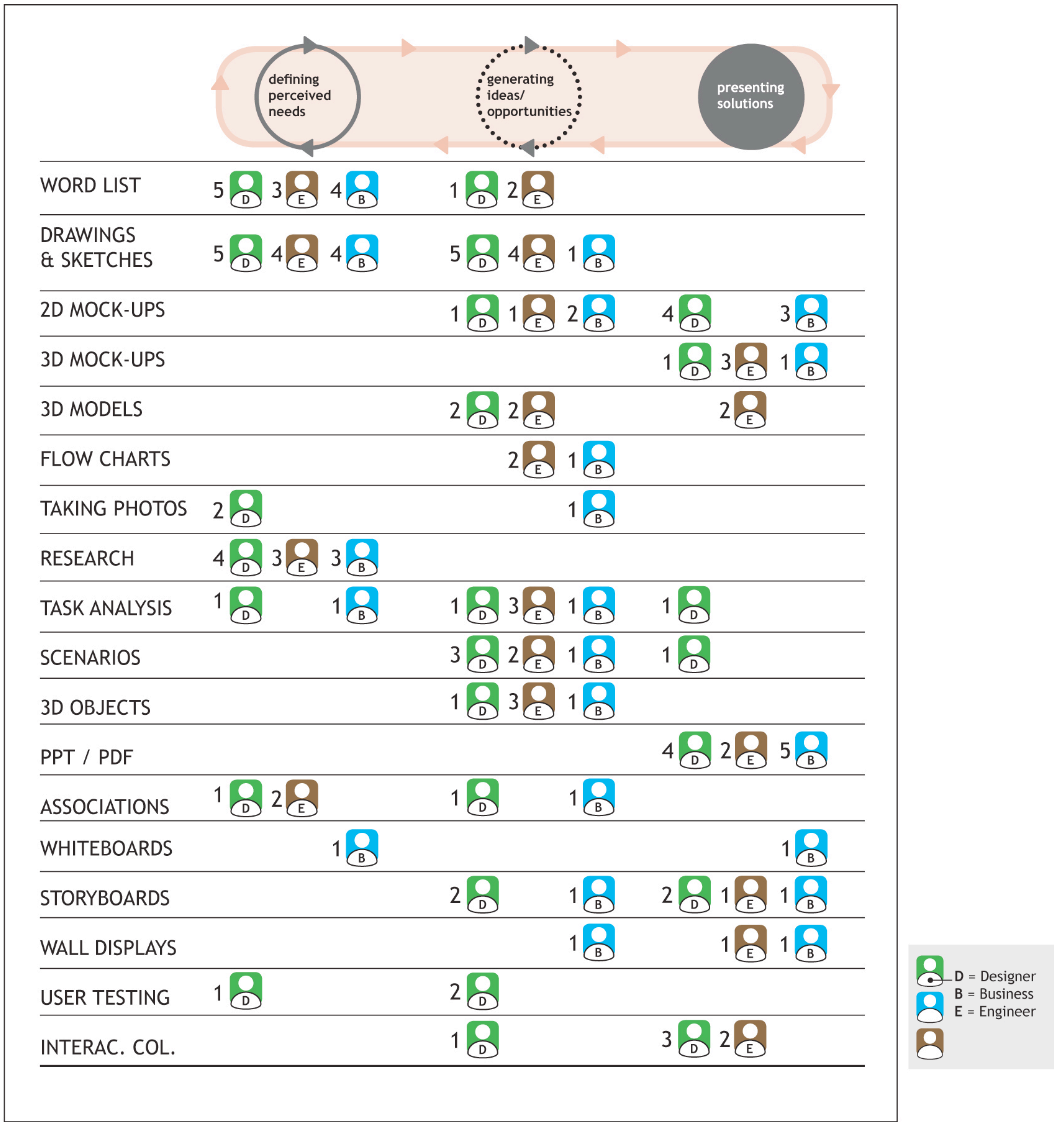

Figure 9
Summary of all the visual means identified by all the interviewees and organized by number of interviewed disciplines and communication activity.

Interviewees utilized more visual means for generating ideas and opportunities than for the other two communication activities. Having all the information arranged in the same visual (chart) triggered the emergence of two basic dimensions in the use of visual means: visual means that were used to generate visual representations (*making*) and visual means used to generate discussion and feedback (*telling*). (See Figure 10). For example, visual means to generate visual representations are drawings, sketches, and 3D mock-ups made out of paper, clay, foam, or cardboard; while visual means to promote discussion and feedback are storyboards, wall displays, and slide presentations. Even though the actual tools may have been the same (sketches, drawings, 2D mock-ups, etc) the communication process they supported was different depending on who the “user” was. For instance, designers and engineers made sketches and models. They used them to support the idea generation process. The visual representations generated from this process, assisted team members in communicating with themselves, and with each other. Business managers, on the other hand, utilized the products of the previous process to support their verbal communication exchange and generate discussion, feedback and additional dialogue.

Comparing the number of interviewees that identified visual means for *making* and the number of interviewees that identified visual means for *telling*, the result is 64 versus 62, which are very similar results. Consequently, it may be suggested that visual means to generate visual representations (***making***) are as important as visual representations used to generate discussion and feedback (***telling***). *Making* and *Telling* are two dimensions of communication embedded in the same visual means, depending on the eye of the beholder and/or the activity that they support. For instance, a logo proposal mounted on a cardboard is “made” by a designer and it serves to “tell” an idea to the client, usually by a marketing professional. The logo proposal is the same visual means and can be “written” (*making*) and “read” (*telling*) in different ways and by different people. Another example is a sketch, which not only supports the mind-hand interaction but also serves to communicate an idea for feedback and to spark the idea generation process. Furthermore, the idea represented in the sketch will change with each “teller” and with each “telling”.

Also, there are visual means primarily used for *telling* (such as a visual presentation) and visual means specifically suited for *making* (such as a 3D prototype). However, somebody had to *make* the visual presentation (organize the information, create visuals to display, know the software, manipulate digital images, etc.) before it could be used to *tell* a story. Same situation with the making of the 3D prototype—there was a need to *tell* through the prototype a concept, function, or idea that was behind the *making* of it. Continuing with this example, if product designers are the ones making the prototype and a project manager is the responsible to explain the prototype to the client, the product designer might enhance the *making* from understanding the way the project manager is going to tell the concept, and the project manager might do a better *telling* from understanding the process of making a prototype. Understanding how the different disciplines make visual representations and how they interpret them for telling purposes, becomes, then, an integrated skill relevant to all parties.

Finally, it is interesting to notice that it is easier to divide visual representations for telling and for making when more specialized skills are needed to produce them (e.g. a CAD model), and the division blurs when more collective creativity and integration is put into the visual means (e.g. information walls), probably because, in the latter case, making and telling are ad-hoc and in-situ (not discipline-dependent or sequence in the process-dependent). Furthermore, making and telling converge in the new domains of co-design (Sanders, 2008, personal communication). Sanders and Stappers (2008) defined co-design in a broader sense to refer to the creativity of designers and people not trained in design working together in the design development process—“...the evolution in design research from a user-centered approach to co-designing is changing the landscape of design practice, creating new domains of collective creativity.”

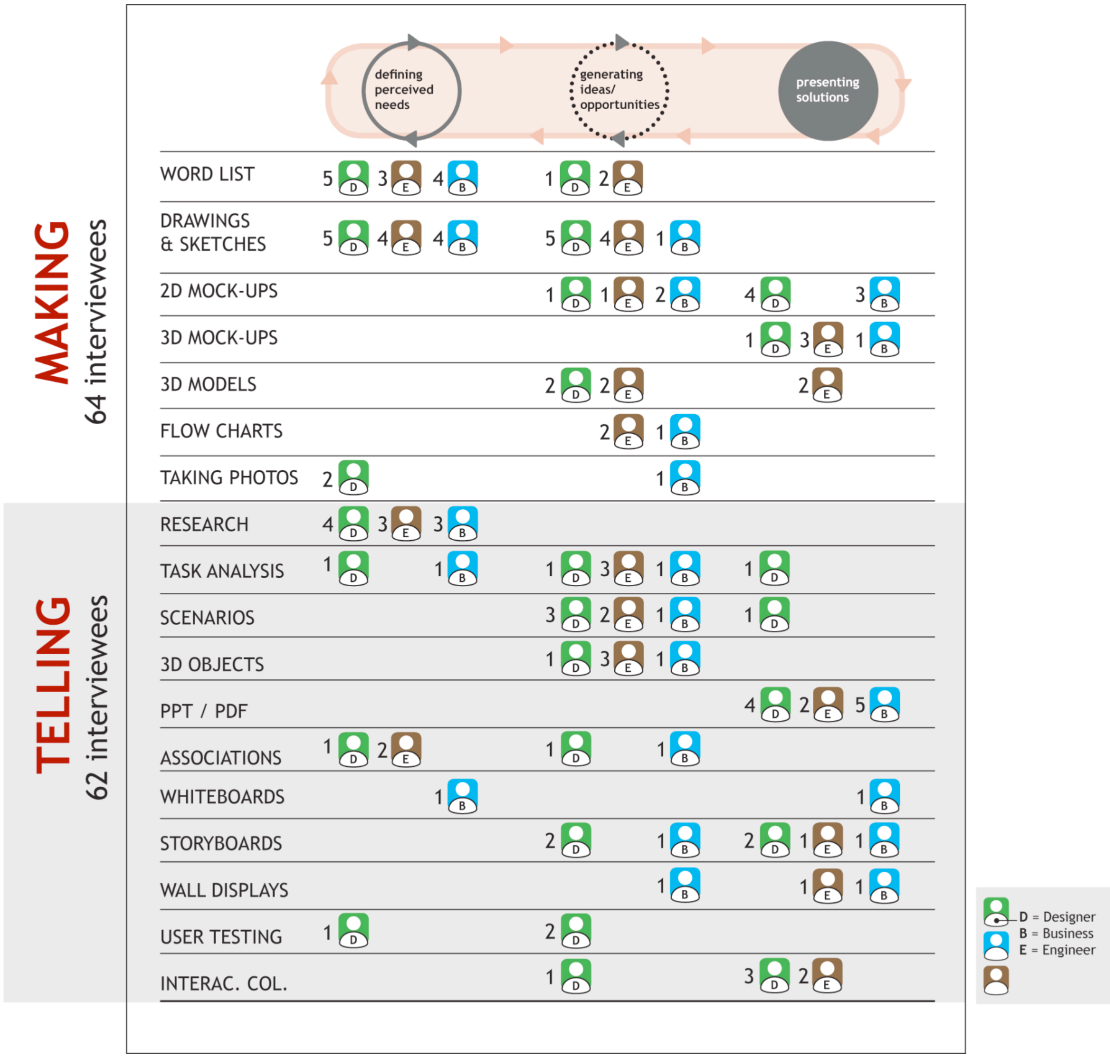

Figure 10
Emergence of two dimensions in the use of visual means: visual means that were used to generate visual representations (*making*) and visual means used to generate discussion and feedback (*telling*).

Conclusions and future work

By understanding how the different disciplines use visual means and at what stages in the communication process, and by identifying the visual means that assist the communication flow within multidisciplinary teams towards effective collaboration, design managers can ensure that information between all the team members reaches across discipline boundaries, and all perspectives are taken into consideration; educators can design interdisciplinary curricula to strengthen visual means for communication and collaboration across disciplines; and professionals in the practice of design, business and engineering can build awareness and understanding of the different disciplinary roles and visual skills involved in the design process.

This study suggests the need for better training in the use of visual means by all disciplines. Some professionals can benefit from learning how to use visual means to generate representations. This can be a powerful tool when the team member is interested in participating in the generation of ideas. Others can benefit from learning how to better communicate by using visual means as communication vehicles to generate feedback, discussions and to sell ideas to the client (Graell and Gill, 2008.)

This study also emphasized that the very essence of design team visual collaboration and communication resided in the ability to reflect on ideas and give them shape through drawings and sketches, and through new forms of integrating words, visuals and symbols. Understanding the function of rough sketches away from their aesthetic value and leveling differences in the knowledge of graphic languages among design team members may result in a more effective collaborative and communicative design space.

This study has also explored emerging visual means to facilitate collaborative sharing of information, and should continue in the future. As the fuzzy front end of the design process is increasing, design professionals and practitioners have to be prepared to work more effectively in multidisciplinary environments. More visual means to define the design problem and generate ideas collectively are needed. Currently, some new visual tools have been developed to collectively solve more complex problems (e.g. mess mapping), but further research is needed to address the different needs of the design industry—new visual tools that speak to different design backgrounds and levels of expertise.

In sum, visuals that facilitate communication and collaboration among multidisciplinary design teams are intuitive and messy, with new forms being developed as new visual languages (visual information murals, visual generative techniques, visual scenarios) are being brought to play to understand the scope and complexity of the design problem as well as the people to design for. In order to find valid design solutions a wide array of relevant variables are to be taken in consideration. Limiting design considerations to aspects that can be thoroughly quantified or that can follow particular processes, is what Roger (2006) calls the obsession to reliability.

Finally, there are opportunities to expand the context of this research study beyond design, engineering and business. The exploration and formulation of new visual languages capable of serving as a common means of expression for [multidisciplinary] teams, is expanding to areas of study beyond the professional practices. For instance, this researcher is currently exploring visual tools for qualitative research in areas such as literacy studies, macrocognitive processes and co-creation.

Experiential, Embedded, Electronic

Integrating Academic Skills Into The Art And Design Curriculum

Alke Gröppel-Wegener, Staffordshire University, UK, a.c.groppel-wegener@staffs.ac.uk

Abstract

The objective of this paper is to reflect on the possibilities experiential learning offers to the fuller integration of study skills into the undergraduate design curriculum.

Undergraduate design courses are experiential at their core. Students are actively engaged in their own learning, constructing it for themselves (often literally). However, this practice needs to be complemented by the ability to critically reflect on these experiences, a knowledge and understanding of its context in the field, as well as the aptitude to communicate these insights. This is where contextual studies and study skills come in.

By taking the natural approach of practical design teaching, could a model be developed that allows students to experience the building up of academic study skills in a similar way to how they engage with practical design skills?

Two main hypotheses were made: firstly that the learning needed to be experiential and secondly that the study skills teaching needed to be embedded as much as possible into the rest of the curriculum. These were complemented by the aim to test whether at least some of this could be achieved by the integration of electronic means.

During a case study at Staffordshire University a module has been developed that takes the students step-by-step through some basic processes of researching, culminating in an essay that conforms to academic conventions. Links to the different awards the students are studying are made at every opportunity, embedding the academic research into, and thereby developing, their reflective practice. In order to allow further student interaction a private wiki has been set up, where students can not only practice and test their skills, but also share their research.

The testing of this model is very much a work in progress and while feedback has been positive, it also has identified a number of issues that need to be developed further.

Keywords
experiential learning; critical reflection; study skills; contextual studies; academic writing; reflective practice

The provision of study skills can feel like an 'odd one out' part of the undergraduate design curriculum[1]. While necessary to provide first year students with the abilities to negotiate their academic studies, if study skills are taught in dedicated modules they might include content (and employ learning strategies) that are markedly different from studio teaching. Taking the study skills modules delivered during the first semester of art and design awards at Staffordshire University as a case study, this paper investigates whether it is possible to utilise teaching strategies that are modelled on the experiential learning that takes place

[1] This paper focuses on awards that predominantly teach practical, rather than theoretical skills. While courses that specialise in History of Design or Design Management, for example, certainly also have opportunities for including experiential teaching into their curriculum, these were disregarded for the purposes of this research.

during studio practice when teaching transferable skills and whether that could lead to a fuller integration of study skills into the undergraduate design curriculum.

After a brief survey of the contextual studies[2] and study skills provision in art and design at Staffordshire University, one of the main differences to studio teaching will be identified as the format in which the teaching is delivered. While studio teaching is largely experiential, both study skills and contextual studies often rely on the more traditional strategy of formal classroom delivery. In order to fully explore this difference, an overview of theories of experiential learning will be given and links to practice (and particularly reflective practice) will be made. Using this as a background, the usefulness of contextual studies in developing skills of critical reflection will be discussed.

This paper then goes on to describe a new model for study skills teaching developed using the main hypothesis that learning should be experiential, but also that it should be embedded as much as possible into the rest of the curriculum and that at least some of this could be achieved by the integration of electronic means. Findings after teaching this module for the first time suggest that, while further research is needed, initial results are positive, but also that a certain distance between studio practice and academic modules in the first year might actually be desirable to train students in their abilities to critically reflect.

Study Skills at Staffordshire University

While some university courses in art and design achieve a seamless integration of theory and practice, a real concern for others is that often a gap between them is perceived, particularly if theoretical teaching is divided from studio practice through being delivered by different staff and in separate modules.

The starting point for this research was a project with the objective to audit the balance of research and practice in art and design awards at Staffordshire University[3] to determine the extent to which theory and practice were integrated by the alignment of the contextual studies curriculum with studio practice teaching. As part of this, a review of the study skills provision was also undertaken.

Study skills at Staffordshire University are taught as a separate module in the first semester of the first year of undergraduate art and design courses. The content includes a breakdown of skills that students will need while negotiating an undergraduate university course, such as note taking, critical reading, giving presentations, finding secondary sources and academic writing. Ultimately, however, all these skills are transferable not only onto other modules of the individual courses, but also onto future life as a professional. In the positioning in the award schemes, the study skills module is the first of the contextual studies modules, which aim to give students an insight into the larger historical and theoretical context of their specialism and thereby allow the students to develop a critical perspective on their own work.

Outcomes sought from this research were recommendations for the enhancement of research skills that help art and design students to integrate theory and practice, as well as the development of a study skills module that would ensure that all students are familiar with research methods, processes and principles.

---

[2] 'Contextual Studies' at Staffordshire University is geared towards giving students the tools and skills to research, critically analyse and understand the various contexts in which their disciplines can operate. Lectures and seminars that provide historical, theoretical and professional practice background information are integrated with research projects that allow students to develop an informed design vocabulary that is grounded in a comprehensive contextual awareness.

[3] Awards being surveyed for this project included 3D Design, Advertising and Brand Management, Animation, Fine Art, Graphic Design, Media Production, Photography, Product Design, Surface Pattern Design and Visual Effects Design

The initial investigation taking place in the academic year 2008/09 explored both the teaching of study skills and contextual studies. Through informal interviews with award staff, reports from external examiners and module feedback from students, it was established that contextual studies and study skills were delivered in a traditional classroom format. The balance between theory and practice was different from award to award, ranging from 10% to 50% on the theory side, but the respective ratios were deemed appropriate for what the individual awards were trying to achieve. However, in some awards the linkages between the 'theory' and the 'practice' modules and the critical engagement that ideally would stem from that failed to make it through to students' work - in both practical and essay form. Particularly students seemed to be too focused on their own speciality, with little or no larger outlook on art and design.

There were 13 study skills modules at Staffordshire University in different art and design awards. For delivery, these were bundled together into four groups which resulted in a ‘one-size-doesn't-really-fit-anyone’ module. Teaching was delivered through lectures that alternated with workshops designed to give the students the chance to apply the previously covered skills to their own research. There were also two sessions in the library giving students electronic research skills and one session introducing them to the Design Collection, the in-house museum. During the theoretical lectures, links to the students' practice were limited to examples of work from the field. However, there was room in the timetable for award staff to deliver additional sessions, an opportunity only some of the awards took advantage of. These modules were assessed through a 1,000 word illustrated essay. Feedback from the students indicated that the essay writing was seen as 'overcomplicated' and ‘very difficult’. While a lot of the students seemed to be aware of the importance of being able to write academically for their degree, there did not seem to be much understanding of possible links to their practice. The theory-practice gap appeared to be firmly in place.

When reflecting on the differences between the two types of modules - studio practice on the one hand, and contextual studies and study skills on the other - one rather obvious distinction was the type of delivery. Study skills and contextual studies modules took place in lecture theatres and seminar rooms, not in the studio spaces familiar to the students. The ‘informal’ was squeezed into a ‘formal’ environment. The hypothesis was formed that the type of learning strategies employed in the studio might also be utilised on the theoretical part of the curriculum.

Experiential Learning

The traditional classroom teaching format can be quite distinct from studio teaching. In its most extreme Freire (1982) criticised this model as basically passive, where no new knowledge is created.

> Education thus becomes an act of depositing, in which the students are the depositories and the teacher is the depositor. Instead of communicating, the teacher issues communiqués and makes deposits, which the students patiently receive, memorize and repeat. This is the 'banking' concept of education, in which the scope of action allowed to the students extends only as far as receiving, filing, and storing the deposits. (Freire, 1982: 45f; in: Beard and Wilson, 2006: 30)

In the context of studio practice, on the other hand, one main learning strategy that is employed is experiential learning (Gray and Malins, 2004). No matter what skills students learn in the studio, they need to learn them by doing, through active exploration.

Largely based on the work of Kolb (1984), and Dewey (1925) before him, experiential learning theory draws a strong link between learning and experience. Indeed, Kolb defines learning as "the process whereby knowledge is created through the transformation of experience" (1984: 38). Beard and Wilson (2006) go even further when they state that "Experiential learning is, in essence, the underpinning process to all forms of learning since it represents the transformation of most new and significant experiences and incorporates them within a broader conceptual framework" (2006: 19). Boud, Cohen and Walker (1993) make a similar point when they argue that

> Learning builds on and flows from experience: no matter what external prompts to learning there might be - teachers, materials, interesting opportunities - learning can only occur if the experience of the learner is engaged, at least at some level. These external influences can act only by transforming the experience of the learner. (8)

However, while all learning may stem from experiences, not all experiences necessarily result in learning, which is one of the main criticisms made of this particular pedagogic model. In order for the experience to become a meaningful basis for learning, it needs to be reflected on (Beard and Wilson, 2006).

The importance of reflection in the context of one's practice has long been a recognised concept in art and design. Donald Schön (1983) and his work on 'reflective practice' promotes the idea of the professional (or practitioner) using two different types of reflection: concurrent (reflection-in-action) and retrospective (reflection-on-action). Reflection-in-action is almost instantaneous learning, it stems from the immediate interaction with external stimuli.[4]

Reflection-on-action is learning through looking back at an experience and analysing it, making sense of it retrospectively. This is a step removed from the experience itself and as such more abstract. It goes through the steps of undertaking an action, evaluating it, learning from it and planning the next action, a variation of which is Kolb's experiential learning cycle.

A third type of reflection has been suggested by John Cowan as 'reflection-for-action' (1998 in: Gray and Malins, 2004: 57) or a 'prospective' analysis of experience by Beard and Wilson (2006: 247f). This is concerned not just with learning from the experience for similar experiences in the future, but also with the question whether this action should be continued with or whether its type needs to be significantly changed. Rather than being instantaneous, it is an evaluation of the practice through not just the experience itself, but putting it into a larger future context. This type of reflection is critical reflection.[5]

Critical Reflection in Practice and in Contextual Studies

Developing a critical perspective on our experiences (and learning) is particularly important because experiences are by their nature subjective. As Beard and Wilson point out, this subjectivity of experiential learning is one of the main criticisms being made of this approach to learning (2006: 38ff) and had already been addressed by Dewey in 1925:

> When the notion of experiences is introduced, who is not familiar with the query, uttered with a crushingly triumphant tone, '*Whose* experience?' The implication is that experience is not only always somebody's, but that the peculiar nature of 'somebody' infects experience so pervasively that experience is merely somebody's and hence of nobody and nothing else. (Dewey, 1925: 1, as quoted in Beard and Wilson, 2006: 40)

This issue is linked to the process of developing research methodologies for art and design and the question whether art and design practice can be part of academic research. As Schön points out:

> ... when we reject the traditional view of professional knowledge, recognising that practitioners may become reflective researchers in situations of uncertainty, instability, uniqueness, and conflict, we have recast the relationship between research

[4] 'Action learning' is another concept that is close to reflective practice and experiential learning, though Beard and Wilson (2006) define it as being located specifically in the workplace and being concerned with project work in groups.

[5] For the purpose of this paper the term 'critical reflection' will be used in an individual or organisational context and not in the sociological definition introduced by the thinkers of the Frankfurt School.

> and practice. For on this perspective, research is an activity of practitioners. It is triggered by features of the practice situation, undertaken on the spot, and immediately linked to action ... the exchange between research and practice is immediate, and reflection-in-action is its own implementation. (Schön, 1983, 308f)

Gray and Malins, whose book *Visualizing Research* (2004) is about developing research methodologies for post-graduate studies in art and design, also discuss this particular problem. Referring to Robson's *Real World Research* (1993), they state that the problem of subjectivity (or 'insider' problems as Robson terms it), is a challenge for all researchers. However, they argue that this

> can be addressed to some extent by always exposing ideas and practices to other professionals for feedback, support and advice. In seeking the views of others, which will inevitably be subjective, we can develop inter-subjective views, which are less likely to be one-sided. Of course, keeping a critical view of your research at all times is essential. (Gray and Malins, 2004: 23)

Through a survey (and their own experience) of previous and ongoing research degrees in art and design Gray and Malins (2004: 20f) suggest the legitimising of the practitioner as researcher, the 'practitioner-researcher', which acknowledges and embraces subjectivity and the ‘insider’ role. They go on to say that

> the interaction of the researcher with the research material is recognized. Knowledge is negotiated - inter-subjective, context bound, and is a result of personal construction. Research material may not necessarily be replicated, but can be made accessible, communicated and understood. This requires the methodology to be explicit and transparent (documentation is essential) and transferable in principle (if not specifics). (Gray and Malins, 2004: 21)

They conclude that there is not one specific methodology that fits art and design research, but rather that because the practitioner-researcher needs to be taken into account, research projects need to be approached pluralistically, combining a number of methods to triangulate results. (Gray and Malins, 2004: 21)

In order to introduce undergraduate design students to this way of working and prepare them for using reflection to develop their practice not just in-action but also on- and for-action, they need to acquire the skills to work rigorously and make their reflection (and thus their practice) transparent. This is done in undergraduate studio practice through the critique or 'crit', where students informally discuss the progress of their work with tutors and peers. This is also where the area of contextual studies, which trains students to develop a knowledge and understanding of the context of their practice in the field, comes in. Training students in their studio practice as well as contextual studies is a first introduction to different methods of reflection, something that ultimately can build up to the pluralist approach to art and design methodology that Gray and Malins (2004) argue for. What provides contextual studies with a different perspective on work is particularly that here the main strategy for assessing student learning is not through practical work, but rather the critical essay.

The process of writing, while sometimes unfamiliar or uncomfortable to design students (Gröppel-Wegener, 2004; also see work of Writing-PAD project), has an important role in critical reflection, even for practitioners. Gray and Malins (2004: 57f) report on the work of McAleese (1999), who proposes the keeping of reflection journals as an 'off-loading' device - one main tool "to enable and externalize reflection-on-action" (Gray and Malins, 2004: 58). They go on to say that while they recognise a possible fear that exists in practitioners that speaking or writing about their work has an adverse affect on working creatively, there are compelling reasons for articulating and exposing practice. They cite four main reasons to communicate reflection: developing various models of practice; developing interdisciplinarity and collaboration through better communication; extending professionalism through self-evaluation; and having better conversations with 'ourselves'. (Gray and Malins, 2004: 58f)

This issue plays into the different kinds of knowledge experiential learning offers. As argued by Biggs (2004) there is a marked distinction between experiential feeling and experiential content. While experiential feelings are subjective and maybe cannot be expressed through words, it is the content that can be communicated that should be at the heart of the research. Biggs argues that experiential feelings are an individual representation of the experiential content, which for the researcher should trigger cognitive reflection in order to uncover the content.

The trick for the researcher is to move from reflection-in-action, which is subjective, is concerned with the experiential feelings and might not be possible to communicate through words, to a reflection-on-action, which uncovers the experiential content that can be externalised.

While Gray and Malins (2004) as well as Biggs (2004) are concerned with post-graduate research in the art and design field, links can be drawn to the undergraduate field as well. When it comes to the design students' journey, it is the same distinction that needs to be grasped - while building up skills in the studio is invaluable, it starts with reflection-in-action, experiential feelings. However, in order to go on to deep learning students will have to realise that these subjective feelings are just a starting point and that through critical reflection they can progress to double-loop thinking and retrospective as well as prospective reflection. This is not just crucial for researchers, but also for the level of development in undergraduate education, progressing practical work.

Studio practice can be so subjective and personal, especially for first year students - many of whom come straight from school, it seems quite difficult for them to realise that it is possible to take a step back and critically reflect on their own work. It might even be too difficult to do this at the very beginning of their studies, when they might not have any experience of critical reflection. This is where study skills as the first contextual studies module encountered can help. Here is an area where students can develop their critical and communication skills that is linked to their interests, but through giving them a historical and/or theoretical perspective, is also detached from their practice. Having developed this skill, students will later be able to transfer the critical thinking skills onto their practice to make the step from reflection-in-action to reflection-on-action (and then reflection-for-action). However, the way that the basics of critical thinking and academic communication are taught seem removed from the studio practice; at least this is how it seems to be in the minds of the students. Feedback from study skills modules at Staffordshire University suggests that these skills are often seen by students as removed from their chosen subject, an academic hoop students feel they have to jump through in order to get their university degree.

Could a model for study skills teaching be developed that took the form of an experiential programme that allowed the students to see the writing of their first critical essay at undergraduate level as an experience similar to the experiences they have in their studio practice?

A New Model

Based on the findings of the initial survey of study skills and contextual studies, a number of parameters were decided by the Director of Learning and Teaching and the Programme Area Manager for Arts, Culture and Design in consultation with the award leaders:

- There would still be one fractional member of staff responsible for the bulk of the study skills teaching.
- The 13 different study skills modules would be consolidated into three groups, 'Studying Art' for students on the Fine Art and Photography awards, 'Studying Design' for students studying 3D Design, Graphic Design, Product Design and Surface Pattern Design, as well as 'Studying Media' for students on the Animation, Media Production and Visual Effects Design awards. This would mean three cohorts of 90-125 students each.

- In order to give students a flavour of the field, rather than just exposing them to their own specific subject, there should be occasional lectures delivered by staff from each award to (and relevant for) the whole cohort.

Based on the aim to develop a study skills model that would ensure that students would become familiar with research methods, processes and principles, while also integrating theory and practice, two main hypotheses were made:

- Study skills teaching should be experiential - In order to allow students to relate to this for many unfamiliar and possibly difficult way of working, the teaching should link as much as possible to their practice by employing experiential learning strategies wherever possible.
- Study skills teaching should be embedded - The content should link as much as possible to award specific subjects in order to embed the study skills as fully as possible into the individual awards.

Since a main concern was how to engage large groups of students with limited contact time and staff, it was hoped that electronic means could be used to give students an active research experience outside of the classroom, that possibly tied into communication skills they already employed during their spare time, i.e. social networking.

Based on these parameters and hypotheses a module template was designed that aimed to take students step-by-step through the process of a research project culminating in an academic essay. An introductory session was followed by three blocks of teaching of three weeks each focusing on primary research, secondary research and writing up respectively. The last week was set aside for emergency drop-in sessions to deal with any specific questions regarding the writing of the essay. Input for making the individual sessions more experiential in nature were taken from a workshop on experiential learning by Dr. Colin Beard and his and John P Wilson's book *Experiential Learning - A Best Practice Handbook for Educators and Trainers* (2006).

The introduction to the module was in two parts. The first one was delivered by study skills staff, covering the basic university regulations, what it means to be a student and giving an overview of the individual sessions in the module. The second part was delivered to the separate award groups by award staff; here links to other modules were established and it was explained why the contents delivered in the study skills lessons were important not only for students, but also for practitioners, in their respective specialisms.

The primary research block was designed to introduce students to rigour and the skills of observation and description in an accessible way. They were introduced to note and image taking 'in the field' through an introduction to the Design Collection (Staffordshire University's in-house collection of 20th century design artefacts), a treasure hunt to help them find their way around the campus and a primary research workshop (by award staff), which on the Media courses became part of a residential study trip. Students were also introduced to presentation skills.

The secondary research block introduced students to the library and academic conventions in regards to finding and collecting sources. It also gave the cohorts the chance to test their group working skills through giving group presentations. This included a session with award staff taking them on a subject specific library tour and an introduction to library resources by library staff.

The writing block was designed to help students become accustomed to academic writing skills. They were divided into seminar groups of 30 and taken through the steps of putting their research into a larger context and finding a focus for their essay, how to structure their essay and how to use formal language. There was also a session with library staff scheduled which focused on researching journals to find further sources.

Throughout the semester lectures were scheduled by members of the awards staff to talk about important contributions to the field. These were meant to expose the students to a wider field outside of their specialism.

In order to gauge the proficiency of the students' writing they were asked to write a 500 word descriptive piece to hand in by the end of week five. This was used as a diagnostic piece to find out whether some students needed further testing for dyslexia and whether there were any problems with the hand-in procedures. Weaknesses in the majority of the students' writing were also exposed, which then fed into the teaching of the writing workshops.

A private wiki was set up for each module to give students more help with their independent study time and as a forum for discussion within a larger group. During the module tasks tying into the students' research activities were set, most of which encouraged a submission to the wiki. There was, for example, a group task asking the students to contribute to and create a page that illustrated their treasure hunt.

Findings

While running the module for the first time between September and December 2009, a number of problems were encountered that had not been anticipated and that allow only a limited conclusion as to whether it is possible and effective to take study skills teaching into a more experiential format as opposed to traditional classroom teaching.

While the experiential approach generated some good feedback and some students remarked how effective the treasure hunt was in getting a better idea of where teaching rooms were located across the campus and meeting people from other awards, others found it 'childish'. It almost seemed like these respondents had expected classroom teaching and did not want to settle for anything else. Overall due to the size of the groups it was difficult to facilitate short activities, but this is something that can be developed in future.

It also became apparent that it was more difficult than anticipated to embed links to the students' practice in the module. This was due to some breakdowns of communication between study skills and award staff. In some cases task instructions given to students by award staff differed from those provided by the study skills staff for the same task, the final essay brief being the worst example. This resulted in much confusion for the students, who complained that lecturers told them different things. However, through a detailed de-briefing and re-planning with award and study skills staff together, these issues can hopefully be ironed out for next year.

In terms of results, the outcomes were inconclusive compared to the previous approach. Comparing the new modules with an average of the respective modules from two years previously, the average pass grade improved slightly for two of them, while the pass rate fell. However, what is possibly the most interesting is that the percentage of non-submissions in one of the modules, Studying Media, almost tripled (from 8.87% to 25.69%, while the other two modules' non-submissions were around the 10% mark). While it is difficult to trace this back to the change in learning and teaching strategies specifically, it could be down to students associating a more playful rather than formal teaching approach with a less important module. What does seem clear is that the issue of motivation has not been solved yet.

The module feedback from students suggests that the sessions taught by the award staff varied in relevance - whether that was in the study skills sessions or in their more contextual lecture on contributions to the field. The latter were often seen as 'not relevant for us', so the attempt to give students a broader perspective on the field failed in this respect.

Using an electronic forum for students to engage with research seemed to get positive feedback. While throughout the parts of the module when the wiki was used anxiety was expressed by some, particularly by mature students, more than half the respondents to the module feedback questionnaires stated that the wiki was underused. If it is paired with giving students the confidence to interact with electronic media as needed, this seems to be a part of the module that could be developed much further. Again a problem here was the size of the groups, going through recent activities on the wiki became an administrative problem for the study skills staff. Looking back it seems obvious that while the potential is there, the practical use of electronic learning in this context was not properly researched in advance in order to properly embed it as a teaching and learning strategy. More research on the design of electronic learning needs to be conducted in order to turn this into a valuable experience for the students and make it work as efficiently as possible.

While the experiential aspects of this module have been successful, they were not enough to change the problem of the students' motivation. It seems that the model of organising this as few 'big' modules dealing with a number of awards in a larger field resulted in a large number of them not even handing their essays in. Consequently the decision was made to change this delivery pattern back to modules that deal with students per award and that have considerably more input from award staff. This will also include a more detailed introduction to how this module is based on the experience of research and how developing a critical perspective on an aspect of their studies will allow them to appreciate the relevance for the development not only of their essay writing skills, but also their critical thinking. There will also be more detailed links between the weekly tasks and the final essay as well as the studio practice. If the tasks could be linked closer to and embedded more firmly into the subject matter of the individual awards, students might be able to be more aware of a problem they could solve through critical intervention, rather than a task they have to fulfil in order to get their degree.

Conclusion

Based on the findings of the case study, it seems that using experiential learning strategies to integrate study skills teaching more fully into a practice-heavy undergraduate design curriculum is a possibility. However, a major element towards making this work is linked not just to learning strategies that reflect each other, but also to the subject matter. It seems that students are prone to dismiss teaching that they feel is not related to their 'real' object of study. Therefore it is important that the study skills teaching is not considered as generic in order to better engage students. Content needs to be embedded in the subject area.

It has been found that electronic activities can support study skills content, but in order to use them as part of allowing students the experience of academic research and reflection, they need to be fully integrated and built on during the teaching.

However, when planning the introduction of more experiential, embedded and electronic ways of teaching study skills it needs to be kept in mind that its particular value for students is as the first step to developing their critical reflection skills. As that (and a stepping stone to contextual studies modules to come), it is an advantage that study skills deals with less experiential feeling, the students are less involved in the subject matter than they are in their practice. The challenge is to find a subject matter which has experiential content that is removed from the students' immediate experiential feelings, yet related enough for them to (want to) engage with it.

Originally from Germany, Alke has made her home in the North-West of England and spends two days per week teaching study skills to art and design students at Staffordshire University. Her research interests include exploring the role of writing in design and design education.

Is Model-Making Sketching in Design?

Benay Gursoy, Maltepe University, Turkey, benaygursoy@gmail.com

Mine Ozkar, Middle East Technical University, Turkey, mine.ozkar@gmail.com

Abstract

Considerable research has been done by various scholars to assess the significance of sketching in the early stages of the design process. However, sketching in design studies usually corresponds to drawing and the extensive research on the cognitive aspects of sketching does not always include three-dimensional sketching through physical and digital models produced in the early phases of design process. The aim of the presented research is to question whether model-making in the design process and design cognition is a form of sketching. Departing from key research on sketching which articulates its uncertain nature as a positive drive in early design phases, this paper looks at whether physical and digital models can also be counted among ambiguous design tools. The inquiry is conducted with three graduate students of architecture having similar degrees of professional experience and skills of making physical and digital models. The participants are given three architectural design tasks which are similar in terms of contextual, functional and programmatic complexity and scale and are asked to solve the given design problems by using three different mediums: free-hand sketches, physical models, and digital models. The design sessions are recorded using cam-corders and the participants are asked to think-aloud during the design protocols. The Linkography method is used for the analyses of the protocol studies and linkographs are developed for each design session. Departing from the assumption that ambiguity of a medium is positively related with the amount of lateral transformations realized during a design session, the outcomes of the linkographs are compared in terms of the transformations generated. We conclude that having too many lateral transformations is not always an indication of ambiguity.

Keywords

design; design protocols; sketching; model-making; reflective practices; cognition; computer-aided design; Linkography.

Sketching is one of the most explored activities in design cognition studies and considerable research has been done by various scholars to assess the significance of sketching in the early stages of the design process. Gabriela Goldschmidt (2003), Vinod Goel (1992), Donald Schön and Glenn Wiggins (1992), Masaki Suwa and Barbara Tversky (1997), Bryan Lawson (2006) are among researchers who have conducted analytical and empirical studies focusing both on freehand sketching with conventional methods (using pen and paper) and sketching in contemporary media using computer-aided sketching tools. However, sketching in design studies usually corresponds to drawing and the extensive research on the cognitive aspects of sketching does not always include three-dimensional sketching through physical and digital models produced in the early phases of design process. Despite the general tendency in literature to underline the importance of model-making in the design process, its effects on the cognitive process are not sufficiently articulated.

Related Work

Key research on sketching articulates its uncertain nature as a positive drive in early design phases. Goel (1992) compares the effects of different representation techniques –drawings- on the cognitive design process. The results accentuate the importance of using ill-structured representations for ill-structured problems which are corresponding to using fuzzy (ambiguous, ill-defined) drawings instead of hard-line (well-defined) drawings during the early design process. Lateral transformation is a term developed by Goel and is defined as a transformation where "movement is from one idea to a slightly different idea rather than a more detailed version of the same idea". Correspondingly, vertical transformation is a transformation where "movement is from one idea to a more detailed version of the same idea" (Goel, 1995). According to Goel, ambiguous media enable lateral transformations, and lateral transformations enable the widening of the problem space and development of kernel ideas. Widening of the problem space is directly related with productivity.

Goldschmidt (1990) proposes the Linkography technique to assess design productivity and defines it as " a representation system that uses links as input and displays structural design reasoning patterns as output. A linkograph is "a simple graphic notation in which the sequence of moves is shown on a straight line and the links are nodes at the intersections of diagonal network lines connecting to related moves" (Goldschmidt, 1992). Design productivity is related to the link index value, which is the ratio between the number of links and the number of moves. According to Goldschmidt, the higher this value is, the more productive a design session is. This implies that having a higher link index value corresponds to having denser links among moves. This is in disagreement with Goel's proposition where design productivity is associated with lateral transformations and dense links are mostly representative of vertical transformations.

Rodgers, Green and McGown (2000) analyze the progress of design projects in the studio on the basis of transformations between successive sketches of the students. They report similarly to Goldschmidt, that over a period of a semester, students' sketches show both lateral and vertical transformations but that students who do well predominantly make vertical transformations and a student whose progress is marked by many lateral transformations makes poor progress in terms of achieving positive complexity.

Productivity towards creativity can be discussed both ways. However in this paper, we assume that expanding the design space laterally in the initial/conceptual stage is more productive in terms of exploration and we take Goel's (1992) argument that ill-structured representations give way to significantly more lateral transformations than do well-structured representations as our departing point in the study.

Goel believes that the ambiguous nature of the freehand sketch facilitate lateral transformations and prevent early fixations. Goldschmidt (2003) also points out that an ambiguous representation prevents the early crystallization of ideas, thus "helps defer commitment to a solution". Paynter, Shillito, Wall and Wright (2002) discuss the role of sketching and model making in design and the reasons why the computer is presently unable to provide appropriate support in the "germinal phase" of the design process. They consider physical model-making already as a sketching tool and argue that in contrast to current CAD programs, freehand sketching and physical model-making allows a designer to communicate multiple ideas rapidly and expressively without a demand for unnecessary precision.

Drawing from this fuzzy character of sketching, this paper looks at whether physical and digital models done during the early design process are also ambiguous and enable lateral transformations. The study is developed as an empirical study that will generate its own answers and does not consider anecdotal data as facts. It benefits highly from the related work cited above while developing its own analytical approach. Considering freehand sketch as an ambiguous media, it seeks to compare the outcomes of the experiments with physical and digital models with the outcomes of the experiments with freehand sketch in order to reveal whether physical and digital models also have ambiguous properties.

Design of the Experiments

The inquiry is conducted as protocol analyses with three graduate students of architecture having similar degrees of professional experience and skills of making physical and digital models. The participants are given three architectural design tasks which are similar in terms of contextual, functional and programmatic complexity, and scale. They are asked to solve the given design problems by using three different mediums: free-hand sketches, physical models, and digital models. In order to neutralize the effect of the individuals, each participant is involved in all the design mediums mentioned. So at total, nine experimental sessions are realized. Table 1 shows the distribution of design tasks among designers and the design mediums used for each design task.

	Design Task # 1			Design Task # 2			Design Task # 3		
	Physical Model	Freehand Sketch	Digital Model	Physical Model	Freehand Sketch	Digital Model	Physical Model	Freehand Sketch	Digital Model
D1	●				●				●
D2		●				●	●		
D3			●	●				●	

Table 1 Design tasks, design mediums, designers (D1-3)

The design tasks consist of formal explorations for mixed-use buildings in urban plots. They are located at the same environment and have common specific topographic qualities such as being sloped, being next to a bridge and on the waterfront, having different levels, etc. that expectedly calls for three dimensional inquiries. The numbers on the satellite view from Figure 1 correspond to the design tasks presented in Table 1.

For design task (DT)1, the participants were asked to design a mixed-use building consisting of housing units and a cinema / a theatre. For DT2, they were asked to design a mixed-use building comprising housing units and an exhibition gallery. DT3 was again to design a mixed-use building with a dormitory and a café. Tasks were designed to be similar in terms of complexity but with programmatic differences. The reason why slight changes on the program exist is to prevent the transfer of experience from one task to another. No specific data were given about the total area of each program unit. However a simple site analysis was provided to the designers prior to the experimental sessions and the participants were allowed to ask further questions.

All the participants started the experiment first with physical model condition. They continued with freehand sketch and finalized with digital model conditions. For the physical model condition, they were provided a cardboard site model of 1/200 scale. On the model, buildings, pedestrian roads, vehicular roads, canal, and the bridge were clearly indicated. The participants were given cardboard, colored papers of different thicknesses, transparent papers, needles, glues, a ruler, and colored pens as materials. They were not allowed to sketch by making drawings to generate ideas. Cardboard and paper were chosen as the primary modeling materials since they correspond to the most commonly used modeling materials in architecture. If the experiment would have been realized by using other modeling materials (i.e. modeling clay, styrofoam) , the results could have been different.

For the freehand sketch condition, the participants were given 1/200 scale site plans and site sections of the design tasks, sketching papers, colored pens and pencils, erasers, and a ruler. The site section from Figure 1 is the site section provided for DT1.

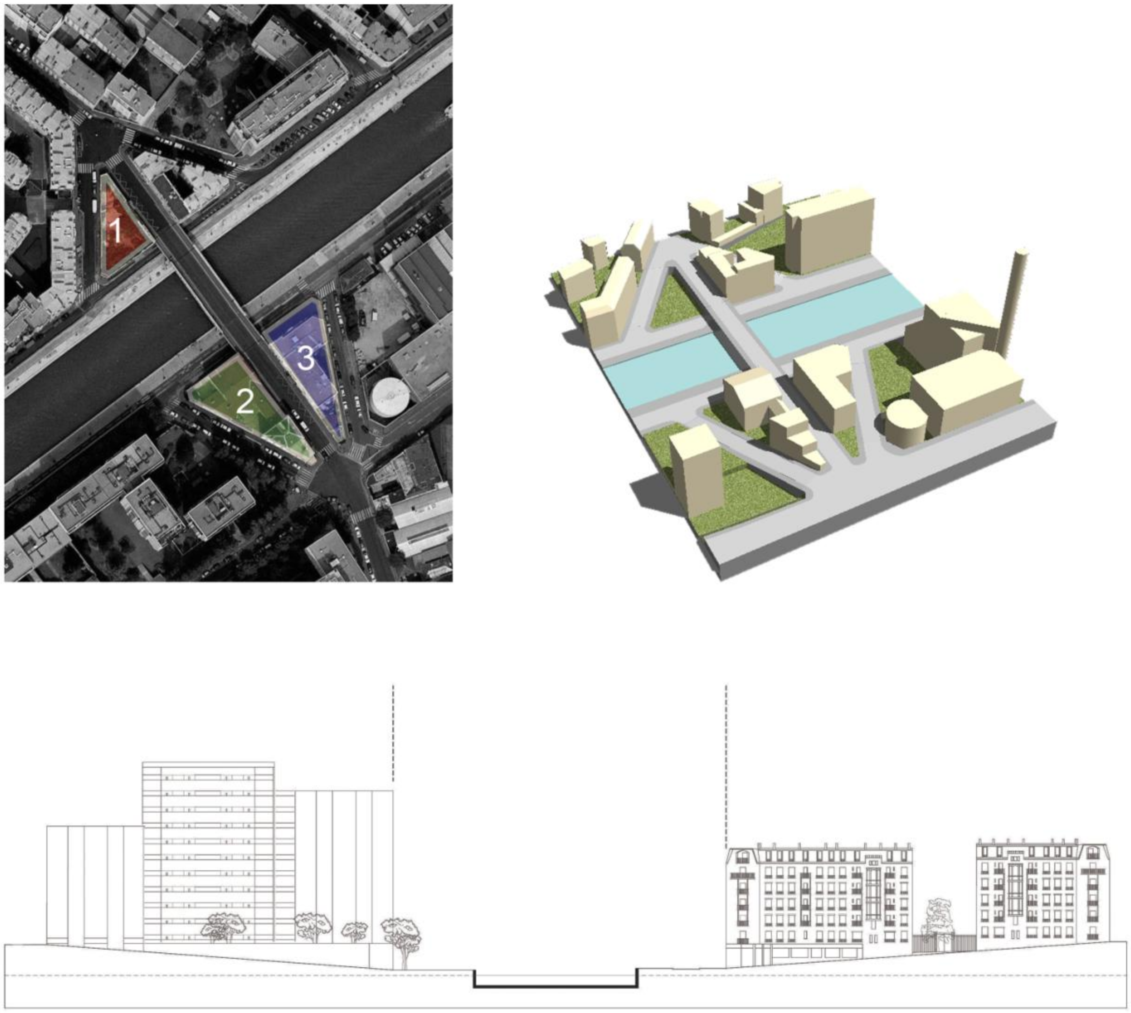

Figure 1 Satellite view, site model and site section

For the digital model condition, the designers were provided Sketch-Up, Rhinoceros, and 3ds Max models of the site comprising the same area as the physical model. Participants were free to chose among these digital modeling soft-wares. D1 has chosen Rhinoceros; D2 and D3 have chosen 3ds Max. The site model image from Figure 1 is the Sketch Up model.

A simple site analysis was presented to the participants prior to the sessions. All of the design sessions were recorded using cam-corders and the participants were asked to think-aloud during the design protocols in their native language.

Experimental Procedure

The experiment of each participant followed this procedure:

1. Presentation of the experiment

2. Presentation of the site analysis

3. A pre-interview with the participant about the experiment. He/she was asked to talk about his/her expectations about the experiment, whether he/she thinks he/she will be successful in the experiment with the given medium or he/she would be more comfortable with another medium and the reasons.

4. Presentation of the design briefs

5. Initial conceptual design phase. At this primary session, the participants were asked to generate conceptual design ideas. For the physical model condition, they were asked to make a match-box physical model of their idea that they will develop in scale further on. The physical model did not have to be in scale but had to clearly explain their ideas. For the freehand sketch condition, participants were asked to make a conceptual diagram of their design ideas. For the digital model condition, they were supposed to make a digital model representing their conceptual design idea. The duration of this initial phase was limited in terms of duration of the conception of their design ideas. It varied between 8 minutes to 21 minutes.

6. Development of the conceptual design idea. At this second stage of the experiment, the participants were asked to develop their design ideas. This time, they were asked to work in 1/200 scale for physical model and freehand sketch mediums and to fit into the given site model for the digital model medium. The sessions ended when the participants declared that they are satisfied with the result. However in cases when they exceeded 60 minutes, they were reminded to straighten up their designs.

7. A post-experiment interview. The participants were asked whether they were right in their expectations about the design session, what the difficulties they have faced were and whether they could have been more successful using another design medium.

Methods of Analysis

In order to analyze the protocols, first the transcripts of the protocols are written. While writing the protocol transcripts, both the verbalizations from the think-aloud sessions and the physical movements the participants have made are noted together with the exact movement time. Later, the protocol transcripts are segmented to the design moves. According to Goldschmidt (1995), a design move is "an act, an operation, which transforms the design situation relative to the state in which it was prior to that move" or "an act of reasoning that presents a coherent proposition pertaining to an entity that is being designed". This definition is taken as reference while segmenting the protocols to its design moves.

The Linkography technique is used for the analyses of the protocol studies. For this study, linkographs are generated only for the initial conceptual design phases since otherwise the linkographs would have been too long to manage. So, it is very important to underline that the following discussion concerns the initial conceptual design phase of a design process and not the detailing phase of a design idea.

The outcomes of the experiments will be analyzed first regarding the quantitative data obtained from the linkographs. Comments and observations of the authors concerning the protocol analyses will be made afterwards.

Limitations of the Study

There are certain severe limitations of the proposed experimental research acknowledged by the authors. These limitations are due to the methodology used to gather and analyze data, the quality and the quantity of the participants, the nature of the design tasks and the sequence of the experimental procedure. It is therefore, of crucial importance to cite that the protocols presented in this paper are not used to state generalizable facts concerning models and model-making in architecture.

Despite the fact that the protocol analysis method is counted among the most commonly used empirical research methods for the study and analysis of cognitive processes in design, it is also commonly criticized for creating an unnatural design process by forcing the designers to solve a design problem within a limited time while they are constantly filmed. Thinking-aloud during the protocol studies is also mainly criticized for obstructing the natural sequence of thoughts of the designers by demanding that they verbalize each thought.

Further on, the Linkography method, which seems as an objective analysis method, is criticized mostly for lacking objectivity in different levels: determining the moves (segmentation process), judging the links among moves (coding process) and interpreting the meaning of the resulting linkograph (analysis process). In order to overcome the subjectivity within the segmentation and coding processes of linkographs, inter-coder arbitration is advised (Mc Neill, Gero, & Warren, 1998).

The results of experiments may vary if the subjects, the design tasks, the settings of the study, the procedure of the study, the materials and software provided to the subjects, the time given for each task, the order of the design tasks were different. Therefore, this paper, instead of ending with a *de facto* argument, presents these protocol studies as an example of how ambiguity of model-making can be sought within design cognition studies and discusses the results only with reference to these specific protocols.

Generated Linkographs

With an understanding of the construction of a linkograph, one is able to comment on the design behaviour without studying the design protocol (Kan & Gero,2005). For each designer, three linkographs are created. These linkographs are shown on Table 2. The difference in length in horizontal direction is due to the number of moves generated to complete the design task. Duration of the experiments is not present on this table as a variable. Therefore lengths of the linkographs do not differ because of the time spent to complete the task but because of the number of design moves generated.

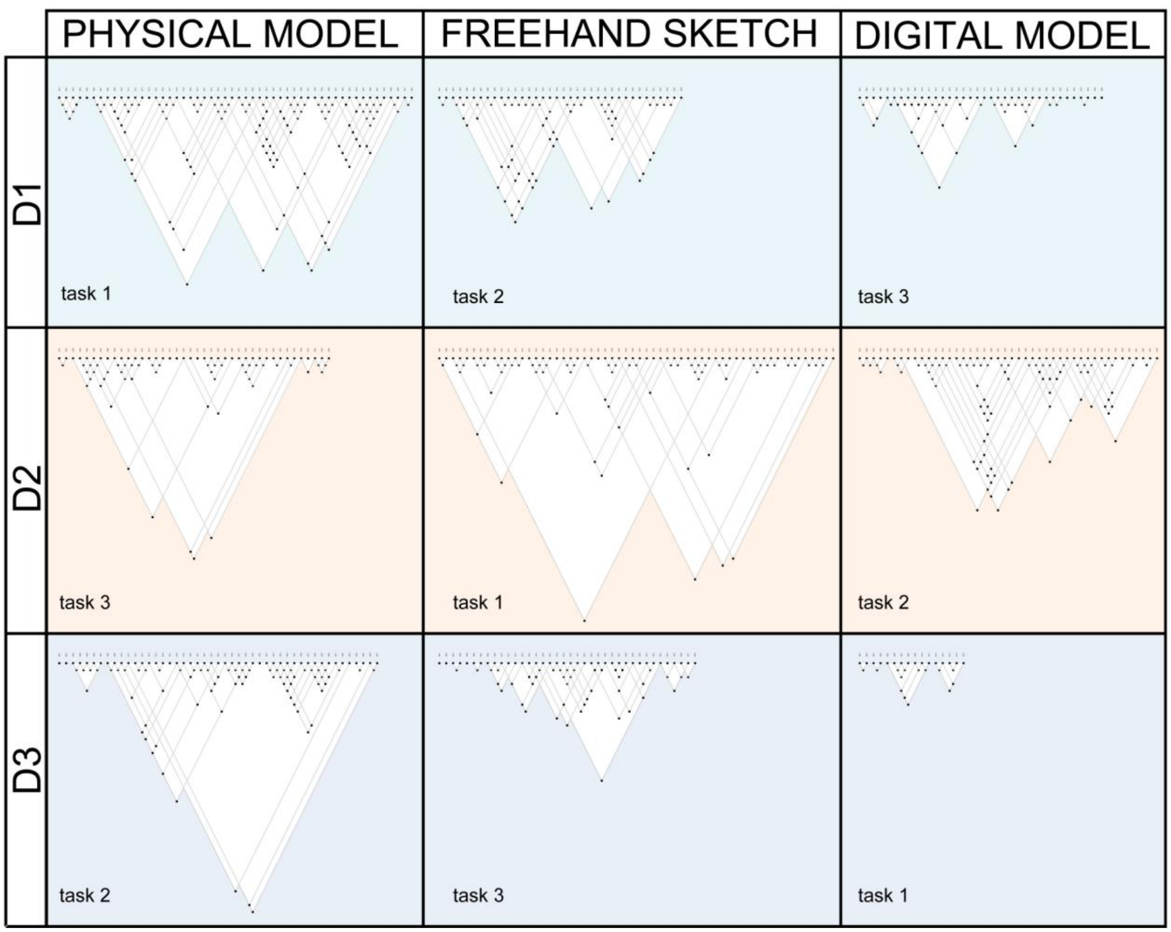

Table 2 Linkographs

Designer	Design Medium	Total # of moves	Total # of links	Link index	Time elapsed	Moves / min	Links / min
D1	Physical model	52	111	2,13	10' 50"	4,8	10,2
	Freehand sketch	36	59	1,63	8' 30"	4,2	6,9
	Digital model	36	36	1	20' 55"	1,7	1,7
D2	Physical model	40	47	1,17	15' 55"	2,5	2,9
	Freehand sketch	58	62	1,06	19' 30"	2,9	3,2
	Digital model	44	77	1,75	9' 25"	4,7	8,1
D3	Physical model	47	70	1,48	21' 50"	2,1	3,2
	Freehand sketch	38	43	1,13	9' 25"	4	4,6
	Digital model	16	14	0,87	9' 30"	1,7	1,5

Table 3 Total number of moves and links, link index values and duration of protocols

Table 3 shows link index values of each participant's design sessions with three design mediums. Time they have spent to finalize the initial conceptual design phase is also indicated and the moves and links they have generated per minute is calculated.

According to Table 3, the link index number was higher for D1 in physical model condition (2,13) compared to freehand sketching (1,63) and digital model (1,0) conditions. Time spent to complete the initial conceptual design phases however was more in the digital model condition (20'55") than the physical model (10'50") and freehand sketch (8'30") conditions. These values indicate that the design session using physical model was the most productive and the design session using the digital model was the least productive process for D1.

For D2, the link index number was higher in the digital model condition (1,72) compared to physical model (1,17) and freehand sketch (1,06) conditions which have closer values. D2 spent very less time to complete the initial conceptual design phase in the digital model condition (9'25") when compared to physical model (15'55") and freehand sketch (19'30") conditions.

According to these values, the design session using the digital model was the most productive and the design session using freehand sketch was the least productive process for D2. For D3, the link index number was higher in physical model condition (1,48) compared to freehand sketch (1,13) and the digital model (0,87) conditions. However, the time spent during the physical model condition (21'50") for the conceptual design generation is comparatively very high than the freehand sketch (9'25") and the digital model (9'30") conditions. For D3, the design session using physical model was the most productive and the design session using the digital model was the least productive process. So for D1 and D3, physical model condition resulted with the highest link index value and the digital model condition, ended with the lowest link index value. On the other hand, D2 had the highest link index value with the digital model condition and lowest with freehand sketch condition.

Link index numbers might be useful in discerning productivity of the design sessions (Goldschmidt,1992) however are not sufficient to analyze the protocols. Linkographs can generate different linking patterns. Designers who start the design process with exploring different options and then select one to develop will produce a very different linkograph compared to designers using a holistic approach without exploring different options (Kan & Gero, 2005).Therefore analysis of these linking patterns are also necessary along with quantitative data while commenting on design productivity.

Through linkographs, Goel's (1992) typology which distinguishes between lateral and vertical transformations can be read. Linkographs can easily indicate what types of transformations are being made by displaying link patterns: dense clusters of links correspond to vertical transformations while scattered links denote lateral transformations (Goldschmidt & Tatsa, 2005). Correspondingly, vertical transformations generally form chunks and webs, while lateral transformations remain as non-interlinked moves or form sawtooth tracks. In this study, linkographs of the nine experimental session are observed with the aim of determining vertical and lateral transformations. Figure 4 shows how this exploration is done through the linkograph of the freehand sketch session of D3. On the given linkograph, first the links forming chunks and webs are identified as triangular areas and those triangular areas are colored to be easily perceived. Later the links that exist only between two sequential moves are explored and the triangular area between two moves are colored. The total number of triangular areas that are formed on the linkograph iscounted.

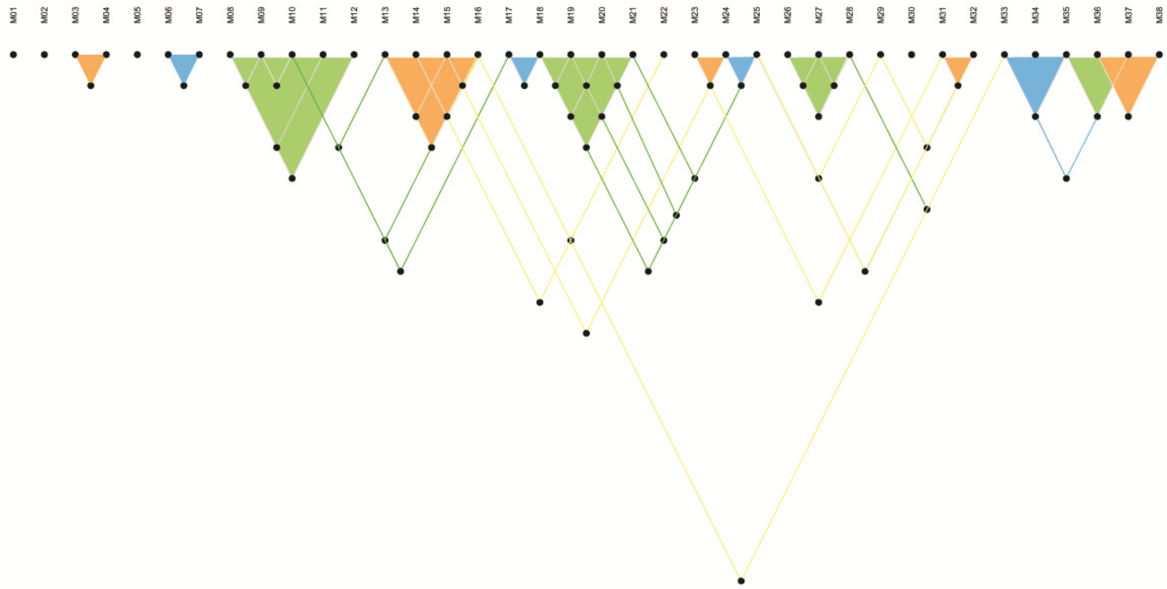

Figure 4 Example of Lateral Transformation Determination on Linkographs

Moves that are unlinked with other moves are also considered as lateral transformations since they are sudden changes in the design process. The sum of these unlinked moves is added to the number of the colored triangular areas. The final value gives the total number of lateral transformations that appear during the design session. Links that are not within a chunk or a web, but are back-links to previous ideas are also indicated on the graph. However since they are not new ideas the triangular areas formed with these back-links are not colored and are not counted as lateral transformations. Vertical transformations are not easily identified as the lateral ones. Kan and Gero (2008) have developed a method where they consider the linking nodes as points in Cartesian coordinate system and find the mean value of X, which is the average location of the nodes in the X-axis and the mean value of Y, which is the average location of the nodes in the Y-axis. The mean value of X is calculated to find whether more nodes appear through the beginning or through the end of the design session. The mean value of Y, is calculated to find out how deep the ideas process, therefore to find out the lengths of the links. In this study, Kan and Gero's method is used to calculate the mean value of Y of the linkographs and those values are used to compare the design sessions in terms of vertical transformations. Table 4 shows the number of lateral transformations and the vertical transformation value of each design session along with the link index numbers.

	Design Medium	Total # of Lateral Transformations	Vertical Transformation Value (Mean Value Y)	Link index
D1	Physical model	15	5,85	2,13
	Freehand sketch	18	6,05	1,63
	Digital model	25	2,66	1
D2	Physical model	16	4,53	1,17
	Freehand sketch	29	5,16	1,06
	Digital model	16	5,98	1,72
D3	Physical model	21	4,88	1,48
	Freehand sketch	17	3,42	1,13
	Digital model	6	2,28	0,87

Table 4 Lateral Transformations and Vertical Transformation Values

According to this table, D1 has made quite a high number of lateral transformations during the design session with the digital model (25) compared to the design sessions with freehand sketching (18) and the physical model (15). However, the vertical transformation value is very low for the digital model condition (2,66) compared to the freehand sketching (6,05) and the physical model (5,85) conditions. These values, together with the link patterns of the linkographs presented in Table 2 indicate that D1, during the protocol with the physical model and the freehand sketch, had generated ideas that she also could develop. Her protocols with these mediums display dense clusters of links. Moves are generally inter-related but not totally connected indicating that there are multiple opportunities for good ideas for potential development. During the digital model session, on the other hand, she has jumped from one design move to another but her moves are random trials that do not have a contribution to the design concept. Her protocol with the digital model, therefore, displays many unrelated moves or moves that are only related to directly preceding them. This indicates that either there are no converging ideas, and hence, low opportunity for idea development, or that the process is progressing but not developing (Kan & Gero, 2008). Link index values of these sessions also corroborate this interpretation with the highest value for the physical model condition and the lowest value for the digital model condition.

During the design session with freehand sketching, D2 made many lateral transformations (29) than in his design sessions with the physical model (16) and the digital model (16). The session with the digital model has the highest vertical transformation value (5,98) and the session with the physical model has the lowest vertical transformation value (4,53).Therefore, D2's protocol with the digital model displays dense clusters of links compared especially to his protocol with the physical model. In his protocol with the physical model, there are quite a number of moves but the chunks are not deep. This indicates that D2, with the physical model, either, could not deepen his ideas, or that he had an already crystallized idea that he did not need to explore further.

D3 had the biggest number of lateral transformations (21) and highest value of vertical transformation (4,88) from the design session with the physical model and the smallest number of lateral transformations (6) and the lowest value of vertical transformation (2,28) from the design session with the digital model. Similarly, her protocol with the physical model displays dense clusters of links forming chunks and webs when compared to her two other protocols. Her protocol with the digital model is radically poor in moves and links. The very few number of design moves indicates that either she could not make use of the design medium to generate ideas, or she had an early crystallized design idea. Eventually, links that are very few in number could not form webs or chunks, indicating that she could not deepen her ideas with the digital model medium.

Observations and Remarks About the Experiment and Comparison with the Linkographic Data

Data deducted from the linkographs concerning the design protocols might be sufficient to analyze the protocols. However personal observations and remarks of the authors must also be taken into consideration.

According to the linkographic data, D1 and D3 had the highest link index value with the physical design medium, while D2 had a comparatively low value. The linkographs of the physical design condition of D1 and D3 displayed dense clusters of links while in D2's linkograph links did not deepen. This difference however is probably not due to the physical model medium but to the design approach of the individual designers. D1 and D3 did not have an early crystallized design idea during the protocols. They explored the problem space with different options and progressively developed their design. D2, on the other hand, had an holistic approach. He came up with a very early idea about the form of the building, and during the protocol, he did not search for other alternatives. This approach continued at the second phase of the experiment where the designers were asked to develop their initial conceptual ideas with a 1/200 scale model as well. D1 and D3, while developing their ideas through physical models, have made unexpected discoveries, but comparatively D2 had very few discoveries of that sort.

D3, at the pre-experiment interview had stated that she was used to conceptualize her ideas through physical models and she thought she would be more comfortable designing with physical model. Although she had the highest link index value with the physical model medium, she spent more than twice the time she spent with freehand sketching and the digital model to generate the conceptual design idea. She later claimed in the post-experiment interview that being supposed to think-aloud was confusing her ideas and that she could not focus on her design. She said that while she is on her own, she makes random moves without knowing the consequences and that these moves end with surprising discoveries. However, she argued that since she is asked to verbalize each move, she could not benefit from that discovery process.

Another very important observation to underline is concerning D2's design session with the digital model medium where he ended with the highest link index value. He might have had the highest link index value with the digital model medium, but most of the moves presented on the linkograph were moves conceived because of his verbal acts and were not totally related with a search or exploration with the digital modeling media. So, it can be said that at least during the initial conceptual design phase of the experiment with digital model, he made intensive use of the mental imagery instead of searching alternatives through digital modeling media. Linkographs however do not reveal this fact.

The reasons why D1 and D3 had the lowest link index values with the digital design medium in the early conceptual design phase are different. D1 had control over the CAD software, she knew the commands and she could do what she wanted to do. However, she did not have control over the design process as much as she had with the physical model condition and the freehand sketching condition. She could not develop her ideas and she made random trials which are not connected with each other. Goldschmidt (1992) notes these kinds of design sessions as being non-productive. D3, on the other hand, did not have control over the CAD software. She spent a lot of time searching for the right commands and ended up by using very few of them for generating her design. She claimed that this caused too much discomfort during the design session and that probably while searching for ways to control the interface of the software, she lost the sequence of the design process and missed good ideas.

Conclusion and Further Discussion

Goel's (1992) experiment reveals the importance of using ill-structured (ambiguous) representations for ill-structured problems instead of well-defined ones in the early design process. His experiment shows evidence that significantly more “lateral transformations” are developed with the ill-structured representations than with the well-structured representations. According to this argument, the ambiguity of the design medium is positively related to the number of lateral transformations done during a design process.

We have utilized linkographs in order to detect lateral and vertical transformations and find linkography very successful for the task. We assumed at the beginning of the research that the reverse was also true and that higher the number of lateral transformations is, the more ambiguous is a design medium. We tried to identify and count the lateral transformations within the nine experimental sessions for the three design mediums in order to be able to comment on the ambiguity of these mediums. However, we perceived that having too many lateral transformations is not always an indication for the ambiguity of a design medium and that considerable amount of lateral transformations may also occur when the designer faces a well-defined design medium. This work thus complements Goel's argument about the relations between lateral transformations and ambiguity. Our follow-up research focuses on identifying factors of ambiguity in the acts of model-making rather than with reference to the generic characteristics of its medium alone.

Despite the immense number of cognitive studies on freehand sketching, there are very few cognitive studies concerning physical and digital models. Further research can be done to compare the design productivity of these mediums in the way that Goldschmidt defines it. We find it challenging to discuss the sketchy aspects of physical and digital models on that level.

Authors' Biographies

Benay Gürsoy

Graduated from Middle East Technical University in 2007, Benay Gürsoy worked in several architectural design firms while pursuing her M.Arch education in Middle East Technical University with Mine Ozkar as her thesis supervisor. She started her doctoral studies in Istanbul Technical University, in PhD program for Architectural Design Computing in March 2010. She is also working as a research assistant at Maltepe University.

Mine Özkar

Mine Özkar holds an MS in architectural studies and a PhD in design and computation from MIT. Her research and publications are on design thinking, the history and theory of basic design education, cognitive processes in design, computation in design processes, and visual computation. After working as George Stiny's assistant (2000-2004) as he prepared his most recent book, SHAPE she became a member of the faculty at Middle East Technical University, Department of Architecture, where she coordinates and teaches design studios and computational design courses at the graduate and undergraduate levels. She is also a partner in two interdisciplinary research projects on implementation of shape algebras and curriculum development for architecture education.

Human Photographs on trust in bank websites

SeungYeon Ha, Iowa State University, USA

Sunghyun R. Kang, Iowa State University, USA

Abstract

On the Internet, trustworthiness is an issue and becomes more important as financial transactions continue to grow. According to our analysis of the top 20 largest US banks, fifty-five percent of the banks' homepages used human photograph(s). The purpose of this study is to examine how image choices of a male, a female, a family, a small group of people in an office, or a diverse group of people in photographs on a bank homepage will have the most positive effect on customers' perceptions of trustworthiness with regard to the website. For the research method, five mock-ups of a bank homepage were created with carefully modified and selected photographs from each image group. Then a web-based survey was conducted. The result, as determined by this study, reveals distinctions among ethnic groups. Asian participants tended to trust homepages using photographs of families the most and Caucasian participants tended to trust homepages using photographs of a small group the most.

Bank website, Trustworthiness, Human photographs, Web design

Technology has changed the way people communicate. Dabholkar (2006) demonstrated that fifty-nine percent (59%) of online consumers visit aggregator sites before accessing websites to purchase (p.259). Consumers gather information, make comparisons, and access decision-making guides. Even though Internet technologies have grown fast and retail outlets have spread their businesses via e-commerce, a majority of the Internet users in the United States feel uncomfortable making payments online for the merchandise they want to purchase (Wang and Emurian 2005, p.106). Seventy percent (70%) of online shoppers abandoned a purchase because of security concerns (verisign.com, 2009, p.1).

Research provides some indications about which factors influence consumers' choices when rating a website (Dabholkar, 2006, p.259). Dabholkar's research showed that website credibility is an important consideration. Online customers want to be assured that they are safe in using the sites, and that the sites are reliable for the purchase they are considering.

Fogg et al. (2001) from Stanford University researched how people evaluate a website's credibility. In this study, participants viewed professionally designed websites and were asked to evaluate them for trustworthiness. Fogg and his associates interviewed 2,440 people to assess how web users determine credibility. Fogg's study found design features are more important than contents. In addition, design structure and layout are also important components in web site evaluation (Fogg et al., 2003, p.24). Fogg et al. mentioned that users' gather their own credible judgments about the websites they visit. Their first look at the website's design is the main issue in determining whether users keep looking for other sites or in determining whether the user will return because they do or do not trust the site (2003, p.26). There are a number of considerations in the way websites are constructed that enhance visitor confidence in the site and therefore also increase return visits.

Trustworthiness is an abstract and subjective concept. However trust must be, at least partially, an element of the first impression of an e-commerce website. Wang and Emurian determined that trustworthiness is conveyed through four characteristics of web design: graphic design features, structure design, content design, and social-cue design (2005, p.106). Fogg's web credibility research supports that 'design look' and 'information design/structure' are top categories which determine online user's credibility of a website (2003, p5). The first contact of the website impacts impressions of credibility (Wathen and Burkell, 2002, p136). Naturally, the initial look of a website is affected by its design elements: color, typography, graphics, and layout.

According to our analysis of the top 20 largest US banks, fifty-five percent of the banks' homepages used human photograph(s). This analysis leads to a question on how viewers will perceive trustworthiness of various photos with different genders, single people, families, or diverse groups.

Steinbrück et al. conducted an experiment on how a portrait image affects customer trust on the site of a German online bank. They designed the site in three different versions. Version 1 showed a portrait photograph of a person with a label identifying that person as a customer service employee. Version 2 showed no label but used the same photograph as version 1. Version 3 did not have a photograph. The empirical study with three identical mock-up websites showed that Version 1, the portrait photography with label, was perceived as the most trustworthy compared to the two others (Steinbrück et al., 2002, p.749). Conversely, Riegelsberger and Sasse (2002) studied the tendency of some homepage images to produce feelings of distrust. This is true when the homepage images lead negative reactions. There are two reasons. One was that non-shoppers do not trust the photographs on a homepage. They believed the photo depicts a fake employee of the company. Another negative influence was when the shoppers believed adding photographs decreased usability by adding clutter and reducing access speeds (Riegelsberger & Sasse 2002, pp742-743). Li et al. studied different images of agents to find out how familiarity affects the trust. They found an agent which resembles the user trusted more than an unfamiliar agent (2007, p194-198). Another study by Riegelsberger et al. (2003) examined the effectiveness of images with genders. Homepage photographs of females received higher credibility ratings than males. However, no research found any changes in trustworthiness of homepages with multiple human photographs.

The purpose of this study is to examine how the image choices of a male, a female, a family, an office grouping, or a diversity group of people in the pictures on a bank homepage will have the most positive effect on customers' perceptions of trust in the website. This study will determine the type of human images that will appeal to most people in building trustworthiness of the bank's web page.

Research Methodology

Web designers need to understand how images, colors, and layout affect the communication of the website. To determine common web design elements of financial institutions, this study selected and analyzed the top 20 banks' homepages (accessed between April and November 2008). The top 20 bank's websites were selected from the US Online Banking Report. (onlinebankingreport.com)

Among the top 20 banks' websites, nine (45%) of the banks' homepages did not display any photographs of humans. Five websites, (25%) of the twenty bank sites studied, showed one person. Twenty-five percent of the banks studied placed the image (25%) of the main image area while five (25%) used one, usually small, human picture on the left side of the homepage (Table 1).

Table 1. Number of Portrait Photographs on main image area of 20 bank websites

Portrait Photographs	No	One	Two	Five or more
Number of bank websites	9	5	4	2
Percentage (%)	45%	25%	20%	10%

Overall, fifty-five percent of the banks' homepages used some form of human photograph(s). With this analysis, the research method was developed.

As the research method, five mock-ups of a bank homepage were created with carefully designed and selected photographs representing each group stated above. A self-administered web-based survey was tested to discover how the five-mock-ups work to give the impression of trustworthiness to the users.

All human pictures were purchased at http://www.photos.com, except the ethnic group picture borrowed from http://question.bahai.org/ taken in March 13, 2009. Table 2 shows the five mock-ups of the website and its variables.

Table 2. Breakdown of five mock-ups of a bank website

Photographs	**Websites**	**Design Variables**		
		Apparel	Position / Gesture	Facial expression
A male		Suit	Sitting/put hands on desk	Smiling
A female		Suit	Sitting/hold hands together on desk	Smiling
A family		Casual wear	Sitting/parents hold their children	Smiling
A small group		Suit	One is sitting, three are standing	Smiling
An ethnic group		National costume	All standing	Smiling

The photographs were re-touched to minimize visual variables, which might affect visual perception. All pictures were cut to show their subjects' upper body while the sitting. For consistency, the female and small group pictures were transformed so the human figures seemed to lean more towards the left-hand side (from the viewer's point of view). Pens located in the man and women's hands were removed from the images. In the five photographs depicting a business setting, the subjects wore a suit, and used the upper part of the body. All of the humans' expressions included a smile or a near smile. Also all colors were converted to black and white to reduce the effect of this variable.

With those five mock-up websites, two questions were asked for this survey:

1. If these are pictures on your bank's website, which would cause you to trust the bank the most? and
2. Why did they select the photographs as the photographs that generated the most feelings of trust?

The survey collected participants' demographic information including gender, major, ethnicity, income range per month, experience with retail banks, experience with online banking, etc.

The participants were students enrolled at University and were 18 years of age or older. Survey participants were contacted by three methods—email, word-of-mouth, and fliers. One hundred eighty-eight participants completed the survey during spring 2009.

One hundred fifteen females and seventy-three males participated in the survey.
The ethnic background of the participants broke down as follows: one hundred twenty-seven Caucasian, fifty Asian, eight Hispanic, and three African American. The participant population was dominated by students from the College of Design (63.8%); one hundred and twenty students participated. The total number of participants outside the Design College was sixty-eight (36.2%)—thirty-eight females (20.2%) and thirty males (16%). Table 3 shows that most respondents of this survey were undergraduate students (69.1%). There were one hundred fifteen females (61.2%) and seventy-three males (38.8%), who participated.

Table 3. Participants by gender, statuses, and ethnicity

	Female				**Male**				**Total**		
	Caucasian	Asian	African American	Hispanic	Caucasian	Asian	African American	Hispanic	Female	Male	Total
Under-graduate	60	11	0	5	33	18	0	3	**76** (40.4%)	**54** (28.7%)	**130** (69.1%)
Graduate	21	9	1	0	8	4	1	0	**31** (16.5%)	**13** (6.9%)	**44** (23.4%)
PhD	3	5	0	0	2	3	1	0	**8** (4.3%)	**6** (3.2%)	**14** (7.4%)
Total	**84**	**25**	**1**	**5**	**43**	**25**	**2**	**3**	**115** (61.2%)	**73** (38.8%)	**188** (100%)

One hundred and one students responded they were accessing the Internet eight or more times daily (53.7%). Only two female participants from Caucasian and African-American backgrounds used the Internet less than once daily, but eighty-four (39.7%) participants connected to the Internet between two and seven times daily. One hundred seventy-seven participants (94.1%) had visited a financial homepage before the survey. There were eight (4.3%) participants who did not have a chance to visit any bank websites yet.

Table 4 shows that twenty participants (10.6%) did not interact with Internet financial websites, however, one hundred sixty-seven (88.8%) had knowledge of banking through the Internet.

Table 4. Online Banking Experience

	Female				Male				Total		
	Caucasian	Asian	African American	Hispanic	Caucasian	Asian	African American	Hispanic	Female	Male	Total
Yes	77	21	1	3	37	23	2	3	**102** (54.3%)	**65** (34.6%)	**167** (88.8%)
No	7	4	0	2	6	1	0	0	**13** (6.9%)	**7** (3.7%)	**20** (10.6%)
Not answered	0	0	0	0	0	1	0	0	**0**	**1** (0.5%)	**1** (0.5%)
Total	**84**	**25**	**1**	**5**	**43**	**25**	**2**	**3**	**115** (61.2%)	**73** (38.8%)	**188** (100%)

Discussion and Findings

Overall, the results indicate a small group photograph (35.1%) was perceived the most trustworthy followed by a family photograph (33%). The analysis shown in Table 5 indicates 7 participants (3.8%) selected the male photograph as the least trustworthy. This result supports Riegelsberger's research (2003). Eleven participants (5.9%) reported that human pictures do not create an impression of trustworthiness on the bank website. This result indicates that single images of females or males do not effectively create a trustworthy impression of the bank web site. Both single images were rated lower than the homepage without images.

Table 5 Analysis of results: Photographs and Trustiness

	Female				Male				Total		
	Caucasian	Asian	African American	Hispanic	Caucasian	Asian	African American	Hispanic	Female	Male	Total
A male	2	1	0	0	3	1	0	0	**3** (1.6%)	**4** (2.1%)	**7** (3.7%)
A female	5	1	0	0	2	1	0	0	**6** (3.2%)	**3** (1.6%)	**9** (4.8%)
A Family	27	11	1	1	11	10	0	1	**40** (21.3%)	**22** (11.7%)	**62** (33%)
A small group	35	5	0	2	18	5	1	0	**42** (22.3%)	**24** (12.8%)	**66** (35.1%)
An ethnic	9	6	0	2	5	6	1	2	**17** (9%)	**14** (7.4%)	**31** (16.5%)
None of these	6	1	0	0	2	2	0	0	**7** (3.7%)	**4** (2.1%)	**11** (5.9%)
Not answered	0	0	0	0	2	0	0	0	**0** (0%)	**2** (1.1%)	**2** (1.1%)
Total	**84**	**25**	**1**	**5**	**43**	**25**	**2**	**3**	**115** (61.2%)	**73** (38.8%)	**188** (100%)

When breaking the data down by ethnic group, the result indicates that the family photograph appealed to more Asian participants than Caucasian participants in creating feelings of trust. The results of this study indicate that perceptions of trust for a financial institution's website increases, for Asian participants, by the inclusion of a family photograph and for Caucasians by a small group photograph. Because the African-American and Hispanic populations had only a small number of participants, the conclusion was indeterminate with regard to these populations.

This study used the SPSS (Statistical Package for the Social Sciences) program to analyze the data. The data indicates that a statistically significant correlation exists between ethnicity and perceptions of trustworthiness. Because the survey group was predominantly Caucasian and Asian, it was possible to compare these two racial groups. If the number in 'Asymp. Sig' of the Chi-squared table is less than 0.05, there is significant correlation. Table 6 reveals a pattern among Caucasian and Asian participants who were asked to select an image-based homepage they would be inclined to trust. Caucasians reported a sense of trust in response to the small group picture, but Asians reported that the family picture inspired the greatest sense of trust. There was evidence of a weak (0.62), significant correlation (table 6).

Table 6 Chi-Squared Test: between Caucasian and Asian

	Value	DF (degree of freedom)	Asymp. Sig (2-sided)
Pearson Chi-Square	10.529a	5	.062
Likelihood Ratio	10.748	5	.057
Linear-by-Linear	0.038	1	.846
N of Valid Cases	175		

As mentioned above, the participant population was dominated by students from the College of Design. However, Table 7 shows no significant correlation between the preferences of design and non-design college participants.

Table 7 Chi-Square of picture data comparing design and non-design participants

	Value	DF (degree of freedom)	Asymp. Sig (2-sided)
Pearson Chi-Square	18.790a	15	.223
Likelihood Ratio	20.703	15	.147
Linear-by-Linear	.033	1	.855
N of Valid Cases	186		

Question 2 asked participants why they selected the pictures of human subjects as the pictures that inspired the most trust.

The qualitative data corrected from question 2 indicates that participants perceived trustiness when photographs looked friendly and comfortable. Some participants' comments are as follows.

A small group photograph (35.1%)
Participants received professional and happy feelings from the small group picture. The reason most participants selected the small group picture was mostly because:

• Appropriate number of people to effectively run a bank.
• Looks like a friendly group, who appear they like to work together for customers.
• Combination of professional looking people.
• Looks like friendly bank employees.
• A small group makes me feel more like I am being taken care of best.

Another response was the group picture had a computer and it made the picture look more like a professional team. Since only option 4 contains a computer, this might have been a source of bias in this study.

A family photograph (33%)
Overall, answers about the family picture were that participants could trust this picture because it is family-oriented and the family structure provides a safe and honest feeling. Asian male participants said that 'family oriented' was important and it portrayed more powerful influences. Most participants who selected the family photo mentioned ideas such as:
• Feeling protected, comfortable, and safe.
• Family picture seems more comfortable, honest, and friendly.

An ethnic group photograph (16.5%)
The main reason for this answer was that there were many people from different backgrounds — both in diversity and national origins. It reminded participants of a bank with services connected to other countries. Participants received the impression from the image that the multi-racial people in the picture were a group or a team at a financial institution. Some participants answered that this picture reminded them of 'Verizon network coverage' as part of their positive judgment. Some other answers are as follow:
• A wide range of people letting me know they are there to help whoever is in need."
• Prefer to work with a group rather than an individual.
• Seems like they are all staff at a bank.
• Diverse staff at part of a bank.

None of these (5.9%)
Only two females and one male of Caucasian out of six were provided comments about this picture. One said it did not really matter if a human picture was included on a bank website, but its services and protection were what mattered most. Another respondent mentioned none of the choices elicited trust.

A female photograph (4.8%)
Caucasian female participants read the woman's leaning-forward body language in the picture as the reason why it created feelings of trust. Another answered, "she looks professional and authoritative." An interesting comment from an Asian female was that she "trusted women more than men."

A male photograph (3.8%)
The lowest ranked percentage was the male picture. However, some of the participants mentioned it looked more business-oriented and the male seemed to be an expert.

Conclusion

Internet banking is fast becoming one of the most popular online activities. Even though people dream about a more convenient life, they face important ever changing issues, such as online security. Each bank had differences in the design style of the homepage, which varied according to the number of human photographs, colors, font types, and layout. Through the existing bank analysis, this research found that more than half of bank web sites use some type of human photographs on their homepage. Based on the analysis, this research explored five different photographs to find out which photograph will generate feelings of trust.

This study found that a small group or family photograph can increase perceptions of trust on an online bank website. Overall, the small group photograph was perceived the most trustful of the photos. However, if the online target population is largely Asian, a family photograph is likely to produce friendly and honest feelings.

Also this study found cultural preferences in perceiving trust with human-subject photographs. Asian participants favored a family photograph over a small group photograph. This result supports the well-known cultural dimension: individualism and collectivism. The United States is known as an individualism country and Asian countries such as China, Korea, and Japan are known as collectivism countries (Hofstede, 1997, p.53). This result indicates that understanding the target audience is important on designing websites to appeal and communicate with them.

An aesthetically appealing website design provides online users a pleasant feeling and invites them to trust the website more positively. Design features, design structure, and layout are important components to build feelings of trust in a website (Fogg, et. al, 2003, Wang and Emurian, 2005). The human photographs are an element among the components to enhance trustiness. All design components and usability should be considered in building a trustworthy website.

Limitations

This research has several limitations. First, mock-ups for this research were sized smaller most current websites. There were some technical issues that restricted image file sizes in the online survey website (surveymonkey.com). Second, the total population of the participants (188) was students studying at one state university in a Midwestern location in the United State. They were limited in this area as undergraduates, graduates, and PhD students. Therefore, these results may not be the same for other areas of the United States. Future studies should include a wider population sample. Third, the dominant population of participants (63.8%) was design majors in this study. The research had been contacted by three methods: email, word-of-mouth, and fliers. The research asked the participants to access the survey website individually. In these reasons, it could not be controlled the percentage of participants' majors. However, this could have biased the results even though there was no significant correlation between design students and non-design students (table 6).

Forth, the human pictures for the five mockups could not be able to be set exactly the same body language such as hairstyles, color of clothes, forms of body representation. These variations were remained to develop more accurate result on the study of credibility for the future steps.

Future research

The results of this study suggest several directions for future research. The most immediate direction is to obtain more precise research data. To do this an even larger population is indicated, particularly with regard to Hispanic and African-American groups. It appears there are correlations that relate human photographs and ethnicity. Therefore, future research should make additional efforts to incorporate cultural difference in diverse ethnic groups.

SeungYeon Ha received a B.F.A degree in visual communication design at Catholic University of DaeGu in Korea. She earned a M.F.A degree in Graphic Design in 2009 at Iowa State University. Her research interests include graphic design, graphic user interface, and human computer interaction.

Sunghyun R. Kang

Sunghyun is associate professor of Art and Design at Iowa State University. She received a B.F.A. degree in the field of applied art from Ewha Womens University in Korea. She earned a M.F.A. degree in graphic communication from the University of Houston and an M.A. degree in graphic design in 1999 from Iowa State University. She joined as a faculty of Department of Art and Design at Iowa State University in 2000. Her teaching and research is focus on graphic design, human interaction, web based design, and visual communication. She has over 20 years of experience in teaching, research, and consulting in these areas in Korea and U.S. She has presented and published at numerous conference including Asian Design Conference, Korean Society Design Conference, and Japanese Society for the Science and Design conference, and America Institute of Graphic Arts (AIGA). She serves as a juror for the Journal of Korea Society of Design Studies and served as a juror for the 6th Asian Design Conference. During summer 2007, she conducted research with *Frito Lay* for Tostitos® Brand as a co-PI. Recently, she received the Bailey Research Career Development Award as a co-PI to conduct research collaboration with the Mayo Clinic.

Seeding social technologies: strategies for embedding design in use

Penny Hagen, University of Technology, Sydney

Toni Robertson, University of Technology, Sydney

Abstract

This paper reflects on the changing nature of participation and design in the context of social technologies and, in particular, our evolving understanding of what it means to do design. When designing social technologies we are effectively creating containers or scaffolds; their shape is formed through participation and user driven contributions and that shape changes over time. In designing successful social platforms around which communities grow, evolve and share, our role as designers extends beyond researching, defining, creating and releasing a product. The facilitation of participation by the 'future community' also becomes a central concern.

In this paper we present, explore and reflect upon the notion of seeding as a useful concept for approaching the facilitation of participation in social technologies. Seeding is concerned with the process of embedding and connecting design within the real world. It draws our attention to the work that needs to be done for design to become part of people's everyday lives, and our role as designers in creating conditions under which this is likely to occur. The theoretical reflections and arguments presented in the paper are based on empirical research into the impact of social technologies on exploratory design research methods used in the early stages of a design project. We present potential strategies for seeding early in the design process that emerged from our research and reflect on the questions about participation, protocol and practice that they raise.

Keywords

design practice, methods, participation, seeding, self-reporting, social technologies

This paper reflects on the changing nature of participation and design in the context of social technologies and, in particular, our evolving understanding of what it means to do design. When designing social technologies we are effectively creating containers or scaffolds; their shape is formed through participation and user driven contributions and that shape changes over time. Services such as Facebook, Flickr and YouTube not only invite engagement, but also depend on contributions to be successful. Furthermore, through our contributions and participation we affect the experience of others. As designers, we may have always conceptually understood design to be 'actualised' in use (Dourish, 2001) however social technologies bring a renewed attention to the relations between design and use because so much of their form is constituted *through use*. Social technologies put a new emphasis on user participation.

In designing successful social platforms around which communities grow, evolve and share, our role as designers extends beyond researching, defining, creating and releasing a product. The facilitation of participation by the 'future community' also becomes a central concern. This is particularly so in community and social settings where uptake and use of systems by individuals is voluntary. Our responsibilities as designers extend to include helping to ingratiate the project with potential users (DiSalvo, Maki, & Martin, 2007); transferring project ownership from designers to the user community (Merkel, et al., 2004) and allowing design to change and grow through user participation (Dittrich, Eriksén, & Hansson, 2002). This points to new skills for designers whose expertise has traditionally focused on the creation of artefacts (Brereton & Buur, 2008; Merkel, et al., 2007). It also suggests changing priorities during the design process.

It is one thing to build a participatory platform, but another to have people take it up and use it. In developing collaborative mapping tools for use by members of the public, DiSalvo et al. (2007) found that more attention needed to be paid to engaging the so-called stakeholders or participants of the system. It is quite possible that at the beginning of the design process there will be no clearly identifiable existing community of users, rather this community will have to be 'brought into being' as part of the project (ibid). DiSalvo et al. warn of falsely assuming a motivated public willing and eager to participate and emphasise the actual work that has to be done to move from the idea of a participatory system, to an actual 'functioning' one.

In this paper we explore the notion of seeding as a useful construct for considering how we can approach the facilitation of participation. Seeding is concerned with the process of embedding design in the world. It draws our attention to the work that needs to be done for design to become part of people's everyday lives, and our role as designers in creating conditions under which this is likely to occur. It refers to the work that we might do as part of the design process to try and 'bring into being' a community around a project. We present three strategies for seeding early in the design process as the basis for theoretical reflection and discussion. These strategies emerged out of practice-led research into social technologies and their impact on early design research methods.

The research in this paper extends earlier work on the concept of seeding (Hagen & MacFarlane, 2008); our motivation is to contribute to an ongoing discussion on the nature of design and participation in the context of social technologies. Whilst for the sake of readability we use the term 'designer' in the paper, we anticipate that the notion of seeding and the theoretical reflections about participation documented here will be applicable to both researchers working in academic contexts as well as designer/researchers working in industry.

The paper begins with a brief discussion of context and motivations, including a summary of the empirical research upon which the paper is based. The concept of seeding is defined, and then the three potential strategies for seeding early in the design process identified in our research are presented. These examples inform the following discussion and reflection about approaches to managing participation and the shifting priorities in design that seeding suggests. The final section draws attention to challenges involved in 'selling' seeding to clients and the nature of design in the wild. The paper concludes with a summary of the issues raised.

Background

This paper reports on one aspect of a larger practice-led research project into the impact of social technologies on early design research methods. Interested readers can find a fuller account of the research here (Hagen, Robertson, & Gravina, 2007) and here (Hagen & Robertson, 2009). For the purposes of grounding the paper we provide a brief background of motivations and a summary of the research below.

Our research is motivated by the changing nature of design and participation in the context of social technologies and the methodological challenges and questions this raises for designers. Traditional methods designed for stationary, workplace contexts cannot be expected to account for the emergent and complex nature of social technologies and designers attempting to apply conventional methods in the context of social technologies face various challenges.

For example traditional contextual methods assume the ability to identify and access the context of use, but users of social technologies are diverse, geographically distributed (Bergvall-Kåreborn & Ståhlbröst, 2008) and potentially anonymous (Clement, 2008; Ehn, 2008). The form of social technologies themselves is emergent and use is constituted through co-experience (Battarbee, 2003). In addition, technology use is now mobile, domestic and woven through complex, ongoing social contexts (Bødker, 2006; Isbister & Höök, 2009). Researchers and designers attempting to gain access to authentic situations of use are challenged both by the pervasive, diverse and emergent aspects of social technology as well as its increasingly personal and social nature.

One way in which designers are responding to these challenges of access is through the extension of self-reporting methods (Hagen, Robertson, Kan, & Sadler, 2005). Increasingly, traditional self-reporting methods such as diaries and probes are being augmented with social technologies *themselves* as tools for documentation, e.g., (Hulkko, Mattelmäki, Virtanen, & Keinonen, 2004; Palen & Salzman, 2002; Pering, 2006; zilverinnovation, 2009). We refer to this emerging group of techniques as Digital Self-Reporting (DSR).

Our empirical research focused on the iterative design and evaluation of a DSR method, Mobile Diaries, in a commercial context. To summarise here, the method was designed over two field studies and then deployed on two further commercial projects. Participants were given mobile phones and cheap video cameras from which they were able to create rich personal messages and document snap-shots of their lives through audio, text and images. In the later two studies these were posted to private research blogs or 'participant diaries'. These blogs became a platform for reflection, comments and discussion between participants and researchers.

The DSR method was intended as an early design research method for use in the design of community platforms and it was evaluated from two perspectives: its capacity to immerse designers in the everyday worlds of potential users, and its ability to support participants to contribute to, and participate in, the design process. We found that the digital, mobile, networked qualities of the tools enhanced the *in situ* nature of the method increasing the sense of immersion for designers. We also found that the *in situ* nature of the method, and the use of social technologies *themselves* as tools for design opened up new opportunities for people to participate in the design process by blurring practices of research, design and use. Specifically activities that were usually understood to be part of *using* social technologies, (such as generating content, sharing daily experiences through image and text, interacting and communicating through blogs and sms) became available in the design research phases. For the remainder of the paper we explore these opportunities through the concept of seeding. We reflect on the assumptions about practice and protocol the concept of seeding prompts us to reconsider, and the larger implications for design, research and participation it suggests.

Seeding

According to the Macquarie Dictionary ("Macquarie Dictionary," 2003) the term *seed* refers to the germ or beginning of anything. *Seeding* is a commonly used metaphor in texts that address design, use and participation e.g., (Botero & Saad-Sulonen, 2008; Darren, 2007; Fischer, 1998; Light, Briggs, & Martin, 2008; Merkel, et al., 2004). It is often used to refer to activities that can act to germinate participation. For example, in an online marketing campaign a solid and well-targeted seed list of email addresses increases the chances of campaign success because of the higher number of likely send-ons. In the development of early virtual communities, the use of seed content, conversations and groups was an important strategy for encouraging, prompting and guiding new contributions and members (Figallo, 1998; Merkel, et al., 2004; Rettig, 1998; Rheingold, 1993). In developing community tools for use in civic contexts, Botero & Saad-Sulonen (2008) make use of living seed prototypes to understand how people might put new technologies to use in context, while Merkel et al. (2004) draw attention to the need to seed ownership of design within communities.

As a design concept then, seeding allows us to talk about the movement and relations between design and use, specifically, the work that needs to be done to move design from the ‘abstract’ into what Lee (2008) refers to as the concrete places where people live. Successful designs are taken up as part of people’s existing ‘ecologies of devices’ in people’s ‘already ongoing life-worlds’ (Ehn, 2008). Seeding draws attention to how it is that happens, and our role in creating conditions for that to occur.

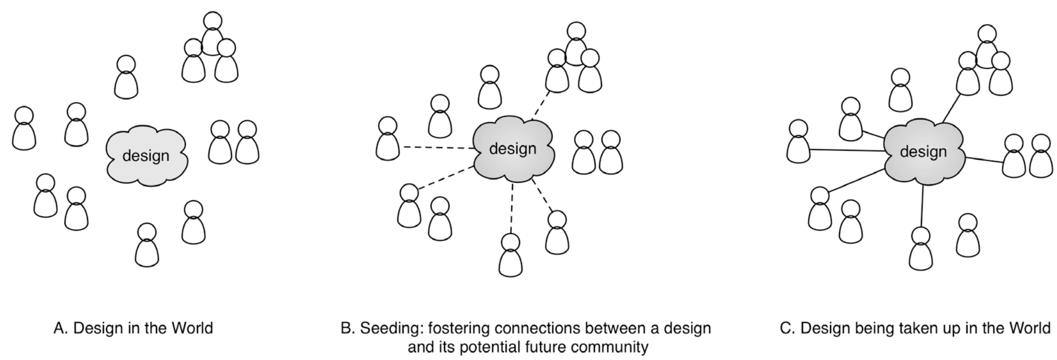

Figure 1. Three different states of design.

Figure 1. depicts, in simple terms, three different ‘states’ of design. Design existing or ‘released’ into the world as a public object (A). The seeding of connections between the design project and people’s daily lives (B), and (C), design having been appropriated and taken up as part of (some) people’s existing ecology of devices. Seeding serves to name activities we can do within the design process, as designers, to try and bridge the gap between A and B; to embed design in the world and to create connections between the design project and the people who may use it. In (C) the design is not taken up by all the people, because, even in such a simplistic representation, it is important to acknowledge that we can only create conditions *for* participation through seeding, we cannot guarantee it.

Seeding, in the context of this paper, places value on opportunities to embed the design project in its potential, future context of use, during project-time. This is based on the assumption that building a sense of interest, ownership or connection with potential future community members during the design project, increases the likelihood that those individuals may then take up the design as a public object, and appropriate it into their everyday lives.

Strategies for Seeding

In this section we present three potential strategies for seeding design early in the design project. We identify these as: socialising the research; bridging gaps between current practices and future practices; and developing early content. Below we describe these three strategies and how they emerged as a result of our research into social technologies as tools for self-reporting.

Socialising the research

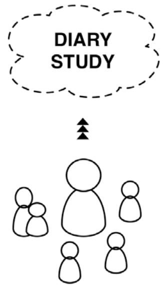

Figure 2. Participating in the diaries becomes a shared activity for participants.

Socialising the research describes the seeding of interest and momentum around the project through participants sharing the research with their wider network. We found that the use of social technologies and tools such as mobile phones and blogs encouraged participants to socialise the research project with friends and family. It was common for participants to include others in the creation of their diary reports, and to share the images and comments from their private blog-diary. The act of participating in the research generated discussions with friends, family and colleagues around both the research and the topic being explored. At least one participant shared experiences of the study on her MySpace page whilst another asked permission to post her diary material on MySpace as well as on the private blog. Figure 2 depicts participation in the diary study as an inclusive activity.

This sharing and socialising of the project takes on a particular significance in the context of developing community platforms. The inclusion of friends, family and peers connects the design project with a larger group of people, increasing the visibility and momentum around the project. Even in small numbers the individuals recruited for the studies could become an important seed community, sharing and promoting the project or future system with wider networks.

Sharing the research is a way in which participants are able to exercise ownership over the process, appropriating the project into their daily lives, activities and relationships. In doing so they indicate how the design project intersects with existing energies and interests in their lives offering designers potential start points and direction for the next steps in the design. We attribute the propensity for participants to 'socialise the research' to the nature of the research tools; in using these tools for research we had appropriated both the tools of social technologies as well as the practices of sharing and communication they made possible.

Bridging the gap between existing and future practices

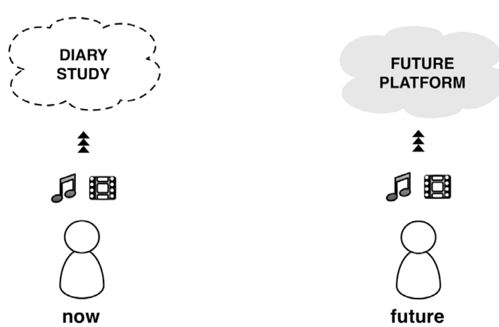

Figure 3. Activities and skills required for the research are the same, or similar, to that of using the future platform.

This strategy talks to the ways in which some design methods can act to bridge the gap between existing practice and future practice. In discussing their use of living research prototypes Botero and Saad-Sulonen (2008) state: “the types of engagements that prototypes and interventions afford offer an interesting and viable path to develop not only systems themselves but the practices that surround them and ultimately make them viable” (p. 269).

We found that digital self-reporting created a similar ‘path’. Participants created videos, sent picture messages, sent mobile blog posts (mo-blogs) and commented on blog messages. As Figure 3 suggests, the activities were similar, if not the same, as those that characterise participation in community platforms. In many cases participants were using these technologies for the first time. By participating in the studies, participants were developing the skills and technology knowledge needed to participate in the social technologies we were aiming to design. In addition to providing insight into future users, the self-reporting method allowed participants to develop skills and seed practices that would make our future designs viable by bridging current and future practices.

Developing early content

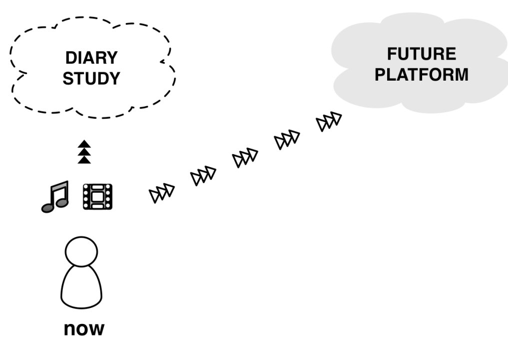

Figure 4. Material generated in the study could also be interpreted as seed content.

Social technologies are driven by the contribution and interaction of users and these contributions shape their form. Our research showed the potential of creating User Generated Content (UGC) early, prior even to development of a specific platform.

In the digital self-reporting studies, we found at times little difference between the material participants produced and what we would hope to see on the user generated sites or platforms we were designing, other than the framework under which it was produced. Figure 4 indicates how material generated during the studies could also be interpreted as seed content. This was due both to the subject matter of the reports i.e., personal images, stories and videos about a particular topic of interest, as well as the format in which they were produced i.e., MMS, blog-posts and MPEG-4 video, all formats developed for publishing and distribution.

UGC developed early in the design process can act as seed content around which the design of the platform can be shaped. Themes, navigation, taxonomies and potential features could evolve in response to this early understanding of the kind of content people might contribute. Whilst acknowledging that participants would censor their material in different ways were it public, reading the early self-reporting material as potential seed content gives insight into how the topic becomes meaningful in peoples lives, as well as how people might go about communicating and sharing it with others. It also creates a greater personal connection between the design project and participant - inviting them to play the role of author and contributor prior even to the development of the platform itself.

Summary

Socialising the research, bridging current and future practices and developing early content are examples of strategies for seeding early in the design process, identified in our research. They demonstrate ways in which the project started to take on its own energy and momentum within the lives of a particular group of participants and their wider networks, in some cases well beyond the formal boundaries of the design research project. The project became a public object in the world 'bringing into being' interested and willing potential community members.

Reflections on seeding, design and participation

In the previous section we identified a number of strategies for seeding design early in the design process. Here we discuss how our capacity to leverage these opportunities was limited by assumptions embedded into our design and research process about participation and the role or relationship of participants to the project. Seeding suggests new values and priorities within design research not necessarily accounted for in traditional approaches. We reflect on these assumptions and findings below as part of developing a better understanding about how such design activities could be framed and supported.

Managing participation

The limitations we encountered are interrelated and stem from assumptions about the kinds of contribution and modes of participation that are possible so early in the design process. Many of our traditional frameworks and protocols for managing participation are modelled around the assumption that activities of research, design and use progress in a relatively linear sequence. Early design research focuses on activities such as understanding user needs (Rhea, 2003), informing and inspiring design (Sanders, 2005) and potentially ideation and concepting (Sanders & Stappers, 2008). These assumptions about what design and participation look like do not anticipate the kinds of participation emphasised through our examples of seeding, or the blurring of research, design and *use* that social technologies make possible.

In traditional early design research, the value of the method is largely realised in the material that is generated. Whether it be to inform understandings of practice e.g., (Grinter & Eldridge, 2003), inspire design e.g., (Gaver, Dunne, & Pacenti, 1999) or foster empathy e.g., (Mattelmäki & Battarbee, 2002) the emphasis is on the generation of design material. This frames the value of the activity around tangible research deliveries, and participation around the generation of that material. It also limits participation to the specific design research project, e.g., a self-reporting study. A close relationship is fostered with participants over this period of time, but when the study stops, so does any formally resourced relationship with participants. Rather than participating in the design process as a whole, participation is limited to that particular research activity.

It is standard research protocol to protect the identity of participants when the outputs from design research activities are then published or shared beyond the immediate design team. These consent protocols don't anticipate the potential to transition or reinterpret the design material into published content, limiting the use of the material produced to the purposes of the research project. Consent forms that assume participation should be represented anonymously make less sense in situations where we might want to facilitate, or make it possible for, participants to engage in the design process in the role of author, contributor or content creator.

These protocols assume a division between the private practices of research and the public spaces in which we live that does not necessarily exist, or that may no longer make sense in the context of social technologies. Predicating participant engagement by guaranteeing anonymity restricts designers and clients in their capacity to develop authentic relationships with participants, and assumes particular roles for participants in the design process. Strategies for seeding such as ‘socialising the research’ and the development of seed content encourage much more public, uncontained and shared levels of participation. Activities usually associated with use, such as generating content and *using* social technologies, move into the early phases of research and design, making it hard to tell where the research stops and the community starts. Our obligation to our participants needs to be rethought in the context of social technologies and the forms of participation in design that they encourage and make possible.

Another barrier to seeding is the tendency to model participation and user involvement around the notion of ‘representative users’. Recruitment is often focused on identifying people who represent different ‘user types’ from an identified ‘target audience’. Under this model participants’ primary role is that of ‘representative user’, rather than as an individual. Seeding, on the other hand, emphasises opportunities to build connections with potential future community members, authors and contributors. This places value on the relationships we can build with specific individuals and their networks.

The concept of seeding suggests that our frameworks for managing participation need to enable different kinds of relationships with participants that privilege them as community members, and empower participants to take on a range of ongoing roles in the design process. When our goals are to seed content, connections and community our protocols for consent need to embrace, support, and appropriately protect participants while also enabling them to participate as authors and contributors, choosing how and with whom their context is shared.

Approaches we might learn from include Participatory Action Research (PAR) and Participatory Design. For example in discussing issues of consent McIntyre (2008) describes the negotiation of consent as a collaborative and evolving process to be renegotiated with participants throughout the process. Participatory Design has always understood research to go beyond data collection and promotes continuous collaboration throughout the ongoing process of design (Ehn, 2008).

Changing priorities and values in design

Putting value on opportunities for seeding participation during project-time also shifts the priorities within the design process. As our goals in the design process begin to expand to include seeding participation and bringing ‘into being’ community (DiSalvo, et al., 2007), what were once opportunities to conduct contextual research, such as self-reporting, also become opportunities to build momentum and interest about a project in the context of where it might be taken up.

The concept of seeding sensitises us to the value of new design experiences such as socialising the research, and seeding content, and other less tangible outputs including the value of maintaining relationships with participants beyond the various formal research and design activities they might be participating in. The relationships, momentum and connections that are built up with individuals and their networks as a result of the participating in such activities go beyond the time frame of the study and outside the bounds of the research phase.

In presenting an argument for rethinking the nature of the ‘design project’ Ehn (2008) suggests that we understand design tools (he uses the example of prototypes) as both representations of the evolving state of design, as well as socio-material public things which support communication or participation across the design project; "they are potentially binding different stakeholders together" (p. 95). Ehn's statement suggests that in the context of designing for participation, the value of design methods is not just to support and inform the creation of artefacts, but also to foster connections between design projects and their potential future community. Seeding puts emphasis on the potential for making connections and content, and even more importantly, maintaining energy, interest and momentum around the project during project-time. In order to prioritise and place value on these additional design outcomes, strategies for seeding design need to be written into our design briefs and effectively resourced.

Selling seeding: design in use

We have suggested that seeding is a way to strategise and communicate about embedding design in use. However embracing the notion of seeding into the design process, and 'selling' it to clients, is not without its challenges. As a design metaphor the concept of *seeding* sensitises us to a number of important aspects to designing social technologies. Two aspects in particular that we have encountered in the course of our research pose particular challenges for selling seeding to clients, these are the risks inherent in seeding and its lack of measurability, and the open-ended approach to design that seeding privileges.

In the context of design, planting seeds doesn't guarantee the survival or sustainability of a project, but it may increase the likelihood of that project being taken up in the world. We may put effort into seeding activities, into building relationships with future community members, but we can't ensure they will be successful, or lead to observable outcomes. This is simply the nature of design in the wild (Hutchins, 1995). Both the risk and the intangibility is something that we need to be able to effectively articulate to clients as an inherent aspect of designing for participatory technologies.

Similarly, the act of seeding necessarily means relinquishing some control over its form whilst simultaneously opening up opportunities for it to be shaped by that exposure. Seeding is about embedding the design in the world, which means making design "a public thing open for controversies" and, "from which new objects of design can emerge in use*"* (Ehn, 2008 p. 96). *S*eeding acknowledges the shaping of the nature of the project through the way in which it becomes meaningful to people in the real world.

The majority of commercial design projects are brokered with the assumption of specific tangible outputs at particular milestones, for a particular cost. Seeding, as an alternative approach suggests the value of investing in design activities that can orient the design around existing momentum, interest or energies in the community. This requires a greater degree of flexibility by the client. Botero & Saad-Sulonen (2008) found that their client, the local council, was initially unwilling to invest in seed prototypes, though they embraced the process once the results were demonstrated. Further case studies and appropriate frameworks will assist clients in building confidence about such open-ended approaches.

Concluding remarks

Traditional Human Centred Design methods equip us well for asking how we might research, ideate, iterate and produce a design object; they prepare us less well for how we bring into being a community around that object. We suggest seeding as a useful concept for approaching and strategising about this increasingly important aspect of design. The examples and discussion above sensitise us to a number of aspects important to consider in the development of social technologies and raise a number of questions for future work. The participatory nature of social technologies prompts us to reflect on, and perhaps reconsider how participant involvement in design is being managed, and the kinds of assumptions some traditional approaches have embedded in them about how participation takes place. The emphasis on participation and the role of users in actualising the design of social technologies also brings to the fore a number of issues with regards to our relationship to clients and the way we structure, resource and strategise about 'design projects'.

We propose the notion of seeding can inform and support an evolving approach to managing the relationship we have with participants, and our own evolving roles and skills as designers. It can also assist us in framing new shapes for design, naming and describing the work important to embedding design in use. In the design of social technologies we are encouraged to find opportunities to move research and design out into the wild, where it can take seed and be nurtured as part of people's already ongoing life-worlds.

Acknowledgements

We would like to give our sincere thanks to Digital Eskimo as well as to their clients and stakeholders for the opportunity to work with them. We would also like to thank Dr Lian Loke & Dr Tim Mansfield and the reviewers of this paper for their input and feedback. Thanks also to our fellow researchers in the IDHuP lab at UTS.

Author Biography

Penny Hagen

Penny specialises in design strategy for online and interactive community projects in Australia and New Zealand. She is an experienced practitioner of human-centred-design approaches and works collaboratively with clients and their stakeholders on social change projects. Penny recently left Digital Eskimo after 3 years as their Projects Director/Strategist to complete her PhD in participatory design methods for social technologies at the University of Technology, Sydney (UTS).

Toni Robertson

Toni Robertson is Associate Professor in Human-Computer Interaction at the University of Technology, Sydney (UTS). She is a specialist in the study of human practice and technology design, and the application of qualitative and participatory research and design methods. She directs the Interaction Design and Human Practice Lab and co-directs the Centre for Human Centred Technology Design Research.

Understanding Senior Design Students' Product Conceptual Design Activities:

A comparison between industrial and engineering design students

Jiang, Hao, National University of Singapore, jiangh82@nus.edu.sg

Yen, Ching-Chiuan, National University of Singapore, akiyc@nus.edu.sg

Abstract
This paper reports an experimental study with a purpose to investigate and compare the design thinking processes between final-year industrial design (ID) and mechanical engineering design (ME) students. Two types of conceptual design activities were observed and analyzed. One was to solve a realistic problem for the current market and the other was to generate "blue-sky" visionary concepts for the future. A qualitative method, derived from design protocol analysis, was proposed to explore the structure of observed design processes. The preliminary result demonstrated the disciplinary difference, between ID and ME students, on formulating and approaching design problems. In contrast with the previous perception that ID process is more solution-led while that of ME is more analysis-oriented, ID students were observed to spend much more time on systematically analyzing target-users and possible contexts of usage, in order to establish new design goals and requirements with regards to the above analyses. Whereas ME students were more dedicated in solving the problems identified from the given design brief and conducted little analytic work before concept development.

Keywords

Variations of design thinking; design protocol study; structure of design processes.

Design thinking is one of the most important issues in design research. During past three decades, design researchers constantly sought to identify the shared core features across all design professions, in order to generalize the cognitive mechanism of designers into a distinguished way of thinking and knowing from sciences and humanities (Archer, 1979; Cross, 1999, 2008; Goel & Pirolli, 1992; Owen, 2006). The term "design", however, does not refer to a homogeneous activity; instead, it includes an extraordinarily broad spectrum of activities, with one end linking to engineering and the other end to fine arts (Lawson, 2004). Normative studies (Akin, 2001; Lloyd & Scott, 1994, 1995; Roozenburg & Cross, 1991) have also identified that significant differences existed in the design models between industrial design and engineering design, which implies there are many variations within the general design approach. This study therefore attempted to analyze empirical evidences from design process to evaluate or refute these pluralism arguments of design thinking. Insights on similarities and differences between different design disciplines are also expected to contribute to the generalization of design cognitive patterns during various design processes.

Conceptual Framework

Our explorative approaches for the variations of design thinking were: (1) to select several related design disciplines within a specific design field and (2) to observe and compare their design cognitive processes.

Product design is the focused area of this study. Two related design disciplines were selected, i.e. Industrial Design (ID) and Engineering Design in particular Mechanical Engineering Design (ME), which are believed to respectively represent the synthetic- and analytic-oriented aspects of product design (Owen, 1998, 2006). It is thus hypothesized that, given the same design problems, these two design disciplines will show distinguished differences between how they approach the problems and synthesize the concepts and solutions.

One way of investigating design thinking is to portray the structure of design cognitive mechanism while performing a particular design task. Dorst (2003) argued that design cognitive processes were nested; analysis, synthesis and evaluation activities were not proceeded in a spiral sequence or simple iterations, but rather in a form of complex nested network of “cycles within cycles”. Our pilot study confirmed this argument. This paper aims to empirically explore the detailed cognitive structure between both ID and ME students’ conceptual design processes and compare the ways of how design activities (i.e. problem analysis, idea generation, etc) were organized within conceptual design processes.

Another concern of our study is the nature of design tasks. The purpose of design tasks and the amount of constraints linked to task type may also alter designer’s cognitive strategies and thus produce different patterns on design processes.

Research Methodology

Design protocol study (an observational, experimental research method, see Cross, Christiaans, & Dorst, 1996; Jiang & Yen, 2009) was adopted as the primary method in this research.

Factorial Research Design

A 2X3 factorial experimental design (shown in Table 1) was applied to this study. Two factors, i.e. major independent variables, are design disciplines and types of design tasks.

Table 1 Comparative Dimensions of Design Experiment

	ID teams	ME teams	Mixed teams
Task A: realistic problem solving for the present (with hard & unalterable constraints)	4 teams	4 teams	4 teams
Task B: visionary concept design for the future (allowing wild imagination)	4 teams	4 teams	4 teams

Final-year ID and ME students from National University of Singapore were recruited voluntarily as the research participants. The unit of participation was a design team consisting of two persons. Three participation categories were designed in this study: ID teams (both participants come from ID), ME teams (both from ME) and Mixed teams (one from ID and the other from ME). A total of twelve teams were observed and analyzed.

This study focused on design conceptualization phase, which is considered as the most creative element of design activities. Two different types of design tasks were assigned to each team. Task A is to design a coffee maker for a Singaporean start-up company. Based on the context of current market, the purpose of this assignment is to create realistic commercial problems with several hard and unalterable requirements. Task B is a visionary concept design, i.e. to design a next-generation personal entertainment system/device for a world leading electronic corporation. Compared with the former task, task B allows much more space for wild imagination and subjective interpretation.

Experiment Procedure & Setup

Each experiment session was conducted as the procedure shown in Figure 1. A pre-test questionnaire was designed to recruit voluntary participants. Their demographic information, basic understanding of design and perception of design process were also collected. All participants were asked to execute both task A and B and a lunch break was provided between these two tasks. In order to balance the sequence effect, half of the teams in each category performed task A first and the other teams performed task B first. After the completion of each task, the participants were allowed to make a short presentation within 5 minutes to explain their ideas.

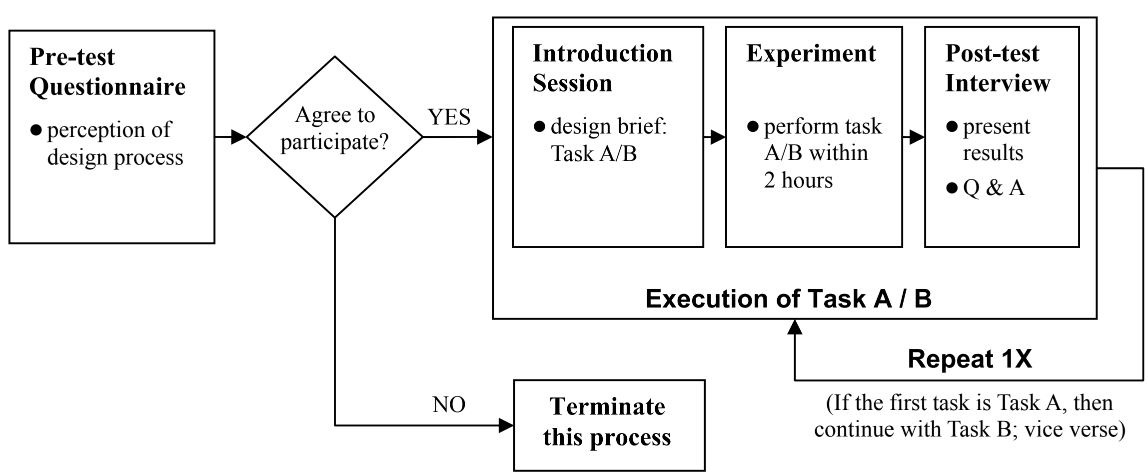

Figure 1 Experiment Procedure

The experiments were conducted in a design-studio-like setting shown in Figure 2. Both traditional design tools (e.g. pencils, pens, sketching markers, paper, etc.) and digital design tools (i.e. a laptop computer which was accessible to internet and pre-installed with CAD software packages) were provided. A white board nearby the workstation allowed designers to write, draw, and use post-it tips to share and collaboratively develop their design ideas.

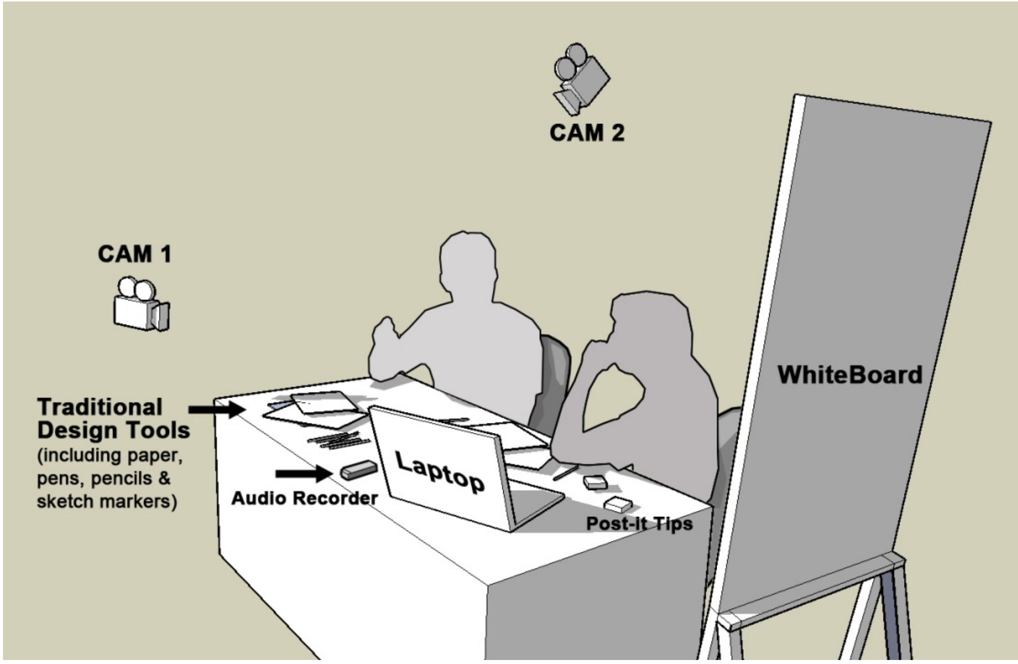

Figure 2 Experiment Setup

Two cameras and one high fidelity audio recorder, illustrated in Figure 2, were set up to capture the details of the observed design process. Thereof, CAM 1 took the overviews of designers' performance (lower part of Figure 3) while CAM 2 emphasized the specifics of designers' work, like sketching processes (upper-left part of Figure 3).

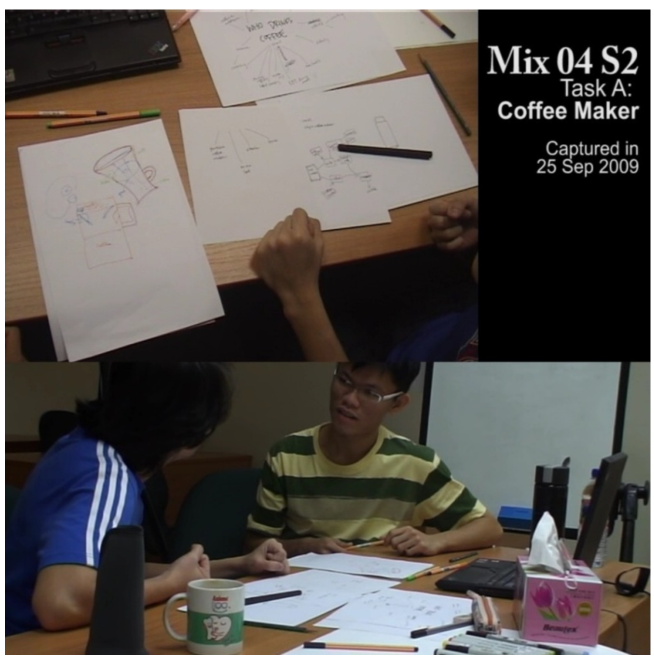

Figure 3 Snapshot of Multimedia file for analysis

After all session, the outputs of CAM 1 & 2 and audio recorder were synchronized into a combined multimedia document (exemplified by Figure 3). All conversation and utterances within the design activities were transcribed in textual form and non-verbal behaviors were recorded as the notes in the transcriptions. The sketches and drawings produced during design processes were collected and numbered with regards to the occurrence sequence. The multimedia documents, text transcripts and sketches collectively constituted the tripartite design protocols for latter analysis, which were considered as the externalizations of cognitive processes of these observed collaborative design activities.

The data of pre-tests questionnaire and post-test interview served as extra references for making sense of design protocols.

Methods for Analysis

One of the most common techniques for design protocol analysis is to segment a protocol (i.e. the record of a complete process) into micro-actions of seconds, code them with a set of priori categories and then explore the coded segments qualitatively and/or quantitatively. This technique can identify the alternations of topics and designers' intentions within a design process, but the connections between micro-actions are severed (Dorst, 1997; Dorst & Dijkhuis, 1995). The observed design process was thus flattened into a simple sequence with iterations between several behavioural categories, rather than maintaining the nested structure of design activities.

"Linkography", on the other hand, is a technique proposed to analyze the interconnections of design actions within a process (Goldschmidt, 1995; Goldschmidt & Weil, 1998). But content of each protocol segment is omitted in this technique. All design actions are simplified as homogeneous design "moves" in a linkograph, i.e. a diagram visualizing the interconnected moves. It is hard to show patterns about major design phases (e.g. problem analysis, idea generation) and their structures.

In order to investigate the nested nature of design processes and relationship between major design phases, a revised version of design protocol analysis balancing the content and interconnection of micro-units of design activities was developed.

Rather than coded with a priori set of categories, we adopted a data-driven approach. A protocol was segmented according to its semantic meanings. The semantic transitions were adopted as the criterion of splitting protocols, like verbal hints that suggested designers were shifting their intentions, as well as silence situation lasting more than 5 seconds which indicated a process breakdown. These segments were usually clusters of several finer design actions. With regards to the dynamic nature of design activities, these segments varied from 1~2 seconds to several minutes.

After segmentation, each protocol segment was then coded based on its semantic meaning rather than a priori coding system. This allows a flexible coding process. New categories of code will be easy to generated and added into the coding scheme, and the existing codes are vulnerable to rearrangement. Table 2 summarized codes applied in our study. The organization of the applied codes resembled Purcell et al.'s (1996) coding scheme of design strategies. The immediate design actions could be mapped to three broader categories of analysis, synthesis and evaluation. Another set of actions, which we tentatively called "strategy", referred to the management of or reflection on design actions. They could be categorized as "meta-cognition", i.e., monitoring, evaluating and regulating people's own cognitive actions (Fayena Tawil, 2007; Jaušovec, 1994).

Table 2 Data-driven Coding Categories

Categories	Sub-categories	Interpretation	Example in transcripts
Problem Analysis	Info	Searching for external information	"Check the ice blend coffee (action: browsing WebPages)"
	Name	Identifying elements related to current design situation	"What factors are essential for entertainments? Audio… visual … touch .. and? (action: drawing a mind map"
	Analysis	Elaborating relevance of identified elements to design procblem	"The interface is important for an entertainment device"
	Requirement	Establishing requirements or specifications	A: "So what do you want attributes of? ... What the ..." B: "Of course you must look trendy, sporty, professional…"
Solution Synthesis	Ideation	Proposing a new (partial) solution	"Playing music with heart beats, or mood of the day (action: brainstorming through post-it tips)"
	Revision	Modifying a proposed solution	"Yah, it must have some transparent thing here" "Maybe put it at the bottom, so it can be easily accessed"
	Synthesis	Combine several partial solution into one coherent solution	"I think these two ideas both
Solution Evaluation	Interpretation	Interpreting and analyzing the proposed solution	"Because there is the ice, there is the coffee, there is the … It sounds you need a lot of coordination" "Basically, when the water is boiled, the coffee is added here, the steam will eventually produce high enough pressure to force the boiling water up to here…"
	Evaluation	Making positive or negative judgments on proposed solution	"I like this idea, very ipod-ish … cool, man" "This is really cute. I want to buy one when it's released"
Strategy	Management	Proposing a design global or local strategy on organizing design process	"Let's do some brainstorming, about 10 minutes … hum, till 10:45, then we exchange ideas"
	Reflection	Evaluating and reflecting on current design strategy	"I think we move on too fast, let's focus on what is users really want at this moment. A: "Do we continue doing mind map?" B: "I think had better move on to concept generation"
Others	No code	The irrelevant verbalization for our study	"This color is quite cool" (comments on the marker we provided) "Wait me a second, I need go to toilet first"

Due to the explorative nature of this stage, the coding of protocol was conducted by a pencil-and-paper approach. No quantitative analysis was executed after coding process. Instead, we proposed a technique to visually manipulate coded protocol segments at a macroscopic view. Inspired by affinity diagram (Beyer & Holtzblatt, 1998), these coded segments were grouped and rearranged in a hierarchical structure, according to their similarity on design topics. Meanwhile, each segment's duration and position in timeline were still maintained. The structural pattern of design cognitive process was thus able to be read from the reconstructed sequence or the "flow" of design activities.

Findings and Discussion

Figure 4 exemplifies the visualization of coded segments. Generally, the top-level of protocol groups, which are not further grouped into another group as a component, could be seen as the phases in a stage-like designing process model. Most of such phases can be well aligned with three broad categories of coding scheme, i.e., problem analysis, solution synthesis and evaluation. Meanwhile, the actions of "strategy" was scattered along with a design process.

However, a closer examination of this visualization shows that the observed designing process was not a simple sequence of these three broad activities. Instead, a nested structure of design cognitive process was found to emerge from the reconstructed sequence or the "flow" of design activities. Nearly all types of actions can be found within each phase. For example, in both sessions of Concept Generation 1 and 2 shown in Figure 4, these two "synthesis" phases include "requirement establishment" actions (that are attributed as "analysis" category) and actions of "evaluation of the generated design alternative" (that are a subcategory of "evaluation" activity) as their components. This finding is consistent with Dorst's (2003) argument of the nested structure of design cognitive processes.

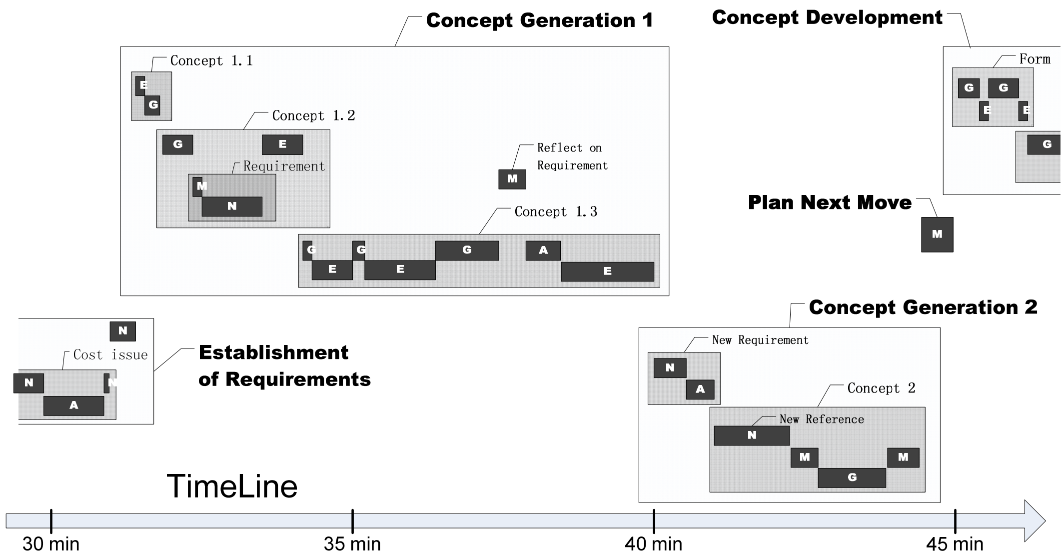

Figure 4 Nested Structure of a Design Process (an example based on a partial process)

Through examining both structural visualizations and the contents of protocol transcripts, some significant features of design processes in each factorial category were identified. Table 3 summarizes the preliminary findings based on qualitative examination at a macroscopic level. The results will be discussed in detail from two perspectives: the dissimilarities of process structure according design disciplines and experimental tasks.

Table 3 Preliminary findings of design protocol study

	ID teams	ME teams	Mixed teams
Task A	• Process: Analysis-Synthesis • Duration of Analysis: 1/3- 1/2 • Content of Analysis: Generic context; product features • Concept: 1 or 2 main concepts with several variations • Emphasis of concept: User experience	• Process: Analysis-Synthesis • Duration of Analysis: 1/5- 1/4 • Content of Analysis: Understand existing products • Concept: 1workable concept • Emphasis of concept: Working mechanism	• Process: Analysis-Synthesis • Duration of Analysis: 1/3- 1/2 • Content of Analysis: Generic context; design precedents • Concept: 1 main concept with several variations • Emphasis of concept: User experience
Task B	• Process: Analysis-Synthesis • Duration of Analysis: 1/3- 3/5 • Content of Analysis: Generic context; product features; design precedents • Concept: 1 major concept but initiated by several crude ideas • Emphasis of concept: User experience	• Process: Synthesis • Duration of Analysis: < 1/5 • Content of Analysis: recognize problem from design brief; hardly found an explicit analysis phase • Concept: 1workable concept • Emphasis of concept: Functions	• Process: Analysis-Synthesis or Analysis-Brainstorming-Evaluation-Synthesis • Duration of Analysis: 1/3- 1/2 • Content of Analysis: Generic context; design precedents • Concept: many crude ideas • Emphasis of concept: Functions

Design Processes: Analysis-oriented vs Synthesis-oriented

It was claimed that, within the comparison of ME and ID's designing process, the process of ME was more analysis-oriented, focusing on "finding" or discovering, whereas that of ID was more synthesis-oriented, emphasizing "making" or invention (Owen, 2006). But the empirical findings of this study appear to demonstrate a reverse phenomenon.

In the observed design sessions, ID participants dedicated a considerable amount of time (more than one third of total time) into problem analysis or design context analysis. Their process was usually initiated by a general exploration of broader design context without consideration of any expected design outcomes. When an unfulfilled need or a more promising potential was identified, the focus of design discussion was relocated to the features of product concepts, or design requirements. Design brief like statements were explicitly made before they went into generating design concepts.

ME participants, conversely, showed a very solution-led strategy. They were observed to spend little time (usually less than 10 minutes) on problem analysis and quickly jumped into the details of design solution. Their analytical work was also closely related to particular aspects of solutions, e.g., understanding existing products' working mechanism.

The general contexts (usually not explicitly concerned with specific product concepts) that were discussed in detail by ID students were seldom observed in ME processes. Only 2 out of 8 ME sessions explicitly, though very briefly, considered their target-user, usage context and design requirements before approaching possible product concepts. Other sessions either stated the abovementioned considerations as hindsight, or simply omitted them.

Moreover, ME sessions spent much less time on problem analysis. Their process thus seemed more "efficient"; the average time of ME sessions was 33 minutes shorter than that of ID sessions, which lasted about 91 minutes on average per session.

The processes of Mixed teams stood somewhere in the middle, depending on which participant was more actively involved in the process.

The above results demonstrate significant dissimilarities between ID and ME students' design strategies. These structural differences of designing processes seem to be correlated to the very different understanding of design held by ID and ME students.

According to the pre-test questionnaires, ME students treated design as a particular type of problem-solving activities. For them, the problem situations were already given or prescribed in design brief; a designer's job is to gather them and identify one or two feasible ways to solve them accordingly. ID students, however, apprehended design from the perspective of its ultimate purpose, i.e., a means of "improving human lives" (excerpted from an ID student's response to pre-test questionnaire).

It is likely that, guided by the different views of design, ME students spend very little time on the problem analysis and tend to consider the designed product as a system. The interactions of subsystems or product components are thus their specific concerns. For example, issues, like proposing a scheme to breakdown components or “functional modules”, were frequently discussed in ME protocols.

In contrast, ID students valued the role of human much more than that of a product. They are thus willing to spend more time to systematically go through the analysis of potential user’s profile and possible usage contexts, and to explore the potential opportunities to create something new and more appropriate. The product concepts, most of time, are discussed under a broader user-product-context framework while the internal structures of designed product are less important. Human-centred values are their major concern. For instance, during the design process, “experience”, “fun”, “feeling” and “interaction” were the terms most mentioned by ID students.

Influences of the Nature of Design Tasks

The structure of designing process seems not only to be influenced by the constituting members of design teams, but is also subjected to the type of design tasks (Table 3); the abovementioned disciplinary differences were more significant in visionary concept design task.

In task A, the processes of all three categories followed an “analysis- synthesis” sequence in general. Most sessions generated one or two design concepts based on their initial analysis. ID students usually experimented with several variations on form or ways of how people could interact with designed product, whereas ME students appeared to be more committed to a single workable solution. The evaluative actions intermediately followed actions of synthesis, thus no extensive evaluation stages came up.

Situations changed in task B, i.e., future-oriented visionary concept design task. ID teams followed a similar “analysis-synthesis” strategy; ideas of expected product were triggered by the analysis and then naturally evolved. ME teams, instead, proposed the possible solutions in the very beginning, and the final outcome seemed to be a simple assembly of everything they had thought of. Both ID and ME sessions, for task B, adhered to the development of a single concept; very little variation of product concept was considered.

The Mixed sessions in task B showed a very different story. Two Mixed teams’ processes resembled those of ID teams, i.e., synthesis stages followed analysis of problems. However, the other two Mixed teams were stuck at the analysis stage, without emerging a promising direction to pursue. Participants resorted to a formal brainstorming for idea generation. The consequence of brainstorming was that designers had to face a variety of solutions (7 and 22 in two sessions respectively); an explicit “evaluation” phase was thus required to perform in order to identify which idea, or an integration of several ideas, was appropriate for further development. These two teams adopted an “analysis-synthesis-evaluation- synthesis” strategy in visionary conceptual design.

In our original conception, task A and B represents two design problems of different nature. According to theory of problem finding (Dillon, 1982; Getzels & Csikszentmihalyi, 1976; Runco, 1994; Starko, 1999), there is a distinction among presented problems, discovered problems and created problems in terms of whether or not there are explicit problems, standard solving methods and/or possible solutions known to solver and/or others. Compared with task A, task B contains more potential and implicit elements requiring designers to identify and actively formulate. It is supposed that task B will involve a longer problem analysis and formulation phase. ID and Mixed sessions confirmed with this hypothesis, but ME sessions did not. This phenomenon is difficult to be accounted for by the traditional view of problem solving, which frames the design processes by analysis, synthesis and evaluation activities, but it can be possibly explained from the view of problem finding and formulating. One probable explanation is that ID and ME students held very different problem formulating strategies.

According to Thomas and Carroll (1979), design is not necessarily associated with a particular type of problem. More precisely, design is rather “a (particular) way of looking at a problem” (p. 5) and any problem can be viewed as a design problem if the solver treats it as ill-defined. In our experiments, a longer problem analysis phase in task B suggests ID students made a greater endeavour to understand the problem situation and create a workable problem when they encountered a visionary design task. On the other hand, the very short phase of ME problem analysis may be explained by ME students’ “convenient” but passive strategy in which they tended to frame the problem situation as well-defined and simply select an available problem representations according to their experience. Retained from reconstructing the problem situations by other possible problem representations, ME students were thus easier to follow an adaptive or variant designing process, rather than conducting an original deigning process (Pahl, Beitz, Feldhusen, & Grote, 2007). The examination of designed outcomes also showed a strong fixation effects in ME sessions.

The different strategies concerning with design problems were consistent with Harfield’s (2007, 2008) two different design “problematization”, i.e., “problem as given” and created problem “as design goal”. They also indirectly refute the argument of design as a particular way of looking at a problem (Thomas & Carroll, 1979). Various ways of looking at a problem may co-exist within design activities.

Experiment Effects

All participants reported the experiment setting was similar to their design studio. They did not feel anything uncomfortable when working in this controlled environment. The observed design activities could represent their daily design processes.

However, a sequence effect (sequence of performing task A or B) was found in our study. No matter which task was performed first, the second task took less time to complete. The total experiment time was reduced almost 1/3 for ID teams and 1/5 for Mixed teams. The proportion of analyzing the second problem also decreased significantly in ID and Mixed sessions. The decrease of total experiment time in ME sessions was less obvious, but their second tasks were also found to last for a slightly shorter time. The latter effect, i.e. the alternation of ratio of analysis to synthesis, however, was not found in ME sessions, as ME students hardly explored the problems while performing task B.

Conclusion

The qualitative examination of design protocols shows significant dissimilarities between ID and ME design processes. This finding reflects different attitudes of ID and ME students to the tasks provided in this study, i.e., treating design brief as a given problem or as an impetus to formulate actual design problems to solve. This conclusion provides evidences for variations within design thinking and cognition.

Due to the explorative nature of this study, it actually raises more questions than it has solved. This study suggests that ID and ME students differ in their problem finding activities. A more detailed analysis will be conducted to investigate their problem finding processes and how problem finding actions are related to synthesis of design outcome.

The current analysis is a qualitative examination of design process structure at a macroscopic view. Further studies will include creating a sophisticated coding scheme and quantitatively analyzing both content and process aspects of design thinking (Goldschmidt & Weil, 1998).

In addition, the design strategies (including problem finding and solving) and understanding of design were taught, directly or indirectly, in the educational programs. Further study should include the discussion of the curricula of ID and ME programs in the National University of Singapore and identify the differences between these design trainings.

Author Biography

Jiang Hao

Jiang Hao is a PhD candidate at Industrial Design Division, National University of Singapore. He has received his Bachelor and Master degrees from Department of Industrial Design in Zhejiang University, China. His current research interests include research into designing, design thinking and design protocol study.

Yen, Ching-Chiuan (Dr.)

Dr. YEN Ching Chiuan is an Associate Professor and Head of Division of Industrial Design, School of Design and Environment at the National University of Singapore. His professional experiences include the Director of Design Centre at Chang Gung University, Board Member of the China Industrial Designers Association, and the Secretary of Chinese Institute of Design. The author and co-author of more than 30 international and national refereed articles, he is one of the few individuals who possesses the ability to combine theoretical thinking and design practice into design education. His research interests lie in research methodologies for design and he champions ‘pluralistic dimension’ of design study for the design research. His ability in supervision is highly regarded, and around 20 international or national design awards received under his supervision in past 3 years, including Braunprize, Red-dot and iF concept award.

Design Education as a practice of affiliation: facilitating dialogue between developed and developing nations

Robert Harland, Lecturer, School of the Arts, Loughborough University, United Kingdom, r.g.harland@lboro.ac.uk

Maria Cecilia Loschiavo dos Santos, Associate Professor, School of Architecture and Urbanism, University of São Paulo, Brazil, CNPq Scholar, closchia@usp.br

Abstract

Exploring Design research and Design education that straddles developing and developed world contexts is the aim of this paper. It is a bold ambition to identify the key debates that inform these two significant aspects of Design – much too big to cover in the limited space here. Nevertheless we speculate on some of the issues that emerge from within Architecture, Urbanism, Philosophy, Sociology, Geography, Education and Design. We do this through the idea expressed by Lang that ‘affiliation’ is the need that links to all other human needs. We hypothesize that affiliation, and our need for belonging not only within our local communities, but also at a global scale, is a central concern that links research and education in developing and developed world contexts. Some design practitioners are shown to be tackling this problem, but too often these are single projects limited in scale. We maintain that these worthwhile and noble efforts must be scaled up to deal with problems of urban planning through first, second, third and fourth order design concerns, recognizing that whilst contemporary design is increasingly occupied with ‘interaction’ and ‘environment’, the established preoccupation with ‘symbols’ and ‘things’ remains out of reach for millions of urban poor. In fact, urban designers consider ‘symbols of affiliation’ as central to city dwelling. Design research and design education must therefore aspire to a material democracy that judges the appropriateness of each given situation on its merits, recognizing the need at times for basic material provision.

Keywords

affiliation; design education; social-actualisation; design for the dispossessed, urban design

In his depiction of the kind of design problems tackled by professional designers, Victor Papanek (1984, p. 57) showed us that professional designers are concerned mainly with a very small share of ‘real’ problems. In the 1960s Papanek indicated that the professional designer’s share is at the ‘tip of the iceberg’, sitting above a world of real problems. Since then, our understanding of design, and the work of professional designers, has moved on. But we might ask what has stopped designer from engaging with the real. The visual coincidence of Papanek’s pyramid depiction matches the same diagrammatic representations often seen in Abraham Maslow’s (1954 [1987]) ideas about self-actualization. We learn from this visual comparison that if, using Maslow’s terminology (1954 [1987], pp. 57–59), ‘motivation and personality’ is too much predicated on ‘one’s own needs’ and ‘individualism’ it is clear why so many ‘real’ problems remain unaddressed. Jon Lang (1994, p. 160) tells us that Maslow expressed dismay at interpretations of the desire to self-actualize, and a disregard for the needs of others. This demonstrates a tension between the self and the social, bringing into question the scale at which this takes place as representation and the notion of social-actualization.

Space does not allow for a full critique of Maslow’s work here, but apparently he believed that most people strive for esteem, but never self-actualize, and it has been argued that the full implications of this in terms of urban design are as yet unclear (Lang, 1994, p. 161). This paper therefore attempts to explore this by examining the step before esteem and self-actualization. Maslow called it *belonging*, but it is also named *affiliation* by Lang (pp. 158–160). Lang argues that affiliation needs are complex and interact with all other needs.

> ‘Participation in a supportive social system is necessary for an individual’s survival with a modicum of psychological comfort. This is particularly so in an urban world. Once their need for survival is met reasonably well, people feel most keenly the need for membership in a group or, more likely in the modern world, a set of groups’ (Lang, 1994, p. 252).

Understanding affiliation is necessary when we attempt to address the real problems identified by Papanek that professional designers are said to ignore. If better understood, this may help the scaling-up of design activity to tackle some of the urban planning challenges associated with the urban poor. See figure 1.

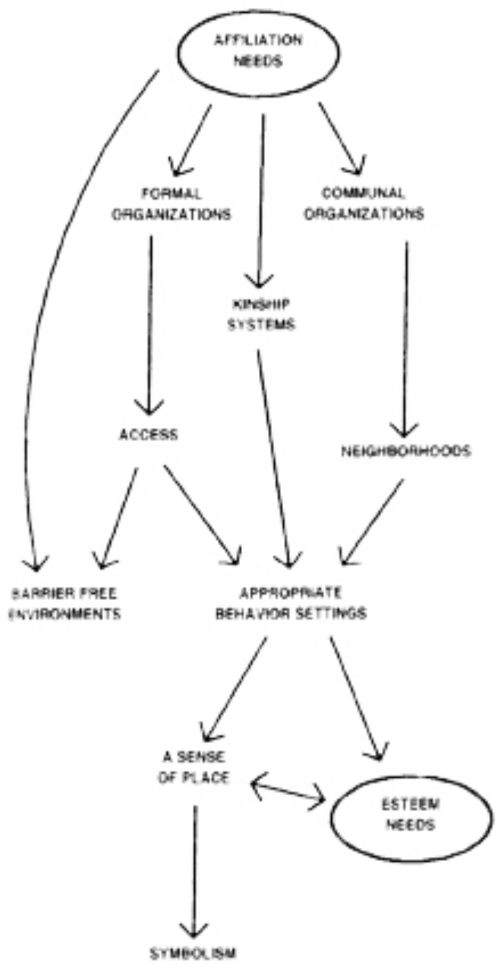

Figure 1. Affiliation Needs
Source. Lang, (1994) p. 253.

This work in progress is being undertaken in the context of developing an approach to design education that can straddle developed and developing world contexts. The potential for knowledge exchange in design research between developed and developing countries is immense. Developed countries have the benefit of history on their side in using design to create prosperous social, cultural, and economic contexts. However, as developed nations aspire to explore the potential for design and 'immateriality', rather than the traditional concerns for material objects, there is the potential for opportunities to be lost, or at very least, disjointed. Especially so when many people remain without basic material needs such as shelter. Developing countries are still yet to mature in their use of design for material gain that benefits the majority. Think of the increasing prevalence of the informal housing and urban homelessness across the world, and the need that millions of people still have for basic amenities that are realized through design in the physical sense. ‘A society cannot claim to be harmonious if large sections of its population are deprived of basic needs while other sections live in opulence’ (UN-Habitat, 2008). How much do we value affiliation in design, research and education? In this paper, it is argued that emphasis on 'affiliated' design research is critical if more social- rather than self-actualization is to be achieved.

What do we mean by affiliation?

The word *affiliate* originates from the Latin *affiliare*, meaning 'adopted as a son'. In modern terms it is commonly associated with officialdom, in the sense that it conveys a formal attachment to an organization, either in person, or as an organization, connected to a larger group or body. Lang (1994, pp. 158–160) uses the term *affiliation need*, placing importance on the process of 'identity-formation' for individuals as part of a group, as much as a need for individual distinctiveness. Special significance is given to the concept of the individual being part of a 'social and moral order' through the sense of belonging to a group. 'People need to have a sense of belonging, community, and relatedness, as well as to receive affection and approval from other people' (p. 158). Critically, this desire places value on participation rather than isolation, and engenders a 'feeling of psychological security' as opposed to worry and withdrawn tendencies. (Privacy is part of this in the sense that public participation also requires private periods of recuperation). The presentation of symbols, unconscious and conscious, subtle and clear, as representations of group membership, is important until the individual and group are synonymous with each other (at which point the display of symbols is less important). In direct relation to the built environment 'the symbolic aesthetic of the places we inhabit is fundamental to our group identities'. It is generally thought that in terms of urban design this is represented in the social interaction that happens in social places such as cafés, bars, pubs and plazas (Lang, 1994, p. 159).

With this in mind, we are concerned in this paper with the symbolism associated with affiliation, in terms of how a *symbolic place aesthetic* is constructed, and whether it is desirable. In this sense we turn to design, and a perceived need for design education that is sensitive to the importance of symbolic representation, through a process of development. This is in respect to how some symbols associated with habitat may project negative impressions, and yet possess positive human values. For example, we might assume that the image of a shantytown, or favela, is a negative symbol, despite the close affiliation of inhabitants with each other. And yet the individuals who occupy these dwellings may be far from negative!

A shantytown or favela is a representation of a certain kind of economic, social and cultural identity. They are associated with poverty, rapid urbanization and the growth of mega-cities such as Mumbai or São Paulo, and smaller cities such as Nairobi. These environments have become 'symbols' of rapidly developing urban environments in developing countries, characterized in familiar images of the modern high-rise building adjacent to shacks. These kinds of image show the habitat of the 'haves' and 'have- nots', and demonstrate the difference between formally and informally designed environments. Design education, or lack of it, is clearly a significant factor in the expectations and quality threshold of occupants in both cases. These images depict in material terms the formal and informal economy.

In this paper we discuss the need to reconcile the intentions of formal design education with the needs of those generally found to be living in conditions associated with the 'informal sector'. Although this distinction might be found in any city in the world, it is most prevalent in those that have significant shantytown populations. It is a worldwide phenomenon. The 2008 UN-Habitat State of the World's Cities 2008/2009 states:

> 'One out of every three people living in cities of the developing world lives in a slum. UN-HABITAT estimates indicate that in 2005, more than half of the world's slum population resided in Asia, followed by sub-Saharan Africa and Latin America and the Caribbean. Slum prevalence – or the proportion of people living in slum conditions in urban areas – is highest in sub-Saharan Africa; 62 per cent of the region's urban population lives in a slum or suffers

> from one or more of the five shelter deprivations that define a slum. In Asia, slum prevalence varies from a high of 43 per cent in Southern Asia to a low of 24 per cent in Western Asia, while in Latin America and the Caribbean, 27 per cent of the urban population was classified as living in slum conditions in 2005.' (UN-Habitat, 2008, p. 90).

Finally, concomitant to these figures there is also the uncountable occurrence of homeless street people, mainly living in the city centre of the contemporary metropolises. It is a troublesome social problem, a human tragedy that prompts design responses to change the situation, in practice and education.

'Developed' and 'developing'.

The use here of 'developed' and 'developing' are terms consistent with those used in Geography in recent decades, although for some time 'North' and 'South' were prevalent in the 1980s and 'Third World' has also been used at times (but less so now). These terms relate to economic wealth. However more recently social well-being has become more a factor, as well as economic growth, and this has resulted in countries being designated as 'more developed', 'newly industrialized' and 'less developed', before the adoption in the 1990s of 'high', 'rapidly increasing' and 'low' classification of Human Development Index that indicates 'quality of life' rather than 'standard of living' (Waugh, 2000, p. 630). A fundamental contribution to broadening the concept of development as well-being and freedom has been the preoccupation of Amartya Sen. According to him development and freedom are intimately related. By freedom he means well being in five categories: political participation, economic well being, social integration, information access and personal security. Thus 'development has to be more concerned with enhancing the lives we lead and the freedoms we enjoy' (Sen, 1999, p. 14). Here, we use the term 'developed' and 'developing' in relation to the concept of world development, and the need for continental affiliation between, made explicit here:

> Few can deny that the world's wealth is highly concentrated. The populations of North America and Western Europe eat well, consume most of the world's fuel, drive most cars, live in generally well serviced homes and usually survive their three full score years and ten. By contrast, many people in Africa, Asia and Latin America are less fortunate. In most parts of these continents a majority of the population lack balanced diets, reliable drinking water, decent services and adequate incomes. Many cannot read or write, many are sick and malnourished, and too many children die before the age of five.'
> (Waugh, 2000, p. 630, citing Gilbert's 'An Unequal World')

It is reasonable to assume most people agree that action is required to change this situation. According to Simon (1981, p. 129), and his broad definition that design changes existing situations into preferred ones, the activity of design is critical in creating 'preferred' situations. How this is done is of major significance. We value close affiliation between the 'developed' and 'developing'; 'North' and 'South'; 'less', 'newly' and 'more' developed countries, in the sense that all humans must benefit from affiliation no matter how close or distant they may be. Social-actualization on a global scale is the ultimate goal.

The design of cities has never been so important than now, at a time when predictions about half the world's population living in urban environments have been surpassed. Educating the 'designers' of cities must deal with two distinct aspects of urban form: what has already come into existence, and what will be created in the future.

Learning and human nature

How can design and design education improve the lives of those living in the poverty of shantytowns, and other less desirable urban environments? We can learn about the environment by studying the environment. But Kaplan (1973, p. 64) points out that this process is vulnerable to self perpetuating institutionalized views, and 'Man is, in these terms, what he has learned.' Another approach is to recognize that despite the lack of macro design planning that has resulted in the spread of shantytown developments, an innate creativity and design awareness resides in the activities of the urban poor, who demonstrate creative ways to adorn their dwellings using image making techniques applied in the arts, such as collage (R. Harland & Loschiavo do Santos, 2008, p. 12). This important aspect of human nature is acknowledged by Kaplan who suggests *human nature* is an important factor in change making. Though not specifically talking about shantytowns, he argues that ‘all programs for reform and all proposals for burning-it-all-down-and starting-over rest alike on certain implicit conceptions of human nature’ (p. 64). Through this, he is arguing for a more ‘intuitive’ (and, perhaps, design lead) response guided by four major types of knowledge:

1. *Where one is*. The identification of one’s current situation is a critical starting point for adaptive behaviour. This requires both perception of the present stimulus array and memory of immediately preceding events.

2. *What is likely to happen next*. The identification of a range of future situations and the estimation of the relative probabilities of occurrence are the essence of prediction.

3. *Whether it will be good or bad*. The question of evaluation of the goodness or badness (or payoff) of predicted situations is also critical in decision making.

4. *Some possible courses of action*. The adaptive organism must not allow himself to become lost in thought

Intuition is part of the designers approach to problem solving, and ‘intuitive’ knowledge offers a framework for dealing with the kind of ‘wicked problems’ (Rittel & Webber, 1973, p. 155–169) likely to occur in attempts to improve of living condition for shantytown dwellers. Design education is in a unique position to make explicit the difficulties and the enormous human tragedies associated with these sorts of problems. The understanding of these wicked problems that shape our times challenge design students from all over the world that are aware of their social responsibility, thus facing the broader issues of our contemporary societies. In these terms, design cannot be ignorant of issues such as homelessness, environmental degradation, social injustice and so on. An interesting example that attempts to collectively address these challenges is the *Moonlight* project for affordable LED Lighting in rural Cambodia. The authors are Industrial Design students from the TU Delft: Ana Maria Alvarez, Loucas Papantoniou, Stephanie Wirth e Doortje van de Wouw. They proposed a new paradigm, from the hegemonic Western approach of design, they provide us with the opportunity of looking at an urgent need in a Cambodian rural village. From the dominant approach of design in urban areas, they invited us to consider the design intervention in rural areas. So, the team had the ability to think and design sociologically, they proposed a shift of values and they have worked based on an ethnographic and participatory research methodology. In cooperation with the local company Kamworks they designed an affordable solar-powered LED lamp for the rural population in Cambodia. This project was awarded the CIFIAL Feel the Planet Earth Award in the year 2009, in Portugal (see figure 2), and offers an example of how design students want to be affiliated to the main pressure issues of our societies, stressing concretely the making dimension of design.

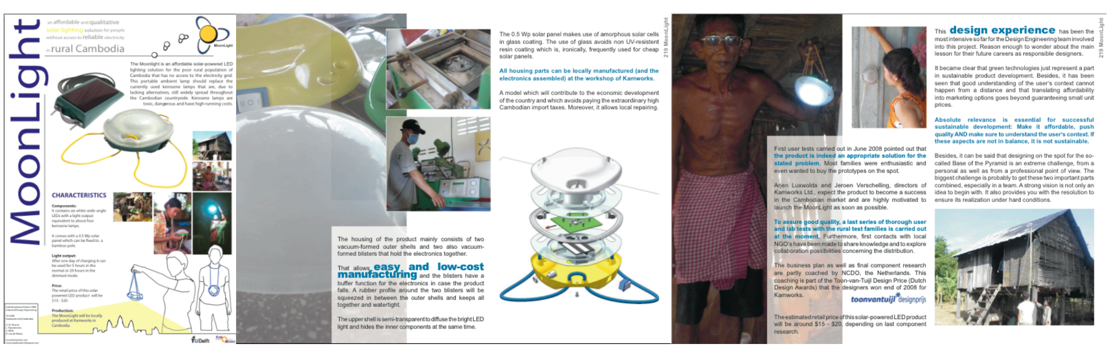

Figure 2. The Moonlight is an affordable solar-powered LED lighting solution for the poor rural population of Cambodia that has no access to the electricity grid. Awarded the CIFIAL Feel the Planet Earth Award in the year 2009, in Portugal.

We have given an indication about *where we are.* What happens next is speculative. But if we allow ourselves to speculate, it is likely that problems associated with poverty will be compounded in the face of continued population increase in the urban environment, especially due to the continuing development of so called ‘megacities’. This is not an original speculation, simply one well-worth restating from the design education and design research perspective. For example, it is forecast that the number of megacities will increase between 2007 and 2025 from 19 to at least 26 (see Table 1). Significantly, Moscow is the only European city, and one other city, Istanbul, is likely to exceed 12 million people over the next 15 years.

2007 population (thousands)		2025 population (thousands)	
1 Tokyo	35,676	1 Tokyo	36,400
2 Mexico City	19,028	2 Mumbai	26,385
3 New-York Newark	19,040	3 Delhi	22,498
4 São Paulo	18,845	4 Dhaka	22,015
5 Mumbai	18,978	5 São Paulo	21,428
6 Delhi	15,926	6 Mexico City	21,009
7 Shanghai	14,987	7 New York-Newark	20,628
8 Kolkata	14,787	8 Kolkata	20,560
9 Buenos Aires	12,795	9 Shanghai	19,412
10 Dhaka	13,485	10 Karachi	19,095

Source: UN-Habitat, 2008, p. 6

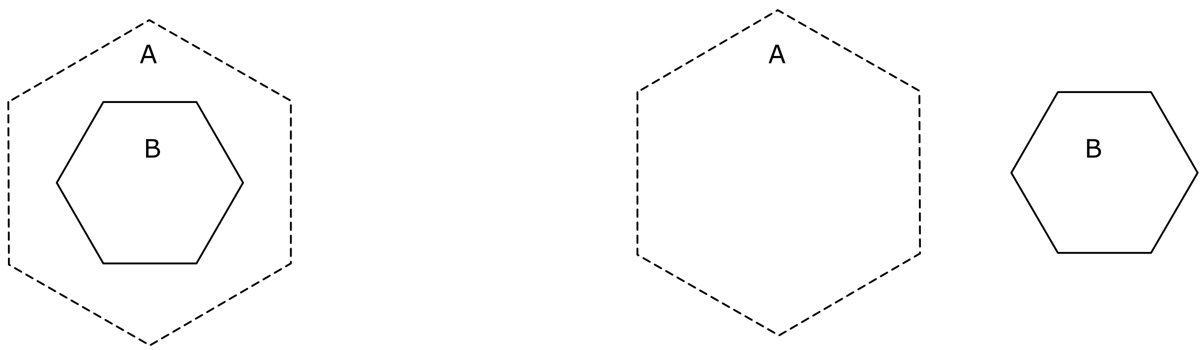
It is of major significance that European cities are not generally growing anymore, according to data spanning 1991–2001 (UN-Habitat, 2008, p. 13). In fact many inner cities are decreasing in size in countries such as UK, Germany, Italy, and Poland, allegedly for reasons associated with increased suburbanization in the surrounding areas. This is attributed to low population increase and decentralized urban development. This is no accident.

The presence (or absence) of design makes a significant contribution to this contrasting scenario. The meaning of design in this context is not only as a ‘visual phenomenon’, but also what Punter and Carmona (1996, p. 2) define in terms of broader social and environmental terms, as well as ‘design as a process’. The attitude to design by metropolitan authorities is therefore critical if it is used for positive affect. ‘Metropolitan growth can happen spontaneously, or by design’ (UN-Habitat, 2008, p. 187).

Materiality and immateriality, and the new ‘order’ in design.

When we talk about ‘material’ or ‘immaterial’ there are two distinct meanings. Material is about the matter used to make something. Immaterial is not – it is not physical (in philosophical terms it means spiritual). There is often-used dual terminology to describe the contrast: for example ‘physical’ or ‘metaphysical’, ‘tangible’ or ‘intangible’. The difference is usually associated with things perceived through the senses or through the mind respectively. We will not examine this in detail here. But although ‘design’ is a ‘disputed’ term (Salustri, undated) it is concerned with what Buchanan (2001, p. 9) offers in his formal definition: ‘Design is the human power of conceiving, planning, and making products that serve human beings in the accomplishment of their individual and collective purposes’. In the conceiving, planning and making, there is a distinction between cognitive (conceiving, planning) and concrete (making) practices that result in material things (or systems). This distinction is shown here in basic diagram form in figure 3, whereby that which is not so visible (cognitive) is indicated with a dashed line, and that which is solid (concrete) has a solid line (R. G. Harland, 2009, p. 10). Some may prefer to separate the two in terms of a division of labour, but we do not differentiate in this way preferring the view that ‘making is thinking’ (Sennett, 2009, p. ix). In this sense design is craft, technology, making and thinking residing in a singular domain. Archer (1976, p. 11) captured this in his definition of design as ‘the area of human experience, skill and understanding that reflects man’s concern with the appreciation and adaptation of his surroundings in the light of his material and spiritual needs.’

A. Immaterial (conceiving and planning)
B. Material (making)



Making as thinking

Thinking and making apart

Figure 3. The material and immaterial dimension of design
Source: Harland, 2009

We place emphasis on this because Buchanan (p.12) argues that the focus in the early part of the twenty first century is no longer on ‘material systems’ (or systems of ‘things’, as he also puts it) but on ‘human systems, the integration of information, physical artifacts, and interactions in environments of living, working, playing and learning’. He goes on to say:

> We are now in the early formative stage of understanding how third- and fourth-order design will transform the design professions and design education, but the beginning has been made. It is difficult to see how design thinking can go back to its earlier centers of attention without a sustained period of exploration of interactions and environments.’ (p.12)

The differentiation between material and immaterial concerns is still highly relevant, but clearly non-material concerns are becoming increasingly significant and expansive. Buchanan’s first and second order concerns of ‘symbols’ and ‘things’ remain important but ‘action’ and ‘thought’ form the basis of third and fourth order future concerns. He states that the ‘visual symbols’ and ‘things’ that so concerned design in the twentieth century in terms of ‘form, function, materials and manner of production’ remain important, but this must now be informed by inquiry into ‘usefulness, usability, and desirability’. Affiliation is one approach to this. For example, Lang (1994, p. 274) discusses how ‘symbols of affiliation’ adapt to formal and informal applications and settings. We might therefore ask the question how do we scale up this approach to resolve the large-scale problems in cities? Or is it that some urban environments are already well advanced in their understanding of third and fourth order design priorities, having addressed first and second order needs at earlier stages in their development process. For example, think of the significant slum clearing activities in major UK cities in the twentieth century.

Working towards a material democracy

How will this development of third- and fourth-order concerns address the basic needs of millions of people? Many are still yet to benefit from first and second-order design thinking. Some are attempting to deal with this through design for social change, or what is often referred to as 'human-centred' approach, now being undertaken by various organizations and individuals in the private and public sector. We identify some of these initiatives here.

IDEO have developed their programme of 'design for social impact' that aspires to have social and environmental impact for 'under-served and disadvantaged lower income communities worldwide' (IDEO, 2009). Since 2002 staff and postgraduate students at the Faculty of Industrial Design Engineering at TU Delft University of Technology in The Netherlands have been undertaking projects focused in developing countries for the benefit of the estimated four billion poor people in Asia, Latin America and Africa who live on less than $3260 per year (Kandachar, de Jongh, & Diehl, 2009, p. 7). This responded to the Millennium Development Goals adopted by the United Nations, and the failure by the 'World Bank, donor nations, various aid agencies, national governments, and civil organizations' since the 1950s to eradicate poverty. The variety of project work is wide-ranging and situated in many countries in the southern hemisphere.

Further to work in industrial design and engineering, since 1999 Architecture for Humanity (www.architectureforhumanity.org) bring together the efforts of 40,000 professionals who dedicate time and services in design, construction and development services for the benefit of those who otherwise could not afford design. Their work in inclusive design aspires to create lasting change in communities through:

- Alleviating poverty and providing access to water, sanitation, power and essential services;
- Bringing safe shelter to communities prone to disaster and displaced populations;
- Rebuilding community and creating neutral spaces for dialogue in post-conflict areas;
- Mitigating the effects of rapid urbanization in unplanned settlements;
- Creating spaces to meet the needs of those with disabilities and other at-risk populations;
- Reducing the footprint of the built environment and addressing climate change.

In the context of the 'wicked problems' related to the housing situation described above, small gestures of design can bring relevant accomplishments, stressing thus the importance of keeping the connection between the cognitive and practical dimensions in design. For example, consider the design of a shelter for the homeless. It must be a practical concern of design practitioners and we must maintain sight of the need to improve the material experience of less fortunate people. In this situation, design ~~can~~ helps to create a sense of dignity and belonging for people who may have few social connections. Also design enables communities to understand and accept the location of homeless facilities overcoming the 'nimbyism' – not in my backyard – always present in the neighborhoods close to these shelters.

Some examples of the notion of design in relation to material benefits can be pinpointed in the work of architects Janna Leavitt, Osamu Ishiyama, Sam Davis. In this context, Japanese architect Osamu Ishiyama has undertaken an outstanding project - the House of Hiroshima in Phnom Penh, Camboja, located in the compound of the largest Buddhist, Temple Unalom, Camboja. It is a school, an orphanage, a factory of prostheses for amputees and an art gallery, where people can reflect on PEACE. The architectural approach combined the alternate layers of concrete and red brick in a rough building without any kind of finishing or polished material. At the façade he used hollow brick exploring different directions and textures, making the structure light and the space airy. At the top of the building there are two cover structures that bring light to the core of the building. The programme is placed in two blocks: one for services and the other for housing and living rooms. It is remarkable the way he placed the bath area under a mushroom/flower shaped structure giving the user a feeling of taking a bath inside/outside, due to the presence of natural light and visual contact with the outside environment.

Canadian architect Janna Levitt has another innovative project to provide housing to adult people previously living on the streets or in shelters. The Strachan House project, in Toronto, Canada. The project is an 80-bed residence, divided into four to seven bedroom shared ‘houses’ in a three-storey brick and timber turn-of-the-century warehouse. The project is comprised of 12 houses – 4 on each floor – with a main "street" or corridor connecting the houses on each level. At either end of each floor level, the street terminates at a stair built in a three-storey atrium space. These open areas provide a strong vertical connection, linking the community as a whole.

American architect Sam Davis also was involved in the design of innovative solutions for the problem of homelessness. He designed the Larkin Street Youth Center in San Francisco, California, providing thus safe temporary housing for most vulnerable youth ages 12-24.

Designs for social relief encompass not only the design activity for the urban homeless, but also the design for the refugees of all kinds of catastrophes. In this sense it is relevant to mention the work of Habitat for Humanity that has been active in hurricane and tsunami relief; Madhousers engaged in building temporary emergency shelters for the homeless; the Rural Studio, based in Auburn, Alabama, has helped provide housing for the rural poor since 1993; and Shelter for Life, a volunteer group based in Oshkosh, Wisconsin that built houses in Afghanistan.

Conclusion

The scope of this paper is wide. Too wide. We have attempted to identify some key concerns moving forward that enable the continuation of a design education and dialogue between northern and southern hemisphere continents. Affiliation has emerged as a potential focal point around which a design education and a design research agenda can be built. This links together design educators, design students, and the less fortunate people who must benefit from their efforts. The idea of affiliation scales up and down, and crosses many disciplines. In this sense it is a social concern that demonstrates potential for social-actualisation, realised in a material democracy. We have seen that some are already working towards this by using their design abilities for good causes. In this sense design and designers are increasingly foregoing the self for the social, and addressing the kind of problems Papanek spoke of. As design continues to be explored across a wide range of disciplines in the spirit identified by the likes of Bruce Archer, increased recognition of design education as a practice of affiliation may be a central concern. We have seen that design for social responsibility is an increasingly frequent practice among young students, and affiliation could serve as a force to bind them together.

Author Biography

Robert Harland is a graphic designer and lecturer in Graphic Design at Loughborough University, United Kingdom, where he works with undergraduate, postgraduate and research students. He is presently enrolled on the PhD programme at The University of Nottingham School of Built Environment where his research focus is the relationship between Graphic Design and Urban Design. Recently he has spoken on this topic at conferences and symposiums in Lisbon, Hong Kong, Dublin, Sheffield, London, and Seoul. Since 2006, his work in graphic design education has encompassed the organisation of three symposiums examining the potential for graphic design research and what might constitute graphic design knowledge. Before pursuing an academic career in 2001, he spent 10 years in independent practice in London, and has exerience of over one thousand projects for a range of national and international clients in United Kingdom, Belgium, France, Germany and Portugal, both in the private and public sector. His work has been reviewed in the national architecture and design press, and he is a Member of the International Society of Typographic Designers.
